Methods: High resolution thermal imaging equipment using an 8 element SP7TITE detector system working in the 8-13 micron wavelength has been used in a study to assess whole body skin temperature patterns in 20 HIV-positive patients with biopsy proven KS lesions and to determine the thermal status of representative KS lesions before and during treatment with isotretinoin acid.

Results: Characteristic and abnormal thermal patterns were found in a high proportion of the patients studied. In addition, a range of quantitative thermal activity of KS lesions at different body sites was recorded. Some lesions showed measurable changes in thermal activity during treatment. These findings will be illustrated.

Conclusion: It is suggested that cutaneous neurological changes associated with HIV infection may produce abnormal thermal patterns on the skin surface and that the technique of infra-red thermography may have a role in identifying such abnormalities and provide an index of peripheral neurological change in HIV patients. Thermographic patterns may also be able to characterize the vascular and metabolic status of cutaneous lesions and thereby help in the assessment of the activity of Kaposi's sarcoma.

W.B.P.243 ART THERAPY WITH PEOPLE WITH AIDS

Eva Sangon, M.A. Couns., Psych., D.T.A.T.I.
Counselor, Art Therapist
Casey House Health Inc.
Toronto, Ontario, Canada

Abstract:

Art Therapy is a useful medium for the expression, recognition and processing of the anxieties of People With AIDS.

In this paper and slide presentation, issues of pain, incompleteness, failure, isolation, dependency, punishment, fear of the unknown and homophobia are expressed in the artwork and subsequent discussion.

The workshop will present one PWA artwork produced over the course of 3 months to illustrate the development of the process of art therapy. Several other examples of specific statements through artwork will also be shown. Two aspects of denial will be suggested.

W.B.P.244 MAINTENANCE OF HOPE IN AN HIV SEROPOSITIVE

Reidish, Judith, Williams, J., Macgregor, R., Reising, Robert
RV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, NY, NY, USA

Objective: To identify social and psychological conditions, susceptible to intervention, that contribute to maintenance of hope in an HIV seropositive.

Methods: 156 gay, predominantly white, well educated and financially successful community volunteers were evaluated to identify overall level of psychological functioning, psychiatric symptoms and syndrome, life outlook, social relationships, life events, HIV status and illness stage. 79% of participants were HIV seropositive.

Results: The following were positively associated with higher levels of hope (Pearson's r, p < .02): social supports (+0.22), internal locus of control (+0.36); commitment (+0.60); number of positive life events (+0.28); and global psychological functioning (+0.21). HIV illness stage and T cell count among HIV seropositive were not significantly related to levels of hope. In the absence of current psychiatric disorder, sero-negative, same difference in level of hope between HIV and HIV+ subjects was not statistically significant. There was, however, more variability of response and more extreme scores within the HIV+ group, at both ends of the distribution.

Conclusion: The large majority of respondents have been able to preserve a sense of faith in the future and the conviction that living is worthwhile, despite HIV infection.

W.B.P.245 A REHABILITATION PROGRAM FOR CLIENTS WITH HIV ASSOCIATED CONDITIONS

Genulis, Patricia, Marshall K., Bennett M., Laquer P., Alexander H., Davis L. Woodhull
Medicaid & Mental Health Center, Brooklyn, NY, USA

Objective: This poster presentation will highlight the special and unique role Rehabilitation Medicine can provide in servicing people with AIDS (PWAs).
Methods and Results: Woodhull Medicaid & Mental Health Center, as part of NY City's Health & Hospital Corporation, provides comprehensive tertiary-care services to a large impoverished and medically underserved community. As part of the Department of Ambulatory Care, Rehabilitation Medicine offers physical and occupational therapy services to a wide variety of patients, including those diagnosed as having AIDS or AIDS-related complications. The growing number of PWAs is challenging all health care specialists to define their role in providing services to this population; Rehabilitation Medicine is no exception. PWAs or AIDS-related conditions may present with a wide variety of physical, emotional, and psychological problems. Consequently, the role of Rehabilitation Medicine will include: 1) maintaining level of functioning in activities of daily living; 2) supporting continued participation in occupational roles; and 3) improving the quality of life.

This presentation will describe and demonstrate a therapeutic rehabilitation group developed for PWAs. Led by an occupational therapist, the goals of the group lie chiefly in teaching coping and adaptive skills specifically for PWAs. Conditioning exercises, breathing and relaxation exercises, and self-care training are integral parts of the comprehensive program.

Conclusions: People with AIDS are faced with the daily challenge of living with their condition. This presentation will highlight what role Rehabilitation Medicine, especially occupational therapy, can play in promoting skills to achieve maximal independence.

W.B.P.246 COMPLIANCE OF HIV-INFECTED INTRAVENOUS DRUG USERS IN CLINICAL TRIALS

Jefferson, C.; Bialik, M. et al. University of Massachusetts Medical School, Worcester, Massachusetts, USA

Objective: To compare compliance of clinical trial subjects whose risk factor is intravenous drug abuse (IVDU+) with those from other risk groups.
Methods: Subjects are HIV sero positive on RIA AZTQ placebo-controlled trials of Zidovudine in asymptomatic infection (019) and early ARC (016). IVDU+ were either drug-free or on methadone maintenance at the time of protocol entry. The number of pills returned at each visit was tallied and periods for which patients returned < 20% of study drug were deemed to represent good compliance. This corresponds to missing no more than one dose per day.
Results: Four of 11 IVDU+ have left the studies for reasons other than protocol endpoints, compared with one of 20 from other risk groups. All 5 were asymptomatic. None of the 9 patients with symptoms of early ARC have left this, although 4 are IVDU+.

All patients on study	Percent of Study Weeks in Good Compliance	
	IVDU+	Others
016 (early ARC)	93	93
019 (asymptomatic)	99	94
> 10 weeks (biweekly follow-up)	86	93
> 16 weeks (biweekly follow-up)	90	92
> 18 weeks (monthly follow-up)	98	89

Conclusions: Although IVDU+ discontinues study participation more often than others, their adherence while on study, as measured by pill returns, does not differ markedly from subjects from other risk groups.

W.B.P.247 INSURING QUALITY OF DATA IN COMMUNITY-BASED CLINICAL TRIALS

Michael T. O'Leary, C.T. Neuwirth, E. J. and Bruce, Donnell
San Francisco County Community Consortium, San Francisco, USA

Community-based clinical trials of experimental HIV treatments offer the potential for rapidly expanding the number of drugs being tested, maintaining the participation of community physicians in HIV research, and improving access to promising experimental therapies for large numbers of patients. Critics of community-based clinical trials, however, argue that the quality of data obtained in community settings is unlikely to achieve standards established in academic research settings.

To meet this challenge, the San Francisco County Community Consortium (SFCCC) designed data collection, protocol management and quality assurance systems which could be implemented in community physicians' offices. In Fall 1989, the SFCCC trained 45 physicians to use these systems and launched 5 clinical trials. Studies include 21 trials of readily available available agents as well as observational databases of current HIV therapies.

To insure consistent data collection by large numbers of physicians located over a wide geographic area, SFCCC uses the same set of case report forms for all clinical trials. To minimize the amount of record keeping required of physicians, the SFCCC uses a computerized follow-up system to prompt physicians to collect data and to dispense study medications at prescribed intervals. To insure data accuracy and completeness, SFCCC staff systematically review all case report forms before data are removed from physicians' offices and entered into the SFCCC database management system.

The experience of the SFCCC suggests that frequent (weekly) monitoring by research staff is necessary but sufficient to insure that data collected in community settings achieve standards established in academic research centers.

W.B.P.240 EVALUATION DE LA CHARGE DE TRAVAIL INFERMIER COMPARAISON ENTRE PATIENTS HOSPITALISÉS INFECTÉS ET NON INFECTÉS PAR LE VIH. CHU DE CHIRURGIE - CHASSAGNY D., BEAUCHEMIN G., LEROY D.,

Centre Hospitalier, F. 92028 TOURNAI, FRANCE.
L'intensité des soins infirmiers ont été étudiées fin 1988. La structure et l'intensité des soins infirmiers ont été étudiées fin 1988. Les données prospectives dans un service universitaire de Maladies Infectieuses par respectif quotidien des informations. 64 données sont disponibles. 29 patients infectés par le VIH (dont 15 PVI) et 25 patients hospitalisés pour pathologie infectieuse non parasitaire non VIH, correspondant respectivement à 516 et 342 journées d'hospitalisation. Les soins de base (alimentation, locomotion, mobilisation, alimentation, hygiène et confort), techniques (diagnostics) et thérapeutiques, relationnels et éducatifs, sont classés de 1 à 5 en fonction de leur intensité.

W.B.P.249 AIDS RESEARCHER REGISTRY (ARR) OF NEW YORK

Long, Iris; Cowing, R. J.; Esig, J. and Huff, R. AIDS Treatment Registry, P.O.B. 30234, New York, New York, USA.

Objective: To provide information about ongoing clinical trials to individuals seeking to enroll in clinical trials, physicians, health facilities and AIDS service organizations in New York and New Jersey.

Method: A local, non-profit organization has established a computerized database to give accurate, reliable information on AIDS-related clinical trials because up-to-date, accurate information is not easily accessible.

Result: It is generally accepted that access to health news and experimental treatments will extend the lives of many infected with HIV. Acquiring information about clinical trials is limited. This has led to underrepresentation of minorities and overall underenrollment in trials.

The latter is one of the factors slowing down the drug approval process. According to the Food and Drug Administration, there are currently over 80 drugs approved for trials and over 100 drug trials.

In October 1989, a federal law was enacted requiring sponsors of AIDS drug trials to make public all AIDS efficacy trials. The impact of the new legislation on the project will be discussed.

Conclusion: The ARR will identify all AIDS/HIV-related clinical drug trials underway locally, collect data from principal investigators conducting such trials to determine where "open slots" exist and what is required of prospective drug trial participants. This information will be developed into a readily accessible report format and distributed to all potential end-users.

W.B.P.250 A REGIONAL MODEL FOR ESTABLISHING A COMMUNITY-BASED, COMPUTERIZED REGISTRY OF AIDS/HIV CLINICAL DRUG TRIALS.

Kigo, James; Cowing, R. J.; Long, I. AIDS Treatment Registry, Inc., Arr, P.O. Box 30234, New York, New York 10011, U.S.A.

Objective: To establish community-based registries of AIDS/HIV-related clinical drug trials at local levels to increase awareness of, and access to, such trials for persons affected by the epidemic, especially among minority populations heretofore largely excluded from enrollment.

Method: Discussion of the steps taken by the ARR to gather information on AIDS/HIV-related clinical trials underway in their area and disseminate that information to members of all affected populations, including intravenous drug users (IVDU), blacks and Hispanics, women and children, and the poor. Discussion topics will include: becoming your own "expert" on clinical trials; developing a database; developing data collection materials; volunteer recruitment and training; overcoming obstacles in collecting data; producing "user-friendly" report formats; developing culturally sensitive education materials covering trial enrollment issues and the use of experimental drugs; establishing a community outreach and distribution network and qualifying for available funding.

Result: ARR's effort has been highly successful. They have obtained the aid of City and State health officials in collecting their data and were funded by N.Y. State in their first year of operation. A bi-lingual "Handbook for Clinical Trial Participants" has been produced. Trial enrollment statistics are closely monitored to quantify the overall impact of the effort. **Conclusion:** A community-based registry of trials can promote greater access to potential treatments and enhance trial enrollment.

W.B.P.251

PROGRAM DIRECTORS' ATTITUDES TOWARDS RESIDENTS' CARE OF PERSONS WITH AIDS. HARRISON S.A., Kowitz, R. K.

Shapiro, M. F., University of Michigan, Ann Arbor, Michigan, U.S.A. * University of California, Los Angeles, California, United States.

Objective: To evaluate the educational strategies and experiences of United States residency programs regarding the training of primary care providers for persons with AIDS (PWAs).

Methods: We mailed questionnaires to directors of all 772 non-military United States Internal Medicine (IM) and Family Medicine (FM) programs. 50% have responded.

Results: While 51% of directors felt that primary care of PWAs is an important educational experience and 84% of programs reported usually having AIDS inpatients, only 15% reported that the majority of trainees cared for PWAs in their continuity clinics. In programs with a high treatment load (average mean ≥ 8), only 39% reported that most residents had either cared for a PWA in their continuity clinic or had rotated through an AIDS subspecialty clinic. More IM than FM directors considered care of PWAs to be too complicated for most generalists (24% vs 9%, p<0.01) and IM directors were less likely to encourage "rounds" to provide PWAs with primary care (51% vs 72%, p<0.01). Among 57% who did not believe or were unsure if their residents were adequately trained in AIDS ambulatory care, only 28% reported inpatient rotation in this area to be a high priority. Among the 39% who do not encourage residents' assumption of primary care, 60% had at least one of the following concerns: resident stress (24%), AIDS care too complicated (31%), or clinic faculty not qualified to supervise (28%).

Conclusions: While program directors view education in ambulatory care of PWAs as important, most do not believe residents are adequately trained, many do not encourage residents' assumption of primary care of PWAs and residents have not provided such care in their programs. Strategies to augment residents' ambulatory experience in the care of PWAs are needed.

W.B.P.252 IMPACT OF SERUM p24 HIV ANTIGEN SCREENING ON PATIENT ELIGIBILITY FOR ANTIVIRAL TRIALS

Hugh, Christi; Mann; Peartree; G. Eigenmann; J.; Comstock; C.

Concord, B. Beth Israel Hospital, Harvard AIDS Clinical Trial Unit, Boston, MA, USA.

Objective: To examine the impact of serum p24 HIV antigen (p24) screening on patient eligibility for an antiviral clinical trial.

Methods: [ACTG 0834 Phase I Trial of Ribavirin in the Treatment of Patients with AIDS and Advanced AIDS-Related Infections (ARCI)] requires positive serum p24 for inclusion. Screening inpatients and review of medical records determined clinical stage of HIV-related illness and Zidovudine (AZT) use. Blood was obtained from patients with ARCI and AIDS and serum tested for p24 using the Abbott ELISA. A level of 2.0 U/ml (program) was

deemed a positive (+) and qualified patients for study enrollment.

Results: 45 patients were screened to the point of p24 testing with the following results:

31.2% +, 14.4% -

8 ARCI, 22 AIDS 4 ARCI, 19 AIDS

15 had prior AZT use 4 had prior AZT use

p24 positive did not significantly correlate with either clinical stage or AZT use by Chi square analysis. Four + patients were later retested and 2 had converted from + to -.

Seventeen + patients have been orally treated and have remained +.

Conclusion: Use of p24 positive as an eligibility criterion for phase I antiviral trials will limit access of significant numbers of clinically indistinguishable patients to these trials. The impact of such exclusion on the applicability of trial results may be significant.

W.B.P.265 CLINICAL CARE AS PART OF INTEGRATED AIDS MANAGEMENT IN A RURAL HEALTH CENTER.
Chela, Silvestre M.; Campbell, L.D.; Silvanaga, Z.
The Clemente Ximé Chamblán Hospital, Marabato, Zambia.

Object: 1) to present an analysis of clinical symptomatology with a summary of major problems for hospital management of patients with AIDS compared with patients in the home based care and prevention programs;

2) to analyze drug use and drug costs in the hospital and in the home based care setting.

Methods: A retrospective analysis of 200 inpatients and 200 patients in the home based care programs was done. The observed manifestations of AIDS are described, by organ systems, and treatment protocols are described, incorporating an analysis of drug use and cost on some of these diseases. Results, tables and figures are presented showing main presenting symptoms found both in hospital and at home, and indicating that treatment protocols followed were similar with respect to drug costs.

Conclusion: It is proposed that home based care and prevention with hospital intervention where required is the most practical and sustainable form of organization for an integrated approach to management for a district rural hospital. Furthermore, it is proposed that therapeutic constraints of certain kinds are acceptable in the context of shared acceptability by therapeutic teams, by patients, and by committees connected to the patients.

W.B.P.266 STUDY OF A SERIES OF 121 CONSECUTIVE AIDS PATIENTS.
CONSELHEIRO, M.S.; SILVA, M.A.; BRANCO-MELO, C.E.; LEITE, C.
FAC. DE MEDICINA, U.F.R.J., RIO DE JANEIRO, RJ, BRASIL.
Clínica Médica A, da Universidade do Rio de Janeiro, UFRJ, Brasil.

The aim of the work was to study epidemiologically, Clinically and laboratorially a series of 121 consecutive AIDS patients, admitted to the Clínica Médica A, da Universidade do Rio de Janeiro, during the 1985-86 period.

METHODS: All the 121 consecutively admitted patients were studied trying to figure out the possible forms of transmission and therefore grouping them in the so called-risk groups. They were scored up as thoroughly as possible, either clinically as laboratorially.

RESULTS: Ninetyten of the patients were women and 102 were men. Of the men 59 were homosexuals and 6 were bisexuals (two of them was also an intravenous drug addict. One was a drug addict, the most frequent infections were systemic candidiasis (56), P. carinii pneumonia (28), tuberculosis (28), toxoplasmosis (12) and cryptococcosis (11). Five patients only had Kaposi's sarcoma.

CONCLUSION: Although the Clínica Médica A, da UFRJ admits both women and men (twice more women) 102 of the 121 patients (84,29%) were men. Homosexuals and bisexuals represented 97% of the total of males and 84,21% of the women probably got the infection through blood transfusions.

W.B.P.267 AIDS ISSUES FOR RURAL HOSPITALS IN U.S. FRONTIER AREAS
CAMPBELL, MARGARET D.; University of Nevada, Las Vegas, Las Vegas, Nevada, U.S.A.

Objective: To identify and assess the experience rural frontier hospitals (under 50 beds) in the U.S. in the provision of care to HIV infected patients and to evaluate the preparedness of these hospitals to provide AIDS care via education and policy development.

Methods: A survey addressing the incidence of HIV infection in the hospital's service area, services provided to HIV infected patients, concerns of hospital employees regarding care of AIDS patients, provision of education and policy development was mailed to all frontier hospitals (n=108) in 8 states.

Results: Frontier hospitals in 7 states had had experience with HIV infected patients. Of the 46 hospitals who responded 13 had had experience with AIDS patients and 33 had not. Of the 13 with experience 9 provided care in the facility and 4 referred the patients. Surprisingly, employees in hospitals with experience expressed more concern about acquiring AIDS than those in hospitals without experience. Nurses Aids had the highest concern 4 had refusals to provide care. AIDS education consisted mainly of video programs, presentations by in-house staff and sending employees away to workshops. Major concerns expressed by the hospitals related to enforcing universal precautions, confidentiality of patient information, staff response, community acceptance and the incidence of AIDS is increasing in rural areas throughout the U.S. Effectiveness of educational programs is questionable given the concern of staff in frontier hospitals with AIDS experience and education. Education and policies are essential to guide hospital personnel in the provision of AIDS care.

W.B.P.268 SEROPREVALENCE OF HIV, HERPES VIRUSES AND IMMUNOLOGIC ABNORMALITIES IN A GROUP OF IV DRUG ADDICTS
Pacheco, Constantino Z.; Scheidt, Luciano, J.; Schaefer, M. Doris, M.; EDWARDS HINES V.A. Hospital, Hines, Ill., U.S.A.

Objective: To determine the prevalence of infection with Epstein Barr Virus (EBV), Cytomegalovirus (CMV), herpes simplex virus (HSV), and HIV, and to correlate seroprevalence with immunologic abnormalities in a group of IV drug abusers.

Methods: HIV status was determined by ELISA and confirmed by Western Blot; viral serology was done by indirect immunofluorescence; lymphocyte subsets were done by flow cytometry.

Results: The seroprevalence of CMV, EBV, HSV, and HIV were respectively 7/103, 103/103, 7/103, and 4/111. No patient had evidence for clinical infection with any of these viruses. Of the HIV infections 28/103 had recent and 11/103 had chronic active infection. These 37 patients had higher percentages of lymphocytes but no difference in CD4/CD8 as compared with all others. Patients with recent or chronic active EBV infection with dual infection with CMV had higher CD8 and lower CD4/CD8 than either those without EBV infection of all others. A similar effect on the CD4/CD8 was not seen with the combination of recent or chronic active EBV infection and HSV infection.

Conclusion: Since dual infection with CMV and HIV may be lower the CD4/CD8, use of this parameter as a prognostic factor or as an indicator for starting therapy in HIV positive patients should be done with caution.

W.B.P.269 PSYCHOLOGICAL ISSUES ASSOCIATED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION IN A CITY HOSPITAL: EXPERIENCE OF THE MULTIDISCIPLINARY PATIENT CARE MEETING.

Chang, Tony; Wiseman, H; McNeil, A. Queens Hospital Center (QHC), Affiliation of the Long Island Jewish Hospital Center, Jamaica, N.Y. 11432 USA

Objective: To survey the prevalence and range of psychosocial issues associated with HIV infection as discussed at QHC AIDS Team multidisciplinary meetings.

Methods: Records of the AIDS multidisciplinary patient care meetings at QHC from March, 1988 to October, 1988 were evaluated for psychosocial issues presented. These issues were broken down into 7 categories: denial, anxiety, depression, suicidal ideation, drug use, psychosis and organcity.

Results: 108 patients were discussed at the patient care meetings. Of these, more than 80% had psychosocial difficulties. The age range was 20 to 64 (mean=34). 74.1% were Black, 11.1% Hispanic and 7.4% were White and Native. 73.1% were IVU, homosexual 11.1%, heterosexual 13.0% and blood transfusion related 2.8%. The psychosocial issues were: denial 7/108 (6.5%), anxiety/fear 18/108 (16.7%), depression 20/108 (18.5%), suicidal ideation 7/108 (6.5%), drug use 15/108 (13.9%), psychosis 13/108 (12.0%), organcity 20/108 (18.5%).

Conclusion: The data reflect the significant psychosocial morbidity associated with HIV disease. This study supports the importance of a multidisciplinary approach to dealing with HIV.

W.B.P.270 TRIAGE SYSTEM FOR POTENTIAL RESEARCH SUBJECTS INTO ACTIVE AIDS CLINICAL TRIALS.
MORSE, V. M.; J. Holliday, M.D.; P. J. Volberding, P.H.D.; N. M. University of California, San Francisco, San Francisco General Hospital, U.S.A.

Objective: To evaluate a computerized triage system for potential research subjects collecting important laboratory and clinical data, identify individuals and specific populations for a targeted recruitment.

Methods: A data base has been created to facilitate access into active AIDS clinical trials. Individuals interested in participating in clinical research are mailed a brief description of the present research, a long-term summary of clinical research methodology, and a preliminary registration form. After completion, the registration form is returned to the AIDS Triage Service. A research nurse then contacts the individual to complete a research profile which is entered into the data base. The profile includes dates and quantitative values of most recent p24 antigen (p24Ag), Beta-2 microglobulin (B2MG), lymphocyte counts, and CD4+ lymphocyte counts and CD4+ antigen status.

Conclusion: The data base is used to preliminarily screen subjects by comparing trial inclusion criteria with the population in the data base. Continuing data base participation requires research profile updating every three months.

Table: A total of 808 subjects are currently in the data base, with 186 seropositive (CD4 \geq 351, CD4/CD8 \geq 1.0), and 200 AIDS (CD4 \geq 100, CD4/CD8 \geq 1.0). Subjects have the following CD4+ lymphocyte count and p24 antigen status.

CD4+ lymphocytes	p24Ag	CD4	CD8	CD4/CD8	CD4	CD8	CD4/CD8
≥400	≤5000	381	400	0.95	186	186	1.00
300-400	5000-10000	117	117	1.00	186	186	1.00
200-300	60500*	43	314	7.34*	3	141	47.0
100-200	100000*	15	15	1.50	3	101	33.7
TOTAL		556	637	1.15	191	109	609

*Percentage of subjects who have their antigen status
Conclusion: A data base of potential research subjects containing clinical and laboratory data enables targeted research recruitment and preliminary screening of eligibility criteria.

Aspects cliniques Clinical Aspects of AIDS

W.B.P.277 DIETHYLDITHIOCARBAMATE INHIBITS THE PROGRESSION OF HIV INFECTION. RESULTS OF A PROSPECTIVE RANDOMIZED CLINICAL STUDY

Authors: Manfred et al.
Bernhard-Noell-Institute for Tropical Medicine, Clinical Department; AK St. Georg, Dermatology; AK Ochsensaal, Neurology; Hamburg; Forschungsinstitut Borstel, Germany, Institut Medizinisch, Garmersy.

Objective: Diethyldithiocarbamate (DTC) is a chelating agent with in vitro and in vivo influence on the production of HIV. Recently, J.M. Lang et al. (Lancet, Sept. 24th, 1986, 702-703) presented their data of a 4-months treatment study with positive response both in improvement of patients and in 14-cells. In 1986, we initiated a study in order to evaluate the efficacy of DTC in patients with HIV infection. Walter Reed 2-4.

Methods: 40 patients were randomized to DTC 5 mg/kg i.v., DTC 10 mg/kg orally once a week for a period of 6 months. Both groups were placebo-controlled. **Results:** The results are given in the following table:
CD4+ classification, progression to AIDS, changes in immunological parameters. In the placebo group compared to DTC (0.4.0.0.0), the oral application showed the same trend (7 placebo patients progressed in contrast to 3 of DTC), in the DTC i.v. group, none progressed to AIDS. In contrast to 6 placebo patients (log Rank test p<0.05), the interleukin-1 production and interleukin-2 receptor expressing monocytes were significantly different at the end of the treatment. The ratio of 14-cells before and after treatment was significantly different between placebo and DTC treated patients.

Conclusion: DTC is effective to slow down the progression of HIV infection in patients with CD4+ classification 2-4. It seems not to be able to increase the absolute number of 14-cells.

W.B.P.279 RECOVERY OF DELAYED-TYPE HYPERSENSITIVITY (DTH) IN PATIENTS WITH AIDS-RELATED COMPLEX (ARC) IN RANDOMIZED TRIALS OF INDS-1

Authors: Hais, Miles, Com, LaFand, Sayre, Eisenhorn Medical Center, Rancho Mirage, CA, USA; *UCLA School of Public Health, Los Angeles, CA, USA.

Objective: INDS-1, an immunoregulator containing tyrosine-glycine (tyrosine) enhances multiple immune functions. We have studied INDS-1 in patients with ARC or Kaposi's sarcoma (KS) regarding efficacy and immunomodulating effects.

Methods: Forty aseptic patients in Southern California were treated every 2-3 months with tetanus toxoid (TT) during the trial and with TT and candida (CA) during compassionate INDS-1 administration after the trial. The following were analyzed: (a) re-activity to patients (2 with KS and 27 with ARC) in the INDS-1 group and 11 patients (all ARC) in the placebo group; (b) re-activity to 27 patients respectively. The 2 groups were comparable with respect to baseline characteristics and the number of dropouts.

Results: In the INDS-1 group, 9 (41%) became reactive to TT after an average of 285 days whereas, in the placebo group, 1 (14%) recovered DTH after 437 days. Six (27%) INDS-1 treated patients and 2 (19%) from the placebo group became pneumoniae (PCP) infected in the INDS-1 group during 11,681 person-days, and 5 opportunistic infections (2 PCP's, 2 wasting syndromes, and 1 demiasis) developed in the placebo group during 3,916 person-days (rates 0.17 (INDS-1) vs 1.37 (placebo) infections per 1000 person-days, relative risk = 7.47, p=0.003).

Conclusions: Forty-one percent patients recovered DTH to TT after an average of 280 days of INDS-1 treatment. Patients initially in the INDS-1 group had better clinical outcome during and after the trial.

W.B.P.281 Inhibition of T Lymphocyte-Related functions by Imunitrol® through down regulation of prostaglandin secretion by monocytes/macrophages.

Authors: M. El-Medany, Dailou, A.H., Bertho, I.M. and Debré, C.HU Pitié-Salpêtrière, Paris, France.

Objective: Description of immunomodulating effect of Imunitrol® (iodium diiodate, DTC).

Methods: PHL, their adherent cells and T cells were assayed for their capacity to produce IL2 and PGE2 in response to PHA with/without 10^{-6} mg/ml Imunitrol®. The effect of Imunitrol on IL2 and PGE2 secretion by adherent cells was also evaluated using thymocytes assay and RIA method respectively.

Results: Imunitrol® increased proliferative responses of PHL to PHA as well as their ability to secrete IL2. This stimulating activity was not seen when these cells were depleted from their adherent cells. In addition, Imunitrol displayed high inhibitory effect on PGE2 production by these cells but IL2 levels remained unchanged.

Conclusions: Imunitrol enhanced non T cell related functions through its ability to down regulate monocytes/macrophages derived PGE2 as these molecules were known to inhibit non T cell related functions and specially helper activities.

W.B.P.278 TREATMENT OF HIV-INFECTED PATIENTS WITH D-PIRACETAMINE - THERAPEUTIC CLINICAL AND IMMUNOLOGICAL RESULTS -

Authors: BERNHARDT, R. HINNE, A., LUDWIG, G., LUDWIG, M., NITZKE, M., JURY, A., ***
*Unit of Clinical Studies, *Institute for Clinical Microbiology and *** Institute for Clinical and Experimental Virology of the Berlin, G.F.R.

Objective: To evaluate the compatibility and clinical, immunological and virological efficacy of D-Piracetam before, during and after a 6-week therapy in HIV-1 seropositive patients (pts).

Methods: Prospective randomized placebo-controlled study, test criteria: lymphocyte-subsets (CD4+, CD8+, CD4+/CD8+), HIV-antibody, lymphocyte-proliferation test (LPT) after PHM and tetanus-antigen stimulation, pH antigen (Daport Co.) and HIV-infection in primary blood lymphocytes. **Results:** 101 pts (17 men) (13 homosexual, 11 v. drug users, age 27 to 62, v. CD4-cells 114, 111 E, 10 F) are randomized to either placebo (n=50) or D-Pir (resulting ratings: 600,100,200 wU/l for 6 weeks orally, the HIV-antibody were generally high, but in 2 pts therapy was discontinued because of drug adverse reaction (fever, diarrhea/vomiting), no stage progression could be seen, the first test showed a slight reduction of lymphocyte subsets and lymphocyte proliferation test (LPT) before and the 6th week after therapy with D-Pir (CD4+/CD8+ ratio: 0.61/0.70/0.30, creatinine 0.80/0.90 wU/l (0.70/0.74), protein/day in urine 4,1/7.4 g/l (0.2/0.1), CD4+ lymphocytes 444/426/274 (1/0.4/0.5/0.7), CD8+ 105/101/121 (0.4/0.6/0.8), CD4+/CD8+ 4.1/3.9/3.9 (1.1/1.3/1.7/0.9), HIV-antibody 88/75/78/67 (1 (0.8/0.8/0.5/0.1) (11 weeks test p=0.38), no change was seen in the LPT, PHM 14/10/13 (2 v. test 0.6/0.7) (2 v. test). PHM antigen could only be detected in three pts. After therapy and seems to be of limited value for monitoring.

Conclusions: First results show a good compatibility of D-Pir in HIV-infected patients; the relevance of the observed alterations in the lymphocyte subsets is not clear yet.

W.B.P.280 EFFECT OF PROPRIOSENE ON HIV-ANTIGENEMIA

Authors: Lutz S. Teubner, S. Kroon, T. Moestruer, B.G. Hansen, B.F. Vestergaard, and Scandinavian Infection Study Group. *Hvidovre Hospital, Denmark, **Uppsala Hospital, Denmark, ***Malmö Almänna Sjukhus, Sweden, ****Statens Serum Institut, Denmark.

Objective: To evaluate the effect of Iproprisine on HIV-antigen levels.

Methods: A multicentre, double-blind placebo controlled study of Iproprisine was carried out in 21 clinical centers in Denmark and Sweden.

Eighty-four HIV-1 positive patients received treatment for 6 months with either Iproprisine 3 grams a day or matching placebo. The study population included anti-HIV-positive patients without AIDS. The patients were block randomized according to the number of CD4+ lymphocytes. Serum samples were collected at entry and during treatment and stored frozen for later antigen detection.

Results: The data will be presented and correlated with clinical and other immunological markers of disease progression.

W.B.P.282 A MULTICENTER RANDOMIZED DOUBLE-BLIND PLACEBO CONTROLLED DOSE RESPONSE TRIAL OF LF 1695 IN P24-ANTIBODY NEGATIVE PATIENTS.

Authors: Rouf, Berré*, Kanner, J.L.**, Demont, D.***, Fleury, H.****, Lang, J.M.****, Meunier, Y.**** and al.
*Scientific coordinator of the trial, Hôpital Militaire Bégin, Saint-Mandé, France; **Member of the trial, Centre de Recherche, Laboratoire Fournier, Dijon, France; *** CRISA, CEA, Fontenay aux roses, France; **** Hôpital Pellegrin, Bordeaux, France; ***** Hôpital Haapijervi, Strasbourg, France; ***** Centre Hospitalier, Tourcoing, France.

Objective: LF 1695 is a synthetic biological response modifier with immunostimulating and enhancing effects in animal as well as in human in-vitro and in-vivo. He has also shown in some in-vivo experiments an inhibitory effect on HIV-1 replication. On the basis of these findings, we conducted a clinical trial to evaluate the virological, immunological and clinical impact of LF 1695 in P24-antigen seropositive patients.

Methods: A multicenter randomized, double-blind, placebo-controlled, dose-response trial in progress in 60 HIV infected patients (CDC group II to IV), with a P24-antigen level higher than twice the cut-off level (Abbott). Patients receive twice a day a placebo or 120 mg or 240 mg of LF 1695 in capsules for three months. Parameters measured are reverse transcriptase level, P24-antigen, T-cell antigen expression, serum immunoglobulin and β_2 -microglobulin, clinical evolution and routine hematological and biochemical tests. Results: Forty seven of the 60 expected patients have actually entered the trial. **Conclusion:** Final results of this ongoing trial will be presented and discussed.

Aspects cliniques Clinical Aspects of AIDS

W.B.P.301 Clinical efficacy of Isonthiol[®] (sodium dithiocarbamate) in HIV-infected patients.

A review of 4 controlled studies and long term follow-up.

CARLAB, JEAN The International AIDS Isonthiol study group (France, Germany, USA), Lyon France.

Between November 1983 and December 1986, more than 2100 HIV-infected patients have been enrolled in double-blind, placebo controlled studies of Isonthiol[®] (sodium dithiocarbamate, DTTC). To date, results from three controlled studies in 170 ARC patients are available and results from a study in 387 ARC patients and 150 AIDS patients in 8 US sites will be available before June 1988. In France, 1,600 asymptomatic/LA patients have been enrolled in a long term double-blind, placebo controlled study between July 1987 and July 1988. This study is ongoing. From the first three controlled studies (US, France, Germany), three clinical end points have reached statistical significance:

1. Isonthiol delayed progression to AIDS in ARC patients: 15 patients progressed to AIDS in the controlled group vs 2 in the Isonthiol group. This was statistically significant in the German study (p progression vs non, p < 0.05; Logrank test).
2. Isonthiol slowed down progression to CDC class in ARC patients.
3. Isonthiol induced regression in some constitutional symptoms of HIV-infection (group IV-A symptoms, lymphadenopathy, splenomegaly).

The US multicenter study on 372 patients is now terminating and results on major clinical efficacy endpoints will be available in June.

W.B.P.303 ACUTE RESPONSES TO AMPLIGN INFESTIONS IN HIV-INFECTED PEOPLE

Paris George J, Wang K, McMahon D, Armstrong JA, Rinaldo G, et al. Pittsburgh AIDS Clinical Trial Unit Investigators, University of Pittsburgh Medical Center, P.A.A.

OBJECTIVE: To report our clinical and laboratory observations in HIV-infected patients associated with acute reactions during intravenous infusions of synthetic sweetened double-strepted SEA (Amplign).

METHODS: Ten acute reactions (flushing, dysphoria, shivering, chills, fever and chest tightness) occurred in 3 of 17 persons receiving twice weekly infusions. Infusions were stopped temporarily during reactions then finished at a slower rate. No reactions required discontinuation of treatment.

RESULTS: Reactions were observed in 0/6 persons receiving 30 µg/ml, 1/6 receiving 40 µg/ml (person #2006) and 2/5 receiving 120 µg/ml (persons #217c and #219). Acute depressions of PMNs were observed as soon as reactions subsided (within 15 minutes) and as of reinfusions and were followed by leukocytosis. Leukocyte counts (x10⁹/ml) are summarized as follows:

patient	Pre-infusion	End-reaction	End-infusion	1-2 hrs. later
#2006 (3 obs.)	5.4	3.1	7.5	8.8
#217c (3 obs.)	6.7	3.1	7.5	9.3
#219	5.3	2.1	3.2	4.3

Granulocytes were mainly responsible for these changes. During 6/7 reactions cytotoxic activity of peripheral leukocytes against E261, 9337 and HIV-infected 4937 targets were depressed 2 hr post-reactions as compared to pre-infusion values. **CONCLUSIONS:** Acute leukopenia associated with amplign-infusion-reactions was followed by leukocytosis 1-2 hrs. later. Cytotoxicity against three different targets was also suppressed at 2 hours.

W.B.P.305 Neopterin and T-helper/neopterin ratio in the monitoring of long-term treatment of HIV-infected patients by Isonthiol[®]

Isidore Elmorh, D.T.C. Mordant, M. Bouchard, André Durkai, Anne Feltesse**
*Hôpital St-Anthoine (Service Prof. Frontier), **Laboratoire Durkai, St-Anthoine Medical, Paris and Lyon, France.

OBJECTIVE: To investigate whether urinary neopterin (UN) and T-helper (T_H) / UN ratio correlates with prognosis in long-term therapy by Isonthiol[®].

METHODS: 36 HIV-infected male homosexuals (age 37, range 22-45 years, weight 71 kg, range 57-86) were treated with Isonthiol[®] (10 mg/kg once a week) for a mean duration of 37 months (range 9-96 months), starting in August 1986. 21 belonged to group III and 15 to groups IV-A and IV-C at entry. 27 had less than 40 T_H cells at entry. Patients were monitored every 3 months. UN (µmol/l) was measured by HPLC and T_H cell count by immunofluorescence.

RESULTS: Among over 100 evaluations, the T_H/UN ratio correlated well with absolute T_H level. In 3 instances, an elevation of UN was seen without decrease of T_H count. This was related to associated infections. Under Isonthiol therapy, T_H/UN ratios increased in 30/36 patients, was stabilized in 20/36 patients and dropped in 6/36 patients. Only one of these 6 progressed to an AIDS-C2.

CONCLUSIONS: T_H/UN ratio is useful in monitoring progression of HIV-infected patients. It remains stable or increases in 30/36 patients treated with Isonthiol for prolonged periods of time.

W.B.P.302 TWO MONTH DOUBLE BLIND PLACEBO CONTROLLED TRIAL OF CYCLOSPORIN IN HIV ASYMPTOMATIC SUBJECTS

J.E. Aboujaif J.M. Aronoff, J.A. Gustafson, P. Debre, B. Milpied-Hornet et al. Groupe INSERM CICL-074, FRANCE

OBJECTIVE: To evaluate, in a multicenter, double blind, placebo controlled trial, the short term effects of cyclosporin on peripheral CD4 counts.

METHODS: 68 HIV asymptomatic or lymphadenopathic seropositive patients with initial CD4 counts between 300 and 620/mm³ were randomly assigned to cyclosporin 7.5 mg/kg per day or placebo for a 8 week period of treatment. Doses were adapted in order to maintain trough blood levels ranging from 400 to 700 ng/ml. Cyclosporin dose was in average more than 6.8 mg/kg throughout the trial. The double blind design was achieved by adaptation of placebo doses of matched controls.

RESULTS: A significant (p<0.01) CD4 increase was observed in cyclosporin group compared to placebo at week 1 (148/mm³) and week 2 (146/mm³). Similar group was observed in CD4 cell and total lymphocyte counts, thus the proportions of CD4 and CD8 subsets and the CD4/CD8 ratio did not change. At week 8 CD4 cell counts were in average identical to the 2 groups. Side effects observed were mild and no adverse reaction to progression to AIDS or ARC occurred during the 4 month period (treatment and follow-up) of the trial.

CONCLUSIONS: The effect of cyclosporin on elevating CD4 + lymphocytes was limited to a treatment and weak increase not possible to come to a conclusion regarding the efficacy of a long term immunosuppressor treatment on the basis of the results of the 2 month trial.

W.B.P.304 Failure of isoprinostone in prevention of ARC to AIDS

Barbara, Dantai and Pragas, K. University of Texas Southwestern Medical Center at Dallas, Texas, U.S.A.

Objective: To determine the effect of an immunomodulator, isoprinostone (isoprinosin) in delaying the progression of disease in HIV seropositive male patients with CD4 counts of 200-400/mm³.

Methods: A prospective, multicenter, randomized, double blinded, placebo controlled clinical trial. 202 seropositive homosexual males were screened in Dallas County and 50 patients were entered into the study.

Results: 23 patients completed 12 months of the trial. 19 patients were discontinued; of these 8 discontinued themselves to go on AZT, and 11 were lost to follow-up. 9 patients endpoint with AIDS. 1 patient developed interstitial nephritis-one of the four reported adverse reactions.

Conclusions: Isoprinostone was ineffective in preventing the progression of ARC to AIDS. Overall, there was no toxicity noted but the drug failed to prevent the destruction of CD4 lymphocytes, development of HIV antigenemia and clinical deterioration. Further studies combining this agent with other antiviral need to be performed.

W.B.P.306 ZINCOPOLYMER AND LITHIUM CARBOANATE FOR HIV PATIENTS

MORILLON D, PORECZ S, LEVIN S, CORREAS J, HARR K, REINSTEIN G, BOYD J, DILLON G, de la Harpe J, Courteson, ALBERTINI G.

OBJECTIVE: It is well known the trophism of HIV, which affects the lymphocytes T4 and monocytes leading to immunodeficiency. A study was undertaken using ZINCOPOLYMER, a stimulator of lymphocyte maturation and a Gramicidin-monomelic colony forming unit activator (GFM-CDF) and Interleukin II *in vitro*, Lithium Carbamate.

METHODS: (1) seven patients infected with HIV; (2) two with demyelinating complex; (3) one with ARC; (1) one with AIDS (3) cases with LAS were 5 homosexual, 2 sexual blood transfusions; they were all males with an age average of 37 years). They had a positive serology for HIV and immunosuppression was showed up, caused by a fall of CD4 under 400 cell./mm³. They were treated with ZINCOPOLYMER 40 mg/kg/duraily and LITHIUM CARBOANATE 300mg./day during a 16 week period.

RESULTS: during the study period (2) two of the seven patients died because of demyelinating complex. The remaining under the treatment: protocol. All of the patients experienced physical improving. Four of these gained weight. Some of the patients experienced any kind of side-effects. There was an increase in the lymphocyte total level, monocyte and CD4.

CONCLUSIONS: After this study period we can conclude that the anti-HIV treatment is necessary for patients who experience a demyelinating complex. The remaining ones manifested a clinical improving. We conclude that ZINCOPOLYMER and LITHIUM CARBOANATE should be used for pre-AIDS, and anti-HIV association for patients on advanced AIDS stages.

W.B.P.307 CASE REPORT OF DIDIZIFIRAM AS FIRST LINE THERAPY IN SEROPOSITIVE PATIENTS ATTENDING A COMMUNITY CLINIC
David L. Parson, F. Morgan A. Morris Jr. et al. Woodhull Medical and Mental Health Center, Brooklyn, NY, USA

Objective: To use didizifiram in treatment for HIV seropositive asymptomatic patients and explore if there is a significant correlative change between 74/78 ratio and/or absolute T4 count.
Method: Seropositive patients with 74/78 ratios less than 1.0 or absolute T4 counts <500 were started on didizifiram - a split weekly dosage of 1000 mg. 74/78 counts and ratios were followed every three months for a period of six months. Pre-treatment and post-treatment differences were evaluated by the Student's T test.
Results: In a sample of 10 patients on didizifiram alone, a comparison of 3rd and 9th month follow-up in the ratio of 74/78 cells, absolute T4 and absolute T4 counts reveals a statistically significant improvement at the .05 level with a one sided T test. Of these 10 patients, 8 had documented improvement in 74/78 ratio. Assuming a population probability of .5 the power to detect a difference is less than .5%. Sample size is small, a statistically significant difference was noted in seropositive patients on didizifiram treatment. These results suggest a large scale study of didizifiram should be initiated to further delineate the treatment effect.

W.B.P.309 RECOMBINANT HUMAN GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR (GM-CSF): A PHASE I TRIAL IN SEROPOSITIVE AIDS PATIENTS
James L. O'Brien, E. C. Concia, et al.
Flomenberg, B., Anselmo, V. and Sommer, E. Memorial Sloan-Kettering Cancer Center, New York, NY, USA and Schering Corporation, Kenilworth, NJ, USA.

Objective: To evaluate the safety, efficacy and biological activity of subcutaneously (SC) administered GM-CSF in AIDS patients (pts) who were asymptomatic as a result of treatment or their underlying disease.
Method: AIDS pts with ANC<500/mm³, PBMC, HbC, platelets >75,000 and CD4<50 were eligible. GM-CSF was given by daily SC injection for 10 days. After an 18 day rest, treatment was resumed for 28 days. Pts were then evaluated for maintenance treatment.
Results: Twelve pts have been entered at GM-CSF doses of 0.5, 1, 3 and 10 µg/kg/d. The median ANC was 900/mm³ (range 400-1700). Five pts were receiving AZT and 7 had maintained neutropenia after stopping AZT treatment. Dose-dependent increases in ANC were seen. Mean maximum ANC was 3467 (0.3 mg), 3813 (1mg) and 5239 (3mg). At each dose there was considerable variation in the ANC response and the degree of eosinophilia. Peak ANC's were generally lower in pts receiving AZT, but in some who had previously discontinued it, AZT could be reintroduced at reduced doses. Fever, malaise, weight loss and increased liver enzymes were observed in some pts. We see no evidence for stimulation of HIV, as measured by serum p24 antigen or cultures of peripheral blood cells; nor were there consistent effects on T cell subsets or the functions of NE cells, neutrophils or monocytes.
Conclusions: GM-CSF can reverse established neutropenia in AIDS pts. Given the variable response, optimal treatment may require dose titration.

W.B.P.311 AMELIORATION OF DETERIORATED POLYMOYONUCLEAR LEUCOCYTES (PMN) PROAGGREGATION FUNCTION OF MONOPHYTES WITH HIV INFECTION BY ADMINISTRATION OF LONG-CHAIN POLYUNSATURATED MONOPHENOLIC ESTER (LPEFAM)
Hideo Kuroki, Gohshi, K., Kishimoto, T. and Aki, T.
Department of Medicine, Tohoku University School of Medicine, Tokyo, Japan.

Objective: PMN phagocytic function (PMN-FC) of hemophiliacs (H) was evaluated in vitro and the effect of long-term treatment with lentinon on impaired PMN-FC was studied. **Method:** PMN-FC of long-term treated H with HIV infection was measured as the intensity of PMN chemiluminescence (PMN-CL) evolved from PMN when stimulated with opsonized *Syngeneis*(O) and/or phorbol myristate acetate (PMA). Ten mg of lentinon was injected (iv) to 7 H (5 AG, 1 AG & 1 HIV negative) with an impaired PMN-FC. **Results:** CL stimulated PMN-CL of 12 HIV positive as well as 17 HIV negative H was recorded to be deteriorated to 0.68 ± 0.31 & 0.74 ± 0.22 (normal range: 0.1-1.2) respectively. This tendency of deterioration was confirmed with PMA stimulated PMN in both HIV positive (0.74 ± 0.23) and negative (0.96 ± 0.24) groups. PMN-CL in 6 out of 7 H on long-term lentinon treatment was recovered to the near normal range within less than 3 months and this normalized PMN-CL was maintained for 6 to 28 months after cessation of the medication. Moderate to marked increase in CD4/CD8 ratio was observed in 11 patients. Long-term treatment with lentinon appears to have a therapeutic potential for HIV infected individuals with impaired PMN-FC by which PMN dysfunction is corrected and the onset of opportunistic infection is prevented. On the basis of these results, open trial of lentinon for HIV infected patients has just started in 10 medical universities and hospitals throughout Japan.

W.B.P.308 IMMUNOLOGIC AND VIROLOGIC PARAMETERS IN HIV INFECTED PATIENTS (PI) TREATED WITH ZIDOVUDINE (ZDV) AS PART OF A MULTICENTER PHASE III STUDY
John M. Coombs, Richard Schoen, R. Mai, D. Solomon, G. Prasad, D. Hughes, J. Fischl, J. Fischl, et al.
The George Washington University Medical Center, Washington, DC, USA

Objective: To assess the effect of ZDV on immunologic and virologic parameters in HIV infected patients (PI) treated with ZDV as part of a multicenter phase III study. **Method:** PI were randomized double-blind, placebo-controlled, crossover (9 control pts in the ZDV group, 9 control pts in the placebo group, HIV seropositive, ages 18-65 years, CD4 counts 100-500/mm³, HIV RNA levels >100 copies/ml). **Results:** Mean CD4 count of 600/pts in control group of which 10 were treated at our center. Mean CD4 count in the ZDV group was 79. **Conclusions:** 6 months of ZDV treatment resulted in a mean increase in CD4 count of 100/mm³. **Table:**

Test	Mean	SEM	Range	CD4		p	CD8	p	CD4/CD8	p
				Control	ZDV					
CD4	600	100	100-1000	79	100	<.05	1000	<.05	1.67	<.05

Aspects cliniques Clinical Aspects of AIDS

W.B.P.319 ALLOGENEIC BONE MARROW TRANSPLANTATION (BMT) PLUS AZIDOTHYDINE (AZT) IN THE AIDS PATIENT WITH NON-SPREADING LYMPHOMA (NSL)

Holland WK, Rossi J¹, Romnesshae AD, Zia JAM², Santos GP, and Sarai N³
¹The Johns Hopkins University, Baltimore, MD, USA
²City of Hope National Medical Center, Duarte, CA, USA

Objective: To evaluate the effect of combined modality therapy (AZT plus allogeneic BMT) on HIV-1 infection in a lymphoma patient with AIDS. **Methods:** The patient, a 41 yo HIV-1 culture⁺ man with NSL, received cyclophosphamide and total body irradiation to ablate tumor, bone marrow and marrow-derived cells. AZT (5 mg/kg q 6h) was begun 2 wks prior to BMT. Nine days after initiation of ablative therapy he received 6x10⁶ nucleated BM cells/kg from his HLA-identical sister. At this time AZT was reduced to 1.5 mg/kg q 6h and administered at that level for the duration of treatment. HIV-1 was monitored by serial and polymerase chain reaction gene amplification (PCR, LTR and ENV, DNA and reverse transcriptase RNA).

Results: Despite continuous AZT, engraftment was prompt (13 days to neutrophil count >500/mm³). Peripheral blood mononuclear cells and BM samples became HIV-1 negative by culture and PCR 33 days after BMT. The patient died of tumor relapse 67 days after BMT. Complete autopsy showed no evidence of HIV-1 by PCR (brain, MI, spleen, tumor, heart, kidney, liver, lung, colon) or culture (brain, MI, lymph node, tumor).

Conclusions: 1) The patient tolerated ablative therapy associated with BMT. 2) Prompt engraftment was attained despite AZT therapy. 3) PCR and culture data suggest clearance of host cells harboring virus and prevention of infection of repopulating donor cells.

W.B.P.321 EFFECT OF COMBINATION OF ZIDOVUDINE AND INTERFERON-ALPHA COMPARED WITH ZIDOVUDINE AND ACYCLOVIR ON HIV-1 RNA IN ASYMPTOMATIC PATIENTS

Yahr, Rainer, Rosenthal, A., Lishy, R., Pugh, R., Sowers, R., and Siegelbauer, W.
 Department of Medicine, University Hospital, Zürich, Switzerland; *Wilhelms Research Laboratories, Muenchen, Germany

Objective: To assess the antiviral effect of zidovudine (AZT) in combination with either zidovudine interferon (AZT/IFN) or zidovudine acyclovir (AZT/ACV) in HIV-1 infected patients. **Methods:** 15 pts in CDC stage I/II with positive p24 antigen were randomized to receive 12 weeks AZT 250mg bid and either ACV 240mg bid or IFN 12 MU 3x wk. 3wks follow-up. Following a washout period of one month, 8 pts (pts 1,2,4,5,6,7,8,9) agreed to continue with a crossover phase. Antiviral activity was assessed by measuring serum p24 antigen levels. Results in 24 antigen levels (Abbott EIA) recorded as a coefficient were:

AZT/IFN wash- AZT/ACV		AZT/IFN wash- AZT/IFN	
wk 0	wk 12	wk 0	wk 12
pt 1	11.52	1.62	1.474
pt 2	1.30	0.59*	1.52
pt 3	2.50	1.14	1.41
pt 4	2.13	1.28	1.87
pt 5	1.94	0.99*	1.12
pt 6	3.84	1.08	2.37
pt 7	1.42	1.42	1.42
pt 8	5.52	3.37*	9.07
pt 9	1.91	1.17	2.73
pt 10	1.41	1.22*	2.73
pt 11	4.97	3.90*	4.99
pt 12	1.86	1.23	1.23
pt 13	2.86	1.23	1.23

*p < 0.05 - not diff
 **NEQ < 0.09
 [pt 14 and 15 discontinued due to side effects
 p24 antigen was transiently negative during AZT/IFN at wk 1 and 2 in pts 3 and 7, respectively. Temporary mild neutropenia occurred in 3 pts with AZT/IFN.
Conclusions: P24 antigen declined in all pts with the above dose regimens. Preliminary results suggest a superior antiviral effect of AZT/ACV, but require dose range finding studies and continuation of treatment to evaluate clinical long term benefit.

W.B.P.323 AN OPEN-LABEL STUDY OF THE SAFETY AND EFFICACY OF CO-ADMINISTRATION OF ZIDOVUDINE AND RECOMBINANT INTERFERON-ALPHA

Burgin, Michael J., and Pallares, R.S., Division of Infectious Diseases, UNIVERSITY OF TEXAS MEDICAL BRANCH AT GALVESTON, U.S.A.

Objective: A phase 1 study of the long-term tolerance of recombinant Interferon- α -beta (Betanase) at doses of 6 or 30 million units when administered subcutaneously as a daily basis to HIV-infected individuals receiving 200mg of zidovudine (ZDV) every four hours.

Methods: Seventeen patients were sequentially been maintained on ZDV alone, for standard indications, were enrolled in the study: 8 patients at 60 million and 9 patients at 30 million units per day (MU/D).

Results: Seven of the 17 patients have terminated from the study: 1 expired, 1 of the remainder terminated due to local skin reactions and/or systemic symptoms such as fevers and malaise. Four of 8 patients enrolled at 90 MU/D underwent dosage reduction, 3 of these secondary to increased hepatic transaminases. In the entire group, an overall 100% increase in transaminases was seen, which peaked at 12 to 16 weeks of therapy. Other toxicities, particularly myelotoxicity (1 of 17 patients) were infrequently observed.

The total white blood cell counts after 2-4 weeks of therapy were approximately equivalent to the patients' entry values. An AIDS-associated opportunistic infection or neoplasm occurred in 7 patients.

Conclusions: Full-dose ZDV and Recombinant-IFN-beta-ser at doses of 45 to 90 million units/day are well tolerated for periods of 40 weeks. In the 17-patient study, patients receiving IFN-beta tolerated full dose ZDV well, without significant myelotoxicity. Prospective, controlled studies are needed to assess the efficacy of this combination.

W.B.P.320 AS 101 IN ASSOCIATION WITH AZT IN AIDS PATIENTS: A PHASE I PILOT STUDY.

J.H. LAURENT, J. PRITCHARD, D. CHODURA, J. J. MONTANO, R. LANGRISH, A. KOPPEL & S. G. DE LUCA

* St Antoine Cooperative Group in AIDS (FRENCH FRENCH)
 ** The Dana University, Haem Onc Dept.

Immersion clinical and biological results have been obtained with AS 101 (a new immunophilin analog) in AIDS patients. However in an effort to further improve patients with advanced disease, we tried to associate AZT with AS 101. 5 patients (all male) were stopped. Hematological tolerance in the 3 other patients was good. 1 patient incurred AS 101 or AZT level, but he had tuberculosis of the liver. We observed no stress of the other biological parameters. In 3 patients the clinical status improved. Further data of AS 101-AZT association will be provided.

W.B.P.322 ZIDOVUDINE VS. ALPHA INTERFERON VS. THE COMBINATION IN PATIENTS WITH BETA2 MICROGLOBULIN NEGATIVE HIV INFECTION

Harley, Richard M., Dewey, Robert J., J., Meier, H., Paauw, A.S., Lamm, H.C., et al. National Institutes of Health, Bethesda, MD, USA.

Objective: To compare the effects of zidovudine (AZT), alpha interferon (IFN), and a combination of these 2 drugs in delaying the progression of HIV disease.

Methods: HIV-infected persons with >500 CD4 count/mm³ and no history of cytotoxic infection (CI) are being entered in this trial. Following a screening evaluation that includes HIV serology, HIV culture, p24 antigen, polymerase chain reaction (PCR), and immune profile, patients are randomized to either AZT alone (200 mg qd), IFN alone (5x10⁶ IU 3x/week increase as tolerated), or a combination of the 2 (AZT 100 mg qd + IFN 1x10⁶ IU 3x/week increase as tolerated). End point criteria include a decline in CD4 cells to <200/mm³ or the first occurrence of an AIDS-defining CI.

Results: The patients enrolled thus far (n=300) have a mean age of 35 (26-49) and a mean CD4 count of 696 cells/mm³ (515-1293). Eight of 30 have had a positive (+) culture for HIV and 2/30 have been p24 antigen +. Unlabeled primer pairs from env, LTR and gag regions, 26/28 have been + by PCR.

Conclusions: Patients with early HIV infection and CD4 cells >500/mm³ almost uniformly have demonstrable virus by PCR testing. However, HIV culture and p24 antigen are generally negative, suggesting that the patients have a low viral burden. The data generated over the next 6 months should permit an evaluation of the relative toxicities and a preliminary evaluation of the efficacies of AZT, IFN, and the combination in delaying the progression of HIV disease.

W.B.P.324 EFFECTS OF A COMBINED DETRANESULFATE/ZIDOVUDINE THERAPY COMPARED TO ZIDOVUDINE MONOTHERAPY IN AIDS

ROCHESTER, H. HERRING, J.L., GOOD, M.
 Dept. of Dermatology, University of Essex, UK

18 HIV infected patients (status WB 6) were randomly allocated to combined (detransulfate (800 mg/d) zidovudine (800 mg/d) therapy (DZ) or a zidovudine (800 mg/d) monotherapy (Z). Each group consisted of 9 patients, age 25 to 35 years, with equivalent amounts of CD4 lymphocytes in both groups prior to therapy.

Before and every 8 weeks during the treatment period we performed a complete history and physical examination, standard medical tests of enzymes, kidney, liver and blood parameters, isolation and enumeration of lymphocytes and lymphocyte subsets, assessment of complement components, immunoglobulin and immune complexes in serum as well as measurement of in vitro lymphocyte blastogenic response to mitogens.

Evaluation of the first 6 months of the study revealed 1 relapse of pneumocystis carinii pneumonia in each group. No alterations were found concerning the individual HIV antibodies and p24 antigen levels. Apart from an initially more profound improvement of immunostatus after 8 weeks of DZ compared to Z there were no differences between the two groups at the first and second months of study. Detranesulfate application did neither enhance adverse effects nor of zidovudine therapy nor of the disorders of blood coagulation. The study is still in progress.

W.B.P.331 ZIDOVUDINE (AZT) TREATMENT OF THE AIDS GENITAL COMPLEX (AGC) - RESULTS OF A PLACEBO-CONTROLLED, MULTICENTERED THERAPEUTIC TRIAL

Prings, Richard H.; Spector, R.A.; Frimberg, J.; Collier, A.; Kennedy, C.; Singer, E.; Price, S.; and AIDS Clinical Trials Group, NIAID, Bethesda, MD, U.S.A.

Objective: To determine the efficacy of AZT in alleviating mild to moderate AGC in HIV-1-infected patients with relatively preserved CD4⁺ cells.

Methods: 40 patients with mild to moderate AGC from 9 centers were randomized to 3 treatment arms: AZT 400mg 5/day, AZT 200mg 5/day, or placebo 5/day. We report the results of preliminary analysis of the initial 16-week phase of the trial comparing the 2 AZT groups (which remain blinded) to the placebo group. Therapeutic efficacy was evaluated using standardized serological assessments of genital tract "microbiological" tests.

Results: This phase of the trial was administratively aborted before the planned accrual. 27 patients completed 8 weeks and 24 completed 16 weeks of the trial; 12 patients were prematurely terminated when the trial was aborted while 2 suffered adverse events and 4 withdrew from the study. The 3 groups were well balanced with respect to baseline parameters including CD4⁺ counts (entry mean, 525). While there was no appreciable change in the overall classification of AGC severity across the 3 groups and individual test comparisons were significant (p<.05) in only 2 of 8 neurophysiological tests at 16 weeks, the placebo group exhibited the least favorable change in 7 of the 8 tests at 8 weeks and in 8 tests at 16 weeks.

Conclusion: Despite the small sample size, these data support a therapeutic effect of AZT in improving neurophysiological performance in AGC patients. Further analysis will be needed to determine whether this is dose-related.

W.B.P.333 SURVIVAL OF PATIENTS WITH HIV DISEASE TREATED WITH ZIDOVUDINE (AZT)

Sheng, David; Lapan, M.; Haggan, C.; Smith, M.; Lammert, M.; Cornell, U. Medical College, March Dunes U. Hospital, Lees Summit, MO., USA.

Objective: To determine the probability of survival in patients with HIV disease treated with zidovudine (AZT).

Methods: From 11/86 through 12/87, patients meeting current CDCR indications for treatment received AZT. Initial dose used was 1-1, 200mg/day, with reductions made at the discretion of the physicians when patients experienced toxicity. Survival was calculated using Kaplan-Meier plots.

Results: 116 patients with the following characteristics were treated: 96 male, 20 female, 54 gay, 47 IVDA, 15 other risk, 100 white, 16 non-white, median age 37. The indication for treatment was AIDS in 60 and 7-helper depletion (HD) in 56. The median follow-up was 68 weeks. Survival at 26, 52, and 78 weeks was 89, 76, and 64%, respectively. Median survival was 94 weeks. Patients with AIDS before HD survived better than those starting AZT within 8 weeks of the HD-defining CD4⁺ count (89 vs. 82 vs. 78 weeks, p<.02). Among patients with AIDS, those starting AZT within 8 weeks of the HD-defining CD4⁺ count (89 vs. 82 vs. 78 weeks, p<.02). When those starting later were excluded, survival was 87, 84 and 76% at 26, 52 and 78 weeks. Survival was not different when analyzed by sex, risk factor, or age >40. A trend toward worse survival in non-white did not reach significance.

Conclusion: This study provides survival data useful for prognostication in patients treated with AZT according to current practices. Because survival is improved in those treated early or early after diagnosis of AIDS, initiation of AZT therapy should not be delayed.

W.B.P.335 A PHASE III TRIAL OF THE COMBINATION OF ZIDOVUDINE AND INTERFERON-2 IN THE TREATMENT OF HIV-RELATED KAPAPSI SARCOMA

Kovacs, Joseph A.; Pines, M.; Gantch, E.; Paves, A.S.; Lane, H.C.; et al. National Institutes of Health, Bethesda, Maryland, USA.

Objective: To evaluate the toxicity and efficacy of the combination of zidovudine and interferon-2 in the treatment of HIV-infected patients with Kaposi's sarcoma.

Methods: In an open study, patients with HIV infection documented by ELISA, western blot HIV-1 antibody, and positive HIV RNA were begun on zidovudine 200 mg q6h. After six weeks, the patients were begun on continuous infusions of 1-2 for 3 weeks, during which time zidovudine therapy was continued. Group 2 patients were treated with increasing doses of 1-2, beginning at 200,000 U/d, until the maximum tolerated dose was determined. The combination of drugs was evaluated for toxicity and efficacy by weekly monitoring of routine blood values, including CBC and chemistry, as well as CD4 count, p24 antigen and HIV culture. Results: Three patients have completed the study to date, all at a dose of 250,000 U/d of 1-2. No significant toxicity has been seen, although 1 patient had recurrent bacteremia due to infected central lines. No significant immunostimulating or anti-retroviral effects have been seen at this dose of 1-2. Two patients remained HIV culture positive, as a patient with p24 antigenemia had no change in antigen levels during 1-2 therapy. **Conclusion:** 1-2 can be safely administered at a low dose in combination with zidovudine. Complete remission will determine if higher doses of 1-2 can also be safely administered, and if there is a beneficial effect seen during combination therapy.

W.B.P.332 STUDY COMPLIANCE AMONG ASYMPTOMATIC HIV SEROPositIVES (ASX HIV) BEING TREATED WITH AZIDOVUDINE (AZT)

Jacobson, Paul R.; Vaseleski, C.; Brown, D.; Gottlieb, K.; Pilgones, G. A.; & Teitel, S. Fenwal Bio-Science-Kettering Cancer Center, New York, New York, U.S.A.

Objective: To measure compliance and identify factors related to degree of compliance among participants in an experimental trial of the efficacy of AZT in preventing/retarding the development of AIDS.

Methods: Twenty (19 male, 1 female) ASX HIV enrolled in a double-blinded, placebo controlled trial in which 3 doses (3 capsules each) per day of high or low dose AZT or placebo were prescribed (AZTC Protocol 019) completed daily forms assessing missed doses and physical symptoms for an average of 60 days (Range=40 to 162) and underwent brief psychological assessment.

Results: Subjects reported missing an average of 5% (Range=0-24%) of all doses. Average number of missed doses per day was approximately 1.15 capsules, with the last dose of the day the most frequently missed - average of 1/3 of the time. No subject dropped out or reported using other prescribed treatments during the period of study. More missed doses were significantly (p<.05) correlated with younger age, nausea, diarrhea, psychological distress, and health beliefs.

Conclusions: Data from our center indicate that, while drop-out among ASX HIV enrolled in a placebo-controlled AZT study is not encountered, missed medication doses are common. Patient self-monitoring provides a useful means of estimating missed doses and investigating the determinants of noncompliance.

W.B.P.334 Reduction of Zidovudine Side Effects by an Intermittent Therapy Scheme

Slingsby, D.; Oswald, J.; Gottlieb, A.; Rehmert, D.; Hein, E.B.;

Hille, W. Universitätsklinik Frankfurt am Main, Frankfurt am Main, Germany.

Medizin, Infektions-Abteilung, FHO

15 in 4 dosage from 1000 - 1200 mg/d. Zidovudine (AZT), in spite of its life prolonging effect, causes myelotoxic side effects. By an intermittent therapy scheme with a drug-free regeneration period, these side effects on hematopoiesis might be avoided.

We therefore report on 16 patients (7 AIDS, 9 ARC) with an intermittent AZT regimen. Therapy scheme consists of application intervals (AI) of 4 wks (1000 - 1200 mg/d), followed by 4 weeks' break. At present, 16 patients have finished 2 AIs, and of these, 10 pts. have finished 3 AIs. Total observation time is 176 wk (median); min. 120, max 204 wk. Initial symptoms (nausea, headache) mainly occurred during 1st. AI and in only 2 of 15 cases also at early 2nd AI. Mean body weight increased > 10 % of initial value (from 68.0 median to 77.0 kg). Also the patients' physical and mental abilities improved significantly. CD4+ cell count increased by 37 % (median) after 1st AI, by 7 % after 2nd AI. During 3rd AI, it went down to initial value. HD and leucocytes were normal; anemia or leucopenia was not found. NCV was only slightly increased. Up to now, there have been no opportunistic infections nor death cases.

Conclusion: Intermittent AZT regimen, an continuous therapy, led to an increase in patients' well-being, and to transient increases in CD4+ cell count. However, the lack of any myelotoxic side effects was remarkable.

W.B.P.336 ZIDOVUDINE'S "M" INTERVENOUS DRUG USE. El-Jahed, Feres, G., Forrester, C., Tomson, R., Johnson, R.S., Saint-Richard's Medical Center, Newark, New Jersey, U.S.A.

Objective: To describe characteristics and effects of zidovudine usage in an intravenous drug user population.

Methods: A retrospective study of 43 patients studied from 2/78 through 7/88 who were followed bi-weekly in a clinic environment with complete cell counts (CBC) chemistry profiles and serological examinations.

Results: Seven patients never filled their prescriptions. Of the remaining 36 (10 males, 4 females) the mean duration of therapy was 6 months. CBC testing showed 14/36 with a significant decrease in white cell count, and 4/36 with a significant decrease in hemoglobin (all four with Mycobacterium Avium intracellulare infection). Subsequently 6/36 felt improvement with four showing greater than 10 pounds of weight gain, 7/36 had worsening of their condition with five developing Mycobacterium Avium-intracellulare infection. No patients showed improvement in CD4 cell counts and 0/8 showed decreases.

Conclusion: Leukopenia was the primary effect noted and Mycobacterium Avium-intracellulare infection the primary documented reason for deterioration on therapy. Side effects however are comparable to those reported in the homosexual cohorts studied.

W.B.P.343 **UPDATE ON AID THERAPY IN AN INNER CITY POPULATION.**
Samuels, J., Silson, R., Simon, V., and Small, C.B. **NYC Center Bronx Hospital/Honolulu**
Clinical Center/Albany State University, Albany, New York, U.S.A.
OBJECTIVE: To evaluate efficacy, toxicity and compliance (comp) with AZT therapy among patients (pts) of poor, minority and intravenous drug use (IVDU) background.
DESIGN: Prospective data was derived on all AIDS and ARC pts on AZT for at least 4 weeks from 7/87-1/89.
RESULTS: 99 pts were evaluable: 75 male, 24 female; 64 Hispanic, 25 black, 6 white, 2 Asian; IVDU 59; homosexual contacts 15; transfusion 1, no known risk for 7; AZT: 27 ARC with low CD4 count (130); mean age 35 (range 22-59); mean Kt 34 (range 21-54); MRC 4400 (range 1.8-10.7); baseline mean Karnofsky score 81.6 (range 50-100); 87/99 (88%) were comp and received AZT for a mean of 20.3 months (range 2-66 mo), 23% pts. All pts eventually received PCP prophylaxis. 57% had mild adverse drug reaction (ADR) requiring dose reduction (ADR) or cessation. Side effects included: anemia 17A (18.2%); neutropenia 17A (18.2%); leukopenia 33A; GI complaints 14%; headache 14%; fever 11%; rash 5%. Rates of anemia, transfusion, leukopenia, neutropenia and leukemia were comparable, and nausea and headache least frequent. Data in published studies of CD4% population ($p < .05$), 83/87 (95%) comp pts tolerated AZT for 4 wks. 17 opportunistic infections (OI) occurred in 14/93 (17%) at mean 28 wks (range 6-63 wks); 13/17 (76%) AZT occurred in pts on reduced AZT, 6/83 (7%) comp pts died (only 1 on full-dose AZT vs 6 on 1/2 dose) noncomp or intolerance pts ($p < .01$). 55A pts had 37% of clinic appointments; 108 kept 50-75%; only 28 kept 50%.
CONCLUSION: AZT can be administered to IVDU and others in inner city clinic settings with acceptable efficacy, tolerance and compliance.

W.B.P.344 **FOLLOWUP WITH ZIDOVUDINE IN A CITY CENTER, AIDS CLINIC**
Miller, Lamm, J., Newman, J., Davidson, A., Qian, S.,
Stewart, James Clinical Research, Denver, CO, USA

Objective: To evaluate the efficacy and toxicity of zidovudine (AZT) in patients (pts) with AIDS and ARC in Denver, Colorado.
Design: A retrospective chart review of clinic and hospital records at CRM was done for all pts started on AZT between Nov. 1986 and Jan. 1989. Follow-up was obtained through IDU, medical record method as well as the AZT and pre-AZT periods.
Results: A total of 137 pts received AZT, 117 less than 12w. Of the remaining 18, 9 had AIDS and 33 ARC at the time of initiation of AZT. AIDS pts were diagnosed 0-900 (mean 836) before starting AZT, ARC pts 0-1124 (mean 500). Pt took the drug for 35-980 (mean 204). Of 128 pts, 112/42% completed at least one adverse event (AE) requiring dose adjustment (mean 2.7 AE, range 1-348). AE included granulocytopenia (30), anemia (37), thrombocytopenia (4), malaise (38), GI intolerance (16), fever (30), rash (6), OI infection (7), headache (5). Of 128 pts, 27 (21%) required blood transfusions (range 2-12 units, mean 3 units/pk). AZT was discontinued (ID) in 18 pts (14%); 10-980 after initiation (mean 824). Reasons for ID included malaise (6), granulocytopenia (5), GI intolerance (3), fever (3), other opportunistic treatment (6), hepatic placement (4). Of the AIDS pts, 28 were followed from diagnosis to death at CRM and were hospitalized 0-4 times (mean 2.9). Twenty nine similar pts previously studied at CRM from 1982 through 1986 (pre-AZT) were hospitalized 1-16 (mean 3.1). At 51 months mean survival of 336 in pre-azt vs compared to 592 in the AZT pts ($p < .01$).
Conclusions: AZT significantly prolongs survival in AIDS pts although it is associated with adverse side effects leading to dose adjustment and ID of therapy. A retrospective analysis reveals to decrease in the number of hospitalizations since AZT has become available.

W.B.P.347 **BENEFITS OF AZT WHEN STARTED AT INCREASING TIMES**
AFTER AIDS/PCP DIAGNOSIS, 90 Rightingals, SE

Farland, Memphis, Tenn., U.S.A.
Parland, Memphis, Tenn., U.S.A.
The survival of 172 patients who had PCP at AIDS diagnosis and received AZT was analyzed by a retrospective case-control analysis, to evaluate of 149 controls who had PCP at AIDS diagnosis but did not receive AZT. Survival was compared from day AZT was begun or day of AIDS diagnosis, whichever came later. Control survival was calculated from day after AIDS diagnosis to matched case started on AZT. Survival of subjects who received aerosolized pentamidine (AP) was assessed at the day AP was begun. We specifically examined the difference in survival between cases and controls as a function of how long after AIDS/PCP the cases were started on AZT.

Days After PCP	Case	Control	P	
AZT begun	Survival	Survival	(Wilcoxon)	
0-9	88	508	<.02	
91-180	37	681	157	<.02
181-270	17	411	50	<.001
271-365	3	189	195	NS
>365	17	210	123	NS
All Cases	111	1388	4,000	<.0001

Within the limits of a retrospective case-control method and in the population studied, a statistically significant benefit of AZT was found only in the subset that began AZT within 270 days of AIDS/PCP.

W.B.P.344 **REVENIR DE 345 MALADES ATTEINTS D'ARC OU DE SIDA**
41 TRAITES PAR AZT PENDANT 4 A 18 MOIS
Egid, Demare, Mathéron, S. Rouzeau, W. Kishon, C. Perronne C
Groupe d'Etude de l'AIDS, Centre de l'ARC, 140-115 Chem. de la Bienville, Paris, France

Objectif: Rechercher à moyen et long terme l'efficacité de l'AZT.
Méthodes: 345 malades atteints d'ARC (80) ou de SIDA (265) depuis 0,5 à 3 mois (médiane 4) ont été inclus dans cette série prospective. La notation initiale a été de 200 mg/6h, puis 240 mg/6h, de 200 mg/6h, puis 100 mg/6h en raison de leur état hématochimique...
Résultats: Chez les ARC, 6 et 3 S. 19 patients et 27 ID sont apparus 27,4 et 16,3 semaines après le début de l'AZT. Si 22 sont apparus 4 à 18 mois après le début de l'AZT, 18 sont apparus 16 à 22 mois après le début de l'AZT, 19 sont apparus 22 à 36 mois après le début de l'AZT, 11 sont apparus 36 à 60 mois après le début de l'AZT, 11 sont apparus 60 à 108 mois après le début de l'AZT, 11 sont apparus 108 à 180 mois après le début de l'AZT, 11 sont apparus 180 à 360 mois après le début de l'AZT, 11 sont apparus 360 à 720 mois après le début de l'AZT, 11 sont apparus 720 à 1080 mois après le début de l'AZT, 11 sont apparus 1080 à 1440 mois après le début de l'AZT, 11 sont apparus 1440 à 1800 mois après le début de l'AZT, 11 sont apparus 1800 à 2160 mois après le début de l'AZT, 11 sont apparus 2160 à 2520 mois après le début de l'AZT, 11 sont apparus 2520 à 2880 mois après le début de l'AZT, 11 sont apparus 2880 à 3240 mois après le début de l'AZT, 11 sont apparus 3240 à 3600 mois après le début de l'AZT, 11 sont apparus 3600 à 3960 mois après le début de l'AZT, 11 sont apparus 3960 à 4320 mois après le début de l'AZT, 11 sont apparus 4320 à 4680 mois après le début de l'AZT, 11 sont apparus 4680 à 5040 mois après le début de l'AZT, 11 sont apparus 5040 à 5400 mois après le début de l'AZT, 11 sont apparus 5400 à 5760 mois après le début de l'AZT, 11 sont apparus 5760 à 6120 mois après le début de l'AZT, 11 sont apparus 6120 à 6480 mois après le début de l'AZT, 11 sont apparus 6480 à 6840 mois après le début de l'AZT, 11 sont apparus 6840 à 7200 mois après le début de l'AZT, 11 sont apparus 7200 à 7560 mois après le début de l'AZT, 11 sont apparus 7560 à 7920 mois après le début de l'AZT, 11 sont apparus 7920 à 8280 mois après le début de l'AZT, 11 sont apparus 8280 à 8640 mois après le début de l'AZT, 11 sont apparus 8640 à 9000 mois après le début de l'AZT, 11 sont apparus 9000 à 9360 mois après le début de l'AZT, 11 sont apparus 9360 à 9720 mois après le début de l'AZT, 11 sont apparus 9720 à 10080 mois après le début de l'AZT, 11 sont apparus 10080 à 10440 mois après le début de l'AZT, 11 sont apparus 10440 à 10800 mois après le début de l'AZT, 11 sont apparus 10800 à 11160 mois après le début de l'AZT, 11 sont apparus 11160 à 11520 mois après le début de l'AZT, 11 sont apparus 11520 à 11880 mois après le début de l'AZT, 11 sont apparus 11880 à 12240 mois après le début de l'AZT, 11 sont apparus 12240 à 12600 mois après le début de l'AZT, 11 sont apparus 12600 à 12960 mois après le début de l'AZT, 11 sont apparus 12960 à 13320 mois après le début de l'AZT, 11 sont apparus 13320 à 13680 mois après le début de l'AZT, 11 sont apparus 13680 à 14040 mois après le début de l'AZT, 11 sont apparus 14040 à 14400 mois après le début de l'AZT, 11 sont apparus 14400 à 14760 mois après le début de l'AZT, 11 sont apparus 14760 à 15120 mois après le début de l'AZT, 11 sont apparus 15120 à 15480 mois après le début de l'AZT, 11 sont apparus 15480 à 15840 mois après le début de l'AZT, 11 sont apparus 15840 à 16200 mois après le début de l'AZT, 11 sont apparus 16200 à 16560 mois après le début de l'AZT, 11 sont apparus 16560 à 16920 mois après le début de l'AZT, 11 sont apparus 16920 à 17280 mois après le début de l'AZT, 11 sont apparus 17280 à 17640 mois après le début de l'AZT, 11 sont apparus 17640 à 18000 mois après le début de l'AZT, 11 sont apparus 18000 à 18360 mois après le début de l'AZT, 11 sont apparus 18360 à 18720 mois après le début de l'AZT, 11 sont apparus 18720 à 19080 mois après le début de l'AZT, 11 sont apparus 19080 à 19440 mois après le début de l'AZT, 11 sont apparus 19440 à 19800 mois après le début de l'AZT, 11 sont apparus 19800 à 20160 mois après le début de l'AZT, 11 sont apparus 20160 à 20520 mois après le début de l'AZT, 11 sont apparus 20520 à 20880 mois après le début de l'AZT, 11 sont apparus 20880 à 21240 mois après le début de l'AZT, 11 sont apparus 21240 à 21600 mois après le début de l'AZT, 11 sont apparus 21600 à 21960 mois après le début de l'AZT, 11 sont apparus 21960 à 22320 mois après le début de l'AZT, 11 sont apparus 22320 à 22680 mois après le début de l'AZT, 11 sont apparus 22680 à 23040 mois après le début de l'AZT, 11 sont apparus 23040 à 23400 mois après le début de l'AZT, 11 sont apparus 23400 à 23760 mois après le début de l'AZT, 11 sont apparus 23760 à 24120 mois après le début de l'AZT, 11 sont apparus 24120 à 24480 mois après le début de l'AZT, 11 sont apparus 24480 à 24840 mois après le début de l'AZT, 11 sont apparus 24840 à 25200 mois après le début de l'AZT, 11 sont apparus 25200 à 25560 mois après le début de l'AZT, 11 sont apparus 25560 à 25920 mois après le début de l'AZT, 11 sont apparus 25920 à 26280 mois après le début de l'AZT, 11 sont apparus 26280 à 26640 mois après le début de l'AZT, 11 sont apparus 26640 à 27000 mois après le début de l'AZT, 11 sont apparus 27000 à 27360 mois après le début de l'AZT, 11 sont apparus 27360 à 27720 mois après le début de l'AZT, 11 sont apparus 27720 à 28080 mois après le début de l'AZT, 11 sont apparus 28080 à 28440 mois après le début de l'AZT, 11 sont apparus 28440 à 28800 mois après le début de l'AZT, 11 sont apparus 28800 à 29160 mois après le début de l'AZT, 11 sont apparus 29160 à 29520 mois après le début de l'AZT, 11 sont apparus 29520 à 29880 mois après le début de l'AZT, 11 sont apparus 29880 à 30240 mois après le début de l'AZT, 11 sont apparus 30240 à 30600 mois après le début de l'AZT, 11 sont apparus 30600 à 30960 mois après le début de l'AZT, 11 sont apparus 30960 à 31320 mois après le début de l'AZT, 11 sont apparus 31320 à 31680 mois après le début de l'AZT, 11 sont apparus 31680 à 32040 mois après le début de l'AZT, 11 sont apparus 32040 à 32400 mois après le début de l'AZT, 11 sont apparus 32400 à 32760 mois après le début de l'AZT, 11 sont apparus 32760 à 33120 mois après le début de l'AZT, 11 sont apparus 33120 à 33480 mois après le début de l'AZT, 11 sont apparus 33480 à 33840 mois après le début de l'AZT, 11 sont apparus 33840 à 34200 mois après le début de l'AZT, 11 sont apparus 34200 à 34560 mois après le début de l'AZT, 11 sont apparus 34560 à 34920 mois après le début de l'AZT, 11 sont apparus 34920 à 35280 mois après le début de l'AZT, 11 sont apparus 35280 à 35640 mois après le début de l'AZT, 11 sont apparus 35640 à 36000 mois après le début de l'AZT, 11 sont apparus 36000 à 36360 mois après le début de l'AZT, 11 sont apparus 36360 à 36720 mois après le début de l'AZT, 11 sont apparus 36720 à 37080 mois après le début de l'AZT, 11 sont apparus 37080 à 37440 mois après le début de l'AZT, 11 sont apparus 37440 à 37800 mois après le début de l'AZT, 11 W.B.P.349 ZIDOVUDINE(AZT) IN HIV POSITIVE HAEMOPHILIACS

Lin Sang-Geo, Lee, C.A. Hayes, M. Giannarone, P. de Kerkoff, P.B.A. Haselden, J. and Haemophilia Unit, Academic Department of Haematology, Royal Free Hospital, London, United Kingdom.

Objective: To review the effect of zidovudine in HIV positive haemophiliacs.
Methods: A retrospective analysis of 21 patients treated with zidovudine at the Haemophilia Centre of the Royal Free Hospital was performed. 14 were CDC IV, 1 was CDC III with thrombocytopenia, 4 had oral candidiasis and 2 were CDC II but elected to purchase zidovudine privately. Median age was 33 (range 21-69) and they had been known to be HIV Ab positive for 42-107 months (median 73 months). They received zidovudine for 1-55 weeks (median 29 weeks).

Results: 9 patients tolerated full dose zidovudine (1000 mg/d) without a change in dosage or side-effects. 12 patients required dose modification or cessation of medication due to anaemia, neutropenia, 13 granulocytopenia, 13 pancytopenia requiring transfusion(1), vomiting(1), poor compliance(1) and conversion to alternative medicine(1). Other side-effects were alopecia, headache or fatigue. Opportunistic infections occurred whilst on zidovudine were oral candidiasis(2), a possible relapse of PCP(1), Salmonella typhimurium replacement(1), cryptosporidiosis(1) and E. Coli sepsis from a UTI(1). 3 patients improved their T4 counts, 4 deteriorated, and 1 remained the same - none of these had a non-sustained rise in their T4 counts. 4 of 5 patients responded to zidovudine, 1 of 8, 2/4. As positive patients became negative, 2 remained positive and 1 has only had therapy for 1 week.

Conclusions: Zidovudine is an effective treatment for symptomatic HIV infection in haemophiliacs, particularly for thrombocytopenia. However, there were significant side-effects, notably in 3/21(14.3%), granulocytopenia in 5/21(23.8%), and pancytopenia in 1/21(4.7%).

W.B.P.350 ZIDOVUDINE THERAPY IN HOMOSEXUAL/BISexual PATIENTS WITH AIDS-RELATED COMPLEX (ARC) IN AUSTRALIA.

Session: Cheryl J. Condon, AIDS Epidemiology and Clinical Research, University of New South Wales, Sydney, NSW, Australia.

Objectives: To monitor the efficacy, toxicity and safety of zidovudine (ZDV) therapy in patients with AIDS-related complex (ARC) in a multi-centre clinical trial in Australia. **Methods:** Patients with ARC have been enrolled in the study since June, 1987. By June 1988, 301 homosexual/bisexual males had been enrolled, 95% of whom were still alive by 20 November, 1988. Using time to development of an AIDS-defining condition (T7AIDS) as a measure of the efficacy of ZDV, Kaplan-Meier survival curves were prepared for baseline clinical and laboratory values for these patients (80, WCC, CD4, age, time from diagnosis (D) to ZDV therapy, Karnofsky performance status, and other variables) using Cox regression analysis. Safety and toxicity were evaluated in terms of mean dose level of ZDV tolerated and need for transfusions during therapy. **Results:** Sixty-nine of the patients (23%) had developed AIDS conditions. Significant differences ($P < 0.05$) in survival curves for T7AIDS were found for CD4 counts (50×10^6 , $30 < 126/161$), D to ZDV time ($12/32$ and $78 > 108$), CD4 counts ($50 < 10^6$ vs the only baseline variable independently associated with poorer T7AIDS in this analysis). The mean dose of ZDV was 150 mg. Sixty-five patients (23%) required transfusions during therapy, of whom 27 were transfused only once. **Conclusions:** ZDV appears to be well-tolerated in this group of ARC patients and baseline CD4 counts is independently associated with T7AIDS.

W.B.P.351 CESSATION OF ZIDOVUDINE (AZT) THERAPY LEADS TO INCREASED FREQUENCY OF VIRAL ISOLATION.

Kalish, J.M., Fleming, R., Gill, J., Gelson, K.; Montaner, J.S.G.; O'Shaughnessy, M.; Thomas, G.; and Ruedy, J. Jewish General Hospital, Montreal, Quebec, Canada, and the Canadian Multicentre Study.

Objective: To carry out a dose-finding study on 77 HIV-infected adults (CDC stages II and III) and to assess viral burden in such individuals.

Methods: HIV-1 was isolated from the circulating mononuclear cells of each subject at regular intervals throughout the study. Subjects received 600 mg drug per day for 18 weeks, 300 mg for 8 weeks, and 1200 mg for an additional 3 weeks. After 36 weeks, drug was withheld for 6 weeks and restarted at 42 weeks at 1200 mg/day.

Results: HIV was isolated from patients about 40% of the time both prior to treatment and at the end of 16 weeks, with average time to culture positivity of 18 days from end of the wash-out and following re-initiation of therapy. HIV was isolated in 75% of cases, with time to positivity of 10 days. These data correlate with the results on circulating p17 levels in these patients, and suggest that a 6-week drug wash-out period may result in increased viral burden.

Conclusion: Shorter wash-out periods should be used, when appropriate, to overcome the toxic effects of this drug.

W.B.P.352 IMPROVEMENT OF SURVIVAL IN AIDS PATIENTS WITH ZIDOVUDINE THERAPY.

Session: Ethel M. Phant, MD and Minsh, E. Department of Infectious Diseases, Compad Hospital, Beiquing, India.

Objective: To compare survival after AIDS diagnosis, in patients admitted to our department before and after the institution of zidovudine therapy.

Methods: We evaluated survival after the diagnosis of AIDS (Kaplan-Meier method) during 1985-1986-1987 (before zidovudine became available at our department) and in 1988 (when zidovudine was available for routine therapeutic use). Zidovudine was administered according to the Indian National AIDS Programme (200 mg every 6 hours).

Results: Out of 100 patients, 93 were available (median follow-up of 2 months), most of them were IVDA, 46 patients, observed in 1985-1987, 48 not receiving zidovudine therapy, majority of them chest contracted. 40 patients, observed in 1988, were treated with zidovudine & depending on the inclusion criteria of the Indian National AIDS Programme.

SURVIVAL FROM AIDS DIAGNOSIS - 1 (Kaplan-Meier method)

Survival	3	12
1985-1987 ("pre-AZT era")	61.4	38.6
1988 ("AZT era")	76.4	23.5

Conclusions: Better diagnosis of AIDS and improvement in treating opportunistic infections, probably combined with the observed increase of survival time. However, our results seem to confirm the favourable effect of zidovudine treatment on the survival of AIDS patients, also in IVDA, for which a poor compliance to long term therapy is to be expected.

W.B.P.353 EFFICACY OF AZT IN A MUNICIPAL HOSPITAL CLINIC

Sessioning: A. Robinson, M.D. and H. Hooper, M.D.; Allen S. Holzman, M.D. New York University-Belmont Hospital, New York, New York, U.S.A.

Objective: To evaluate survival of AIDS and ARC patients treated with zidovudine (AZT) at a municipal hospital clinic.

Methods: Patients (pts) eligible for AZT under the treatment END or the F10A3 increased indications were treated in a specially designated clinic at Bellevue Hospital. Records of criteria with at least one follow-up visit between Dec 88 and Nov 89 were reviewed using a standardized data form. Results: 245 pts fulfilled the criteria for analysis: 220 males, 25 females; 117 whites, 61 Hispanics, 67 others; 146 non-Hispanic men, 82 with history of IV drug abuse; 82 pts had ARC and 163 AIDS. Median age was 37. Median survival (ms) of the entire group by the product limit method was 523 days (range 6-721) from the time of starting AZT. There was no difference in survival by sex. ARC pts lived longer than AIDS pts (ms 553 v 480, p<0.1). Pts with 1 opportunistic infection (OI) prior to AZT lived longer than those with more than 1 OI (ms 501 v 357, p<0.03). Initial absolute lymphocyte count above 1188/cu mm, absolute CD4+ lymphocyte count above 110, and albumin over 4 g/dl were associated with significantly longer survival. univariate analysis. Pts who started AZT within 90 days of their first AIDS diagnosis lived significantly longer. Those who tolerated an average AZT dose above 0.6 grams/week survived longer than pts treated with lower doses (p<0.03). Adverse reactions included anemia in 80 pts, leukopenia in 70 pts, neutropeny in 25, hepatitis in 25, uremia and myositis in 16 each, and other toxicity in 36.

Conclusion: Patients from a municipal hospital population treated with AZT survived at least as long as those reported in other trials.

W.B.P.354 THE EFFECT OF ZIDOVUDINE (AZT) ON SURVIVAL OF AIDS PATIENTS IN SAN FRANCISCO

Session: George F. Paine, S.F.; Neal, D.P.; Rutherford, G.M. San Francisco Department of Public Health, San Francisco, CA, U.S.A.

Objective: To evaluate the effect of zidovudine (AZT) on survival trends for AIDS patients in San Francisco (SF) in 1988 and 1987.

Methods: Information on antiviral therapy was available for 568 (25%) of 2,212 AIDS patients treated in SF in 1988 or 1987. In SF, we evaluated survival for 172 AIDS patients treated with AZT at some point during the course of their illness compared with 396 patients who were not treated with any antiviral therapy at time of diagnosis (and, if known, subsequent to diagnosis). Eleven patients surviving after other antivirals were excluded. Median survival was calculated using the Kaplan-Meier product-limit method.

Results: The median survival for patients on AZT (21.3 months) was significantly longer than for patients not on any antiviral therapy (13.9 months) (p<0.02). Improved survival for patients on AZT was found for both patients with (21.6 vs. 14.5 months) and without (21.3 vs. 13.1 months) pneumocystis carinii pneumonia within 3 months of diagnosis (p<0.001). Improved survival for patients on AZT was found for all subgroups of patients who stratified by initial diagnosis, year and hospital of diagnosis, age, race/ethnicity, or risk group, suggesting that the improved survival for patients on AZT was probably not due to biases inherent in the study.

Conclusion: Survival for patients on AZT was significantly longer than that for patients not on antiviral therapy in a sample of AIDS patients in SF.

W.B.P.361

TREATMENT WITH RETROVIR IN DIFFERENT STAGES OF THE HIV INFECTION

SAIO G., IZZO C. M., MARZILLO R., MORGONICO S., MARZILLO G. G., COTRURO MONTUORI L. V. PAROLI - ITALY
54 HIV-ab positive patients (of 11 group, 13 of III group, 35 of IV group of CDC classification) received AZT in doses of 1200mg/die for 3-6 months; of these patients (80%) were drug abusers (d.a.); 16 of them (33%) resulted dropped out. During the first three months (I of group, 6 of III group and 9 of IV group) there were not d.a. among those who aren't d.a. At the follow-up since the beginning (time 0) showed of CD4 > 400. There were serious side effects in 26% of the patients, which resulted in interruptions of the treatment. There were none in those from I and III groups. In spite of the treatment, 40% of the patients of the II group and 29 of those of III group showed development in more advanced stages of the syndrome, without correlation with the number of CD4 at time 0. Among the followed 26 patients of IV group, 73% showed stationary conditions during the time and 13% died (we have registered deaths in 54% of other 39 patients of IV group, who didn't receive AZT). Among 13 d.a., followed, we observed a development of the syndrome in more advanced stages in 40% of those who went on taking drugs and only 30% of those who had given up this habit (p < 0.05). Of the six patients not d.a., 66% have remained stationary and 11% a. 6% died.

W.B.P.363

LONG TERM ASSESSMENT OF TOXICITY AND CLINICAL OUTCOME IN TREATMENT OF HIV INFECTION WITH ZIDOVUDINE

Conrad F., Gump J., Geay J., Bender J., Boudier J., AIDS Clinical Research Project, Children's Hospital of San Francisco, California, U.S.A.
Objective: To evaluate the toxicity and assess the long term clinical outcome of Zidovudine therapy in HIV infected individuals diagnosed with AIDS or who have been asymptomatic with less than 200 CD4 cells.
Methods: A prospective, open-ended multicenter study of Zidovudine therapy began in December of 1986. By the end of December 1989, we enrolled and treated 27 patients with AIDS and 19 patients with HIV related symptoms and less than 200 CD4 cells (CDC stage II disease).
Results: Mean follow-up of 69 weeks is available for 26 patients with AIDS and 26 weeks for 12 of 19 patients with CDC stage IVa disease. Neutropenia with less than 700 cells per cubic millimeter occurred in 37% of patients (11 with AIDS); 3 with stage IVa disease). Transfusions were required in 24% of patients (8 with AIDS); 1 with stage IVa disease). Recurrent opportunistic infections including PCP, CMV retinitis, CMV colitis, and disseminated MAC were noted in 30% of the AIDS patients. 3 of 13 (23%) evaluable CDC stage IVa patients have progressed to AIDS. 50% of patients diagnosed with AIDS at start of therapy have died while 27% remain on drug. 81 of evaluable patients with symptoms and less than 200 CD4 cells at start of therapy had died while 72% remain on drug.
Conclusion: Our experience with Zidovudine therapy in HIV infection is similar to that of other investigators. Zidovudine prolongs survival in this population by decreasing morbidity from recurrent OIs. The major limiting factor in prolonged use remains the hematologic toxicities.

W.B.P.365

CORRELATION BETWEEN P24 ANTIGENEMIA AND CD4+ T-LEUCOCYTES RATIO IN AZT-TREATED PATIENTS

Crossibile Paolo, Lixoli A., Panseri WP., Filippi C., Arcidiacono I., Nardelli M. - Dapedale Maggiore - 20076 LODI (Italy)

Objective: to verify whether CD4+/neopterin ratio (R) correlates with clinical condition and p24 antigenemia (p24Ag) in AZT-treated patients infected with HIV.
Methods: 14 HIV-positive pts (18 males, 4 female, mean age 24.5, range 20-35) treated with 1200 mg AZT per day, at enrollment were daily administered 18 mg/kg AZT per day for 1 year. Every 3 months they were clinically evaluated (according to CDC criteria) and tested for serum Neopterin levels (ENL), CD4+ cell counts and p24Ag; R was also 3 monthly calculated for each patient.
Results: Clinical condition did not worsen in any of the 14 pts during the 18 months' treatment; in fact clinical improvement was noted in 4. According to "between-variance" analysis, however, no statistically significant immunological improvement (CD4 and R increase, ENL decrease) was observed in our pts, regardless of their initial p24Ag status.
Conclusion: in our experience R proved to be the most sensitive index of immunological response to treatment correlating, to a certain extent, with p24Ag. In fact, it may be proposed as the only immunological index (replacing p24Ag) in the monitoring of AZT-treated patients.

W.B.P.362

EFFICACY AND TOLERANCE OF ZIDOVUDINE IN PATIENTS WITH ACQUIRED HIV INFECTION ON WITH PGL.

A. Cristiani, F. Dulio Cataldo, S. Mosca, G. Bonadoni, L. Pisciotta, M. Piana. CLINIC OF INFECTIOUS DISEASES UNIVERSITY Naples-Italy.
Objective: Evaluation of the effects and tolerance of Zidovudine (ZDV) in HIV seropositive patients.
Methods: 10 asymptomatic patients (CDC group II) and 10 with PGL (CDC group III) all with initial T4 counts ranging between 150 and 350/mm³ were given ZDV 7 mg/kg for 4 times a day for the first month and 3.5 mg/kg for 4 times a day for an additional 3 months.
Results: No patients showed CO. II and/or tumor. Nausea and headache were not frequently observed. All subjects developed mild decrease in haemoglobin (mean 8g/dl, 38 g/dl at entry and 14.04 at month 8) and in WBC cell counts (mean 9000-2533/mm³ at entry and 2407 at month 8). Anomalous CPK values were observed in 3 subjects during treatment. In 2 patients EPT values 3 times the normal values was observed in the first month followed by normalization. HIV Ag was detected in serum of 3 patients at entry and 2 became persistently HIV Ag negative during the treatment. Mean T4 count was 180/mm³ at entry and 170/mm³ after 8 months.
Conclusion: ZDV at the dose indicated was fairly well tolerated during first 8 months of therapy. The slight T4 cells decrease is an expression of the efficacy of the treatment. Further study will be needed to determine the long-term effect of therapy.

W.B.P.364

ZIDOVUDINE TREATMENT IN 100 CONSECUTIVE PATIENTS WITH AIDS OR AIDS RELATED COMPLEX

Corbelli A., Gagnoli F., Marzulli M., Ghislini A., Casanovi B., Kozakovic J., Lyonnet F. et al. Hopital Necker Mondor, 94010 Creteil, France.
Objective: To analyse Zidovudine treatment in severe HIV infection in terms of survival, toxicity and clinical maintenance.
Methods: 100 consecutive patients with AIDS and ARC received Zidovudine at a starting dose of 800-1200 mg per day. The drug was always given orally every 8 hours. The patients comprised 55 AIDS patients (50 O.I., 18 isolated K.S., 7 with both), 2 with neurologic disorders) and 45 ARC patients. The mean duration of follow-up under treatment was 8.2 mo (0.2-18). 15% of the patients were IVDA.
Results: At 8 mo after beginning AZT only 35% of the patients (33% of ARC) received the initial dose. The causes of regimen alteration included hematological toxicity (41%), intercurrent infections (10%), combination therapies. 8 ARC patients progressed to AIDS under treatment. 42 O.I. were observed in 24 patients. The 12 mo survival rates from the beginning of AZT treatment were 70.4% in ARC patients, 68.4% in AIDS with I.D., 72.4% in K.S patients, 42.9% in O.I. patients. The 18 mo rates were 70.4% in ARC but only 55.5% in AIDS.
Conclusion: Zidovudine provided a better quality of survival which might be slightly prolonged. But starting doses are reduced in 2/3 of the patients within 8 mo because of toxicity. Moreover 20% of ARC patients moved to AIDS while treated although the initial dose had been maintained in most.

W.B.P.366

Studi clinico e biologico de 108 malato trattati per ZIDOVUDINE sui principi de 12 a 18 mila.

Bellou, Gerone ; PERCE, A. ; QUARANTA, J.F. ; VITTI, R. ; TALLAS, B. ; CASUTO, J. C.

C.N.R.U. de NICE, FRANCE. Ligue Nazionale Française de lutte contre le SIDA.

Objective: Evaluated a long term, survival, l'apparition des infections opportunistes et la modification des lymphocytes T4 des 108 malato - gruppo 3 et 4 trattati per ZIDOVUDINE.
Methods: 108 patients with AIDS and ARC with biological annual de 108 malato sur un principe de 12 a 18 mila.
Results: - **survival:** de survie 7 steps 3 a 4 confondus.

W.B.P.367 AZT THERAPY IN SEROCONVERSION INDICATORS (INDS) AND THEIR GENITAL PARTNER
Research: Adams, I., Levinson, S., Shaffer, R., Chagnrin, E., Debovitz, J., Kings County Health Dept., Health Science Center at Brooklyn, U.S.A.

Objective: Describe the experience of our clinic in administering AZT to INDs and to sexual partners of INDs.
Methods: 39 consecutive patients (25 female) or who were sexual partners of an IND were begun on AZT between 1/87 - 3/88.
Results: 33 were male INDs (mean age: 37.5, range: 23-56), 24 were female (mean age: 33.2, range: 20-59), 19 females were INDs and 14 were sexual partners of an IND. 46 had AIDS (immunocytochemistry-39, other seropositive infection: 7); 13 had AIDS with a mean T4 of 135 (range: 60-192), 30/59 (64%) pts were compliant with therapy for a mean of 10.9 months of follow-up (4/25 p=months); 13 died after a mean of 10.5 months (range: 15-19), 12 are alive after a mean of 15.8 months (range: 10-24), 7 required discontinuation of AZT due to toxic reactions after a mean of 8.7 months (range: 1-19), and 4 reinfected or another facility after mean of 9.8 months (range: 2-24). 20/59 (34%) were lost to follow-up after mean of 5.7 months of therapy (range: 1-11) (p=months). 23 developed an opportunistic infection while on AZT, 18 required hospitalization. 21 reported dose reductions due to nausea (11) or maculopapula (11).
Conclusions: Most patients of seroconversion INDs and sexual partners of INDs were compliant with AZT therapy as judged by their record of clinic attendance. Efficacy was not advanced due to the lack of a control group. Adverse reactions to AZT were similar to those previously described in other groups of pts.

W.B.P.369 AN INTERMITTENT ZIDOVUDINE REGIMEN: TOXICITY AND EFFICACY
Background: Cooper, David A. 80003 Special Unit in AIDS Epidemiology and Clinical Research, U.S.W., Australia.

Objective: To assess the efficacy and intermitent regimen of zidovudine. **Methods:** 21 men (6 with AIDS, 15 with ARC) who developed hematotoxicity on continuous zidovudine therapy were randomized (1:2) to 0.75/0.6g twice daily followed on an intermitent regimen of AZT (4 weeks of 1 g per day, 4 weeks without drug). The effect of zidovudine on clinical response, transfusion requirements, blood counts, virotests and CD4 cells was analyzed on continuous therapy (24 weeks) compared with intermitent therapy (23.4 weeks).
Results:

	Pre AZT	Continuous AZT	Intermitent AZT
Raw obs or ES	10	3 (2 subjects)	3 (2 subjects)
p24 ₄ no vire	10	9	9
pgAL	377 ± 236	113 ± 28	272 ± 20
CD4 cells x10 ⁶ /l	131 ± 118	105 ± 47	83 ± 15
Transfusions patients	34	10	10
number (units)	36 (240)	16 (16)	16 (16)
WBC x10 ⁹ /l	13.9 ± 2.31	7.9 ± 4.2	11.6 (11.9, 12.3)
HCC x10 ⁹ /l	4.29 ± 3.4	2.53 ± 2.20	2.95 (2.81e, 3.09e)
Glycemia x10 ³ /l	1.44 ± 2.23	1.30 ± 1.33	1.66 (1.61e, 1.67e)

all values are mean (SE) ± n on zidovudine, ↑ off zidovudine.
Conclusion: Azsima improved markedly on intermitent AZT and transfusion requirements were minimal. Despite more severe hematotoxicity and anemia consistent with more advanced disease at the time of commencement of intermitent therapy, the occurrence of new opportunistic disorders was similar for both regimens on the basis of these findings, argues of the efficacy of intermitent zidovudine as initial therapy should be undertaken.

W.B.P.371 USE OF ZIDOVUDINE (AZT) IN THE MANAGEMENT OF AIDS (IND) RELATED HIV INFECTION - CLINICAL COURSE
Open: M. Flapp, M. McCollum, R., Brettle, R., Gray, M., et al. Infectious Diseases Unit, City Hospital, Edinburgh, U.K.

Objective: To evaluate clinical outcome of AZT therapy with ID-related HIV infection (IDRHV) in view of increased AZT levels in opiate users.
Methods: 32 HIV seropositive patients were assessed of which 23 (78%) became infected between 1983-85 by ID. Of 51 AZT treated patients 37 saw male (72.5%) and 14 female (27.5%) ID partners. 11 (29%) were ID seropositive. Clinical course was assessed in terms of clinically significant opportunistic infections (OI), side effects (SE) attributable to AZT and survival since starting AZT.
Results: 22 patients started AZT when developed AIDS (CD4 < 200/μl). 19 were ID (mean duration of treatment [D]-40 weeks) and 10 were IDRHV (D=30 weeks). SE requiring dose reduction developed in 5 (23%) IDRHV and in 6 (46%) ID. Significant OI of 6 weeks post start of AZT occurred in 3 (20%) IDRHV and in 6 (42%) ID. Three (23%) ID with AIDS have died of their disease (mean time from starting AZT=56 weeks). Two ID started AZT when they had AIDS (CD4 < 200/μl) (D=43 weeks) compared with 19 IDRHV (D=39 weeks). SE requiring dose reduction developed in 1 (5%) IDRHV and in 1 (5%) ID. Significant OI developed in 3 (16%) IDRHV but in neither ID. As yet no ARC patients have proceeded to AIDS. One (6%) IDRHV has to date died from non HIV causes. Post IDRHV were CD4 status 3 (D=44 weeks). None of them developed SE or OI.
Conclusions: The frequency of serious events (OI and SE) is not greater or efficacy less in IDRHV despite opiate/haemostatic changes having an effect on AZT pharmacokinetics.

Aspects Cliniques Clinical Aspects of AIDS

W.B.P.368 TREATMENT OF SYMPTOMATIC HIV SEROPOSITIVE SUBJECTS BY ZIDOVUDINE (AZT). A CONTROL STUDY IN 36 PATIENTS
Authors: D'Amico, L., LaRosa, J.J., Lamb, P., Matis, J.P., Roussois, C., Corcoran, J.A., et al., Bach, J., et al., Pitt of Immunology, Hospital Necker; ** I.N.T.S., Paris, France.

Objective: To determine the effect of AZT in symptomatic HIV seropositive subjects.
Methods: Comparison of 2 cohorts of 28 asymptomatic subjects (CDC II or III) matched according to CD4 cell count (> 200/mm³) and p28 antigenemia (Ag) (detectable or undetectable). A group of subjects was untreated while the other received AZT (300mg every 6 hours) + acyclovir (800mg/day) during one year. Clinical and biological (CD4 and CD8 cell count, p28 Ag) evaluation was performed at 0, 6, 12 months.
Results: 26 treated subjects were evaluated; 2 subjects were excluded due to drug induced anemia. No significant modification of haemoglobin level and total leucocyte count occurred in the others. No modification of clinical staging was noticed in treated subjects while 3 untreated subjects became CDC IV. p28 Ag was initially undetectable in 11 subjects in both groups, remained undetectable in all treated subjects while became detectable in 11 untreated subjects. A decrease of p28 Ag level was noticed in treated subjects when p28 Ag was initially detectable (respectively 210/8 and 80 pg/ml at 0,6,12 months p28). No modification of total lymphocyte count was noted in either group. A CD4 cell count increase was noted in treated subjects (330,429 and 445,531) at 0,6,12 months p28, contrasting with a decrease in the untreated (329,245 and 319,953) p28. A CD8 cell increase was also noted in treated subjects (701,927 and 999/mm³) p28.1.
Conclusion: AZT is not effective in symptomatic HIV infection despite the risk of anemia. Placebo controlled trials requiring long follow-up are warranted and ethically suitable only in subjects having CD4 cells > 400/mm³ and an undetectable p28 Ag.

W.B.P.370 LONG-TERM SAFETY AND EFFICACY OF ZIDOVUDINE IN LARGE COHORTS OF 70 DRUG ABUSERS: 20 MONTHS EXPERIENCE WITH 200 ZIDOVUDINE, 500 ARC AND 100 AIDS PATIENTS.
Yello, Stefano*, Nemati Ippolito, F., Agresti, M.C.* and the Italian Zidovudine Evaluation Group.**

* National Institute of Health, Rome, Italy.
Objective: To evaluate the long term safety and efficacy of zidovudine (ZDV) when administered in I.V. drug abuser HIV-infected patients.
Methods: Data contained in the Italian National Registry of ID-treated patients have been analyzed. The Registry prospectively collected enrollment and quarterly follow-up forms of 1100 patients referring to 105 clinical centers involved in ZDV therapy, which started in Italy in July 1987. Multivariate analysis has been performed in order to evaluate the effect of possible co-factors on therapeutic response in this particular population.
Results: Frequency of adverse effects appeared to be similar to frequency reported in other risk categories of patients, hematological adverse reactions being minimal in AIDS and ARC patients who initiate therapy with over 200 CD4/cell. IDV also appeared to be very well tolerated in asymptomatic patients, with no unexpected adverse reactions. One-year survival of AIDS patients was 90.5%. The 18-month actuarial progression rate to ARC and AIDS has also been evaluated for the studied population.

W.B.P.372 ZIDOVUDINE IN ARC AND AIDS PATIENTS: CLINICAL, IMMUNOLOGICAL AND VIROLOGICAL EFFICACY
Open: M. Flapp, M. McCollum, R., Brettle, R., Gray, M., et al.

*Medical Clinic Edinburgh, **Institute of medical virology and *** clinical and experimental virology, 1000 Rue St-Jacques, Montreal, Canada.
Objective: To evaluate the clinical, immunological and virological efficacy of Zidovudine (AZT) in ARC and AIDS patients (pts).
Methods: 100 patients were assessed of which 23 (23%) were ID seropositive. Clinical course was assessed in terms of clinically significant opportunistic infections (OI), side effects (SE) attributable to AZT and survival since starting AZT.
Results: 22 patients started AZT when developed AIDS (CD4 < 200/μl). 19 were ID (mean duration of treatment [D]-40 weeks) and 10 were IDRHV (D=30 weeks). SE requiring dose reduction developed in 5 (23%) IDRHV and in 6 (46%) ID. Significant OI of 6 weeks post start of AZT occurred in 3 (20%) IDRHV and in 6 (42%) ID. Three (23%) ID with AIDS have died of their disease (mean time from starting AZT=56 weeks). Two ID started AZT when they had AIDS (CD4 < 200/μl) (D=43 weeks) compared with 19 IDRHV (D=39 weeks). SE requiring dose reduction developed in 1 (5%) IDRHV and in 1 (5%) ID. Significant OI developed in 3 (16%) IDRHV but in neither ID. As yet no ARC patients have proceeded to AIDS. One (6%) IDRHV has to date died from non HIV causes. Post IDRHV were CD4 status 3 (D=44 weeks). None of them developed SE or OI.
Conclusions: The frequency of serious events (OI and SE) is not greater or efficacy less in IDRHV despite opiate/haemostatic changes having an effect on AZT pharmacokinetics.

W.B.P.373 COMPLIANCE WITH ZIDOVUDINE (AZT) THERAPY IN AN INNER-CITY HIV-INFECTED POPULATION
William, Krista Y., Bell-Comer, J. & El-Sadr, W.*
Marion Hospital Center, New York, N.Y. U.S.A.

Compliance to AZT was retrospectively evaluated in HIV-infected outpatients. Eighty-two patients (82%) were prescribed AZT between 11/86-7/88. Thirty-five are alive and on treatment (82%). were referred elsewhere, 1 requested stopping AZT and 11 never started AZT. Twenty-eight pts were followed from start to their death. There were inadequate data on 4 pts. Charts of 26 of the latter group were reviewed. All 24 pts were black and 22 (91%) were men. The mean age was 40.4±9.4 yrs (range 21-62 yrs). Eighteen of the 24 (75%) were intravenous drug users (IVDU); 5 of 24 (20.8%) were homosexual men and 1 (4%) the primary diagnosis was HIV. Eighteen (67.3%) cryptococcal meningitis (CM), 18 (69.2%) and 3 (4.1%) each of Kaposi's sarcoma, TB, salmonellosis and HIV positive. The pts were on AZT for a mean of 6.9±2.1 months (range 1-18, median 3.5). Fourteen (54%) of the 26 pts were excluded as they remained hospitalized. There were 22 scheduled appointments (apppt) for 20 pts and 42.3% were kept. The mean percentage (%) of apppt kept by pts was 24.2% (range 0-75%, median 35%). There was no statistically significant difference in compliance 1 between IVDU versus homosexual men and above 40 yrs, that is, those in and outside the hospital catchment. There was a significant association between compliance 1 and the duration of AZT, 40.2% in those 9 months versus 24.3% in those 9 months. In conclusion, this study shows that acceptable though not ideal compliance was achieved in a subgroup of black predominantly IVDU with HIV disease.

W.B.P.374 INTERFERON (IFN) ALPHA + AZT IN AIDS-ASSOCIATED KAPOSI'S SARCOMA (KS): FINAL RESULTS OF A PHASE I TRIAL
Kocum, A., Bandow, D., Gauschbauer, B., Gold, J., Fimmesberg, H., Armstrong, D. Memorial Sloan-Kettering Cancer Center, New York, NY, U.S.A.

Objective: To evaluate the safety, tolerance and maximum tolerated dose (MTD) of IFN- α + AZT in AIDS patients (pts) with KS: to assess anti-tumor, immunological and antiviral effects of the combination.
Methods: HIV-positive adults with biopsy-proven KS, T2/T3, AIDS-200, HbA_{1c} 5.0 and no prior IFN or AZT were eligible. Cohorts of 4-6 pts were entered at various daily IM doses of IFN- α or IM plus AZT, 100 or 200mg QD qth. **Results:** IFN- α at a dose of 3x10⁶ IU/300 or 100 or 200mg of AZT induced dose-limiting toxicity in 4/6 and 4/6 cases, leading to discontinuation of this arm of the study; tumor response was seen in 3/6 and 1/3 evaluable pts, respectively. For IFN- α , a wider dose range was evaluated:

IFN Dose (IU/d)	AZT Dose (mg/d)	Grade 1 Toxicity/eval.	CR/PR/eval.
4.5	2/0	2/6	1/3
4.5	2/0	2/6	2/3
9	2/0	2/6	3/6
9	2/0	2/6	4/6
18	2/0	2/6	5/6
18	2/0	2/6	4/6
18	2/0	2/6	4/6
18	2/0	2/6	4/6

Two MTDs were defined: 4.5M2 IFN- α QD + 200mg AZT qth and 18M2 IFN- α QD + 100mg AZT qth. Neutropenia was the major dose-limiting toxicity. Skin test reactivity increased, while and CD4 cells declined. 4/6 pts with elevated serum p24 antigen, 6 showed a decline to undetectable levels.
Conclusion: IFN- α and AZT can be safely combined and induced a high tumor response rate and p24 suppression in some patients. (Supported by NIAID-ACTC)

W.B.P.375 OUTPATIENT TRANSDUCTION THERAPY FOR RETROVIRUS-ASSOCIATED ANEMIA
Weiss, Susan; Viseer, S.; Rodgers, P.; Mollenhag, A; Schlam, H.
AIDS Program, Bellevue Hospital Center, New York, NY, USA.

Objective: To demonstrate the feasibility and safety of outpatient transfusion therapy for patients with Retrovirus-associated anemia (RAA) **Methods:** In a designated section of the general outpatient clinic of a large municipal hospital in New York, up to three patients with RAA, with a hematocrit between 18 and 30, were transfused during each of 1 or 2 weekly 8-hour sessions. The transfusion was initiated by an MD, who remained on call for emergencies. A RN observed the patient continuously. Adverse effects were managed by strict protocol.
Results: During the period from 7/87 until 1/89, a total of 604.5 units of packed RBC's were transfused in 66 patients with RAA (62 males, 4 females) including 10 homo/hemodialysis, 10 patients with history of intravenous drug abuse, 3 with multiple AIDS-risk, 2 with other risks. 28 patients received transfusions on multiple occasions. Each patient was transfused an average of 3.7 units per session. Nine patients had unhealing cutaneous sores occur. Only 6 adverse effects were observed including 4 non-hemolytic febrile reactions, 1 severe allergic reaction and 1 episode of hypotension caused by concurrent infection, resulting in hospital admission. There were 0-1m adverse reactions per patient transfusion session.
Conclusion: Transfusion therapy for patients with RAA can safely be provided in the outpatient clinic setting. Stable clinical status can be maintained in patients with RAA requiring transfusions without the need for admission to the hospital.

W.B.P.376 Self Care Program for AIDS/ARC via Computer Network
Karlitz, J., Frenkel, M., et al. Principal Investigator
Stefan, Ralph M., Project Director
Frances Payne Bolton School of Nursing, Case Western Reserve University

This three year study analyzes the use of a free, public access computer network as a vehicle for the delivery of nursing services in the treatment of Acquired Immune Deficiency Syndrome (AIDS) and AIDS-Related Complex (ARC). To represent traditional methods of nursing care delivery with a new approach that will (1) enable nurses to meet the individual needs of well persons concerned about AIDS/ARC (2) foster self-care of people with AIDS/ARC ("PWA/PNARC") and their caregivers through in-home support, counseling, and education. Currently underway is a six month assessment involving 100 PWA's and their caregivers.
Computer networks create electronic links between clinics. In this project we will put computers in the home of PWA/PNARC to provide links to clinical agencies or to other homes. Through this terminals people can access an existing computer system and use the special programs and communication services constructed to support the entire range of AIDS/ARC patients: healthy people needing information, persons diagnosed with AIDS/ARC, and the informal care partners of PWA/PNARC. The messaging and support services will facilitate peer as well as professional contact, serving as a "support group without walls".
This intervention's effectiveness in disseminating information, enhancing problem solving skills, and distributing isolation will be evaluated in a series of field studies. The increasing emphasis on non-institutional care demands new approaches to delivery treatment and support, while the availability of computer technology provides the means to do so. Preliminary findings from the needs assessment suggest that due to cognitive impairment computer interface employ icons (pictures) as well as text.

W.B.P.377 COMPLEMENTARY THERAPIES AT CASEY HOUSE HOSPICE: A MODEL FOR TRADITIONAL/ALTERNATIVE INTERACTION

William E. Berinatti, M.A., D.C.,
Chair, Complementary Therapies Committee,
Casey House Hospice Inc.
Vice-President, Casey House Hospice Inc.
Founding Board Member, Psychiatry Clinic for
AIDS-Related Concerns, St. Sina's Hospital, Toronto

The descriptors "alternative" and "traditional" regarding care of the HIV infected individual often suggests a dichotomy, which can imply a rift between "medical" and "non-medical" orientation. Casey House Hospice made a firm commitment, from the outset, to utilization of "alternative" therapies in its hospital-affiliated program. This presentation will describe the philosophy, planning, and implementation of Complementary Therapies at Casey House, touching on the affiliation agreement with St. Michael's Hospital, educational aspects, and case studies involving a variety of therapies. The broader implications for both the overall treatment of HIV infected persons in the community or hospital setting and the marriage of the "traditional" and "alternative" health care systems will be introduced.

W.B.P.378 WORKING IN AN AIDS HOSPICE SETTING
Bloom, Jeff A., Flannery, J.
Casey House Hospice, Toronto, Ontario, Canada

Casey House is a free standing hospice dedicated to people with AIDS. The Hospice has 13 beds (12 palliative, 1 respite care) and opened in March 1988. It was expected that the emphasis of medical/nursing care would be on symptom management (pain, nausea, skin problems, and minor infections). Although the residents/legal guardians (for deceased residents) accept the philosophy of palliative care, denial of death can situate patients in a limbo. In the first 13 months, Casey House has admitted 82 people, 38 have died and 12 have been discharged. The health and functional capacity of the residents in the Hospice affect the criteria of the next admission. As acute health situations arise, residents may elect to be transferred to an acute care facility. Unexpectedly, new residents improve so they no longer require the level of care provided at the Hospice. Because their recovery was unexpected, discharge planning has been difficult. Community systems are not presently organized to assist these people. Problems occasionally arise regarding residents who wish to continue to use unapproved drugs or have remedies with which the care-providers are unfamiliar.
Conclusion: AIDS is less predictable than cancer in the final stages. With overarching approaches to therapy, all involved persons must be ever flexible in the definition and provision of palliative care. We must continually review the policies of the Hospice in accordance with changes in illness and management change in the community to provide an effective continuum of care.

Hémophilie Hemophilia

Th.B.P.1 LYMPHOCYTES CYTOCHEMISTRY BEHAVIOR IN HEMOPHILIC PATIENTS WITH HIV INFECTION.
Gabriella Gamba, S. Tavea, L. Ponchio, R. Invernizzi, P. Di Pasio, C. B. Ippoliti. Dipartimento di Medicina Interna e Terapia, Università Medica, Via di Clinica Medica II, IRCCS Policlinico San Matteo, Università di Pavia, Italy.

The cytochemical and immunological characterization of lymphocytes of 31 hemophilic patients (6 of whom anti-HIV positive without symptoms and signs of AIDS) chronically treated with commercial clotting factor concentrates were studied. In comparison to aged cross matched male controls, hemophilic patients presented significant increase of absolute number of lymphocytes and subpopulation of CD4+ cells (CD4, CD8, CD3, CD4, CD8, CD45) PAM reaction showed a lower grading score in hemophilic and the staining for alpha-naphthyl butyrate esterase (ANBE) acid phosphatase (AP), beta-naphthyl azeluroaminidase (NABG) gave significant reduction of the percentage of the lymphocytes with coarse granules in the same pts. The percentage increase of AP reactive lymphocytes with coarse granules was directly related to the percentage number of CD4 and CD8. The anti-HIV positive pts presented lower percentages of CD4 and of dot-like AP reactive lymphocytes. In conclusion, the increase of acid phosphatase reactivity, especially the dot-like AP reaction, may represent a useful, simple and unexpensive method for following modification of CD4 subset in pts at risk of developing AIDS.

Th.B.P.3 AGENESIS OF HIV-2 INFECTION IN HEMOPHILIA IN BUENOS AIRES
Nancy Beltrán, Susana M. Simon, Susana Machin, O. Pichetto, P. Tello, V. Lelonek, P. P. R. Narkov, I. A. *

*IDEM, Academia Nacional de Medicina, Buenos Aires, Argentina, *Hospital Clinico Bernardini, Paris, France

Objective. Since HIV-2 probably spread by the same transmission routes as HIV-1, and considering that our patients received American and European concentrates, we evaluated HIV-1 antibodies previously screened for HIV-1.

Methods. Presence of HIV-2 antibodies was investigated in the sera of 60 hemophilic: 33 HIV-1, 27 HIV-2. Sera were screened for HIV-2 antibodies by an ELISA assay (ELAVIA 2) (Diagnostics, Parter). Samples repeatedly positive or undetermined were tested by RIBA.

Results. None of the 60 sera was HIV-2 positive when confirmed by RIBA; however, 21 samples were initially considered positive in the ELISA assay, no sample could be confirmed when tested by RIBA.

Conclusion. Although the number of tested sera does not allow to ascertain conclusions, it seems HIV-2 infection is very infrequent in this high-risk group in Argentina. (Supported by a grant from Fundación Rossmers).

Th.B.P.5 RESPONSE TO HEPATITIS B IMMUNIZATION IN HEMOPHILIC CHILDREN: RELATIONSHIP TO HUMAN T-CELL DEFICIENCY TYPE I (HIV-1) VIRUS INFECTION.

Chan, Wendy, Pettit, M., Wang, N., Koren, G., Reed, J., Blachette, V., Departments of Pediatrics and Virology, Hospital for Sick Children, Toronto, Ontario, Canada.

Hemophilic who received pooled plasma concentrates for control of bleeding are at high risk for hepatitis B infection. In our Hemophilia Clinic, children susceptible to hepatitis B infection (non-HBeAg, anti-HBeAg) have been immunized using a plasma-derived hepatitis B vaccine (Heptavax-BB Merck Sharp and Dohme). Three injections are given at 0, 1 and 6 months. We now report serial anti-HBeAg titres, measured by radioimmunoassay (Austab-B, Abbott), in a population of 23 children with hemophilia A (n=19) or B (n=4). Twelve of the children were HIV-1 antibody +ve (11 CDC Group III, one Group IV-E), and 11 were HIV-1 antibody -ve. The median age of the HIV-1 positive and negative groups were 5.6 and 5.3 years respectively (range for both groups 0 months to 13 years, 8 months). Results are as follows:

Time from start of Immunization (months)	HIV-1 Positive	HIV-1 Negative	P
12-24	11/47 ± 1983	43/86 ± 3560	<0.05
25-36	13/27 ± 1983	23/96 ± 2663	<0.01
37-48	17/24 ± 2275	22/61 ± 2109	<0.005

Values are means ± 1 S.D. At the time of reporting, anti-HBeAg titres have fallen below protective levels (<40 RIA units) in 4 children (3 HIV-1 +ve, 1 HIV-1 -ve). One HIV-1 positive child, not included in this series, failed to respond to immunization. We conclude that hemophilic children with HIV-2 infection have an impaired response to hepatitis B immunization. In such children, follow-up of anti-HBeAg titres in conjunction of immunization and yearly serologic B recommendations.

Th.B.P.2 ANTIPHOSPHOLIPID ANTIBODIES AND HIV INFECTION IN HEMOPHILIA.
Sofia Taita, L. Ponchio, M. Montani, C.M. Montecucco*, G. Cascone, G. Gamba. Dipartimento di Medicina Interna e Terapia, Università Medica, Via di Clinica Medica II, IRCCS Policlinico San Matteo, Università di Pavia, Italy.

Objective: to study the presence of antiphospholipid antibodies (lupus like (LAC) and anticardiolipin (ACA) in Hemophilia. Patients: 30 pts. with Hemophilia B, 7 FPL+ positive for anti-HIV antibodies, without symptoms and signs of AIDS. Methods: LAC diagnosed by prolongation of Russell Viper Venous Time (RVVT), not corrected by adding of normal plasma. ACA detected by immunoenzymatic Test (ELISA), using POC conjugated with anti-murine antibodies against human IgG, IgM, IgA, IgE. Results: we detected ACA in 8 out of the 2 pts. with HIV infection. 6/8 in 4 of them also LAC, among the anti-HIV neg pts. only 4 showed ACA and 2 LAC. In pts. with ACA no correlation was found between serum IgG levels and IgG ACA prevalence of IgG ACA was observed in anti-HIV pos pts. (87.5%) while IgM ACA in HIV neg ones (75%). Conclusions: our results indicate that in Hemophilia: HIV infection induces the production of antibodies against phospholipid components; idiosyncratic behavior of ACA by Isotypes (IgG, IgM) was observed in relation to the presence of HIV infection; HIV infection promotes the formation of ACA earlier than of LAC.

Th.B.P.4 HIV INFECTION AND CHAGAS' DISEASE IN HEMOPHILICS IN ARGENTINA
Nancy Beltrán, Susana M. Simon, Susana Machin, O. Pichetto, P. Tello, V. Lelonek, P. P. R. Narkov, I. A. *

*IDEM, Academia Nacional de Medicina, Hospital de Niños, Buenos Aires, Argentina.

Objective. To analyze the relation between HIV-infection and Chagas' disease (CD) in 72 hemophilic (HF).

Methods. HIV serology was assayed thru ELISA (Abbott, recombinant). Positivity reacting samples were confirmed thru Immunofluorescence or Western Blot (Daport). CD diagnosis was performed by means of direct agglutination and indirect immunofluorescence (Polychuch), Titers 1:16 for both serologic tests were considered positive.

Results. Twenty-two out of 37 HIV-1 positive sera showed a positive test for CD. In addition, 18 out 33 HIV-1 negative sera gave a negative reading in the same assay.

Conclusion. Ch is an hemoparasitosis, endemic for our country. Blood transfusions constitute one of the major ways of dissemination. Ch shows the same prevalence on HIV-1 positive and HIV-1 negative HF (p>0.05). Similar results were observed in other HIV-1-risk groups, such as homosexuals (30), and drug abusers (30). By contrast with the reported occurrence of other endemic diseases (for ex., tuberculosis) as second opportunistic infections, in our serologic infected patients did not present higher susceptibility to Ch than that exhibited by HIV-1 negative HF.

Th.B.P.6 BENEFICIAL EFFECT OF AN ULTRAPURE FACTOR VIII CONCENTRATE ON HYPERANEMICOLICEMIA IN HIV-POSITIVE HEMOPHILIC.

Schulman, Sam and Johansson, B. Department of Internal Medicine, Karolinska Hospital, Stockholm, Sweden.

Objective: Elevated IgG-levels are often seen in hemophilia. The etiology is multifactorial, including passive transfer of IgG via the factor concentrates, antigenic stimulation by foreign proteins, chronic hepatitis and HIV-infection. We still remainly the possibility of a direct substitute of immunoglobulin proteins and CIX of F VIII. Since 1987, we have had access to an ultrapure factor concentrate, containing only F VIII and albumin.

Methods: Immunoglobulin G, A and M were followed at 2 months intervals since 1988 in 19 HIV-positive patients. Nine of those were switched to an ultrapure factor concentrate (Benefil B, Baxter) during Aug 87 - Apr 88. The remaining 8 patients ("control group") continued using conventional concentrates. Results were analyzed with Wilcoxon's signed rank test.

Results: The mean IgG-level in the Benefil B group increased from 16.4 in 1988 to 20.4 at the time they were switched to Benefil B (p=0.08) and then decreased during the following year to 17.9 (p<0.02). In the control group the mean IgG-level was at corresponding times, 16.4, 19.2 and 18.7, thus also an initial increase (p<0.02), but thereafter no changes. In the Benefil B group it was mainly the 3 patients with the highest IgG-levels (23.0; 29.7 and 37.4 g/L), who had a beneficial effect. The last one also had pulmonary hypertension, which improved spontaneously. IgA and IgM did not change.

Conclusion: Switching to an ultrapure factor concentrate seems to have a favourable effect in HIV-positive hemophilic, especially in those with pronounced hypergammaglobulinemia.

Th.B.P.19 HEMPHILLIC AGE AFFECTS IMMUNE FUNCTIONS IN HIV INFECTED PATIENTS

Adams, W. ¹Abu² Wallif, K.*; Lamotte, C.*; Deal, C.*; Morgan, J.*; McMillin, M.*; Heston, K.*; ¹University of Louisiana at Monroe, ²Louisiana State University School of Medicine, ³Department of Pediatrics and the Tulane/LSU AIDS, New Orleans, Louisiana, USA.

We have followed approximately 200 hemophilic (H) at our State Center since 1980. Overall 53% (103) of the patients who used any non-treated factor VIII or IX concentrates seroconverted. Of those children (C) (13) 27/99, adolescents (Ado) (18) 27/45, and adults (A) 52/117 developed specific HIV antibodies. 100% of the children, 90% of the adolescents and 85% of the adults had seroconverted to seropositively develop T4's <500 but without AIDS (Ado's) 40% or Ado's - 60, 28, and 37 this reduction occurred at a rate of approximately 30 (11-36) T4 cells per month. Eight patients after a period of 25-75 months following seroconversion with CD4 T4 cells without developing disease though 8 others suffered AIDS with such low numbers. Fourteen patients - 3 C, 1 Ado, and 10 Ado - have developed AIDS after a period of 25-75 months following seroconversion. Of all H who remain seronegative, 2/60 T4 counts have been <500 and none have developed AIDS. Such findings may alter our concepts of approach of therapy of HIV infected H and a better understanding of the immune abnormalities such patients exhibit. Patients may remain well with few T4 cells. No assessments can yet be offered since none will deteriorate, usually after suffering symptoms suggestive of latent AIDS.

Hémophilie : autres virus Hémophilie: Other Viruses

Th.B.P.21 COMPARAISON D'UN NOUVEAU SÉRUM POUR LE VIRUS VIH 2

Trochu, J.-L., Jolly, J.-M., Puel, J.-M., Bore-Milinet, A., Givry, G., Bégin, C.
* Laboratoire de Virologie, Hôpital de Neurologie Cléop, France; ** Laboratoire de Virologie, CHU Purpan, 31009 Toulouse Cedex, France; *** Laboratoire de Virologie, Hôpital St Bernard, 75000 Paris, France.

Objectif: Possibilité de contamination d'un jeune hémostatique par le virus VIH 2 en mars 1985 à partir d'une perfusion de facteur de substitution non stérilisé gardé par négligence.
Méthode: Surveillance sérologique et biologique depuis 1984. Les études virologiques comportent un dosage des AC en ELISA, un sérotype en Western-blot pour VIH 1 et VIH 2 (high et low), et études virales sur lymphocytes pour confirmation.
Résultats: Les différents bilans révèlent une co-infection par le virus VIH 1 en Décembre 1985.
Un an après le contact, il va développer un syndrome lymphodémothétique avec parallèlement une baisse des lymphocytes T4 (CD4) et une inversion transitoire du rapport T4.

La confirmation de l'infection par le virus VIH2 a pu être apportée par RPA et culture sur lymphocytes.
Conclusion: La contamination d'un hémostatique par le virus VIH 2 est rare en France. Il n'y a pas de différence dans l'expressivité clinique et biologique entre l'infection par le virus VIH 1 et VIH 2 étant donné qu'elle présente des caractéristiques communes de lymphotropisme et cytopathogénéité.

Th.B.P.23 AIDS RISKERS OF HEMIPHILIC-BORN VIRUS IN HIV-INFECTED HEMPHILLIC PATIENTS.

Aspects cliniques Clinical Aspects of AIDS

Th.B.P.31 PSYCHOLOGICAL AND NEUROPSYCHOLOGICAL STATUS OF HEMOPHILIACS AND MEN WITH HIV INFECTION: A CONTROLLED INVESTIGATION.

Catlin, J., Kline, J., Bond, A., Garrod, A., Day, A., and MacC.***

*Dept. Clinical Psychology and **Oxford University Dept. Psychology, Mansfield Hospital, Oxford, and ***Oxford Hemophilia Centre, Oxford, U.K.

Objective. To establish prevalence of psychosocial and neuropsychological problems in HIV subjects; to compare the two transmission groups; to identify the characteristics of those with problems.

Methods. HIV hemophiliacs (n=38) and HIV hemophilia controls (n=35) and HIV men (n=20) and HIV men controls (n=25) were studied. Measures included psychiatric state (PSE, POMS, Impulsiveness), coping (Herdines), locus of control, social and sexual adjustment, neuropsychological screen (Trail A and B, digit symbol, verbal fluency).

Results. In both transmission groups HIV individuals had higher levels of psychological symptoms than HIV controls. Increase of HIV status gay men had higher levels of psychological problems than hemophiliacs, and this difference was especially marked in the case of negative individuals where it was found that gay men had much higher levels of psychological problems than negative hemophiliacs. No differences were found between groups on neuropsychological measures.

Conclusions. HIV infection appears to be associated with psychological problems irrespective of transmission category. Asymptomatic individuals do not show neuropsychological impairment. HIV men (whatever their HIV status) seem more likely to experience psychological problems. The therapy implications of this finding need to be considered.

Th.B.P.33 PREDICTION OF SAFER SEX PRACTICE AND PSYCHOLOGICAL DISTRESS IN AIDS-RISK HEMOPHILIACS AT RISK FOR AIDS

Farley, Kathy L., Mendel, J., Thomas, J., and Gompertz, E.*

*Childrens Hospital of Los Angeles, **University of California San Francisco, San Francisco, CA, U.S.A.

Objective. To determine which behavioral factors are predictive of consistent condom use and psychosocial distress in hemophilic adults at risk for AIDS. **Methods.** A self-administered questionnaire was sent to all 975 identified persons with hemophilia in California in 1987-88. Items were designed to identify factors associated with decreasing transmission of HIV to partners and with psychosocial distress levels indicative of need for intervention.

Results. Analyses of data from 351 respondents indicate that only one-third report consistent condom use during vaginal intercourse. Predictors to consistent condom use were discussion of safer sex with partner, knowledge of HIV test results, and postponement of obtaining these factors produced a cumulative R² of .44. 56% of respondents indicated experiencing significant distress. Predictors to psychosocial distress were worrying about transmitting HIV, perceived chance of developing AIDS overall, occupational stress, and knowledge of HIV test results, again with a cumulative R² of .44.

Conclusion. Assessment of HIV serostatus appears to be linked both to safer sex practice and psychosocial distress, emphasizing the need for ongoing support to these individuals and their families. Couple communication and perceived risk of AIDS for self and others are key factors in partner use of AIDS. A better understanding of the impact of the AIDS threat on partners and couple functioning, in order to facilitate communication and shared responsibility for risk reduction in couples, is needed.

Th.B.P.35 A TEAM RESPONSE TO HIV/AIDS CARE IN PERSONS WITH HEMOPHILIA

Reza, M., G.S.G.W., C.S.W., Robert O'Neill

Social Services Advisor, Federal Centre for AIDS, Health and Welfare Canada, Ottawa, Canada; Canadian Hemophilia Society

This paper describes how interdisciplinary "dialogue days" was used as an approach to team building in introducing HIV/AIDS care to Canadian Hemophilia Care. The "dialogue days" conducted in 1987 and 1988 involved hematologists, nurses, coordinators, social workers and psychologists. The dialogue health care professionals identified dimensions of HIV/AIDS care needs in the hemophilia community, shared information, re-examined roles and recognized important linkages.

The extended "results" of these dialogue days will be presented at this conference. The results will demonstrate how interprofessional "dialogue days" can be a critical step in re-defining the roles of various health care team members in response to a new health care situation.

Th.B.P.32 RISK FACTORS FOR PSYCHIATRIC DISTRESS AMONG HEMOPHILIACS INFECTED WITH HIV

Rea, Mary Annala; Ragan, M.***; and Sherris, J.***

University of Pittsburgh, Pittsburgh, Pa., USA; *Hemophilia Center of Western Pennsylvania, Pittsburgh, Pa., USA.

Objective. To assess psychiatric correlates of HIV infection in a major risk group for AIDS; to identify psychosocial characteristics of HIV+ men that increase their risk for psychiatric distress following infection.

Methods. All moderate/severe hemophiliacs residing in western Pennsylvania, USA, plus mild hemophiliacs known to the regional Hemophilia Center, were contacted. Seventy-five men (73% of the population) were interviewed and their medical records were reviewed: 31 were HIV+ and 44 were HIV-.

Results. HIV+ men had significantly higher SCL-90-R symptom scores than HIV- men, particularly in depression and anxiety areas. There were no differences among HIV+ men according to infection stage or clinical severity of hemophilia. Factors associated with the effects of infection on mental health: family psychiatric history, low social support from wife, low family support, low friend support, a poor sense of personal efficacy, perceiving high daily stress related to HIV, and experiencing recent life events involving loss. HIV+ men with one or more such characteristics were clinically more distressed than HIV- men with multiple factors were present.

Conclusions. These data suggest that clinical services to alleviate distress in infected populations should be targeted to intervene on these psychosocial assets and liabilities that individuals bring to the situation.

Th.B.P.34 GUIDELINES FOR DEALING WITH PREGNANCY IN SEROPOSITIVE HEMOPHILIACS AND THEIR SPOUSES

James, E., and Borcher, S.

NEW England Hemophilia Center, Worcester Regional Hospital, Worcester, Massachusetts, U.S.A.

Objective. To describe a protocol for HIV testing in pregnancies of seropositive hemophiliacs and their spouses.

Methods. All patients followed at the New England Hemophilia Center receive counselling concerning HIV transmission. "Safe sex" practices and avoidance of pregnancy is strongly advocated. However, pregnancies among seropositive hemophiliacs and their spouses have occurred. Since 1983, a protocol for testing wives awaiting on pregnancy has been instituted. The wife is tested every 2-3 mos. until conception, condom use is recommended except at time of ovulation. HIV Ab testing is performed at 6 to 8 and 12 to 16 weeks gestation (so that termination is an option if seroconversion occurs), and at 3 mos.

Results. Since 1983, 13 pregnancies have occurred in 9 couples with a seropositive hemophiliac. Eight pregnancies were monitored according to our protocol, and all wives were seronegative. There were 3 full term pregnancies (children alive and well at ages 4 mos. to 2 1/2 yrs.), 2 were miscarriages and 3 are ongoing (2 at 3 mos. gestation, 1 at 5 mos. gestation). The pregnancies have been monitored (on protocol), one completed and one ongoing at 5 mos. gestation. At 8 wks. gestation of the first pregnancy the wife was found to be seropositive, the couple decided to continue the pregnancy after intensive counselling. The baby was seropositive at birth.

Conclusions. Despite efforts to inform seropositive patients and their wives of the risks of HIV transmission, some will choose to become pregnant. HIV testing during the pregnancy will allow the couple to make informed decisions about the pregnancy should seroconversion occur.

Maladies mycobactériennes Mycobacterial Diseases

Th.B.P.36 TUBERCULOSIS IN AIDS PATIENTS IN RIO GRANDE DO SUL: A NEW EPIDEMIC?

Spring, Eduardo, Krowfki, M.

Hospital de Clínica de Porto Alegre, Rio Grande do Sul, Brasil.

Universidade Federal, Porto Alegre, Rio Grande do Sul, Brasil.

Objective: Establish the incidence and the most common sites affected by Mycobacterium tuberculosis in AIDS patients in Rio Grande do Sul (RS) state.

Methods: It was reviewed, at random, 50 AIDS inpatients at Hospital de Clínica de Porto Alegre, from July to December, 1988, considered positive if the culture, from any site, "in vivo" or "post-mortem", identified Koch bacilli.

Results: In 50 patients (40%) Koch bacilli was present. 25 (50%) were at three or more sites (mainly lungs, bones, lymph nodes and gastrointestinal tract); 25 (50%) at gastrointestinal tract; 20 (40%), in lungs; 20 (40%), in lymph nodes; 1, in pericardium and the other with lung and joint involvement.

Conclusion: These are expressive numbers. First, it is one of the highest incidence of tuberculosis in the world. Second, the site of involvement does not seem to influence the mortality of the group. Last, it is very important to consider the presence of Koch bacilli in AIDS patients coming from RS state.

Th.B.P.37

Th.B.P.37 **GASTROINTESTINAL TUBERCULOSIS IN AIDS PATIENTS** THE RIO GRANDE DO SUL, BRAZIL
 Maria Luiza Mendes, Ronaldo, F.
 Hospital do Clínicos do Centro Médico Rio Grande do Sul, Brasil, Universidade Federal do Rio Grande do Sul, Brasil.
Objective: Study the incidence of gastrointestinal tuberculosis and its relation with diarrhea in Rio Grande do Sul (RS) State, Brazil. The registers of 57 AIDS inpatients at MCOB between July and December 1987 were reviewed (6 were excluded, as they did not have diarrhea).
Results: From the remaining 49 cases, 16 (32.6%) cultures of *Mycobacterium avium* (M_{av}) or gastrointestinal biopsy at necropsy (n=2) yielded *Mycobacterium tuberculosis*. In all 7 cases the diarrhea improved with the use of anti-tuberculous drugs.
Conclusion: Our findings support the importance of gastrointestinal tuberculosis as a common treatable cause of diarrhea in patients with AIDS.

Th.B.P.39 GASTROINTESTINAL TUBERCULOSIS IN AIDS PATIENTS THE RIO GRANDE DO SUL, BRAZIL

Th.B.P.39 **GASTROINTESTINAL TUBERCULOSIS IN AIDS PATIENTS** THE RIO GRANDE DO SUL, BRAZIL
 Maria Luiza Mendes, Ronaldo, F.
 Hospital do Clínicos do Centro Médico Rio Grande do Sul, Brasil, Universidade Federal do Rio Grande do Sul, Brasil.
Objective: Study the incidence of gastrointestinal tuberculosis and its relation with diarrhea in Rio Grande do Sul (RS) State, Brazil. The registers of 57 AIDS inpatients at MCOB between July and December 1987 were reviewed (6 were excluded, as they did not have diarrhea).
Results: From the remaining 49 cases, 16 (32.6%) cultures of *Mycobacterium avium* (M_{av}) or gastrointestinal biopsy at necropsy (n=2) yielded *Mycobacterium tuberculosis*. In all 7 cases the diarrhea improved with the use of anti-tuberculous drugs.

Th.B.P.41 DRUG-RESISTANT TUBERCULOSIS IN AIDS AND ARC

Th.B.P.41 **DRUG-RESISTANT TUBERCULOSIS IN AIDS AND ARC**
 Polio-Hermes A, Raddilung M.C, Batten R.C.
 Department of Medicine, Cabrini Medical Center, N.Y.C., USA
Objective: Tuberculosis (TB) is now frequently reported in AIDS, and its proper treatment remains to be determined. We reviewed the prevalence of drug-resistant Mycobacterium tuberculosis in patients with AIDS or ARC.

Methods: We searched our mycobacteriology registry for all cases of TB from 1982 to 1988. Of 137 patients, 13 had AIDS or ARC; their clinical records were reviewed.

Results: There were 11 men and 2 women (mean age 38); 4 were Hispanic, 3 black, 3 white and 1 Asian. Risk factors were: homosexual/bisexual in 7, intravenous drug abuse in 4, heterosexual contact in 1, and unknown in 1. Two patients had ARC, 11 AIDS. Five patients had a history of TB. M_{av} tuberculosis was isolated from lungs (1), blood (1), bone marrow (2), CSF (1), lymph node (1). Chest X-ray showed apical lesions with or without cavitation in 4 patients, and diffuse interstitial infiltrates in 4. In only 3 patients was TB only and alone in the lungs. Most patients initially received 3 drug and improved; two died of other AIDS-related diseases. Resistance to either INH, RMP, EMB or SM was present in 7 cases (5/21 versus 0.13 in our total TB population), and in 2 of them (homosexuals) to both INH and RMP.

Conclusions: Atypical manifestations of TB were common in our patients with AIDS or ARC. Resistance was seen in 3 cases; in 2 of them 3 drugs, but these patients were homosexual and drug-resistant TB may be expected. Thus, AIDS/ARC patients are not associated with increased drug-resistant TB, and an initial 2-drug regimen is probably sufficient.

Th.B.P.38 THORACIC RADIOGRAPHIC ASPECTS OF TUBERCULOSIS IN AIDS

Th.B.P.38 **THORACIC RADIOGRAPHIC ASPECTS OF TUBERCULOSIS IN AIDS**
 Taisabala, R.K., Accetturo, J., Casapalheiro, S.A., Siqueira, J., Passaro, and Zamboni, A.M., *Department of Imaging Diagnostics, Division of Infectious Diseases, Health Center, *Department of Pathology, ESCOLA Paulista de Medicina, São Paulo, Brazil.

The authors present an evaluation of thoracic X-rays in patients with AIDS and tuberculosis, its value for the diagnostic and therapeutic orientation.

Patients were clinically classified according to CDC (Centers of Disease Control), of USA, being 25 men and 2 women (aged between 18 and 46 years, 16 homosexuals, 3 bisexuals, 7 cases of intravenous drugs and 3 undetermined) all cases with positive ELISA. The diagnostic of the Mycobacterium tuberculosis was confirmed by analyses of sputum (6 cases), bronchial washing (1 case), endoscopic biopsy (1 case), pleural biopsy (1 case), necropsy (9 cases) and therapeutic trial (3 cases). Other 4 cases had corroborated disease by aspiration biopsy (3 cases) and liquor (1 case).

Lesions more frequently found were adenopaly, in 20 cases and nodular lesions, less than 5mm, in 17 cases. The association between nodular and adenopaly were the most significant. Patients with correct diagnostic and treatment showed partial or total resolution of the thoracic lesions (16 cases). Later diagnostic of untreated patients had not good prognosis. Association of thoracic lesions and therapeutic trials can give the diagnostic of the tuberculosis as showed in 4 patients treated with died, with proven diseases in autopsies.

Th.B.P.40 TUBERCULOSIS AND AIDS

Th.B.P.40 **TUBERCULOSIS AND AIDS**
 Silveira, Maria Lucia Mendes; Mendes W.S., Rodrigues G.A., Stefan, H.N., Le G. S., Mendonça J.S.
 Department of Infectious Diseases - Hospital do Servidor Público Estadual - São Paulo - Brazil.

Between 1985 and 1988 we studied 19 patients with positive anti-HIV serologic test and tuberculosis diagnosed by positive cultures for *M. tuberculosis*. Tuberculosis was the first manifestation of HIV related infections in 12 patients; concomitant with other HIV related conditions in four cases (two Kaposi's sarcoma); three patients had presented an opportunistic infection previously. *M. tuberculosis* was cultured from sputum in 11 patients, lymph node in three, liver, two, lung one, urine one and gastric lavage one. CD4+ count was performed in all patients but three and was low in all cases with a median count of 156 cells/mm³ (range 17 to 378). CD4+ count was above 200 in five patients (group A) and lower than 200 in 11 cases (group B). Group A had two patients with pulmonary tuberculosis, two with disseminated tuberculous lesions and one with pleural tuberculosis. Group B had eight patients with disseminated tuberculosis, two with pulmonary tuberculosis and one with renal tuberculosis. Seven of 14 (50%) patients treated with RFP, INH and PZA had benefits during the first two weeks of treatment. There was total normalization in all cases after change to EFB and SM. Further reevaluation of 106 6 cases was well tolerated. The authors call attention to the low CD4+ counts in all cases, not related to the clinical form of tuberculosis. They also observe that hepatitis was very frequent, only and probably not related to BM.

Th.B.P.42 MYCOBACTERIUM HAGERSTRI (M6) INFECTION IN HIV INFECTED PATIENTS: A 3 YEAR REVIEW

Th.B.P.42 **MYCOBACTERIUM HAGERSTRI (M6) INFECTION IN HIV INFECTED PATIENTS: A 3 YEAR REVIEW**
 Carls, N., Vaidyanathan, G., and Gower, D. R.
 *University Medical Center, LSU Medical Center, New Orleans, LA, USA.

Objective: A significant increase in the number of isolates of M6 associated with HIV infected patients has been observed. We reviewed all patients (PB) with M6 cultures identified at our mycobacteriology reference laboratory.

Methods: A retrospective review of all patients with a culture between 1985-88 was performed. Clinical presentations, radiographic findings, therapy, and outcome were reviewed to identify M6 disease with an emphasis on HIV PB. **Results:** M6 was cultured 205 times from 72 PB over a 40 month period: 23 (34%) were HIV coinfectees, of these 21 had AIDS and 2 had ARC with the first isolation. An increasing % of isolates were from HIV PB (zero in 1983 to 80% by 1987-88). Respiratory isolates were the main source of a culture (90.3%), yet only HIV PB manifested dissemination (liver, stool, bone marrow, blood) with 1 exception. Most had high level M6 (2.0 x 10⁶ cfu/ml) resistance (60%). The clinical presentations were nonspecific. Fever, weight loss, cough and night sweats were seen in 80%. The chest radiographic findings (61.2% pneumonia, 0% cavitation) as well as the frequent coexistence of PCP (84%) made it difficult to identify true M6 disease in this population. Known (51.6%) PB isolates within 30 months of infection. **Conclusions:** The isolation of M6 from HIV infected PB may contribute to their overall morbidity and mortality. Distinguishing disease from colonization is difficult using currently accepted criteria.

Th.B.P.49 MYCOBACTERIAL PNEUMONIA INFECTION IN 15 PATIENTS WITH CLASS IV HIV INFECTION: CLINICAL AND MYCOBACTERIOLOGIC FINDINGS

Blair, C., Miller, G., Aude, J., Kushner, Y.,
Merritt, D., Spector, J., et al.

* Department of Medicine, The University of Chicago, Cook County Hospital, Chicago, U.S.A.

Objective: To evaluate the clinical and mycobacteriologic features of *M. tuberculosis* infection in the presence of class IV HIV infection.

Methods: All patients with *M. tuberculosis* infection between 1978 and 1979 were cross-referenced with all persons with Class IV HIV infection, and a retrospective chart review was conducted, including clinical, radiologic, immunologic, and mycobacteriologic data assessment.

Results: Of 46 patients with *M. tuberculosis*, 15 (32.6%) had Class IV HIV infection. Of these, 11 (73.3%) were black and 4 (26.7%) white. Two (13.3%) were a woman, and 9 (60.0%) were 19-30 years of age, 2 (13.3%) 31-40, and 3 (20.0%) other adult age behaviors. 11 (73.3%) had AIDS and 4 (26.7%) had Class III HIV infection. 12 (80%) were diagnosed by sputum analysis and 3 (20.0%) by bronchoscopy and sputum. 12 (80%) patients had pulmonary disease, 4 (40%) had disseminated disease, of which all were extrapulmonary. 1 bone marrow, and 1 sputum, retropharyngeal (1/3) had certainty disease, and 10 (66.7%) local or interstitial disease. In 9 patients, the case 11 patients were AIDS. Serostudy results revealed relative TB to 2 of 4 TB indices and partial resistance to INH in 3 of 4 isolates. Serostudy clinical response was observed in 11 (73.3%) of patients with pulmonary disease, and in 10 out of the patients with disseminated disease.

Conclusion: *M. tuberculosis* infection in cases of HIV infection is an acute care phenomenon to some extent in later stages with advanced immunodeficiency. Upper lobe priority disease is common. A higher and interstitial disease is common. Dissemination to the brain, and bone marrow occurs. Treatment may be successful in early stages. Resistance to PZA and INH occurs. Alternatives for specific treatment are necessary.

Th.B.P.51 TUBERCULOSIS AS PULMONARY COMPLICATION AIDS - ASSOCIATED

Pierantoni, Nicolò, Guida B. Dpt. Inf. Dis. Galliera Hosp. Genoa, Italy

Objective: To study pulmonary Mycobacterium tuberculosis (M) infection in AIDS patients (pts). **Methods:** In 42 cases of AIDS from June '86 to June '88 we observed 10 male patients with pulmonary tuberculosis: they were heroin-addicts aging from 28 to 40. **Results:** Bacteriological tests were positive for M in sputum (3 cases), in B.A.I. (4), in pleural (1) and in gastric fluid (2). The X-ray and CT examinations have shown a high frequency of medium and/or basal pulmonary infiltrates (8pts) and only one pulmonary cavitation. Only the last infested PFD (5pts) in 9/10 of the pts the 67-68 radiographic proved the mediastinum involvement. The recovery occurred in 8/10 of the pts, they had X-ray modification in 60 days and bacteriological negativization in nearly 35 days. **Conclusion:** In our country at the opposite of USA, tuberculosis is often a pulmonary complication (23% even if it isn't diagnostic for AIDS); their L-P patterns are topographically unusuals - the diagnosis may be complicated by the coexisting other opportunistic infections - the long-term therapeutic response is satisfactory in spite of immunodeficiency - the high frequency of pulmonary tuberculosis suggest opportunity anti-Mt prophylaxis in early stages of HIV infection in narcotic-addicts.

Th.B.P.53 PLEUR, WEIGHT LOSS, ANEMIA, SPERMATOZYDIA AND ARCHONAL LIVER DYSFUNCTION IN PRESUMED OR DISSEMINATED MYCOBACTERIOSIS IN PATIENTS WHO ARE HIV ANTIBODY POSITIVE.

Cone, Lawrence; Woodard, D; Mode, D; Curry, N; Brougham, W; Pfaller, R. Section of Infectious Diseases, Department of Medicine, Department of Radiology and Pathology, Eisenhower Medical Center, Rancho Mirage, CA, USA.

Disseminated mycobacteriosis due to *M. avium-intracellulare* (MAI) or less commonly due to *M. tuberculosis* (MTB) occurs in nearly 25% of patients with AIDS during the Course of their illness. In most individuals the lungs are spared and organisms are found in lymph nodes, blood, bone marrow, liver, spleen and gastrointestinal tract. In 28 patients with AIDS in whom these sites revealed mycobacteria, 18 underwent CT scanning of the abdomen. Whereas all patients with mycobacteriosis exhibited an anemia (Hb10 g/ml), fever (37.2-38.1 C), weight loss (10% in 3 wks), TB also revealed splenomegaly and TB, abnormal lymphadenopathy on CT. AIDS patients with other opportunistic infections (1) (Pneumocystis carinii pneumonia (6)), cytomegalovirus infections (11), disseminated coccidioidomycosis (1), and toxoplasmosis (1) (lymphoma (6) and Kaposi's sarcoma (4)) manifested lymphadenopathy in 0-35% except for Kaposi's sarcoma (79%) and coccidioidomycosis (100%). While an splenomegaly occurred in less than 25% of patients with Kaposi's sarcoma and PCP. However, indicating that this pattern of clinical and radiographic findings is not universal, anemia, fever and weight loss seen in patients with disseminated MAI and MTB. We conclude that this pattern of clinical and radiographic findings is not universal. This array of events relates to the pathogenesis of mycobacteriosis.

Th.B.P.50 SEROPREVALENCE OF HIV INFECTION IN 183 CONSECUTIVE PATIENTS WITH TUBERCULOSIS (TB) AT A NEW YORK CITY HOSPITAL

Blaser, Robert, R. Citriguero, Gladys, M., Baboonian, S., Longmire, S.H. SUNY-Health Science Center at Brooklyn, N.Y., U.S.A.

Objective: To determine the prevalence of HIV infection in pts with TB. To determine the extent of immunosuppression in HIV infected pts with TB. **Methods:** Between 10/87-6/88, all hospitalized adults with newly diagnosed, culture-proven TB, were offered HIV testing and TB lymphocyte levels. **Results:** 170 (88%) were intravenous drug users (IVDU), 20 (11%) were Haitian, 11 (6%) were homosexual, and 82 (48%) denied risk factors (RF) (except possible heterosexual contact). 74 (43.5%) evaluable pts with RF were HIV infected (AIDS-1, 0C-1, HIV serology); 23 were not evaluable due to refusal (13), death or discharge prior to serological contact(1), serological inaccessibility(2). Retrospectively, in 33/82 (40.4%) HIV infected pts and in 14/27 (51.9%) HIV-pts (p=NS). Disseminated TB (adrenal, marrow, or liver culture, or culture from 2 retropharyngeal sites) was present in 21/82 (25.6%) HIV infected pts and in 2/27 (7.4%) HIV-pts (p=NS). Median TB of pts with HIV serology (without AIDS or RF) was 207 (range:23-677) IU/ml. Median TB of HIV-pts was 433 (range:128-1616). Median TB of HIV-pts with pulmonary TB (24) was similar to median TB of HIV-pts with local RTB (330) (p=NS). But not to median TB of HIV-pts with disseminated TB (70) (p=NS). **Conclusion:** TB often the first illness experienced by HIV infected pts. TB in IVDU, Haitians, and homosexuals was frequently associated with HIV infection. TB in pts without RF was also associated with HIV infection. Most HIV-pts with TB had marked TB lymphocyte depletion.

Th.B.P.52 TUBERCULOSIS IN HIV-INFECTED INDIVIDUALS IN THE PROVINCE OF BRITISH COLUMBIA (1983-1988)

Wattson, Eric, Todd J, Lawson, L. Steddy J and Montaner, NS. AIDS Research Program, St. Paul's Hospital, Respiratory Division, UBC and Division of TB Control, Ministry of Health, Vancouver, BC, Canada.

Objective: To describe the clinical presentation, laboratory findings and outcomes of all cases of tuberculosis (TB) in HIV infected individuals diagnosed in the Province of British Columbia over the 6 year period ending December 31, 1988. **Methods:** Cases of TB in HIV infected individuals were identified by a linkage between the provincial TB laboratory and the provincial AIDS Surveillance Registry. Medical records of all of the identified cases were retrospectively reviewed.

Results: Fifteen cases were identified. None had AIDS at presentation. Symptomatic onset was present in 13/15 (87%). Respiratory symptoms were common (cough 9/15, shortness of breath 6/15). Diarrhea was present in 4/15. Mean helper count and R/U ratio were always low at diagnosis (90 and 33 respectively). LTBI was diagnosed in all cases. Sputum culture 21 sites in 15 patients revealed 21 smears (100%) and 22 cultures (95%) were positive. Sputum available in 10 patients was smear positive in 5 (50%) and culture positive in 8 (80%). Sputum specimens available in 15 patients were culture positive in 10 (67%) where sputum biopsy (sputum and small biopsy) was also positive. CXR abnormalities were commonest cause for radiological diagnosis. All patients were treated with INH, Rifampin for 12 months + PZA or EMB for the initial 6 months. Except for 2 patients given shortly after diagnosis from overwhelming disease, clinical response was apparent within the first week of therapy. No relapses or failures of treatment were seen. Eight of 13 serostudies demonstrated opportunistic infections (OI) (diagnosis of AIDS within 8 months, 4 of these were PCP). **Conclusion:** TB in HIV infected individuals present most commonly as disseminated disease. Systemic symptoms were common. However, respiratory symptoms were also prominent and frequently provided a clue for diagnosis. Lymph node involvement and gastrointestinal complaints, while clinically apparent, provided a meager source of diagnostic material. TB appeared to occur as a relatively late event in the course of HIV infection as demonstrated by the already low helper count and the rapid progression to OI.

Th.B.P.54 MYCOBACTERIOSIS AND AIDS. THERAPEUTIC APPROACHES.

SCHIRMERS, DIETZ *, Ruf, R. M. **, Meuch, H. ** ; Pabst, H.D. *

* II. Department of Internal Medicine, Rudolf Virchow University Hospital, Freie Universität Berlin; Heckhausen Hospital, Berlin, FRG

Objective: To gain data on the effectiveness of chemotherapy in mycobacteriosis. **Methods:** Course and the effect of therapy was evaluated in 51 patients. Drug susceptibility of strains involved was determined.

Results: Tuberculosis (TB): 17/21 patients treated (common drugs for 8 months, followed by maintenance therapy). One of 17 (6%) died, 7 years later on due to other causes. In all untreated cases, TB was in the course of death. Follow-up: max. 36 months, patients alive > 1 year (87%), > 2 years (84%), no relapse. One of 21 strains was resistant against RMP and INH. All strains were in addition susceptible against rifabutin, ciprofloxacin and ciprofloxacin. MAI-infection: 17/38 patients were treated, 9 showed at most temporary improvement. 13/16 patients died, 3 due to MAI-infection. MAI was isolated post mortem in all cases in spite of treatment with ciprofloxacin. 4/17 cases diagnosed early improved rapidly and treatment included rifabutin (80%), ciprofloxacin and macrolides (60%). All macrolides completely resistant against common drugs and chinolones, but were susceptible against rifabutin and ciprofloxacin. MAI: In the range of achievement, early start may be curable using modified regimen including rifabutin, ciprofloxacin and macrolides.

Th.B.P.79 ALVEOLAR MACROPHAGES FROM PATIENTS WITH HIV INFECTION

OPPORTUNISTIC RELEASE TUMOR NECROSIS FACTOR
 Agostini, Carlo*, Trentin, L. V., Poletti, V. M., Zambello, R., Spiga, L. M.,
 Conti, F. P., Feruglio, C., Pavesi, G. P., Pavesi, V., Zambello, R., Spiga, L. M.,
 *University of Padua, Padua **Istituto and Maggiore Hospital, Bologna, Italy.

Objective: To clarify whether HIV infection affects functional capabilities of alveolar macrophages (AM). AMs from bronchoalveolar lavage (BAL) of 6 patients with full-blown AIDS and 6 patients with ARC were examined for their ability to kill tumor necrosis factor (TNF)-sensitive tumor cells and to release TNF.

Methods: Untreated AMs freshly recovered from BAL were tested against U937 target cells in an overnight ⁵¹Cr release cytotoxicity assay. In addition, cell free supernatants obtained from untreated and TNF- α (100 IU/ml) and LPS (5 μ g/ml) treated AMs were tested for their cytotoxic activity against U937 targets in an overnight ⁵¹Cr release assay. To confirm that TNF was the cytotoxic factor, either anti-TNF MAb (Genzyme) was added to the cell free supernatants in the TNF bioassay.

Results: Untreated AMs from patients with AIDS and ARC exhibited a significant cytotoxic activity against U937 targets at all effector:target ratios tested whereas normal AMs did not kill TNF-susceptible tumor cells (p<0.001). Supernatants from untreated AMs of HIV patients showed significantly higher levels of cytotoxicity with respect to normal AMs (p<0.001). Incubation of AMs with anti-TNF MAb inhibited the cytotoxic effect caused by supernatants. Treatment of AMs from HIV patients with TNF- α and LPS failed to enhance the TNF production, whereas following these stimuli normal AMs significantly increased their TNF activity.

Conclusions: AMs from patients with HIV infection are activated and spontaneously release TNF. The heightened capacity of HIV AMs to produce TNF may be involved in the pathogenesis of pulmonary complications observed in patients with AIDS.

Th.B.P.81 IMMUNOLOGICAL SUBTYPING OF LEUCOCYTES OBTAINED FROM BRONCHOALVEOLAR LAVAGE (BAL) AND PERIPHERAL BLOOD IN HIV-1 INFECTED PATIENTS WITH PNEUMONIA.

M. A. E. Hens, W. K. Koopman, C. Spaah, R. Russ, E. and G. P. University Hospital, Zurich, Switzerland.

Objective: Recent reports have characterized differential cell counts in bronchoalveolar lavage (BAL) of HIV-infected patients and have suggested that immunological subtyping. To further investigate these findings and to characterize the local immunological situation in the lungs we studied U937 cells of BAL compared to peripheral blood leucocytes by means of immunological subtyping. 11 HIV-positive patients with clinical signs of acute pneumonia (aged 2 to 60 years) were included. Six of our patients suffered from histologically confirmed Pneumocystis carinii pneumonia (PCP) and five patients had pneumonia other than PCP.

Methods: Leucocytes obtained from BAL and peripheral blood were double-stained with the following combinations of monoclonal antibodies: CD4 / HLADR, CD4 / 84A, CD8 / HNK1, CD200 / CD44 / HLA-DR. Two-color immunofluorescence flow analysis was carried out using an EPICSM² PROFILE system (Coulter).

Results: Major differences between BAL and peripheral blood could be found with CD4 / HNK1 and CD44 subtyping. The ratio of CD4/HNK1-double-positive cells to CD8-positive cells was higher in the peripheral blood than in BAL. Conversely, the ratio of CD4/CD44-double-positive cells was higher in BAL. The percentage of CD4-positive lymphocytes was much higher in BAL than in peripheral blood, which was in contrast to findings in non-HIV-infected patients with pneumonia.

Conclusion: The data indicate that in HIV-patients with pneumonia major immunological differences between BAL and peripheral blood are present, which could be relevant for the prognosis.

Th.B.P.83 INCREASED PRODUCTION OF SOLUBLE IL 2 RECEPTOR IN PATIENTS WITH HIV INFECTION

Yoshida, Yumiko*, Kitamura, K., Yamada, K., Mitsuyasu, R.**,
 Chayama, K.**, and Honda, M.**,
 *National Institute of Health, AIDS Research Center, Tokyo, Japan, **NIAID, Medical Center, Los Angeles, California, U.S.A., **Institut National de la Santé et de la Recherche Médicale (INSERM), Marseille, France.

Objective: To see whether the production of soluble IL 2 receptor (sIL 2R) in patients with HIV infection increases as the disease advanced and correlates with other clinical parameters.

Methods: The monoclonal antibodies against IL 2R were used for the fluorescence antibody ELISA. Sera of patients with HIV infection were collected from UCLA Medical Center and INSERM of France and grouped according to the CDC classification of AIDS.

Results: Elevated sIL 2R levels were observed in the sera of patients with HIV infection. Moreover, sIL 2R levels gradually increased as the disease advanced. Statistical analysis showed a negative correlation of those with CD4 cell counts, lymphocyte counts, and CD4-CD8 ratio, but neither WBC counts nor CD4 counts correlated. We examined the production of sIL 2R in vitro. Neither P84C of AIDS patients nor any of the 19 HIV-1- or HIV-2-infected cell lines produced sIL 2R in the supernatant, while P84C of patients with HIV-1 infection or HIV-2 positive cell lines produced sIL 2R.

Conclusion: We observed gradually increased serum level of sIL 2R in patients with HIV infection as the progression of the disease, and this level was negatively correlated with CD4 cell counts. From *in vitro* study, we suggested that these sIL 2R might be produced by non-T cells.

Aspects cliniques Clinical Aspects of AIDS

Th.B.P.80 CD4 LYMPHOCYTE COUNTS AND SERUM P 24 ANTIGEN OF NO DIAGNOSTIC VALUE IN MONITORING HIV INFECTED PATIENTS WITH PULMONARY SYMPTOMS.

Orskov, Marlene, Nielsen, T.L., Jensen, J.,
 Department of Infectious Diseases, Sydhavns Hospital, University of Copenhagen, Denmark.

The aim of this study was to determine if the prognostic markers CD4 lymphocyte count and serum HIV p24 antigen were of any diagnostic value in HIV infected patients with pulmonary symptoms.

Method: During 1987 and 1988 143 fiberoptic bronchoscopy procedures were performed on 104 HIV infected patients with pulmonary symptoms. The bronchoscopic specimens were evaluated for Papanicolaou smears (P), cytomegalovirus (CMV) and other pathogens. CD4 counts and serum p24 antigen were measured within 2 weeks before or after the bronchoscopy.

Results: Pulmonary opportunistic infection (O.I.) was found in 83 examinations (79-79, CMV-2). There was no difference in CD4 counts between the patients with and without O.I., p=0.85. The CD4 count was 200 in 67% and in 62% respectively. All of the patients with O.I. had p24 antigen, while this was the case in 42% of the patients without O.I. 32% of the patients in both groups had a CD4 count below 200 combined with presence of serum p24 antigen. **Conclusion:** The CD4 count and p24 antigen have been shown in this study to be of no diagnostic value in monitoring HIV infected patients with pulmonary symptoms.

Th.B.P.82 CUTANEOUS-DERIVED LYMPHOCYTES IN DRUG ADDICTS.

Ulla Antoniazzi-Chaves, Giovanna Casanovi, Luciano M. Cavallari-Filippi, Fabiana Fratelli Hospital, Milan, Italy.

Objective: To evaluate the utility of cutaneous derived lymphocytes (CDL) tests in drug addicts (DA) and to apply them the Walter Reed Classification (WC).

Methods: We studied 127 DA (95 male and 32 female), mean age 29 years; 40 HIV- and 67 HIV-. Clinical examination, TA and 18 counts and skin test (Pwittest CM, Merck) were done. WC has been used to classify the patients (pts).

Results: There were significative differences between HIV- and HIV+ for TA⁺ (77/73 vs 17/20), p<0.002, 18⁺ (121/46 vs 31/36), p<0.005, number of positive reactions to antigens on CDL tests (1-6/3 vs 2-5/9), p<0.025 and score (4-6/4 vs 6-8/4), p<0.025. Thirty-four pts resulted hyperergic (17 HIV- and 17 HIV+); 18 pts resulted eugergic (16 HIV- and 2 HIV+). The pts were classified as follows: WHO, 46 (37.8%); M1, 9 (7.1%); M2, 1 (0.8%) (including 3 in M2B); M3, 3 (3.9%); M4, 5 (3.9%); M5, 4 (3.1%) (including 1 in M5B and 1 in M5C); M6, none. Thirty-nine pts (30.7%) CDL HIV- and 19 HIV+ (with partial or complete antigen counts of 14 lymphocytes above 400/mm³) did not fit into any stage of the WC. Also 2 pts (1.6%) HIV- with TA<400/mm³ and normal skin tests were unclassifiable.

Conclusions: CDL is diminished in the DA (also HIV-). Skin tests may be an useful test to evaluate DA immunologic state and they were significantly in the HIV+ subjects. The WC does not accommodate all DA subjects, because of their "background" immunologic abnormalities.

Th.B.P.84 CHANGES IN CD-16 RECEPTOR EXPRESSION ON THE NEUTROPHILS OF HIV INFECTED INDIVIDUALS

Stacy, Peter, Johnson, J. A., Bobos, J., and Umlas, J. C.,
 Mount Sinai School of Medicine, New York City, New York, U.S.A.

Objective: To examine changes in the expression of CD-16 receptor on the neutrophils from HIV infected individuals.

Methods: Neutrophils from whole blood samples from HIV infected individuals in various clinical stages and normal volunteers were double stained with phycoerythrin-Leu-19 (anti-CD16) and fluorescein-isothiocyanate (anti-CD16 or FITC-IL-1). As a control, we used the anti-CD16 (Fc-IL1) ab FITC-Fc-IL1. Analysis was carried out on FACSTAR II cell sorter.

Results: A significant decrease in the CD16 receptor expression has been found in HIV-infected patients compared to normal individuals. The greatest number of CD16-negative neutrophils was measured in patients with AIDS. No correlations were found with the TA/T8 ratio. CD16 expression on the neutrophils was not affected.

Conclusions: Neutrophil Fc-IL1 (CD16) is a phosphotyrosine (tyrosine) glycosylated membrane receptor that is released following treatment of neutrophils with phorbol esters. The finding of decreased CD16 expression might reflect prior activation of neutrophils and might be a marker of the neutrophil dysfunction leading to common bacterial and fungal infections in advanced HIV infections.

Th. B.P. 85 ANTIBODY RESPONSES TO HIV-1 IN RETROVIRUS INFECTED DISEASES
Yokoyama, Mitsuo, Hirose and Tsuboi.

Objective: ADA isoenzyme levels in sera of patients with adult T-cell leukemia (ATL) and acquired immunodeficiency syndrome (AIDS) were analyzed. **Method:** Total ADA activity was determined by an enzyme spectrophotometric assay. ADA isoenzyme activity which was inhibited by erythrocyte-(G-2-phospho-3) neryl adenosine was designated as ADA1 and the remaining activity as ADA2. **Result:** In the case of ATL subtypes, ADA1 activity was significantly elevated in acute and lymphoma types (p<0.01) in comparison to chronic and smoldering types. No significant difference in ADA2 activity was noted in smoldering type as compared with chronic type of ATL. ADA2 activity was elevated in sera of acute, lymphoma and chronic types of ATL patients (>0.01) as compared with smoldering ATL and HTLV-1. In the case of AIDS, immunofluorescence virus-(HIV)-1 infections, ADA isoenzyme activities were higher in sera of patients with AIDS and HIV-1 antibody-positive individuals in homosexual (p<0.01) when the results were compared with HIV-1 antibody-negative homosexuals and normal controls. A significant elevation of ADA2 activity was seen in sera of AIDS patients (p<0.01) than that of HIV-1 antibody-positive homosexuals. **Conclusion:** ADA isoenzyme activities in sera of patients with retrovirus infection reflect the condition of these diseases. To measure of ADA isoenzyme activities may therefore provide an additional parameter for distinguishing subtypes of ATL and may prove to be considerable prognostic and therapeutic monitors in retrovirus infection.

Th. B.P. 87 LYMPHOCYTE REACTIVITY TO ARTI-CD3 AS A PROGNOSTIC MARKER IN HIV-1 INFECTED BEROSEAL HIV
Houtz, J., Meadew, J., Jansen, P., Schalkhaas, Central Lab. Health, Red Cross blood Transf. Serv. and the Lab. of Exp. and Clin. Immunology of the Univ. of Amsterdam, Academic Medical Center, Amsterdam, The Netherlands.

Objective: In patients with ARC/AIDS, lymphocyte reactivity to antigens declines earlier and more severely compared to nonspecific nitrogen response. Because antigens stimulate T cells via the T1/T2 complex we studied whether CD3 reactivity followed the same pattern as antigen reactivity and could be used as a prognostic marker for AIDS. **Method:** Reactivity was measured to aCD3 in Whole Blood Lymphocyte Cultures (WBC) in a longitudinal study of seropositive homosexual men and expressed as I reactivity per 3 lymphocytes compared to healthy controls. **Result:** In HIV-1 infected asymptomatic men, the response towards aIS and PMA was stable (100) for 40 months after intake into the study, whereas the response to aCD3 showed a gradual decline (from 70 to 40%) during the same period. In the population that developed AIDS or the AIDS reactivity remained largely unaffected until 3 months before diagnosis; PMA reactivity started to decline (from 80 to 10%) from about one year before diagnosis. However, the aCD3 reactivity was always very low (10%) one year before diagnosis. **Conclusion:** A severely depressed aCD3 reactivity is the first sign to herald progression towards AIDS in HIV-1 infected individuals.

Th. B.P. 89 DEPARTMENT OF POLYMEROPROTEOLYTES (PMO) CHEMOTACTIC AND BACTERICIDAL ACTIVITY IN HIV-INDUCED CHLORAL
Nelson, Edmund, Martin, S., Eddy, J., Venn, D., Walsh, T., Poon, P. and Rubin, M. National Cancer Institute, Bethesda, Maryland, USA.

Objective: HIV-infected children have an increased incidence of serious bacterial infections, which has been attributed to antibody dysfunction. Although PMOs are the most important of these defense against bacteria, PMO function in this group has been unexamined. Accordingly, we compared the functional activity of PMOs from both asymptomatic (ASX) and symptomatic (SX) HIV-infected children. **Method:** PMO was obtained from 10 ASX and 10 SX children. PMO were assayed for chemotactic activity (in units to 111 per 10⁶ per 30 min) for functional assays performed were: 1) chemotaxis to P-M (PM2), 2) bactericidal activity against *Escherichia coli* (E. coli) at 37°C, 3) response to DCV granules following stimulation by 5 X 10⁶ PMNP, and 4) phagocytosis of S.A. and *Candida albicans* (C.A.). **Results:** Chemotactic: Chemotaxis of PMOs from ASX children was uniformly decreased compared to controls (median/interquartile range = 1.18 +/- 0.4 for ASX children vs 1.74 +/- 0.7 for controls (p<0.005), and increased in SX children (2.14 +/- 0.6, P<0.05). Bactericidal activity: Killing of S.A. was defective in 5/9 ASX and 18 SX children (85% reduction in colonies after 60 min incubation - 56 +/- 4 for controls vs 42 +/- 6 for ASX children (P<0.05) and 27 +/- 3 for SX children (P<0.005). There was no correlation between presence or degree of bactericidal impairment and CD4 number or CD4/CD8 ratio. Responses from HIV-infected children did not inhibit the bactericidal activity of normal PMO. Preliminary data suggest that in vivo measures with GM-CSF possibly correct the defect. DCV granules: No abnormalities in DCV products were found (mean 10⁶ per 10⁶ cells - 2.2 +/- 0.2 for controls, vs 2.0 +/- 3 for ASX and 2.4 +/- 3 for SX children). **Diagnosis:** There was no abnormalities in phagocytosis of S.A. or C.A. (66 +/- 4 for controls vs 67 +/- 5 for ASX and 67 +/- 7 for SX children) or of C.A. (66 +/- 4 for controls vs 66 +/- 9 for ASX and 66 +/- 4 for SX children). **Conclusions:** Defects in both bactericidal activity and chemotaxis may contribute to the increased incidence of bacterial infections in HIV-infected children. Further study to define a potential role for GM-CSF in these patients is warranted.

Th. B.P. 86 CD4+NEOPTERIN RATIO CORRELATES WITH P24 ANTIGENEMIA IN HIV INFECTED PATIENTS.
Eckstein, Franz, Litzl, A., Heiderich, E., D'Accetto, P., Cambis, G., Cantaluppi P., Ospedale Maggiore - 28878 Lodi (I)

Objective: To verify the possible correlation between CD4/neopterin ratio and p24 antigenemia during HIV infection. **Method:** 72 patients (64 men and 8 females; mean age 26.2, range 18-33 years) were classified according to the WRB8 criteria; they were also tested for p24Ag and serum neopterin levels (SNL). R was also calculated for each patient. **Results:** WRB group (32 pts): 6/32 were p24Ag pos. (18.75 %); WRB group (16 pts): 4/16 were p24Ag pos. (25.00 %). **Ratio:** WRB group (24 pts): 16/24 were p24Ag pos. (66.8 %)

WRB	SNL	R
p24Ag pos.	9.23	0.3
p24Ag neg.	26.37	17.9

Conclusion:confirming literature data, we found a good correlation between p24Ag and clinical stage; a good correlation was also found between R and the WRB8. We point out the high significance of R (p<0.001) in differentiating, within the WRB 8 criteria, between p24 pos from p24 neg patients with all the prognostic implications involved. By contrast as far as WR 8 and especially WR 6 classes are concerned low differentiating significances of mean values point to disease progression and clinical deterioration reflecting increasingly severe immunologic disorder regardless of the patients' p24Ag status.

Th. B.P. 88 NEUTROPHIL RADICAL RELEASE AND LIPID PEROXIDATION IN HIV INFECTED PATIENTS
Jernstam, G., Carlsson, C., Ohnnerberg, A. and ÅKERLIND, B.***

* Hudinge Hospital, Hudinge, Sweden; ** Pharmacia, Uppsala, Sweden; *** Roslagstul Hospital, Stockholm, Sweden. **Introduction:** Since a transitory increase in Nitroblue tetrazolium (NBT) reduction of neutrophils, reflecting an increased production of oxygen free radicals of these cells, has earlier been found during acute viral and bacterial infections, a long term elevation in NBT-reduction was expected in the chronic HIV infected patient. Oxygen radicals are known to induce peroxidation of fatty acids occurring for example in cell membranes. A product of this process is malondialdehyde (MDA), which has been used extensively as a sign of lipid peroxidation. **Methods:** Colourless NBT is reduced within the neutrophils by the superoxide anion to carbonyl formazan which was measured spectrophotometrically. MDA was measured by a reversed phase liquid chromatography method. **Results:** In 17 patients with the lymphadenopathy syndrome (LAS) the NBT reduction of resting neutrophils was significantly higher than that of controls (p<0.01). Further, the plasma content of malondialdehyde in 22 patients with LAS or AIDS related complex was found to be higher than that in controls (p<0.001). **Conclusion:** Radical production and resulting lipid peroxidation might contribute in the tissue damage and the premature ageing (Dorian Gray syndrome) seen in patients with HIV-infections.

Th. B.P. 90 OXIDATIVE BURST ACTIVITY AND CELL SURFACE ANTIGEN EXPRESSION OF MONOCYTES AND T-LYMPHOCYTES IN HIV-INDUCED CHLORAL INFECTED INDIVIDUALS (AMI) LANGE, Alan; Kessler, R.; Jansen, C. P.; Phair, J. P.; Rothberg, L. B.; Spear, G. et al. * Wash Medical Center, Chicago, IL; ** Northwestern Medical Center, Chicago, IL, U.S.A.

Objective: To identify functional and phenotypic alterations of peripheral blood monocytes isolated from AMI. **Methods:** Peripheral blood monocytes from immunocompetent, HIV negative donors. For oxidative burst measurements, cells were incubated with endotoxin (lipopolysaccharide (LPS)) or phorbol myristate acetate (PMA), calcium ionophore (I2B) or heat aggregated IgG (HA). After stimulation, cells were stained by PE labeled anti-CD14 antibody. Shifts in green fluorescence which correspond to relative oxidative burst capacity of monocytes was measured by dual parameter flow cytometry. Expression of cell surface markers CD13, CD33 & HLA-DR on CD14+ monocytes was also evaluated by dual parameter flow cytometry. **Results:** Significantly lower oxidative burst activity was observed with monocytes from AMI compared to HIV negative donors stimulated with PMA (57.1 vs 96.2 relative fluorescence units, p<0.0001) and I2B (57.1 vs 96.4, p<0.0001). No significant difference was noted with LPS. The percentage of CD13 and CD33 monocytes was also significantly lower among AMI compared to HIV negative donors (86.4 vs 95.3 for CD13, p<0.02; 92.1 vs 99.7 for CD33, p<0.02). **Conclusions:** Monocytes from AMI have significant alterations in function. These alterations may contribute to immunodeficiency and disease progression.

Th.B.P.91 STRATIFICATION OF RFL ALLOANTIGEN PRESENTING CELL FUNCTION IN PATIENTS WITH AIDS. **Jacobs Alan**, Clerici, H. M.; Kessler, R. M. and Shesner, G. W. ¹ NIH, Bethesda, Md. ² Chicago, IL and ³ Experimental Immunology Branch, NIH, Bethesda, Md. U.S.A.

Objective: To test the ability of peripheral blood mononuclear cells (PBMC) from patients with AIDS to serve as stimulating cells as well as alloantigen presenting cells (APC) to responding FMC from HIV seronegative (HIV-) donors.

Methods: HIV- unfractionated FMC or FMC depleted of monocytes (FBL) by plastic and nylon wool adherence procedures (CD4+ cells) were stimulated in vitro with allogeneic FMC from AIDS patients. The mixed lymphocyte reaction (MLR) was assessed by ³H-thymidine incorporation and by interleukin 2 production.

Results: Our data indicate APC function of FMC from AIDS patients can be stratified into three groups in which: (a) the MLR was normal irrespective of whether the HIV FMC or FBL were used as responders (9/22, 41%); (b) the MLR was normal when HIV FMC were used as responders but were defective when HIV- FBL were used as responders (7/22, 32%); and (c) the MLR was defective irrespective of whether HIV- responding FMC or FBL were used (9/22, 41%).

Conclusions: These results suggest that AIDS patients can be stratified based on alloantigen presenting functions. These results also suggest a possible approach for assessing monocyte (APC) function in AIDS patients as a potential indicator of drug efficacy in patients enrolled in therapeutic trials.

Th.B.P.93 VARIABILITY IN ISOTYPE-SPECIFIC IMMUNOGLOBULIN (Ig) SECRETING CELLS IN ASYMPTOMATIC HIV INFECTION

Th.B.P.97 STUDIES OF THE IN VITRO SECRETION OF HIV SPECIFIC ANTIBODIES BY PERIPHERAL BLOOD MONONUCLEAR CELLS FROM HIV INFECTED SUBJECTS.

Vendell, J. G., Corbeil, P., Douss, J.-F., Reynes, J.,***, Hugnot, M.F., Ucker, A.,***, Cassat, A.,***
* INSERM, ** Laboratoire d'Immunologie, Hôpital Lapeyronnie, ***Service des Maladies Infectieuses, Hôpital St Louis, MONTPELLIER, FRANCE.

PMC from 114 HIV seropositive subjects (73 asymptomatic, 15ARC, 26 AIDS) and from 10 HIV negative controls were incubated: a) in the wells of the ELISA kit (Pasteur) to the HIV antibodies secreted in vitro and fixed on the antigens were revealed by the use of a low noise enzymatic complex; b) in antigen free conditions the supernatants were tested instead of PMC by the same amplified ELISA technique or submitted to Western blot analysis on nitrocellulose strips from commercial kits.

RESULTS: a) Positive results were observed in all cases with the PMC of HIV seropositive subjects and in some with the control PMC; b) Positive results corresponded to an active secretion and not to a release of passively adsorbed seric antibodies. c) Active secretion and antigen and antigen induced and occurs within 18 hours' incubation; d) The capacity for in vitro antibody production is constitutive and not a transient phenomenon in seropositive subjects as opposed to classical models of immunization; e) Cells corresponding to all HIV specificities may be present in the blood stream of HIV infected subjects and the env-coded gp bands are always present in both PMC supernatant and serum Western blots; f) When supernatant and seric patterns differ, the seric patterns are more specific; g) HIV specificities are not profused in the PMC supernatant than in the serum.

CONCLUSION: The continuous capacity of in vitro HIV antibody production seems to be an important feature of HIV infection. The detection of such cells could prove useful for the follow up of subjects at risk and of neonates.

Th.B.P.99 NORMAL AND HIV ASSOCIATED FUNGICIDAL ACTIVITY OF MONOCYTES

Malattie Infettive, Antimicrob. A., Norace G., Manera S., Ortona A.

*Ist. Clin. Malattie Infettive, **Ist. Microbiologia-Università Cattolica-Roma-Italy

Objective: 1) to evaluate the ability of monocytes (M) and monocyte-derived macrophages (m-M) of AIDS patients to kill *Candida albicans* and the role of rIFN in their activation, and 2) to study the effect of HIV-lytase (HIV-lys) on M and m-M fungicidal activity in healthy individuals (normals). **Methods:** Ten AIDS patients and 9 normals were studied. Cell monolayers ($0.25 \times 10^6/ml$), untreated or treated with 3000 IU of rIFN- γ , 0.4 $\mu g/ml$ of HIV-lys, 1 $\mu g/ml$ of anti-gp120 were challenged with $0.1 ml$ of *C. albicans* (10^6 CFU/ml) for 2 h. The killing activity was expressed as % reduction of *C. albicans* CFU.

Results: AIDS M killing was lowered (31.6-31.5 vs 48.7-8.8; p<0.005) and partially restored by rIFN- γ (35.5-12.7); AIDS-m-M killing was slightly reduced (46.9-12.7 vs 57.0-7.4). HIV-lys resulted in heterogeneous reduction of activity by normal M, but not m-M; the defect was not overcome by anti-gp120.

Conclusion: 1) M, but not m-M, killing was impaired in AIDS; different killing systems could be operative in M and m-M; oxidative and non-oxidative mechanisms could be involved; rIFN is one of, but not the only, factor required to induce M effector reactions (I-2 or GM-CSF as cofactors); 2) HIV-lys can induce AIDS-like defect in normal M but not in m-M; a role of envelope proteins (gp1) but not gp120 could be suggested.

Th.B.P.101 REFRACTORINESS OF T CELLS TO REGULATION BY IGF IN HIV INFECTION

Gloria Echeverría de Pérez, L. Deibis, R. Ramirez, Z. Rios, M. de Márquez, J. Blasco, M. N. Blanco.

Clinical Immunology Madrid, Centro MID/IAS/UCM, Caracas Venezuela.

CD4⁺ CD45⁺ large granular lymphocytes (LGL) behave as helper cells of immunoglobulin (Igf) synthesis by peripheral blood lymphocytes (PBL). As measured in cultured supernatants by ELISA. We evaluated such capability in 21 HIV-1 individuals (11 of group II and 10 with AIDS), 12 HIV negative homosexuals (HN) and 11 heterosexual controls. Spontaneous IgG levels were significantly higher in HIV-1 when compared to HN or controls (1812 and 1553 vs. 432 and 425 ng/ml). PBL (1.25×10^6) co-cultured with increasing amounts of mitogenic IL-2 (5 and 7.5×10^3) in the presence or absence of PBL (1/200), caused no further enhancement of IgG synthesis in HIV-1, while values in both HN and controls were significantly increased (2000 and 1500 vs 600 and 710). Antibodies to CD20, gp41 and gp24 were detected by western blot in culture and occasional supernatants from HIV-1 individuals. We suggest that T cell function in HIV infection is resistant to regulatory signals not only from T cell but also from LGL.

Th.B.P.98 ENHANCED ENDOGENOUS TNF α PRODUCTION IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF HIV-1 INFECTED PATIENTS.

L. Heuvelink, R. Voth, R. Brouwer, K. de Boer, M.A. M. Meier, M. van't Hof-Grootenboer, and J. van't Hof-Grootenboer, Institute of Johannes Gutenberg University Mainz - Veterinärmedizin. Institut für Infektionskrankheiten, FISCAL, DEUTSCHLAND.

OBJECTIVE: To study the role of TNF α in HIV-1 infected patients. **METHODS:** Blood samples positive for HIV-1 were obtained from 100 patients at various stages of disease. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll-Paque and stimulated with various inducers for TNF α production. TNF α was quantified by using a highly sensitive ELISA.

RESULTS: It turned out that corynebacterium parvum was the most potent inducer of TNF α when compared to classical TNF α such as various preparations of LPS of *Serratia* sp. in a group of 56 healthy donors mean level of endotoxinogeny produced TNF α yielded in 10.2 pg/ml. However patients at stage 2 (CD4⁺ 1 to 4 were able to produce up to 28 pg/ml TNF when stimulating their lymphocyte with 145 pg/ml of corynebacterium parvum. In all groups of patients and in healthy controls, enhanced TNF α levels in patients with HIV infection may account for conclusions: Our data suggest that TNF α plays a major role in regulating TNF α secretion. Enhanced TNF α levels in patients with HIV infection may account for conclusions: Development of coxsackie, PCR and show monocyte dysregulation early in HIV-1 infection.

Th.B.P.100 AUGMENTATION DE LA PRODUCTION DE RADICAUX LIBRES DE L'OXIGÈNE PAR LES PHAGOCYTES DU SANG CIRCULANT DES MALADES INFECTÉS PAR LE HIV-1.

Vuitton, Dominique A., Druier, J.M., Vuillier, J.; Bertrand, M.A.; Drobachef, C. et al. Centre de Recherches sur le SIDA - Franche-Comté.

Centre Hospitalier Régional et Universitaire, F-25030 Besançon, France.

Objectif: Appréhender, par l'étude de la chimioréactivité, la production de radicaux libres de l'oxygène par les phagocytes du sang au cours de l'infection par HIV-1. **Méthodes:** Le chimioréactif (Cl) des cellules du sang dilué au 1/100 et au 1/1000 a été mesuré en présence de luminol et de lucigénine chez 37 sujets HIV-1. Après traitement par azidothymidine (ZD) des groupes II et III, il a été basal et après stimulation par Con A, F-Met-Lys-Phe, phorbol myristate acétate, interleucine et zymosan, exprimé en intensité lumineuse (IL) par 1000 phagocytes et en IL stimulés/basale, et comparé à celle obtenue chez 35 sujets témoins sans apparus par l'âge.

Résultats: La Cl des phagocytes des malades HIV-1 était 37 fois significativement supérieure à celle observée chez les témoins qui soit le réactif utilisé et tant à l'état basal qu'à l'état stimulé (p<0.01). Cette différence répond principalement sur une hyperactivation basale des phagocytes, qui n'était pas significativement différente dans le g.r.IV comparé aux g.r.II et III la sensibilité aux différents stimuli utilisés était diminuée. Il n'existait pas de relation entre la Cl et l'existence d'une complication clinique particulière ou le nombre de lymphocytes circulants.

Conclusion: L'hyperproduction de radicaux libres de l'oxygène par les phagocytes contraste avec la diminution rapportée d'autres fonctions phagocytaires chez les malades HIV-1. La responsabilité des monocytes et des polymorphes dans ces modifications et l'analyse séquentielle de la Cl chez ces malades sont en cours d'étude.

Th.B.P.102 ACTIVATION T-CELLS (TC) AND HUMAN IMMUNODEFICIENT VIRUS (HIV) PRODUCTION

Prasert, Theodor; Rowell, E.N.; Hensley, E.E.; Butzin, C.

US Air Force HIV Program, Lackland AFB, San Antonio, Texas, USA.

Background: HIV is a retrovirus (RV) tropic for CD4 cells. Proliferation of RV requires the translation and transcription of the host genome. Cellular activation. Activation of TC should correlate with progression of RV infection. One marker of TC activation is the production of HLA class II (Ii) antigens (A2) which are not present on resting TC, but are elaborated within 24-48 hr after activation.

Methods: OEA marker class II antigens. When quantitating lymphocytes by flow cytometry the value OEA class II antigen (a pan-cell marker) at all cells have class II A2) should represent activated TC (i.e., a OEA/CD20-population). **Results:** Restoration of available data on the 7700 cases of HIV positive patients in the WHC HIV data base shows: 1) patients with 25% TC consistently had failed subsequent values of 10.3 while those who had decreased TC had values of 12.0 (p<0.01). 2) Pre with absolute CD4 counts consistently 3400 had values of 11.1 while those with 4400 had values of 11.9 (p<0.01) 3) Naïve B-cell (NB) stages 1 or 2 without progression at 1-2 yrs had values of 11.1 while those progressing to WB-3 had values of 14.8 (p<0.01).

Conclusions: These data suggest that activation of TC as measured by OEA-CD20 cells correlates with HIV disease progression. We are aware that the activated TC may, in fact, be CD8 cells (Kiehlbas-Hatthorn et al., JCI, 8(6) 678, 1988) and prospective studies to elucidate which TC population is activated in our patients are in progress.

Aspects cliniques Clinical Aspects of AIDS

Th.B.P.145 A FOLLOW-UP OF IMMUNE PARAMETERS IN HIV INFECTED PATIENTS

CREATED WITH LOW DOSE AZIDOTHYIMIDINE (AZT).
Bryson M., Falson J. and Swinburn W.
** Institut Pasteur, 25 Avenue de la Croix Nivette,
** 69622 Saint Illiers, Saint Maurice de Lillay, Belgium.

Objective: To assess the effect of AZT on immune function of HIV infected patients.

Methods: Seven HIV infected patients were submitted to oral low dose AZT (750 mg/3 days/week). Immune function was assessed at three-monthly intervals by *in vitro* lymphoproliferation towards PHA and PWM and for interferon α and β production. Immune parameters at the onset of the study and the duration of AZT treatment were as follows:

Patients	CD4 (cells/mm ³)	%T4	%T8	PHA (cpm)	PWM (cpm)	ATF (weeks)		
1	2	405	4.47	18124	2615	34		
2	3	iv drugs	3.96	0.46	23456	3680	40	
5	2	AC2	300	0.15	1449	8667	19	
7	9	AC2	Africa	14.0	0.15	15146	1877	18
10	4	AC2	Europe	0.15	1449	8667	19	
108	4	AC2	Europe	252	0.34	14875	544	37
121	4	AC2	Europe	24	0.06	892	187	37

Results: All but one patient (patient #121) presented an increase of CD4 cells during AZT therapy. However, no significant improvement of the immune function was observed during treatment in any of the patients except in patient 37. Interpretation of this improvement must be made with precaution, as this patient cooperated with the AZT treatment, stopped his drug-abuse.
Conclusions: These preliminary results concerning patients with yet advanced disease suggest that low dose AZT induced an increase of CD4 cells but couldn't improve the immune function.

Th.B.P.147 SOUS-POPULATIONS DE LYMPHOCYTES CD4+CD45RO+ ET

CD4+CD45RO- CHEZ DES PATIENTS AVEC INFECTION VIH.
BARBIER P., TOURNARE J., CALDESIERBIANE L., VIVROET J.-M.,
GILNEY C., TOURNARE A.
* Lab. Immun. Hop. Necker/Marcé P., P. Lyon. Hôp. H. Henri L. LYON FRANCE.

Objectif: Evaluer l'effet de la numération des lymphocytes CD4+294+ et CD4+484+ dans la prédiction de l'évolution chez les patients avec infection VIH.

Méthodes: 79 patients VIH-1 séropositifs ont été groupés. On évalue les taux des EPICs CD4+294+ et CD4+484+ (PFC-PHE) CD4+294+ et CD4+484+ (Anticorps monoclonaux Coulter Diagnostics).

Résultats:

Groupes: Niveau de sérum CD4+294+ et CD4+484+ et CD4+294+/CD4+484+ (Ratio)

Témoin n SD n SD n SD n SD

1 16 752 148 214 82 241 82

2 16 752 148 186 83 181 79

3 16 462 98 122 62 184 71

4 24 297 78 82 33 138 80

5 18 257 94 50 42 120 80

6 18 257 94 50 42 120 80

Il existe une différence significative de nombre de cellules CD4+294+ dans le groupe 1 (séroconversion) par rapport aux autres (P<0.0001), test de Student) ainsi que ceux des CD4+ et des CD4+294+ ne sont pas significativement associés (P=0.4 et P=0.7).

La détection des lymphocytes CD4+ dans le groupe 2 par rapport au groupe 2 est prépondérante dans le groupe des CD4+294+ (P<0.0001) sans différence significative pour les CD4+484+ (P=0.046).

Conclusions: Ces résultats préliminaires suggèrent que le sous-population CD4+294+ est associée prédominamment dans l'infection VIH et que le sous-population CD4+294+ est associée prédominamment dans l'infection VIH et que le sous-population CD4+294+ est associée prédominamment dans l'infection VIH et que le sous-population CD4+294+ est associée prédominamment dans l'infection VIH.

Th.B.P.149 CONSISTENCY OF ROUTINE CD4+, CD8+ AND PERIPHERAL LYMPHOCYTE MEASUREMENTS

J.D. Aboumzer, B. Autren, K. Balgord, F. Tournare, M. Tubiana, J.D. Bryson, et al. Groupe INSERM-ILM-CLC4 et SERCOG, France.

OBJECTIVE: To assess the consistency of routine measurements of CD4+ and CD8+ lymphocytes in whole blood using HIRSHMAN-ILM-CLC4 et SERCOG, France using a sample of 12 university laboratories.

METHODS: Two groups of 12 and 12 patients each, with CD4+ lymphocyte ranging from 20 to 1000/mm³ were tested. Each blood sample was fractionated into duplicate aliquots (2 x 12) in order that each sample could be tested blindly within each lab during the subsequent 4 hours. Each one of the 12 labs used its own routine method for whole blood IF staining and analysis. In total, among the 12 labs, 3 sources of lysing solutions and of reference FITC conjugated anti-CD4 and CD8 mAb were assessed and the IF was analysed on 4 distinct types of cytofluorimeters. Total lymphocyte counts were evaluated by both automatic and microscopic hematology methods (7 distinct automatic devices).

RESULTS: A 15% coefficient of variation was found for overall CD4+ cell measurements from 200 to 1000/mm³. This weak variability might be mainly attributed to the immunological and hematology devices rather than to the operators or to the reagents.

CONCLUSION: The high consistency and reliability of CD4+ lymphocyte counts, required for both clinical and research purposes, can be routinely obtained in different laboratories provided automatic counting methods (good statistical validity of microscopic counts) are used by trained operators during each step of the process.

Th.B.P.146 AN UPDATE OF THE LYMPHOCYTE IMMUNOPROLIFERATIVE QUALITY

ASSESSMENT THROUGH 75 SUBJECTS OF THE AIDS HIV SYNDROME.
Richard, William J., Wastell, M.J., Medical, C.***
Dando, J.D., and Burke, D.L.*** Walter Reed Army Institute of Research,
Washington, DC, USA and INRS System, Inc., Rockville, MD, USA.

Objective: To determine the degree of interlaboratory variability among Army Regional Medical Centers (AMC) that evaluate HIV patients.

Methods: Monthly shipments of 3 whole blood specimens are delivered by overnight commercial carrier to seven AMC for lymphocyte and lymphocyte evaluation: CD2, CD3, CD4, CD8, CD4/20 and NK cells, were determined by a standard flow cytometric lymphocyte immunophenotyping protocol.

Results: Since June 1987, 383 specimens from 54 normal donors have been analyzed by the participating AMC with an overall standard deviation (SD) of 5.2 and coefficient of variation (CV) of 13.1% for all lymphocyte cell types. The SD for CD4 percentages have ranged from 3.0 to 9.7% (mean of 3.3), while the SD for CD8 absolute counts have ranged from 69 to 477 cells/mm³ (mean of 227). The cumulative interlaboratory CV for the absolute CD4 count is 29.2%.

Conclusion: In order to provide reliable CD4 determinations for multicenter HIV treatment protocols, a high degree of interlaboratory reproducibility and accuracy must be required and can be achieved through the implementation of a comprehensive quality assurance program.

Th.B.P.140 CD4 AND TOTAL LYMPHOCYTE COUNT (TLC) IN PATIENTS WITH

ANTIBODIES TO HIV-PREDICTING VALUE, CLINICAL SIGNIFICANCE AND ADDITIONAL TRENDS FOLLOW-UP HAVE BEEN STUDIED.
B. Clotet, A. J. Tor, J. S. Sierra, M. Dominguez, JM Gimeno, JM For. Infectious Diseases Unit Hospital de Barcelona "Germans Trias i Pujol" Badalona, Barcelona, Catalonia, Spain.

Objective: To assess the value of CD4 and total lymphocyte count follow-up in HIV seropositive patients.

Material: 164 seropositive patients (110 intravenous drug abusers [IDA], 38 heterosexuals; 16 heterosexuals). No patient had AIDS at entry, CD4+ and TLC were determined each 6 months or before if symptoms developed. Mean follow-up has been 18 months (range 6-48).

Results: Would be shown in tables and figures.

Discussion: There is a trend towards a decline in CD4 and TLC through the follow-up. The decrease in CD4 is more marked in heterosexuals than in IDA. A spontaneous increase in CD4 is occasionally seen during the first year. Total lymphocyte count should suffice for monitoring the progression of the disease because it mimics the decline in CD4 cell count and is less expensive. IDA with low CD4 cell count at entry below 400 x mm³ subsequently developed AIDS more frequently than patients with CD4 400 x mm³ at enrollment (p < 0.005).

Patients with P. carinii pneumonia (PCP) had a 95.5% of cases total lymphocyte count below 900 x mm³ and CD4 200 x mm³. A total lymphocyte count (TLC) major than 1200 x mm³ rules out PCP. Primary prophylaxis for PCP is required in patients with CD4 < 250 x mm³.

Th.B.P.150 IMMUNOLOGICAL FEATURES IN HIV-1 POSITIVE PATIENTS: CLINICAL CORRELATION

G. Sileri, I. Mezzarona, C. Papetti, A.M. Pesca, E. Pieter, M. Cherchi and F. Aiuti. Dept. of Allergy and Clinical Immunology, University of Rome "La Sapienza", Rome, Italy

Objective: To describe immunological features during HIV-1 infection.

Methods: 112 HIV-1 positive patients, 193 sera were significantly reduced as well as routine assays (lab number of T lymphocyte subsets, skin test, EAC coat, serum immunoglobulins) have been evaluated in infected patients. 789 subjects belonging to various at risk categories were selected from 2011 individuals. 180 were diagnosed CD-II and 490 CD-II-1.

Results: Total T cell number was constantly diminished in the clinical stages of AIDS and CD4+ cells were significantly reduced (40-11) in 42% of asymptomatic patients, 56% of PLE and 92% of ARC. AIDS patients showed defective "in vitro" responses to PHA, production of IL-2 and IFN- γ induced by specific stimuli. NK from B9C showed decreased activity in AIDS and CD-II-1.

Clinical correlation: at least two subgroups of seropositive patients may be included in CD-II-1 and II-1 classified subjects. These showing immunologic abnormalities and those with one or more immunologic alterations.

Conclusions: Unknown co-factors may be involved in the clinical evolution of seropositive patients; their relationship with immunological parameters is a central point for a better knowledge of HIV-1 infection.

Aspects cliniques Clinical Aspects of AIDS

Th.B.P.151 IMMUNOLOGICAL PARAMETERS OF HIV1 AND HIV2 SEROPositIVES

Le Bouché, Bernard, Gervais, J.L.

Institut Pasteur de Dakar, Dakar, Senegal.

Objectives: To compare immunological consequences of HIV1 and HIV2 infections in a West African population.
Methods: Serological screening was done using HIV1 and HIV2-specific ELISA and confirmation by specific Western Blotting (Diagnostic Pasteur). Analysis of lymphocyte sub populations was done on a FACS flow cytometer using fluorescein labeled monoclonal antibodies. IgG and IgM were quantitated by radial immunodiffusion, IgG by a sandwich ELISA test and the B2 microglobulin using a competitive ELISA test (all reagents from Becton Dickinson). Immune Circulating Complexes were also tested by ELISA (immunozyme).

Results: Comparison of data from seropositives, asymptomatic seropositives and AIDS cases showed that CD4 and absolute count of T4 cells were the more significant markers of evolution. Comparison of HIV1 to HIV2 asymptomatic seropositives and HIV1 to HIV2 clinical cases showed no difference in the studied parameters.

Conclusion: Parallels of immunological parameters are the same in our HIV1 and HIV2 infected cases and clinical cases. Immunological differences observed in immunologic and evolution of the diseases due to these 2 viruses.

Th.B.P.153 RELATIONS BETWEEN DISTRIBUTION PATTERNS OF LEU8⁺ SUBSETS AMONG CD4⁺ AND CD8⁺ T-LYMPHOCYTES IN THE PERIPHERAL BLOOD

Uthoff, Barmatz, Kunze, R.O.F., Krasser, R., Trölsler, P., Elm, I., Paul, G.

Akt. Virologie des Robert Koch-Instituts und AIDS-Zentrum, BGA Berlin

The CD4⁺ and CD8⁺ cell number and the resulting CD4/CD8 ratio is still the most valuable parameter to assess the cellular immune status during HIV-infections. Both lymphocyte populations are heterogeneous with respect to functional activity and other surface markers. We analysed the coexpression of either CD4 or CD8 with Leu 8 in the peripheral blood of 45 HIV-infected persons. Lymphocytes were isolated from blood by density-gradient centrifugation, stained with fluorescein-labelled Leu 8a (anti-CD8) or Leu 2a (anti-CD4) antibodies together with phycoerythrin-labelled Leu 8 antibodies and then measured on a FACScan flow cytometer. Irrespective of the clinical stages of HIV infection Leu 8⁺ subsets behave differently in the CD4⁺ and the CD8⁺ populations. The shifts in the CD4⁺ lymphocyte population strongly correlate with Leu8⁺CD4⁺ cells ($R=0.98$) but not with Leu8⁺CD8⁺ cells ($R=0.03$). On the contrary, the changes in the number of CD8⁺ lymphocytes are almost exclusively caused by Leu8⁺CD8⁺ cells ($R=0.91$) but by Leu8⁺CD4⁺ cells ($R=0.1$). Furthermore, the serum levels of shedded CD8 molecules correlate well with the Leu8⁺CD8⁺ subset ($R=0.77$) but not with Leu8⁺CD4⁺ ($R=0.1$). The observed relations led us assume that the recruitment of different subsets from lymphatic organs is heavily altered already during early stages of HIV-infection.

Th.B.P.155 CORRELATION OF IN VIVO CELLULAR IMMUNE FUNCTION WITH CD4 NUMBER AND DISEASE PROGRESSION IN HIV SEROPosITIVE PATIENTS

Hicks, Deborah¹, Rhodes, J., Tronost, E., Carter, C.,

Burke, D., ²Bedford, B., ³Walter, David, ⁴National Research Group,

Rockville, MD, U.S.A.

Objectives: 1) evaluate in vivo cellular immune function in HIV seropositive patients, 2) determine its correlation with circulating CD4 (+) cells, and 3) determine its ability to predict HIV disease progression.
Methods: 1500 seropositive patients and simultaneous CD4 counts were performed in 1000 patients. The seropositive patients were divided into 4 groups: 1) CD4 > 1000, 2) CD4 500-1000, 3) CD4 200-500, and 4) CD4 < 200. The seropositive patients were followed for 12-36 months. 300 of the 1000 patients have been followed serially for 24-64 months and observed for HIV disease progression.

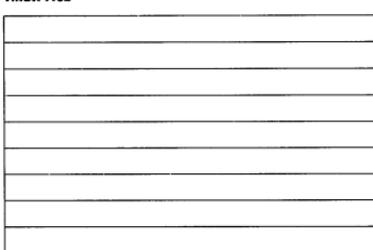

Results: Antigen reactivity

	(n)	(%)	CD4 (IQR)
0/6 (seroneg)	218	14	109-127
1/6	166	11	259-162
2/6	247	16	388-199
3/6	494	33	497-223
4/6	240	15	577-285
5/6	290	19	685-351
6/6	146	9	787-361

Antigen responsiveness significantly correlated with CD4 number ($R=0.95$). Progressive loss of antigen reactivity independently correlated with HIV disease progression to opportunistic infection.

Conclusion: This panel provides a clinical parameter that correlates with absolute CD4 number and is independently predictive of HIV disease progression and development of opportunistic infection.

Th.B.P.152

Th.B.P.154 PREDICTION OF CD4/CD8 RATIOS FROM SERUM PARAMETERS

Kunze, R. O. F., Uthoff, Barmatz, Krasser, R., Trölsler, P., Beck, A., Paul, G.

Akt. Virologie des Robert Koch-Instituts und AIDS-Zentrum, BGA-Berlin

FEDERAL REPUBLIC OF GERMANY.

The CD4- and CD8 cell number and the resulting CD4/CD8 ratio still being the most valuable parameters for monitoring the cellular immune status of HIV-infected subjects and to assess disease progression. Usually, the CD4/CD8 ratios are obtained from freshly isolated peripheral blood lymphocytes. As an alternative, we tried to predict CD4/CD8 ratios from serum immunopareters. Blood and serum samples were collected from 49 persons, 39 of which were HIV-positive and belonged to the stages asymptomatic, LAS, ARC. In a multiple regression analysis 30 parameters, among them percentages of CD4 and CD8 cells, neopterin, β_2 microglobulin, the immunoglobulin G, A, M, the immune complexes C1q, C3b, IgG, IgA, IgM, autoantibodies against the lymphocyte surface antigen CD5 (s-ab-CD5), soluble CD8 antigen (s-CD8), and soluble inter-leukin-2 receptor were proved for their usefulness to predict the CD4/CD8 ratio. The best result ($R=0.86$) was obtained with a linear combination of only two parameters, s-ab-CD5 and soluble CD8 antigen irrespective of the clinical stage. This method offers the possibility to estimate CD4/CD8-ratios from stored sera retrospectively.

Th.B.P.156 HIV-2 INFECTION AND IMMUNOSUPPRESSION

Lisse, I., ¹Jølsen, Anne-Grethe², Aaby, P., ³Rydsted, S.,

⁴Björk, E., ⁵Diem, P., ⁶Wassenaar, K., ⁷Lauritzen, E.,

⁸Hvidovre Hospital, Copenhagen, Denmark, ⁹Høstpræsteværket, Copenhagen,

Denmark, ¹⁰University of Copenhagen, Copenhagen, Denmark, ¹¹Abnatorion

National de Sude Public, Niamey, Guinea-Bissau.

Objectives: To evaluate the effect of HIV-2 infection on T-helper cell numbers and T-helper/T-suppressor ratio (Th/S).
Methods: Forty-seven HIV-2 seropositive adults identified in a cross-sectional community study in Bissau, Guinea-Bissau, were re-examined after 10-12 months follow-up, as were 87 controls matched for age, sex and civil status. A physical examination was done. Separated cryopreserved blood was collected, and the same day WBC and blood smears were made. The blood smear was fixed in methanol for differential counting; the others were stored at -20°C until labelled by immuno-alkaline phosphatase technique (APAAP), using monoclonal antibodies against T-helper and T-suppressor cells.

Results:

	HIV-2 seropositives	Controls	p-value
T-cells $\times 10^6 \times 10^9/l$	747	2787	<0.03
Th/S co. 8	16/47	7/87	<0.0005
T-cells $\times 10^6 \times 10^9/l$ and W/S co. 8	6/47	0/87	<0.0005
T-cells $\times 10^6 \times 10^9/l$ or W/S co. 8	17/47	9/87	<0.0005

Conclusion: HIV-2 is significantly associated with low T-helper cell numbers and inverted T-helper/T-suppressor ratios.

Th.B.P.157

Th.B.P.157 **IMMUNOLOGIC ANALYSIS OF PROTECTIVE AND REACTIVE GAY SEX BEHAVIOR.** R.L. Wilton, R.L. Tronzo, S. Lippert, M. Schneiderman, K. University of Miami Center for Epidemiological Studies, AIDS, Miami, FL.

OBJECTIVE: To determine the early immunologic effects of HIV infection in healthy gay men and to compare immunologic status of gay men to age and sex matched controls.

DESIGN: Factors of cellular immune function were determined for 54 healthy gay men, 395 anti-HIV positive (+), enrolled in a longitudinal study, and 25 age and sex matched controls.

RESULTS: Factors of cellular immune function were determined for 54 healthy gay men, 395 anti-HIV positive (+), enrolled in a longitudinal study, and 25 age and sex matched controls. Results: The (+) gay men in this study did not differ from the (-) gay men or the controls in total number of lymphocytes, CD4 cells, CD8/T4 ratio, cells of the inducer subset, CD45+CD45+, or CD80 cells. The number of CD4 cells, as well as the helper subset, CD45+CD45+, were significantly depressed in (+) men when compared to the controls or to (-) gay men. CD4 cells in these latter two groups did not differ from each other. CD8 cells were elevated in (+) men as compared to either (-) group, and there was a greater proportional increase in CD8/T4. CD4/CD8 was 1.3 in the (+) gay males, significantly higher than the (-) group (0.7), but also significantly lower than the controls (1.8). The ratio CD45+CD45+/CD80 cells was 1.8 for the (+) men, 4.8 for the (-) gay men and 3.7 for the controls. There was a significant elevation of CD8+ cells in both groups of gay men as compared to controls. The mean response to both 1 cell and 1/8 cell antigens of the (+) men was one-half that of the (-) gay men and one-fourth that of the controls. Natural killer (NK) cytotoxicity was similar for both groups of gay men but was significantly lower than the (-) control group. Conclusions: Early immunologic changes which may be related to HIV-1 infection were decreased in the helper subset of CD4 cells, elevations in CD8/T4 ratio and CD8+ cells and marked depression of lymphocyte response to antigens. Healthy (+) gay men had decreased antigen response and cell activity compared to controls. (supported by NIH 1986 RR4243)

Th.B.P.161 AIDS PREDICTORS

Th.B.P.161 **AIDS PREDICTORS**
R.H. Johnson, Department of Immunology, School of Pathology, University of the Witwatersrand and the South African Institute for Medical Research, Johannesburg, South Africa

OBJECTIVE: To evaluate and compare new β_2 -microglobulin (β_2 -micro) levels, IgA and CD4 lymphocytes as predictors of AIDS.

METHOD: 806 patients were studied for HIV-1 infection in Johannesburg by testing for the presence of HIV-1 antibodies and their immunological status. CD4 lymphocytes were counted using a cytotoxicity assay, β_2 -micro was measured using the Pharmacia β_2 -micro EIA test and IgA by turbidimetric methodology.

RESULTS: Of the 806 patients studied, 504 (61%) were exposed to the HIV and 74 (9%) developed AIDS. Sixty seven (90.5%) of the AIDS cases had elevated levels of β_2 -micro and 33 (44.6%) had elevated levels of β_2 -micro, IgA and decreased numbers of CD4 lymphocytes ($<400 \times 10^6/l$). Fifty three (71.6%) had elevated β_2 -micro levels and decreased CD4 lymphocyte numbers but 37 (50%) had both elevated levels of β_2 -micro and IgA. β_2 -micro levels were elevated in 38 (50.7%) of the 77 AIDS cases prior to their developing AIDS. The remainder were assessed when they already had AIDS.

CONCLUSION: (1) Elevated β_2 -micro levels were shown to be the most consistent predictors for AIDS and usually indicated a poor prognosis. (2) The possible use of elevated β_2 -micro as an indicator for the initiation of prophylactic AZT requires evaluation.

Th.B.P.158 EVOLUTION DES DEPONDANTES SOUS-POPULATIONS CD4 et CD8 AU COURS DE L'INFECTION PAR LE VIRUS HIV-1.

AGAZ, Moutiel, Pons, S, Pons, A, Pons, J, Sola, R, Ouen, L, Centre de Recherche Médicale Université de Caugli, Cagliari, Italie

La cytométrie à flux en deux couleurs et l'emploi d'anticores monoclonaux spécifiques pour les antigènes CD 4, CD 8, CD 16, CD 161, Leu-1, Leu-2, ont permis de définir un grand nombre de sous-populations lymphocytaires. On évalue 20 cellules saines sous 1000 individus HIV-1 séropositifs, dont 30 séropositifs asymptotiques (SPA), 30 avec lymphodépression généralisée persistante (PGL), 20 avec ARC et 20 avec SIDA.

La diminution progressive des lymphocytes CD4 dans les stades de SPA, PGL, ARC et SIDA concerne toutes les sous-populations CD4 positives, mais dans les cas de PGL, les sites de recrutement à une classe de subset CD4, le subset CD4-CD8 sont presque normaux, alors que dans les cas de SPA, de ARC et de SIDA, les deux subsets CD4 et CD8 sont diminués. Il faut remarquer la présence d'une pourcentage variable de cellules qui possèdent CD4 et CD8 dans les stades de SPA, PGL et ARC. Ceci peut refléter dans l'activation immunitaire des lymphocytes CD4 par le virus. Les lymphocytes CD8 augmentent dans les SPA, la PGL, et dans une partie de l'ARC. L'augmentation est due essentiellement à une sous-population définie par une haute densité de l'antigène CD8 (CD8-Hi), avec sous-population CD8-Low. La composition est une de fractions Leu-1 définies dans subsets CD8-Hi, CD8-Low, CD8-Hi, CD8-Low, CD8-Hi, Leu-1, Leu-2. Le premier pic correspond à des cellules qui sont dans les SPA et la PGL, les deux autres segments sont surtout les subsets CD8-Hi, CD8-Low, Leu-1, Leu-2, et le dernier sont les CD8-Low. Le passage à l'étape de ARC et surtout de SIDA est marqué par une chute progressive des cellules CD8 (avec hausse) et des augmentations de sous-distribution de subset CD8-Hi, CD8-Low, Leu-1, Leu-2. Il est notable à signaler que des subsets CD8-Hi (dont augmentent) et CD8-Low (à basse densité), sont été observés seulement dans les stades HIV-1. La signification des variations observées entre les subsets qui cellule CD4 et CD8 est discuté en fonction de l'évolution clinique de l'infection rétrovirale vers le SIDA.

Th.B.P.160 DEPLETION OF CD16 NK CELLS IN HIV INFECTION DUE TO A SELECTIVE DECLINE IN THE CD16⁺CD8⁺ COMPARTMENT.

Memoir, J, Dainin, C, Gagnier, P, Lefrère, J, Rouger, Ph, LaFrance, J, J, Meyhans, M, C, Rouger, Ph, et Salmon, Ch, Institut National de Transfusion Sanguine, Paris, France, *Hôpital Saint-Antoine - Service des maladies infectieuses, Paris, France.

OBJECTIVE: To analyze the Natural Killer (NK) cells in HIV-infected patients.

Methods: Using monoclonal antibodies and two-color flow cytometric analysis, we analyzed the NK cell subsets in 121 HIV-infected patients (53 CDC II, 37 CDC III and 37 CDC IV: 4 IFA, 2 IFA, 15 IFA, 5 IFA, 2 IFA and 7 IFA) and 59 healthy controls.

Results: The CD16 NK cells showed a depletion in all stages of HIV infection compared to controls. The mean count and the mean percentage in stage II, III, IV and controls were respectively: 191 cells/mm³, 15%, p < 0.001; 147 cells/mm³, 9%, p < 0.001; 123 cells/mm³, 8%, p < 0.001; 274 cells/mm³, 15%, using the presence of the CD8 surface antigen on CD16 cells as a discriminating criteria, we analyzed two subsets: CD16⁺CD8⁺ and CD16⁺CD8⁻. The CD16⁺CD8⁺ subset showed no statistically significant difference in all HIV infection stages compared to controls, whereas the CD16⁺CD8⁻ cells showed the same profile of depletion as the total CD16 cells (53 cells/mm³, 3%, p < 0.001 in stage II; 35 cells/mm³, 2%, p < 0.001 in stage III; 31 cells/mm³, 2%, p < 0.001 in stage IV; 111 cells/mm³, 6% in controls).

Conclusion: We observed a depletion of the CD16 NK cells early in HIV infection. It seems that only the CD16⁺CD8⁻ subset accounts for this depletion and not the CD16⁺CD8⁺. The etiology of this selective depletion is still unclear.

Th.B.P.162 DICHOTOMY OF TWO CD8⁺ LYMPHOCYTE SUBSETS IN HIV-INFECTED PATIENTS - Depletion of CD8⁺CD3⁺ and expansion of CD8⁺CD3⁻ subsets

Memoir, J, Dainin, C, Gagnier, P, Lefrère, J, Rouger, Ph, Institut National de Transfusion Sanguine, Paris, France.

OBJECTIVE: To help understanding the expansion of CD8 lymphocytes in HIV infection.

Methods: We analyzed two CD8 subsets: CD8⁺CD3⁺ and CD8⁺CD3⁻, using monoclonal antibodies and two-color flow cytometric analysis in 120 HIV-infected patients (53 CDC stage II, 31 stage III, and 37 stage IV) and 59 healthy controls.

Results: In HIV-infected patients, we observed a depletion of the CD8⁺CD3⁺ subset and an expansion of CD8⁺CD3⁻ subset.

	CD8 ⁺	CD3 ⁺	CD3 ⁻	CD3 ⁺	CD3 ⁻	Mann Withney U test
	CD8 ⁺	CD3 ⁺	CD3 ⁻	CD3 ⁺	CD3 ⁻	
CDC	1/2	1/3	1/4	2/3	2/4	3/4
CD8 ⁺	3141	5642	5642	6342	*	NS ** ***
CD3 ⁺	57821	105528	95557	85678	*	NS NS NS
CD8 ⁺ CD3 ⁺	821	36	24	24	*	NS ** *
CD8 ⁺ CD3 ⁻	14924	5847	4245	2742	*	NS ** *
CD8 ⁺ CD3 ⁺	231	5642	5242	6642	*	NS ** **
CD8 ⁺ CD3 ⁻	41624	82875	87258	82875	*	NS NS NS

U: Lymphocytes; * p<0.001; ** p<0.01; *** p<0.05

Conclusion: The apparent expansion of the total CD8 population in HIV infection is, in fact, the consequence of an increase of the CD8⁺CD3⁻ subset which conceals a severe depletion of the CD8⁺CD3⁺ subset.

Immunologie : réactions Immunaires Immunology: Antibody Responses

Th.B.P.169 IMMUNOMETRIC ANALYSIS OF HIV SEROLOGY ON IMMUNOBLOTTING : PROGNOSTIC INTEREST.

RIEYER JACQUES, ESCAICH S, CHEVALIER P, TREPO C, SEPTIANT N, LAROUYERIE G, SAMPY, LEBLANC, LYON, FRANCE, INSERM U271, LYON, FRANCE.

Objective: To quantify the anti-HIV antibody reactivity on immunoblotting in relation to clinical stage.

Methods: We have studied 450 sera between october 1988 and January 1989, with anti P18/P24 antibody assay (recombinant antigen ELA, Abbott), HIV antigenemia (ELIA, Abbott) and scanning densitometry on immunoblotting (Biorad). The same pool of sera was used in each immunoblotting assay as external standard. Results are expressed in percentage of external standard reactivity.

Results: Antigen/protein antibodies (GP 120 and GP41) and anti P24 gene products antibodies (P26 and P32) variations did not correlate with any clinical feature (Stages II, III, IVA and IVG1/IV2 from the CDC classification). Anti core protein antibodies exhibit a moderate (P18 and P25) or a high (P24 and P40) correlation with clinical stage. Mean anti P24 reactivity was 22% in AIDS, 31% in ARC and 64% in asymptomatic patients. **Conclusion:** We confirm the decrease of anti core protein antibodies reactivity with disease progression. A retrospective and prospective study will confirm the prognostic interest of this method compared with other markers: HIV antigenemia, CD4+ lymphocyte numération.

Th.B.P.171 SECRETORY AND SYSTEMIC IMMUNITY IN HIV-INFECTED INDIVIDUALS

San-Di Fauth, P. A. Archibald, D. University of Maryland at Baltimore, Baltimore, MD, U.S.A.

The secretory immune response to HIV has been proposed to play a role in viral transmission of HIV. We investigated the oral secretory and serum antibody response to HIV and its relationship to clinical status in 20 randomly selected HIV-infected individuals. By CDC clinical criteria, 7 individuals were in group I, 10 in group III, and 3 in group IV. Saliva and serum were collected and assayed for HIV specific antibodies by immunoblotting. HIV were found with saliva or serum, then with a histiolytic post-exposure antibody and finally with a streptavidin-biotin HRP complex. Antibodies to HIV gag antigens gp120 and gp160 were detected in saliva and serum in all individuals of group I and IV. Antibodies to viral core antigens p24, p53 and p17 were detected in 6/7 group II patients (6 with CD4-counts > 200/mm³) in both saliva and serum. Antibodies to core antigens were not found in the saliva, but were detected in the serum of 3/3 group III and 10/10 group IV patients (all with CD4+ > 200/mm³). The difference between group III and group IV or IV core antibody detection in saliva was significant (p<0.01). The difference between the presence of antibody to core antigens in saliva and serum was also significant (p<0.001) as tested by Chi-square. The antibody titres to HIV in serum were more than 1,000 times greater than those in saliva (1:1,000,000 vs. 1:1000). The range of antibody titres in parotid saliva was 1:3 to 1:200. Decreased secretory antibodies to core HIV antigens may correlate with presence of symptoms and a higher CDC clinical stage in HIV-infected individuals. Some independence in systemic vs. secretory antibody response is also suggested.

Th.B.P.173 INDETERMINATE HIV-1 IMMUNOBLOT REACTIVITY IN LOW AND HIGH HIV-1 SEROPOSITIVE GROUPS: PROBABILITY OF REDUCTION OF IMMUNOBLOT REACTIVITY BY IMMUNOPRECIPITATION ASSAY.

Barclay, Linda E., Khoshdel, G., Gomon, R., Kaplan, J., Laine, M., Centers for Disease Control, Atlanta, Georgia, USA.

Objective: Define patterns of indeterminate HIV-1 immunoblot (IB) reactivity in sera from low- (e.g. blood donors) and high- (e.g. IVDRS) seroprevalence groups, and determine the probability that HIV-1 antibody (Ab) status of sera with these patterns will be resolved by radioimmuno-precipitation assay (RIPA).

Methods: Sera repeatedly reactive by HIV-1 ELISA were tested by IB. Sera with indeterminate IBs (n=20) were compared with either one viral band, but not reactive to both p24 and gp41 or gp41/48) were analyzed by RIPA.

Results: All of the 170 indeterminate IBs studied were gag reactive only: 63 (37.0%) were p18 p24, 58 (33.5%) were p17, p24, and 57 (33.0%) were p18 p24 p32. Indeterminate IB reactivity differed in low and high seroprevalence groups: in groups with low HIV-1 seroprevalence (CD 18), 21/26 (81.5%) were p18 p24; in high seroprevalence groups (2 x CD 18) this pattern was seen in only 2/40 (5.0%) ID sera. Indeterminate IB patterns with p24 represented 7/78 (8.9%) sera in low HIV-1 seroprevalence groups and 27/40 (67.5%) ID sera from high seroprevalence groups. RIPA detected Ab to gag proteins and resolved (confirmed) the antibody status of 71/78 (91.0%) of the ID sera. Indeterminate sera: 44/53 (83.0%) of p18 p24 sera, 27/58 (46.6%) of p17-p24 sera, and 0/27 (0.0%) of p18-p24 sera. Conclusions: Sera reactive only with gag proteins were responsible for all of the indeterminate IB reactivity seen, and the pattern of gag-only reactivity differed with seroprevalence. RIPA detected Ab to gag proteins present in low titer in a significant number of IB gag-only reactive sera, and resolved the Ab status of these sera.

Aspects cliniques Clinical Aspects of AIDS

Th.B.P.170 CORRELATION OF CLINICAL DIAGNOSIS OF HIV INFECTION WITH THE RESULTS OF ELISA, KAPAS ELI TEST AND WESTERN BLOT

ANT-HIV ANTIBODIES. Pawlino, U.H.M., Green-Dinco B., Immunodeficiency Clinics, Infectious and Parasitic Diseases Service, Faculty of Medicine, Federal University of Minas Gerais, Belo Horizonte, BRAZIL

Objective: Correlate the level and type of anti-HIV antibody with the clinical diagnosis of the infection.

Methods: To evaluate 549 individuals examined from February 86 to May 88, we have employed three tests for the detection of anti-HIV antibodies: ELISA, KAPAS ELI TEST and WESTERN BLOT. One hundred sixty and two hundred (30.6%) were HIV positive. 105 had symptoms: 23 PGL, 50 ARC and 32 had AIDS.

Results: In percentage: Antigenic PGs AUC AIDS
ELISA 2x cut-off) 76.6 73.9 48.0 34.4
KAPAS (above 1:2500) 21.6 8.7 10.0 6.3
WESTERN BLOT(2x) 96.7 95.7 82.0 68.7

Conclusion: In our sample the clinical diagnosis of AIDS correlated with low levels of antibodies (Karpas and ELISA) and with the absence of P24 on Western Blot. Routine evaluation of these parameters in the follow up of HIV-positive individuals may be of prognostic value.

Th.B.P.172 IgG SUBCLASS ANTIBODIES AGAINST SYNTHETIC PEPTIDES OF HIV-1 PROTEIN IN HIV-1 INFECTED INDIVIDUALS

Bel, Barbara, Ramos, A.C., F. S. SOARES, G. M. G. M. G. M., and Wally, G.

AIDS-Serumus and Robert Koch-Institut des Bundesgesundheitsamt, Berlin, FRG.

Objective: To evaluate the significance of HIV-specific IgG subclass antibodies against synthetic peptides in monitoring HIV infection.

Methods: IgG subclass antibodies were measured in an ELISA using seven synthetic peptides derived from immunodominant regions of gag and env. Serum from patients with AIDS (9), ARC (10), PGL (21) and without symptoms (10) and follow-up sera drawn at intervals of 6 months (follow-up 1.5 to 2.5 years) from 9 patients in different stages and with different clinical outcomes, were investigated.

Results: IgG1 and IgG3 were the principle reactive subclasses. A significant lower frequency of IgG2 to all peptides was seen in patients with AIDS. Most of the H-terminal peptides of gag, a steadily declining frequency of IgG1 to all peptides was seen with ongoing disease. No follow-up sera little change in antibody patterns occurred, suggesting that an established pattern was maintained. Most changes appeared in IgG1. Multivariate statistics were performed to correlate these findings with other data such as CD4/CD8 ratio, R-2-macrophilic index, soluble interleukin-2-receptor and p24 antigen.

Conclusion: Although IgG1 titres showed a significant difference between AIDS patients and patients without AIDS, the subclass antibody pattern in follow-up sera showed no correlation with clinical course.

Th.B.P.174 SALIVARY IgA TO HIV IN PATIENTS WITH OR AT RISK OF AIDS

Ngw E., Kwevinda A., Davelar E.

+ Institute of Immunology, University of Natal, Durban, Natal, South Africa
+ Institute of Experimental Pathology and Therapy, Subunit, Hungary

Objective: To analyze the presence and diagnostic value of HIV specific serotype IgA antibodies in saliva of patients infected with HIV, and to compare it to HIV specific IgG level of the serum of the same patient.

Methods: Whole saliva samples were collected by expectoration from 15 haemofiliac (13 adults, 2 children) and 16 heterosexual men. HIV specific IgA were tested in an ELISA using monoclonal antibodies to IgA (A-5). Serum samples taken at the same time were tested in two ELISAs (Oragon and Papanicolaou-2) assay.

Results: In a (68%) of HIV seropositive adult haemofiliacs, saliva samples contained HIV specific IgA. Out of the 9 heterosexual children 6 were HIV seropositive and 5 (55%) produced salivary antibodies to HIV. Among the 16 heterosexual men in 11 cases (75%) we could detect HIV specific IgA in the saliva (in 11% of AIDS, 68% of ARC and 90% of asymptomatic patients), while all were seronegative. We could not detect salivary antibodies to HIV in seronegative individuals.

Conclusion: Testing antibodies to HIV in saliva of patients infected with HIV indicated that the virus is capable of eliciting a response in the intestinal-associated lymphoid system characterized by IgA antibodies. As an alternative, saliva may prove useful for rapid HIV antibody testing, first of all in populations in which venipuncture is difficult or contraindicated.

Th.B.P.161 HIV-ANTIGEN, VARIOUS ANTIBODIES AND T4 CELL COUNTS AS MARKERS OF CLINICAL PROGRESSION IN HIV-INFECTION

Kleinshmitt, Andrea*, Mueselke, A.*; Schauer, D.**; Schewe, S.*; Miller, W.**; Peters, G.**; Gochel, P.D.*; Brhn, V.* and Rohmann, R.**
*Med. Poliklinik der Universität München, D-8000 München, FRG; **Klinikum Zollingstrasse oder Universitäts-Heldberg, D-8000 München, FRG; ***GSP, Abt. für Molekulare Zellbiologie, D-8042 Neuberg, FRG; ****Max-von-Planck-Institut, D-8000 München, FRG

Objective: Study of serological markers as to their stability in clinical prognosis of HIV-infection.

Methods: We have analyzed 600 sera, collected from 145 HIV-infected persons during a five year period, for HIV-antigen, the presence and titers of various antibodies (anti-core, anti-nucleocapsid, anti-gag, anti-p24, anti-p18) as well as the T4 cell counts. The results were correlated with the clinical and serological (Walker model) stages of the patients.

Results: Almost all healthy HIV-infected persons exhibited the full spectrum of antibody reactivity. During the clinical progression the mean anti-p24 antibody titer decrease (LA5-sera 1:320; AIDS-sera 1:32) while the p24-antigen levels increase (30% of LA5-sera and 63% of AIDS-sera are positive). The titers of neutralizing antibodies can be correlated to those of the anti-nucleocapsid. Using selected patients as examples we show that a change in serological markers precedes clinical progression.

Conclusions: Our results indicate that the combined use of a variety of quantitative antibody, HIV-antigen and T4 cell determinations can also be of prognostic value in individual HIV-infected patients.

Th.B.P.163 PROSPECTIVE MULTICENTER CHEMOKINEMY IN HEMODIALYZING MEN IN PBC. OBSERVATION OF IMMUNOLOGICAL PARAMETERS IN A 4-YEAR FOLLOW UP

W. J. Schmalzer¹, R. Borchardt², R. Pauli³, G. for the Study Group AIDS-Sentrum in Bundesrepublik Deutschland, Berlin, FRG

Objective: To evaluate the correlation between HIV-antibody-patterns (AB), HIV-immunity (AI) and circulating immune complexes (CIC) in the course of HIV-infection.

Methods: In 1984 a prospective multicenter cohort study was started in FRG. Of a total of 432 HIV-infected homosexual men 4 groups with typical courses of HIV-infection were selected: Group 1 - 3) individuals without noticeable or only moderate progression of clinical symptoms in different stages of HIV-infection; Group 4) individuals with rapid progression to AIDS. Cohort members are examined twice a year and specimen sera taken for laboratory testing. Antibodies were tested by a peptide-ELISA (5 peptides representing different viral proteins, HIVCORE) and Western-blotting. HIV-antigen p24 was measured by capture assays (Dupont and Coitex). CIC were measured after precipitation with PMS.

Results (Serological): The typical patterns of AB, AI and CIC were seen: Individuals with a non progressing stable clinical course (even with ABC) had high titers of AB (slightly decreasing during time of observation), low titers of AI and CIC. Individuals with rapid progression to AIDS had already in the beginning of the observation low titers of AB and CIC, while AI-titers were consistently elevated. These findings may result in additional prognostic markers.

Th.B.P.165 NEUTRALIZING ANTIBODIES IN HIV PATIENTS: A 3 YEAR FOLLOW UP

Germann, Michael*, Brockmeyer, B.** and Thranhardt, O.*.

*Hiroshima Medical Virology and Immunology, **Clinic for Dermatology, University of Essen Med. School, Essen, P.R. Germany

Objective: To study the significance of neutralizing antibodies in the course of HIV infection.

Methods: Fifty one sera from 13 HIV-infected patients collected during periods of 10 to 36 months (median 31 months) were tested for their capacity to block HIV infection of 89 T lymphocyte cell cultures. After 90 minutes of preincubation at 37°C of different serum dilutions with thawed cell-associated HIV, cells were cultured for 10 days, isolated and evaluated for HIV infection by immunofluorescence. During the study period, lymphocyte counts, T4 and T8 subclasses and beta-2-microglobulin levels were also determined and the clinical status recorded.

Results: Titers of HIV-neutralizing antibodies (NT) ranged from 1:10 to 1:140 and varied by more than factor 2 (1:10 to 1:140) in only 2 persons.

NT 1:10 1:20 1:40 1:80 1:160

NT 0 0 0 0 5 (3 pat.)

T4 400-2000/ccl 4 20 7 3 (no-aid sera)

Statistical correlations to beta-2-microglobulin concentrations, T4/T8 ratios or clinical status could not be assessed.

Conclusions: Levels of neutralizing antibodies in 11 of 13 patients were unchanged for a median time of 31 months. Whether these neutr. ab. titers parallel the clinical course or are independent of the clinical status has to be determined by longer follow up and larger groups of HIV patients.

Th.B.P.162 Correlation between HIV-1 p24 Antigenemia, Anti-p24 Antibody and Neutralizing Antibody Response in All Stages of HIV-1 Infection. P.E. Topp¹, J.R. Sartin², J.S. Spector¹, J. Sack¹, J. Mical¹, J. Welzel¹, J.P. Robos¹, P.S. Sartin², and J.C. Sussell¹, 1. Mt. Sinai Sch. of Med., NY, NY 10029 USA; 2. HIV-RC, USA.

The relationship between HIV-1 p24 antigenemia, neutralizing antibody (NA) and anti-viral core protein (p24) Ab was elucidated in the sera of HIV-1 infected individuals during their progression to AIDS. All AIDS patients (836) and 68 (101/149) of the homosexual males were HIV-1(+). Of these 48 (324) who were HIV-1(+), 3 were converted in 2 years. HIV-1(-) subjects had an early but transient p24 Ag which preceded NA and anti-p24 Ab. After seroconversion, p24 Ag could not be detected. Of the 101 HIV-1(-) subjects 148 rapidly progressed to AIDS and 7 of these 148(4%) died within 2 years. In subjects with poor prognosis, NA and anti-p24 Ab appeared at the onset reaching peak levels just prior to developing AIDS and declined as AIDS clinical course worsened. p24 Ag remained undetectable in as long as there was quantifiable NA and anti-p24 Ab. Reappearance of p24 Ag in sera was associated with rapid progression to AIDS. These data suggest 1) an inverse relationship between viral antigenemia and host humoral response, 2) that the presence of both p24 Ag and anti-p24 Ab in sera is of prognostic value, and 3) multifactorial defects in the host's immune surveillance may cause loss of NA leading to increased HIV-1 replication, antigenemia and profound immune dysfunction in AIDS.

Th.B.P.164 EVALUATION OF ANTIGENEMIA, LOSS OF ANTIBODIES TO HUMAN IMMUNODEFICIENT VIRUS REVERSE TRANSCRIPTASE (RT) AND IMPAIRMENT OF CELLULAR IMMUNITY TO DEVELOPMENT OF AIDS IN DRUG ADDICTS. Ferrandis-Coca, Eduardo; Garcia Novales, J.; Fernandez, J.; Fernandez, A. and Labay J.V.

Division Immunology-Hospital General "Gregorio Marañón", Madrid, Spain.

We have studied in a prospective follow-up lasting 1 to 39 months, the evolution of HIV infection in HIV-antibody positive IV drug addicts (IVDA) seropositive serum samples from 90 IVDA were analyzed for antibodies to viral proteins (Lar-blot I) and HIV antigenemia (ELISA AG I). Results were correlated with cellular immune parameters and clinical outcome. Twenty three drug addicts (27%) who showed at the first follow-up visit a decreased number of CD4⁺ lymphocytes (<350/mm³), anergy, loss or low level of antibodies to P24 proteins (p22 RT/p24) and to GAD proteins (p55) and HIV p24 antigenemia (>50719 ng/ml), had a clinical progression towards AIDS and opportunistic infections (n=20) or a progressive course to the next stage (n=3). In contrast, 60 IVDA (63%) who showed at the first visit: p24<3500 ng/ml, normal delayed hypersensitivity response, presence of antibodies to the viral proteins (p22, p24 and p55) and absence of antigenemia, had a non-progressive course. There were no significant changes in the above parameters throughout the follow-up study in either group. There was no significant difference between the clinical status of the two groups at the first visit. Drug addicts with AIDS at the first visit (n=77), showed a substantial lowering of CD4⁺ cell levels and no significant changes in the others parameters throughout the follow-up. The loss of RT antibody as well as the other above described predictive markers may be early indicators of the progression of virus infection and may have diagnostic and prognostic value.

Th.B.P.166 PREVALENCE OF HIV-1 P-24 ANTIGEN (AG) IN DIFFERENT POPULATIONS AT RISK FOR HIV INFECTION IN ZAIRE: A COMPARISON OF THREE DIFFERENT RISK GROUPS. N. Chabbert, S. Lina, M. Kissa, M.R. Ryder, R.*.

Ndumu, A.C. Quinza, T.C., et al; Projet SIDA, Kinshasa, Zaïre;

**NAID, NIH, Bethesda, MD

Objective: To determine the frequency of HIV-1 Ag reactivity in selected Zairian (ZR) populations.

Methods: 711 patient sera and serial dilutions of 3 HIV-1 viral culture supernates (vcs) (LA101, ZR4, ZR5) were tested for HIV-1 Ag in sera and the vcs were tested on three commercially available kits (Coitex, DuPont, Abbott). Repeatedly positive samples were considered reactive for Ag.

Ag Reactivity

ZR Ag HIV-1 Antibody (+) (n=200) 12.5%

American AIDS Patients (n=7) 21 (64.9%)

DuPont and Coitex Ag assays detected in vcs in dilutions from 10 to 100 times more dilute than those detected by the Abbott assay. Additional patient samples that tested Ag positive with the DuPont assay included 7 (8.0%) of 88 ZR

antibody AIDs; 15 (16.9%) of 88 ZR hospital AIDs; 5 (17.6%) of 28 ZR AIDS

postmortem samples; 3 (12.8%) of 23 antibody-negative clinical AIDS patients; 3

(4.7%) of 74 ZR antibody-negative partners from HIV-1 discordant couples.

Conclusions: In our seroprevalence HIV-1 Ag in Zairian patients is lower than in North American patients (P<0.0001), but increases with severity of disease (seroprevalence vs. hospitalization, P<0.0002). Determination of Ag may aid in the evaluation of disease progression and HIV-1 infectious status in high-risk individuals, such as seronegative partners with AIDS-like illnesses and HIV-1 discordant couples.

Th.B.P.193 INCIDENCE OF THE AIDS DEMENTIA COMPLEX AS THE FIRST MANIFESTATION OF AIDS. A PROSPECTIVE STUDY
Abbas J, Graus F, Alon J, Miró JM(*), Galadí D(*),
Tabares E, Neurology and (*)Infectious Diseases Unit, Hospital
Clínic, University of Barcelona, Barcelona, Spain.

OBJECTIVE: To evaluate the incidence of the AIDS dementia complex (ADC) as the first manifestation of AIDS.
METHOD: From August 1987 to September 1988, 102 patients who satisfied the CDC criteria for AIDS were consecutively diagnosed. The clinical diagnosis of ADC was considered in patients who presented with dementia, no previous neurologic or psychiatric disease and no evidence of opportunistic infections or tumors in the central nervous system.

RESULTS: In six patients (5.9%) the presenting manifestation was ADC. None but one of the patients was known to be seropositive before the diagnosis of AIDS. The presenting neurologic symptoms included progressive cognitive impairment and motor dysfunction. At the time of diagnosis, HIV-1 serology was positive in serum and CSF. MRI of the head was normal in four patients, in the other two there was evidence of white matter lesions. All patients were immunosuppressed with a mean CD4 cell count of 193 per cc. (range 130-280) at the time of diagnosis was characterized by progressive neurologic deterioration. In the two patients who died, the ADC was confirmed at autopsy.

CONCLUSIONS: 1) ADC is the first manifestation of AIDS in 5.9% of the patients and represents an important cause of dementia among young adults. 2) Laboratory evidence of severe immunosuppression is invariably present at the time of diagnosis.

Th.B.P.195 NEUROPSYCHOLOGICAL FOLLOW-UP OF SUBJECTS ON AZT LICENSING TRIAL: SAN DIEGO COHORT
D.M. Koenig*, S. Grant, L. Atkinson, H. Brysk, L. McCutchan, T. Nelson, R.K. * et al.,
San Diego State University ** Univ. of California, San Diego, CA, USA

Objective: To document occurrence of dementia in the San Diego cohort of the Zidovudine (AZT) licensing trial by 24 month follow-up neuropsychological evaluation.

Methods: Thirty-two ambulatory homosexual men with the acquired immunodeficiency syndrome (AIDS) or advanced AIDS-related complex (ARC) were evaluated prior to starting zidovudine treatment with a comprehensive neuropsychological test battery. Survivors were evaluated at 6, 12, 18 and 24 month intervals with the same battery. In order to minimize practice effects, alternate versions of the tests were employed at follow-up sessions. Diagnosis of dementia was determined according to neuropsychological test performance and DSM-III criteria for dementia. **Results:** The table shows the cumulative number of subjects who met criteria for dementia at each follow-up evaluation. The cumulative total of 9 subjects represents 28% of the original sample.

Baseline	Cumulative Number of Subjects with Clinical Dementia			
	6 Months	12 Months	18 Months	24 Months

Conclusion: These results are consistent with notions that dementia is a frequent, rather than a rare complication of AIDS.

Th.B.P.197 A SYSTEM FOR STAGING THE AIDS DEMENTIA COMPLEX: CORRELATIONS WITH NEUROLOGICAL AND NEUROPSYCHOLOGICAL ASSESSMENTS
Feldman M, Rowe, B.J, Sidel, M, Sadler, A, Kulp, J, Wolf, W, Birnham, L. Memorial Sloan-Kettering Cancer Center, New York, NY, U.S.A.

Objective: To assess the utility of a clinical staging system for the AIDS dementia complex (ADC).

Methods: Based on previous criteria of cognitive and motor functional status in daily living, the ADC staging system segregates patients as: 0-normal; 0.5-subclinical or equivocal; 1-mild; 2-moderate; 3-severe; 4-stage II; 5-Infect. Dis. 1987: 1083-1088). ADC Staging was compared to neurological and neuropsychological assessments in a group of HIV-1-infected individuals at various stages of systemic infection and with various degrees of ADC. Comparisons were made in untreated patients at initial evaluation (n=168), untreated patients including multiple evaluations (n=87), and combined untreated and AZT-treated patients undergoing multiple evaluations (n=73).

Results: ADC Stage was highly correlated ($p < .001$) with salient clinical and neuropsychological assessments. For example, at combined evaluation, ADC Stage correlated with: clinical cognitive ($r = .77$) and motor ($r = .70$) ratings; clinical ($r = .80$) and neuropsychological ($r = .70$) and combined ($r = .84$) impairment scores; ADC-sensitive neuropsychological tests including finger tapping ($r = .70$), visual ($r = .63$), trail making ($r = .77$) and ($r = .70$), grooved pebbard ($r = .71$), digit symbol ($r = .69$), Trial 5 of the key word learning test ($r = .71$) and the Benton visual retention test ($r = .71$).

Conclusions: ADC Staging is a simple but useful method of patient classification for epidemiological, natural history, pathogenetic, and therapeutic studies as well as for clinical practice.

Th.B.P.194 MYELOMAPA AS PRESENTATION OF AIDS-TREATMENT WITH AZT.

Cooper, J., Sallatelli, Clara, Solanet, J., Saporiti, M., Orsato, R., La Villa, R.,
Niguarda Cal' Brande, Milano, Italy.

Paraneoplasia is frequently observed in the end stage of AIDS, vascular aplasia being found at autopsy of adult pts with AIDS. We refer here, as rarely reported, on a case of acute paraneoplasia but the clinical onset of AIDS.

Since July 1986 to January 1988, 4 males (mean age 27 yrs and drug abuse history) were admitted for aplasia and HIV infection. They complained of prolonged febrile illness and malaise before appearance of leg weakness in all and sensory symptoms in 3 pts. The first neurological examination showed hyperreflexia, white and papillar clonus, Babinski sign and in 1 pt. also gait ataxia with asterior intorcion without sensory levels. All pts had oral candidiasis, mild anemia, leukopenia, low counts of CD4 cells (mean 30x10⁶), response of CD8, particularly of CD8⁺ low T_H 1 subsets. CT scan and/or MRI showed cerebral atrophies in 4 pts, periventricular white matter change in 2 pts, spinal cord abnormalities in the dorsal tract in 2/4 pts. EEG was altered in all. CSF showed mild elevation of albumin and globulin, oligoclonal banding for anti-HIV was positive in 1 pt, 1 pt. still had band, others without response for anti-HIV, anti-EBV and toxoplasma.

The pts developed 01. lymphoblastoid cell lines and died after 6-12 months with acute AIDS. In 3 of these cases unsuccessful AZT therapy was eventually administered. Rigent cells morphology and vascular aplasia were found at autopsy. The 2 other pts are on AZT treatment since admission (12-18 months of follow up). They are free of AIDS, but their paraneoplasia is slowly progressive. Proneoplastic etiological link or different pathogenesis of aplasia may explain poor response to antiviral treatment.

Th.B.P.196 PERIPHERAL NEUROPATHIES AND HIV INFECTION / SPECTRUM AND NATURAL HISTORY.

Léon Jean-Nève, Delgout F., Hulin D., Rosenheim N., Bouche P., Chauvo R.P., Gantillon M., New J., Brunet P., Hôpital de la Salpêtrière, Paris, France.

Methods: A clinical and electrophysiological study was performed in 29 patients referred for a peripheral neuropathy between November 1986 and June 1988. CSF was examined in 21 cases. A neuromuscular biopsy was made in 12 cases. Follow-up was conducted from 3 months to 6 years.

Results: There were 27 Caucasian and 2 African males (26 homosexual/bisexual/1 African female, ranging from 27 to 58 years); 1) Six otherwise asymptomatic patients presented an inflammatory desmyelinating polyneuropathy (IDP), acute in 1 case and subacute in 5. CSF showed pleocytosis in all cases. In nerve biopsies an infiltration of the endoneurium and/or the epineurium by mononuclear cells, and sometimes microvasculitis, were seen in 7 cases. The 6 patients recovered either spontaneously (4 cases), or with corticosteroids (1 case), or plasmapheresis (1 case). In follow-up from 6 to 48 months, they all have progressed to ARC but none progressed to AIDS. 2) In 5 patients with ARC, we found 1 chronic IDP and a distal sensorimotor peripheral neuropathy (DSPN). The neuropathies remained stable to 2, 2 patients died. 3) Of the 18 patients with AIDS, 2 had a mononeuropathy multiples and 12 a painful DSPN. EKG studies indicated an isomyopathy which was predominant in nerve biopsies in 5/7 cases. Seven patients died within 6 months. The last patient had a polyradiculopathy with lymphocytic meningitis. He died and autopsy found an infiltration of the meninges and the spinal roots by a B-cell immunoblastic lymphoma.

Th.B.P.198 PHARMACOKINETIC ANALYSIS OF THE ENHANCED DISTRIBUTION OF ZIDOVUDINE INTO HARBOR CEREBROSPINAL FLUID CAUSED BY PROBENECID.

Sambak, Ronald J. and Hodaya M.A.,
University of Minnesota, Minneapolis, Minnesota, USA.

Objective: The resolution of AIDS-related neurological dysfunction during zidovudine (AZT) therapy provides a clear rationale for the importance of antiviral drug therapy in treating AIDS dementia complex. The objective of this work was to study the kinetics of AZT distribution into the cerebrospinal fluid and to examine the effect of probenecid on this distribution process.

Methods: In this study two groups of rabbits (n=3) received a single IV dose of 10 mg/kg AZT in the absence (control) and presence of a continuous IV infusion of 30 mg/kg-probenecid. Plasma and CSF samples were obtained frequently over a period of 3.5 hours, and analyzed for AZT and probenecid by HPLC.

Results: Probenecid coadministration caused a 3-fold increase in the AZT AUC_{0-3.5} in probenecid-treated rabbits when compared with controls. The AUC_{0-3.5}/AUC_{0-3.5, plasma} ratio increased from 0.152 ± 0.023 in controls, to 0.568 ± 0.022 in probenecid-treated rabbits. The CSF/plasma AZT concentration ratio during the postdistributive phase increased from 0.34±0.012 in controls to 0.65±0.12 in the probenecid-treated rabbits. A linear pharmacokinetic model, which assumes first-order transfer rates between plasma and CSF, was used to describe distribution of AZT between plasma and CSF. Analysis of intracompartamental clearance showed that the CSF exit rate constant decreased from 0.028±0.010 in control to 0.025±0.006 in probenecid-treated rabbits. **Conclusions:** The results indicate that probenecid enhances AZT distribution into the CSF by decreasing its CSF to plasma clearance.

Th.B.P.199 TRANSFUSION-RELATED HTLV-I NEUROLOGICAL DISEASE: A PUTATIVE MARKER OF DISEASE ACTIVITY AND RESPONSE TO THERAPY

Reza, H. J., Hardy, M., Politz, B., Ehrlich, S., Larson, R., Goto, J., Ball, M., Price, W., Memorial Sloan-Kettering Cancer Center, NY, *State University of New York, Syracuse, **Centers for Disease Control, USA

OBJECTIVES: To report two cases of HTLV-I neurological disease including a putative marker of disease activity, and response to therapy. **Methods and Results:** A 2 year old Caucasian male, resident in the US, developed HTLV-I associated myopathy (HM) 6 months after multiple transfusions for fulminant pancreatitis. Investigations were remarkable for raised concentrations of δ -microglobulin (δ M) (Pharmacia, Sweden) for raised CSF than serum. Treatment with aldofluorolone and later with clonazepam was ineffective, whereas corticosteroids lead to minor improvement. The clinical response to therapy was reflected in a fall in the δ M concentrations. In addition, during the 3 months after the first, it was transiently positive by ELISA and is now positive only by polymerase chain reaction. Her illness began 3 months after her partner's and consisted of a mild transient peripheral neuropathy.

Conclusions: This is the first documented case of transfusion-related HM in the US. The change in δ M concentration may be useful as a marker of therapeutic response. The second case illustrates the difficulties in serological diagnosis and suggests that peripheral neuropathy may be an early manifestation of HTLV-I.

Th.B.P.201 THE EPIDEMIOLOGY OF AIDS-RELATED NEUROLOGICAL DISEASES

Wilder, Mary Ann; Kemp, G.P.; Neal, G.M.; Payne, S.P.;

*California Department of Health Services, Rutherford, CA.

**San Francisco Department of Public Health, San Francisco, California, USA.

Objective: To describe the epidemiology of diseases of the central nervous system (CNS) in AIDS in San Francisco (SF). **Methods:** We analyzed the demographic and transmission categories of 5634 AIDS cases reported in SF from 1981 through 1988 with respect to CNS diagnoses of toxoplasmosis, primary lymphoma of the brain, progressive multifocal leukoencephalopathy, cryptococcal meningitis, and HIV encephalopathy. Median survival was calculated using the Kaplan-Meier product-limit method. **Results:** 415 (7.1%) AIDS patients were initially diagnosed with a CNS disease. CNS diseases as an initial diagnosis rose significantly from 1.9% of total cases in 1982 to 9.4% in 1988 (p<.001). 770 (13.2%) AIDS patients had a CNS disease at some point during their illness. The mean age of AIDS patients aged >20 with CNS disease was 38.2 years compared with 37.5 years for persons without (p<.001). Intravenous and intramuscular drug users were more likely to have a CNS disease (26.5%) than gay men with (15.5%) or without (12.5%) intravenous drug use (p<.001). There were no significant differences in gender or race/ethnicity distribution among patients over having CNS disease vs. those without. Median survival for AIDS patients with CNS disease (6.8 months) was significantly shorter than that for patients without (12.9 months) (p<.001).

Conclusion: CNS diseases are increasingly common among AIDS patients. AIDS patients who develop CNS diseases are more likely to be older and be intravenous drug users. Survival is shorter for AIDS patients with CNS disease.

Th.B.P.203 NEUROLOGICAL INVOLVEMENT IN GROUP IV HIV+ PATIENTS: NEUROPHYSIOLOGICAL AND CLINICAL DATA

Monetta, Francesco; Grappi, A.; Di Felice, M.;

Colao, M.G.; Bartolotta, G.; Ghislini, P.; Fazio, P.;

*Ist. Mal. Infective Ospedale Garibaldi; **Ist. Mal. Nervose e Mentali Università Cattolica, Roma, Italy.

For purposes of prognosis and therapy, we sought to identify the initial site where HIV begins to exert its deleterious effect. The subjects, all asymptomatic, were in the neurological period of virus, where B IVCS and D IVCS or IVA patients (pts.). The spinal and cortical SEP responses were recorded during 10 nerve stimulation. The electrophysiological results were compared with clinical assessment and serum and CSF HIV markers. In both groups we observed a slowing of nerve conduction along the active afferent pathway. While this was not significant at the level of the peripheral nerve, it became marked and highly significant at the CNS level for about 1/3 of the IVCS or IVA and for 2/3 of the IVCS pts.. The major part of the delay occurred in the mid and lower medullary tract. This results agree with neuroanatomical findings from post-mortem examination of AIDS pts., similar to that described for other lymphotropic virus and oncogenic viruses. The higher incidence of electrophysiological alterations in the CNS of group IV has already been described in pts. with neurological deficit; however, it has not been satisfactorily documented in neurologically asymptomatic HIV pts.. Our findings point to the possibility of using our approach to identify those HIV pts. who might best benefit from early treatment.

Th.B.P.200 NEUROPHYSIOLOGICAL FOLLOW-UP OF 1787 PARTICIPANTS IN THE MULTICENTER AIDS COHORT STUDY

Zaback, Richard A.; Miller, E.S.; Sata, P.;

Stulen, G.; Cohen, J.; Becker, J.; English, P.;

McArthur, J.***; Los Angeles, California; **Johns Hopkins University, Baltimore, Maryland; ***Bartowaters University, Chicago, Illinois; University of Pittsburgh, Pennsylvania, U.S.A.

Objective: To determine the frequency and severity of neurologic involvement in HIV infection in MACS participants. **Methods:** 1787 homosexual/bisexual men were enrolled in the Neurophysiological substudy. 288 were enrolled in Baltimore and 238 in Chicago in 1986, and 209 in Pittsburgh, and 1041 in Los Angeles in 1987. A 20 minute screening battery of neurophysiological tests and a 22 min questionnaire on neurologic symptoms were administered at each visit, approximately 6 months apart.

Results: 600 patients on P-P Screen Mean # of Neurologic Symptoms

System	Visit 1	N	Visit 1	Visit 2
Seronegativity	187	5	1.0	0.4
Seropositivity	416	2.6	4.0	1.1
Seroreverter	122	2.5	7.7	1.3
AIDS	75	6.0	10.0	1.8

Conclusions: Asymptomatic seronegativity and seroreverters did not differ from seronegatives on the P-P tests either at Visit 1 or Visit 2. In seroreverters, although fewer neurologic symptoms were reported on the P-P screening tests as well as reporting more neurologic symptoms at each visit.

Th.B.P.202 NEUROPHYSIOLOGICAL FOLLOW-UP IN PATIENTS WHO HAVE PROGRESSED TO AIDS: THE MULTICENTER AIDS COHORT STUDY (MACS)

Miller, E.A.; Miller, R.M.; Maravice, J.L.; Cohen, B.***; Becker, J.***; Sank, A.L.; Multicenter AIDS Cohort Study, Johns Hopkins Medical Institutions, Baltimore, U.S.A.; Los Angeles, CA; *Northwestern University, Chicago, Ill.; **University of Pittsburgh, PA, USA

Objective: To evaluate changes in neurophysiological (NP) performance in participants in the Multicenter AIDS Cohort Study (MACS) who progressed from asymptomatic (CSC group I/II) to AIDS (CSC group IV).

Methods: Standardized NP testing was available for 7% participants in the MACS Neurophysiological Study who had developed AIDS. Of those, 30 had at least one previous NP evaluation prior to developing an AIDS-defining illness. The performance of these participants was compared with that of 20 age and education matched seronegative (SN) controls. NP testing included tests of attention/concentration, memory and word learning and psychomotor speed, previously shown to be sensitive to HIV-related neuropathology. Individual performance was classified as impaired if scores on one or more tests were below 2 standard deviations based on SN controls. 10 of the participants with AIDS were taking zalcitabine (AZT).

Results: The average number of months between initial and follow-up testing was 12 months (range 4.7-34.5 months). At the initial visit, 1/20 (5%) participants had impaired NP performance, as compared with 4/26 (15%) at the follow-up visit with AIDS. Comparison of group means at initial and follow-up using one-tailed, non-paired t-tests, showed a significant decline in only 1/6 tests (Crawford Pegboard, non-dominant hand). There was no significant difference between the performance of SN controls and participants with AIDS in any of 17 tests used.

Conclusions: These findings demonstrate that progression to AIDS in this well-defined cohort was not associated with significant decline in cognitive functioning as measured by standardized NP testing. Therefore, although fewer neuroimaging may be necessary for the development of HIV-related neuropathology, it may not be a sufficient criterion.

Th.B.P.204 EFFECT OF MANNITOL IV INFUSION ON DISTRIBUTION OF ZIDOVUDINE BETWEEN PLASMA AND CEREBROSPINAL FLUID IN RABBITS

Wang, Yinfeng; Hodge, M.A.; Sawchuk, R.J.

University of Minnesota, Minneapolis, Minnesota, USA

Objective: This work was performed to examine the effect of intravenous infusion of mannitol on the penetration of zidovudine (AZT) into the cerebrospinal fluid (CSF) in order to study the kinetics of AZT transfer between plasma and CSF. **Methods:** Rabbits were assigned either to a control group (n=3), receiving a single IV dose of 1 mg/kg AZT alone, or to a mannitol-treated group (n=3), receiving a single IV dose of 10 mg/kg AZT as well as a continuous IV infusion of 1.5 g/kg-hr mannitol following a bolus of 10 mg/kg of 25% mannitol. Plasma, CSF and urine samples were obtained frequently over a period of 3.5 hrs and analyzed for AZT by HPLC.

Results: The results showed that the AUC_{0-3.5h}/AUC_{0-3h} ratio increased from 0.15 ± 0.02 in the control rabbits to 0.45 ± 0.089 in the mannitol-treated rabbits. The CSF/plasma AZT concentration ratio during the postdistributive phase increased from 0.24 ± 0.03 in control to 0.68 ± 0.24 in the mannitol treated rabbits. A linear pharmacokinetic model, which assumes first-order transfer between plasma and CSF, was used to analyze the data.

Conclusion: This study demonstrates that changes in CSF/plasma AZT concentration ratios caused by mannitol administration can be explained by alterations in intercompartmental clearance of AZT.

Th. B.P. 247 MODIFICATIONS BIOLOGIQUES DU LCR AU COURS DE L'INFECTION PAR LE VIH

SAINTE-MARIE, L. VERONE, A. CALOGERO, C. TOUPOURNE, F. LAFRANCOISE JM., QUINCY O., TOUPOURNE J.

Unité P. Hospital Edouard Belin 59047 Lille Cedex 03, FRANCE.

1 Laboratoire d'immunologie, Hôpital Neurologique 69534 Lyon Cedex 03, FRANCE.

Objectif: Définir le profil biologique d'évolution du LCR au cours de l'infection par le VIH.
Méthodes: Étude chez 43 patients VIH+ (20 patients avec complications neurologiques et 23 sans complications) des modifications biochimiques et protéiques du LCR par la recherche des enzymes lactate/déshydrogénase (LDH) et adénosine déaminase (ADA) associées à la présence de bandes oligoclonales (BO), d'arborose et VIH confirmée par Western-blot de l'échantillon de LCR.

Résultats: Les perturbations cellulaires lymphocytaires et/ou cytotoxiques inflammatoires, l'augmentation de la protéinase avec modification de la bande arboréogène LCR et d'un système protéolytique d'arborose en présence de bande arboréogène, sont observées associées au VIH au cours de l'infection.

En l'absence de toute modification biochimique et de la bande arboréogène, nous observons les enzymes lactate/déshydrogénase et adénosine déaminase et VIH à des titres élevés. L'évolution de la bande de la bande ADA se traduit par une diminution significative de ses activités.

Conclusion: L'absence de bande arboréogène et de la bande arboréogène, sont observées associées au VIH au cours de l'infection.

Les enzymes lactate/déshydrogénase et adénosine déaminase et VIH à des titres élevés. L'évolution de la bande de la bande ADA se traduit par une diminution significative de ses activités.

Conclusion: Au titre élevé de l'enzyme les perturbations biochimiques du LCR sont plus fréquentes et plus marquées. Ces résultats montrent que l'évolution du LCR est plus précoce.

Th. B.P. 249 CLINICAL-PATHOLOGICAL FEATURES OF HTLV-1 ASSOCIATED MYELOPATHY (HAM) IN AIDS

OSSENBERG, M.; BERN, BRUCE J.; ARONOW HA; HARDY, M; CROFTIN, K; PRICE, RW. Memorial Sloan-Kettering Cancer Hospital, New York NY USA

Objectives: To delineate the clinical and pathological features of two patients infected with HIV-1 and HTLV-1, both of whom had HAM.

Methods and Results: Two black 25 patients, both with AIDS, were found to have HTLV-1 antibodies in the serum. The first patient had had symptoms of a myelopathy in 1973, 9 years before developing AIDS. His leg weakness was clinically stable until the last few months of life. The spinal cord pathology consisted of marked atrophy, meningeal fibrosis and small vessel proliferation without perivascular infiltrates or vacuolar myelopathy. The brain showed a multicystic-cell encephalitis with detectable HTLV-1 p24 antigen. The second patient had a myelopathy that developed in the terminal phase of AIDS and disseminated prostatic cancer. The spinal cord pathology was notable for meningeal fibrosis, proliferation of small vessels and minimal perivascular perivascular infiltrates but again without vacuolar myelopathy. The brain showed white matter pallor and astrocytosis without detectable HTLV-1 p24 antigen.

Conclusions: HAM may occur and progress in AIDS patients despite the concomitant immunodeficiency. Its clinical features are indistinguishable from myelopathy but the pathological changes are separate. The relative lack of inflammation may pertain to "burnt out" disease or the effects of immunodeficiency. Whether HAM pursues a different clinical course in HIV-1 infected patients awaits larger studies.

Th. B.P. 251 INTERNET DE LETUQUE ULTRASTRUCTURALE LOIS DES NEUROPATHIES PERIPHERIQUES ASSOCIEES A L'HYV

BIGOT, J.P., MEYER P., P. LAURENT, J.P. SAHJ, P. STOEHLER, M. MICROT

* Clinique Médicale et des Maladies Infectieuses - ** Laboratoire de Pathologie Cellulaire - Centre Hospitalier Régional - Clermont - France

Objectif: L'atteinte neuropathique périphérique possède un pronostic incertain. Nous avons étudié la relation entre la fréquence de survenue des inclusions ultrastructurales (IUR) au microscope électronique, et la gravité de l'infection.

Méthode: 19 patients atteints d'étapes de neuropathie périphérique ont été étudiés: 5 SIDA, 2 HAM, 2 lymphomatiques. Dans tous les cas, l'immunohistochimie a confirmé le neuropathie et une neuropathie musculaire radicaux. Nous avons compris une étude de microscopie optique et électronique.

Résultats: Chez chaque patient, il a été noté une atrophie musculaire de type neuropathique associée à une neuropathie axonale ou axone démyélinisation. L'aspect ultrastructural à l'échelle des IUR dans les fibres nerveuses périphériques était 7 cas sur 8. Le pourcentage de vaisseaux contenant des IUR a été corrélé de façon significative avec l'intensité de l'atteinte neuropathique. Le stade clinique, et le rapport IUR.

Conclusion: Cette étude confirme l'intérêt de la mise en évidence et de la quantification des IUR chez les patients HIV+ atteints de neuropathie. Une fréquence de survenue parallèle associée au stade évolutif de la maladie.

Th. B.P. 248 PRODUCTION INFECTION BY HIV OF HUMAN CENTRAL NERVOUS SYSTEM (CNS) TISSUES

BUCKDA, HERBERT. Neurological Institute, University of Vienna, Vienna, Austria.

Objective: To clarify frequency, cellular tropism, and relation to disease pathology, of productive HIV infection in human CNS.

Methods: Immunocytochemistry for HIV p17, p24, and gp41, for specific cellular markers, and for opportunistic pathogens, on serial sections of formalin-fixed, paraffin-embedded CNS autopsy tissue of 57 patients (56 with AIDS) with various pathologies.

Results: HIV antigens detectable in 37 cases (65%). In 26 cases large amounts of virus in lesions histopathologically diagnosed as HIV-induced (Buckda, Acta neuropathol. 77:225, 1989), including vacuolar myelopathy and leukoencephalopathy. In 7 cases isolated immunoreactive cells unassociated with pathology. In lesions of opportunistic infections HIV cells absent (24 cases) or rare (6 cases); only in 3 cases massive HIV coinfection. Immunoreactivity limited to cells with phenotype of microglia or macrophage.

Conclusions: Productive HIV infection of the CNS is frequent in AIDS, with the microglia/macrophage as target. Early HIV production without associated pathology involves isolated microglia. Massive production of HIV is invariably associated with prominent and specific histopathology. HIV pathogenicity in the CNS appears as microglia/macrophage-mediated, possibly by means of productively infected cells of myelinoctonic factor(s).

(Supported by the Lord Mayor's Medical-Scientific Fund, Vienna)

Th. B.P. 250 CAN HIV-1 ALONE INDUCE A SUBACUTE ENCEPHALITIS? A HISTOPATHIC AND IMMUNOCYTOCHEMICAL STUDY

DELMONTE, M.; RAY, R.; HANCOCK, R.; SACHDEV, J.S.; KILGUS, C.; HAN, J.-W.

* La Salpêtrière and ** Institut Pasteur, Paris, France.

Objective: 1) To study the relationship between the topography of microglial nodules and multinuclear giant cells in a series of 30 patients with HIV-subacute encephalitis and their higher cortical function. 2) To determine by immunocytochemical methods how often HIV is associated with other pathogens (infections/tumors).

Methods: We studied 20 paraffin and 6 cellulose sections (250 nm) in 30 cases and in 20 of them we reviewed numerous from sections (10 nm) for immunoreaction of HIV-1 antigen (immunoperoxidase, DAB, and propogin vapour).

Results: Study per case had less than 10 microglial nodules. Multinuclear giant cells were observed in only 22/30 cases and 7/24 had less than 5 giant cells. Giant cells and microglial nodules were not spatially linked and neither was their number linked to other lesions. Microglial nodules were significantly more frequent in the basal ganglia and brain stem. Giant cells predominate in the pallidum and HIV-1 antigen. The presence of HIV-1 antigen did not depend on the density of microglial nodules or giant cells. In all cases, HIV-1 was detected in subacute encephalitis associated with opportunistic infection or lymphoma. There were no instances of subacute encephalitis associated exclusively with HIV-1.

Conclusions: 1) The topography of subacute encephalitis is mainly basal. 2) Protein tumor in structure known to be involved in subacute encephalitis. 3) Opportunistic infection or lymphoma may either facilitate the entry of HIV-infected cells or trigger the replication of HIV-1 in latently infected reservoir cells of the brain and thereby lead to subacute encephalitis.

Th. B.P. 252 EARLY ASTROCYTIC INVOLVEMENT IN MEDULLA

BERNARDI, DOMENICO, B. MARRAS, G. MARRAS, F., FAUSTINI, G., STAGI, G., FRANCESCHI, D., DONATI, G.

* Laboratorio di Strutturazione, Istituto Superiore di Sanità, Roma; ** Istituto di Malattie Infettive, Università di Pisa, Italia.

In the studies on the neuropathology of AIDS, astrocyte involvement has generally received little attention. The frequency and diffusion of astrocyte hyperplasia in cerebral tissue, however, better correlates with the frequency and extension of CNS involvement in AIDS, especially when compared with the incidence of other lesions, such as microglial nodules and multinuclear giant cells, which are considered the hallmarks of neurotoxicity. Here, we studied the patterns of astrocyte involvement on paraffin sections from the cerebral tissue of 9 subjects, including 4 patients with diffuse CNS involvement before the entry, by the immunohistochemical demonstration of GFAP. The most frequent modification was an increase in number and size of astrocytic foot processes around blood vessels, which was present in 8 out of 9 cases, was often associated with clustering of astrocytes around the vessels and was sometimes the only histological abnormality present in the grey matter. A diffuse increase in astrocytes was less frequent, especially in the grey matter. Microglial nodules, which were present in 2 cases, did not appear to be composed of astrocytes. Although around them an increase in number and thickness of astrocytic cell processes was often evident, in 3 cases hyperplasia of astrocytes was observed. The finding of astrocytic foot processes hyperplasia, in absence of histopathological signs of other neural cell type involvement, suggests that astrocytes may be involved early in the neuropathology of AIDS.

Th.B.P.253 ETUDE PAR RESONANCE MAGNETIQUE DES ATTENTES CEREBRALES AU COURS DU SIDA DE L'ADULTE: CONFRONTATIONS AUTOPSIQUES.

Trotet J.M.,Bertrand-Tronca C.,Lévesque R.,Vassak M.,Mathisen L., Gray F.,Mikol J.,Vedrine C.
O.S.U.L. Pasteur,Paris,France.

Objectif: comparaison entre le diagnostic visuel sur l'image de Résonance Magnétique (RM) et l'anatomie du cerveau post-mortem.

Méthode: à partir de 300 cerveaux examinés après cas comportant RM anatomotopographique traditionnelle et étude après congélation par hybridation in situ et immunomarqueage. **Résultats:** dans certains cas le contraste est net (atoude cortico-sous-corticales, LEMO à l'encéphale vital), dans d'autres est plus difficile (syndrome, cryptococcose). Cependant le problème à plus délicate reste celui des anomalies effuses: signification des augmentations effuses de signal des centres postérieurs de la chaine ventriculaire? les tumeurs ventriculaires, les hyperintensités des zones de haut signal (S-20) sontomies toxiques ou desinfectées? analyse des attitudes de la base postérieure?

Conclusion: la confrontation anatomo-radiologique permet d'apporter dans la compréhension de ces divers troubles. Bien souvent les attentes ne sont pas inversées et l'on retrouve 2, 3, voire 4 signes à l'heureux anatomie.

Th.B.P.254 APPORT DE L'IRM AU DIAGNOSTIC PRECOCE DES COMPLICATIONS ENCEPHALIQUES DU SIDA

P. J. Tronel, M. Thibaut, A. E. Cabas, R. Laveyrie, J. M. Bigot, G. Vignaud, Institut Pasteur, Paris

Objectif: déterminer l'apport de l'Imagerie par Résonance Magnétique (IRM) au diagnostic des complications encéphaliques: encéphalites sous-acute ou lésions focales, infectieuses ou tumorales.

Méthode: A partir des dossiers des 300 derniers patients hospitalisés comparaison IRM/Tomodensitométrie (TDM). Confrontation avec les résultats des épreuves thérapeutiques, des biopsies stéréotaxiques et des autopsies.

Résultats: deux tableaux cliniques peuvent être opposés: 1) lésions focales de fibres et de troncules neuro-axonaux - détérioration progressive de début insidieux.

2) lésions de type "la TOM est souvent suffisante pour reconnaître l'existence d'une ou plusieurs lésions focales, cependant la section précoce des lésions tomographiques est le fait de l'IRM avec ou sans Gadolinium.

Dans le second l'IRM permet de différencier lésions focales et diffuses, parcellaires ou multiples. Les lésions focales sont identifiées par des plaques discontinues sous-corticales (leuco-encéphalites à papovirus), lésions punctiformes ou linéaires disséminées, hyperintenses diffus des centres ovales, avec ou sans dilatation ventriculaire. **Conclusion:** essai de mise en place d'un algorithme de décision.

Th.B.P.255 SINGLE PEROXIDASE POSITIVE TROPHIC (SPPT) FINDINGS IN HIV INFECTION. PREVALENCE ROLLS.

Pignatelli F.,Papa F.A.,Galassi S.,Bertetto P.V., Ricci M.A.,Viano Giuseppe et al.

U.S.L. IRV10-Corrienti/Roma, Accademia Med. Inst. "G. Gemelli" Hosp. Neurology Dept.,

"G. Gemelli" Hosp. Infectious Dept., Rome, Italy.

OBJECTIVE: To evaluate the sensitivity of SPPT cerebral blood flow studies to disclose brain involvement in HIV infection in comparison to CT scan and MRI findings.

METHOD: This study included 25 patients 17 AIDS, 4 HIV and 4 HIV seropositive all with neurologic signs or symptoms. Local cerebral blood flow was evaluated by 99mTc-DTPA SPPT and related to clinical, CT and MRI findings.

RESULTS: SPPT showed pathological findings consisting in cortical thinning, cortical focal hypoperfusion and basal ganglia hyperfusion in 20/25 cases. Cortical hypoperfusion was more frequently observed in frontal cortex (16/25). CT was positive in 14/25.

CONCLUSIONS: Our preliminary data on SPPT cerebral blood flow studies in HIV related cerebral disease are encouraging. However results are of course not specific, but they may be very sensitive in showing pathological dysfunction at an earlier stage than CT or even MRI, even if the possibility of "false negatives" has to be taken into account. There in, thus, the concrete hope to disclose neurological involvement in asymptomatic HIV seropositive patients.

Th.B.P.256 BRAIN MAGNETIC RESONANCE IMAGING (MRI) FINDINGS IN HIV INFECTION.

Tosti V.,Giordano R.,DiGiacomo S.,Bucci M.A.,Molinaro V.,Viano Giuseppe et al.

U.S.L. IRV10-Corrienti/Roma, Accademia Med. Inst. "G. Gemelli" Hosp. Neurology Dept.,

"G. Gemelli" Hospital, Dept. Neurology, Rome, Italy.

OBJECTIVE: To define MRI patterns of brain involvement in HIV infection and to correlate these findings to the clinical, pathological and CT brain data.

METHOD: MRI and CT of the brain were performed in 107 HIV positive patients with neurological signs or symptoms. MRI findings were compared to the clinical picture in all patients and, in 20 of them, also with the pathological diagnosis.

RESULTS: The following MRI patterns in 24 weighted images were observed:

A) an enlargement of the cortical sulci and ventricles was detected in most patients independently to correlate lesions within the white matter were observed in HIV seropositive only. Cholinergic or multiple-hypertensive areas localized in the cortical and subcortical regions were present in primary CNS lymphoma and in neurocysticercosis. D) multiple, focal hyperintense areas in the deep white matter of fronto-parieto-occipital lobes were noticed in multifold progressive leuco-encephalopathy. E) small, solitary or multiple subcortical hyperintense lesions were detected in different modes but any specific correlation was found in our patients.

CONCLUSIONS: MRI patterns abnormalities, although being largely useful in suggesting differential diagnosis in HIV patients with neurological symptoms, cannot be considered as pathognomonic. MRI seems to be a highly sensitive method for diagnosis of brain involvement, particularly for the early detection of HIV encephalopathy.

Th.B.P.257 CEREBRAL ATROPHY IN HIV-1-INFECTED PATIENTS: RELATIONSHIP TO NEUROLOGICAL AND NEUROPSYCHOLOGICAL MEASURES

Reardon, D., Bickel, J., Bickel, J., Bickel, D., Price, R.W. Memorial Sloan-Kettering Cancer Center, New York, NY, USA

OBJECTIVE: To evaluate the relationship between cerebral atrophy, assessed by computerized tomographic (CT) head scans, and neurological and neuropsychological impairment in HIV-1-infected patients.

METHOD: 34 patients (age 40) received a total of 42 CT scans in the context of clinical evaluation. Patients were examined neurologically, staged with respect to the severity of the AIDS dementia complex (ADC), and received neuropsychological tests. Using a set of predefined "standards", scans were assigned numerical ratings corresponding to normal, mild, moderate, or severe with regard to sulcal, ventricular, and Sylvian fissure enlargement. Ratings were summed to derive an overall index of atrophy.

RESULTS: Cerebral atrophy increased significantly with increasing ADC (p<0.05); moderate to severely demented patients had significantly greater atrophy than equivocal or mildly demented patients (p<0.05). Atrophy correlated with the following neuropsychological tests: Trail Making A (p<0.05) and B (p<0.05), Digit Symbol (p<0.05), Verbal Learning (p<0.05), and Timed Bait (p<0.05).

CONCLUSIONS: Mild cerebral atrophy may be seen in patients without clear functional neurological impairment, while more severe atrophy correlates with progressive ADC and worsening neuropsychological performance.

Th.B.P.258 AUTORADIOGRAPHIC ANALYSIS OF AIDS BRAIN LESIONS WITH AN ¹²⁵I-PERIPHERAL TYPE BINDING/ASSOCIATED BINDING SITE ANALOG

Brinley, M.C., Johnson, J., Cornu, P., Sedwinski, V., Brille, M., Kivert, D., Daverkos, C.,

Helm, D. Hôpital de la Salpêtrière, Paris, France.

OBJECTIVE: To describe the brain localization of ¹²⁵I-AIDS encephalopathy.

Methods: Twelve brain samples from 5 cases of AIDS subacute encephalopathy and from 3 control brains were frozen in isopentane and processed for ¹²⁵I-AIDS as previously described (1, 2, 3). An irreversible (¹²⁵I-PK 14105) ¹²⁵I-AIDS analog was used to determine the microscopical localization of these binding sites (A1-A5 stained centers). In addition, the following studies were performed on serial sections: acid phosphatase, Lux-13, Lux-15, K105, K1107, and 6FAP and anti HIV (p16 and p25) antibodies.

Results: In AIDS subacute encephalopathy, the emission autoradiography of irreversibly bound ¹²⁵I-PK 14105 (total label either single cells or cell clusters grouped to form microglial nodules or perivascular cuffs. Other techniques suggested a predominant macrophage localization of these sites.

Conclusions: ¹²⁵I-AIDS sites were labeled in HIV+ as in HIV- brains.

Conclusion: ¹²⁵I-AIDS sites label macrophages in AIDS encephalitis as they do in other neurologic diseases (3), and not the presence of HIV-1. The available positions (¹¹¹In-PK 11195) and ¹²⁵I-PK 11195 emitting ligands of ¹²⁵I-AIDS may render possible their in vivo detection and help to the diagnosis and study of AIDS subacute encephalitis.

Th.B.P.312 EFFECT OF ENTERAL NUTRITIONAL THERAPY ON BODY CELL MASS IN AIDS.

Evans, Robert, Koster, D.P., Cuff, P., Thomas, A.R., Smith, R., Hayward, S. & Lally, Raymond. *Harlem, Columbia University, New York, NY, USA.*

Objective: To determine if enteral nutritional therapy can successfully restore body cell mass in malnourished AIDS patients to decrease morbidity and associated with improvement in rates of infectious disease.

Methods: Six AIDS patients who had lost more than 10% of weight, at less than 80% of estimated needs, had adequate tylose absorption, and no severe active complications were chosen for study. Nutritional therapy was provided via percutaneous endoscopic gastrostomy tube (PEG), and consisted of a hypotonic protein solution (Nutrena HN, Orléans France). Nutritional assessments were performed 1 month pre and 2 months post and included determinations of total body potassium (TBK), a measure of body cell mass, in a whole body counter, total body and extracellular water volumes by isotope dilution, and body fat content by anthropometry. In addition, selected immune studies were performed subsequent to enteral nutritional therapy.

Results: The values for TBK increased significantly in all patients. There was a more variable effect upon body weight and body fat content. No significant changes were seen to total CD4+ lymphocyte counts or serum immunoglobulin concentrations.

Conclusions: Enteral nutritional therapy can promote body mass regain in AIDS. Successful nutritional therapy is not associated with obvious health or immune function.

Th.B.P.313 LOW VITAMIN B₆ LEVELS AND IMMUNE SUPPRESSION IN HIV-1 INFECTION.

Morono-Alvarez, E.,* & Diaz, R.S.,** Van Hiel, T.W.,* Flitscher, M.A.,** Kayan, R.M.,* Kadoctor, C.G.,* Furchtgott-Rot, D.*

*Department of Epidemiology & **Biopsychosocial Center For Studies of AIDS, University of Miami, School of Medicine, Miami, Florida, USA.

Objective: To determine vitamin B₆ status and its relationship with immune decline in HIV-1 infection.

Methods: Subjects were 50 homosexual males aged 20-50 years who tested HIV-1 seropositive by Western blot and who remained asymptomatic other than lymphadenopathy. Pyridoxine status was evaluated by assessing stimulation of red cell aspartate aminotransferase. CD4 cell number and immunoglobulin (IgA) stimulation were performed by standard techniques.

Results: Thirty-five percent of study participants showed overt pyridoxine deficiency and an additional 10% marginal deficiency in spite of adequate B₆ dietary intake. A variable degree of depression and immune dysfunction was also noted; when correlated with pyridoxine status, individuals with vitamin B₆ deficiency had uniformly lower CD4 cell counts than were participants with normal vitamin B₆ levels. However, the response of peripheral blood lymphocytes to phytohemagglutinin (PHA) demonstrated significant correlation once the entire continuum of vitamin B₆ levels; subjects with the most deficient vitamin B₆ status had the poorest response to PHA (p<0.05, p<0.004).

Conclusions: Pyridoxine deficiency occurs relatively frequently in HIV-1-infected individuals and may play a significant role in immune dysfunction and disease progression in the HIV-1 continuum.

Th.B.P.314 NUTRITIONAL KNOWLEDGE, HEALTH BELIEFS AND PRACTICES IN THE HIV-1 INFECTED SUBJECT.

Morono-Alvarez, E., Furchtgott-Rot, D., Van Hiel, T.W., Flitscher, M.A., Kayan, R.M., Kadoctor, C.G., & Diaz, R.S.,**

Center for the Biopsychosocial Study of AIDS, University of Miami School of Medicine, Miami, Florida, USA.

Objective: To assess nutritional beliefs and knowledge in HIV-1 positive gay males.

Methods: Seventy-five HIV-1-infected homosexual males, asymptomatic other than generalized lymphadenopathy, were interviewed to determine the nutritional health beliefs and knowledge using a standard questionnaire.

Results: 50% of the participants changed their diet at the time of, or subsequent to diagnosis of HIV-infection. The most common alternatives were decreased intake of red meat (73%), whole milk (33%), butter (31%) and alcohol (31%). Increased intake of vegetables (33%), fruits (32%), seafood (30%) and whole wheat breads/cereals grains (23%); 87% of the participants felt that vitamin and mineral supplements could favorably influence their immune function with 59% reporting an increase in their requirement of such supplements since diagnosis. 90% did not know the daily requirements of essential vitamins and 50% concerning supplements did not know the amount they were consuming. The most frequently reported sources of nutritional information and counseling were friends (79%), newspapers and magazines (68%). Approximately 80% of HIV-1-infected patients view nutritional and dietary issues of high importance in maintaining their immune function and asymptomatic status. **Conclusions:** Subjects adopt strategies based upon a poor information base and these strategies may, at times, be ill-advised. Practitioners must provide the HIV-1-infected patient with basic nutritional information.

Th.B.P.315 THE ROLE OF ZINC IN HIV-INDUCED IMMUNOSUPPRESSION.

Falouts, Jilina, Thoulas, C., Deutsch, G.

Montreal General Hospital, McGill University, Montreal, Canada

Objective: HIV infection causes a progressive but variable rate of CD4+ cell depletion. Confounders may thus be important in disease progression. Zinc (Zn) deficiency causes reversible cell-mediated immune (CMI) abnormalities similar to those observed in HIV disease. We determined serum Zn levels and studied its functional role in HIV-infected subjects.

Methods: Serum Zn was measured in 200 subjects and controls (CDC HIV classification) by atomic absorption spectrophotometry. T cell subsets and serum albumin were assessed. Proliferative responses of isolated mononuclear cells (PMMC) to phytohemagglutinin (PHA) were determined in 36 HIV positive subjects. Statistical analysis was based on Student's t-test between groups and regression analysis between variables.

Results: Groups IVb, IVc, and IVd had serum Zn levels significantly less than in HIV negative controls (96±12.8, 34±12.0, and 31±12.0 μmol/l; p<0.05, p<0.01, and p<0.001 respectively). A significant correlation was found between Zn (range 3-23.5 μmol/l) and the proliferative response of PMNC to PHA (p<0.01) but not between the number of CD4 cells (range 16-765/microl) and the proliferative response to PHA. There was no correlation between serum albumin (range 32-51 g/l) and PHA response.

Conclusions: Serum Zn decreases significantly in advanced HIV disease, and is correlated with the proliferative response to PHA. The absent correlation between albumin and PHA response suggests that the decreased serum Zn is of multifactorial origin. The lack of correlation between serum albumin and CD4 concentration requires further investigation. Zn may be an important cofactor in the progressive immunosuppression occurring in HIV infection.

Th.B.P.316 FUNCTIONAL CORRELATES OF DECREASED SERUM ZINC IN HUMAN IMMUNODEFICIENCY VIRUS (HIV) DISEASE.

Falouts, Jilina, Thoulas, C., Deutsch, G.

Montreal General Hospital, McGill University, Montreal, Canada

Objective: To determine the functional significance of the decreased serum zinc (Zn) that we have previously shown occurs in HIV disease, we studied the immunologic effect of Zn on lymphocyte from patients and controls.

Methods: In HIV men and 16 HIV controls were studied. Proliferative responses of mononuclear cells (PMMC) to mitogens Zn, in concentrations from 0.01 up to 2.00 μM, either in the absence or presence of PHA, were determined. The percent increase in the stimulation index (SI) at each Zn concentration relative to either control was determined. Statistical analysis of the antigenic effect of Zn in Zn was determined using t-tests for paired comparisons.

Results: Mean serum Zn of the HIV- & HIV+ groups were 17.0±2.5 & 14.1±2.8 μmol/l, respectively (p<0.01). Zn had a significant mitogenic effect on PMNC from controls only at the highest dose [Zn: 2.00 ± 2.00 μM; SI: increase of 159±170% (p<0.01) and 125±143% (p<0.01) whereas in HIV+ PMNC's, a greater degree of added Zn produced a significant response [Zn: .20, .50, 1.00, & 2.00 μM; SI: increase of 42±7% (p<0.05), 52±7% (p<0.05), 66±7% (p<0.01), and 34±10% (p<0.05) respectively]. In controls, no concentration of Zn augmented the SI achieved with PHA stimulation. In HIV+ subjects, both 0.50 & 1.00 μM increased the SI due to PHA [24±7% (p<0.01), and 34±11% (p<0.01) respectively].

Conclusions: PHA from HIV+ subjects, with lower serum Zn, may be more sensitive to the mitogenic effects of Zn. Zn in HIV+ subjects only may augment PHA induced proliferative responses. The decreased serum Zn found in advanced HIV disease may be a cofactor in HIV-induced immunosuppression.

Th.B.P.317 INCREASED PROLIFERATIVE REACTION IN HUMAN IMMUNODEFICIENT VIRUS (HIV) INFECTION IN ZINC AND SERUM ALBUMIN DEFICIENT SUBJECTS.

Kaplan, Nancy, Pappas, S.C.,* Deacono, M., Griffin, E.L., Chan, L.F., Fitching, A.J. and Harris, J.A.,*
St. George's and for, Bay's Hospital, Jamaica, Jamaica.

Objective: To assess serum zinc proteolytic function (ZPF) in HIV infection.

Methods: Chronic diarrhea and weight loss are common features of HIV infection and have been associated with altered vitamin absorption in the absence of enteropathogenic or intestinal malabsorption. Data suggests may however be more in zinc proteolytic insufficiency (ZPI). This study has been to determine the ZPF in HIV infection.

Methods: ZPF was measured using the PMA test in 25 Jamaican homosexual and 25 Jamaican heterosexual HIV-infected subjects presenting at different clinical stages of infection (20 group I, 11 III or IV). Control values were obtained in 25 Jamaican and 25 Jamaican healthy volunteers.

The recovery of P-aminocaproic Acid (PAA) in urine (expressed on a 6ml dose) following oral administration of labeled P-aminocaproic Acid correlates well with direct measurement of latent cytochrome activity and is a validated index of ZPF. P-aminocaproic Acid (PAA) stimulated concentration serves as a marker of PMA secretion and immunoreactivity. Reduced PMA with normal PAA recovery results in low PMA secretion index (ZSI) and characteristic of ZPI.

Conclusions: HIV was present in 11/25 Jamaican and 4/25 Jamaican subjects and is therefore not a cause of ZPI in HIV infection.

Gender	Control (n=25)	ZPF (normal/μmol)	ZSI (normal/100)	ZPI (normal/100)
Male	25	26.4±7.2	26.4±7.2	26.4±7.2
Female	25	26.0±10.0	26.0±10.0	26.0±10.0
Control (n=25)	25	27.8±2.2	27.8±2.2	27.8±2.2
HIV-1 (n=25)	25	42.0±5.5	42.0±5.5	42.0±5.5
HIV-2 (n=25)	25	40.0±20.0	40.0±20.0	40.0±20.0

Th.B.P.318 NUTRITIONAL STATUS PARAMETERS ASSOCIATED WITH PSYCHOLOGICAL WELL-BEING IN AIDS/RAC CLIENTS AT AN OUTPATIENT CLINIC IN SAN FRANCISCO.

Jonnie Broderick, J. Masnet, M.P.H., R.D., Mt. Zion Hospital & Medical Center/Better Health Program, San Francisco, CA, U.S.A.

The purpose of this study was to (1) document changes in nutritional status from baseline measurements, (2) determine the efficacy of nutritional counseling, (3) define appropriate nutrition interventions, and (4) determine if nutritional status parameters correlated with psychological indicators.

Patients underwent comprehensive nutritional assessment at both the initial outpatient clinic visit and after three months of routine nutritional counseling. Assessments consisted of anthropometric and biochemical measurements, three-day food records, nutritional histories, Hopkins Symptoms checklist, and Personal Orientation Inventory (POI), self-assessment and baseline questionnaires. Education was provided on general nutrition and strategies for management of symptoms associated with opportunistic infections and other HIV disease-related conditions that may impact nutritional status. Additionally, a positive correlation between nutritional status and quality of life parameters were found.

Th.B.P.320 SITES AND RELATIVE PREVALENCE OF HAIRY LEUKOPLAKIA, PSEUDOMEMBRANOUS CANDIDIASIS, AND ERYTHROPLAKIA CANDIDIASIS.

Georgina Delgado,¹ Michael L. S. McDonald,^{1,2} Georeanna J.¹ The Schools of ¹Dentistry and ²Medicine, University of California, San Francisco, Oral AIDS Center, San Francisco, CA, U.S.A.

Objective: To describe the sites in the mouth where hairy leukoplakia (HL) and the various forms of candidiasis with their relative prevalence in a retrovirus population (Oral AIDS Clinic).

Methods: The Oral AIDS Epidemiology project initiated a uniform prospective of data collection procedures for the oral complications of HIV in both community cohorts, AIDS clinic and the Oral AIDS Clinic. This analysis is based on the findings in the retrovirus patients in the Oral AIDS Clinic. This analysis is based on the findings in the retrovirus patients in the Oral AIDS Clinic. This analysis is based on the findings in the retrovirus patients in the Oral AIDS Clinic.

Results: Hairy leukoplakia was the most common lesion observed in 236 individuals. 87% of patients had involvement of the lateral (including extension to the ventral surface), and 29% of the dorsum of the tongue. The buccal mucosa was less frequently involved, 25% on the buccal palate (45%) (No lesions were seen on the hard palate). Pseudomembranous candidiasis (thrush) was observed throughout the mouth in 108 patients, most commonly involving the tongue, 42% lateral 48% dorsum. The hard palate 20% and soft palate (19%) were also frequently observed, as was the buccal mucosa (19%). Erythroplakia candidiasis (n=65), early involvement with a flat appearance, was most frequently seen on the hard palate (65%), soft palate (17%), and dorsum of the tongue (57%) when dysplasia was a common finding. Angular cheilitis due to candida was observed in another 14 patients. **Conclusions:** Hairy leukoplakia although absent unilaterally found on the lateral surface of the tongue also appears in the buccal mucosa. Pseudomembranous candidiasis occurs almost twice as often as the oral manifestations of candida and can affect almost any surface in the mouth. Erythroplakia candida is much more characteristic of the tongue and hard palate. Concurrent HL and candida was a common finding.

Th.B.P.322 SINGLE DOSE THERAPY FOR HIV CANDIDIASIS WITH FLUCONAZOLE IN HIV-INFECTED PATIENTS

Richard D. Davis, Dept. for Clinical Studies on AIDS (HIV, AIDS) Division of Infectious Diseases, Cedars-Sinai Medical Center, Los Angeles, California.

Objective: To assess the efficacy and tolerance of a single dose of fluconazole for the treatment of oral candidiasis (OC). Fluconazole (FC) is a new antifungal agent with a good oral bioavailability and a long half-life.

Methods: From 10/1987 to 1/1/1988, all patients presenting with OC were proposed a single 150 mg dose of FC. Diagnostic criteria for OC included white plaques (leukoplakia), fissured and signs (white plaques on a hyperkeratotic base) and a positive yeast culture. Patients were asked to attend weekly visits for two months. Clinical response was defined by the total disappearance of signs and symptoms. Responses were treated with another single dose.

Results: Forty-five patients were included: 30 of them had presented a 1st prior episode of OC within the last 12 months, and 15 had presented in 2nd or 3rd episode seen in 18/45 patients (40%) on day 1 and in 14/45 (31%) on day 21 after the first 150 mg dose. The median follow-up observation period was 15 days (range 11 to 81), with a cumulative total of 2300 patient-days. During this follow-up period, 17 patients (38%) including 12 with AIDS presented in relapse, all of which responded to a single dose FC. Median interval before relapse was 10 days (range 1-15). Analysis of relapse showed that patients with AIDS and previous OC history, 7% were more likely to relapse. All together, of the 11 clinical OC episodes during this study, 15 (81%) responded to a single 150 mg dose. The patients had no major side effects (nausea).

Conclusions: FC single dose was easy to administer, effective and well tolerated in this pilot study. Relapses were more frequent in patients with a history of OC and with a symptomatic HIV infection. These findings support the use of another FC single dose, suggesting the absence of clinical resistance. The single dose approach could avoid continuous treatment in patients already receiving multiple therapies.

SIDA buccal Oral AIDS

Th.B.P.319 SINGLE DOSE THERAPY FOR PSEUDOMEMBRANOUS CANDIDIASIS WITH FLUCONAZOLE: A PILOT STUDY.

Chantal P. Villette,¹ Veronique, F.¹, Magallan, B.² and Cassier, F.P.³ ¹ Division of Infectious Diseases, ² Division of Gastroenterology, Cedars-Sinai Medical Center, Los Angeles, and ³ Medical Clinic I, Loma Linda, California.

Objective: Pseudomembranous candidiasis is a frequent complication of asymptomatic HIV infection. In this setting, topical azoles are ineffective, clinical resistance to azoles is common, and amphotericin is poorly tolerated. Moreover, amphotericin has to be stopped for oral candidiasis because of its side-effects potential. In this context, the pharmacokinetic properties of fluconazole (a novel triazole antifungal agent), such as a good oral bioavailability and a long plasma half-life, are of special interest.

Methods: Fifty-eight patients with a biopsy-confirmed pseudomembranous candidiasis have received a single oral 150 mg fluconazole dose as sole treatment and have been seen again on days 3 and 7. The clinical response was associated in all cases by a second administration of 150 mg. The culture and biopsy of oral lesions.

Results: 100% of patients with oral lesions at 3/7 patients, who received a second 150 mg fluconazole dose. Symptoms had disappeared in all patients on day 7, and endoscopic examination was normal in 100% cases. The patient presenting persistent endoscopic inflammatory signs, but with evidence of fungal or biopsy and culture. One other patient relapsed 11 days later (relapse: 1-25 days, median 11 days). Transitory headache and nausea have been observed in one patient. No significant laboratory or immunologic changes. In other subjective side effects: oral or buccal or hematologic signs had been recorded.

Conclusions: These preliminary results suggest that a single oral dose of fluconazole may cure pseudomembranous candidiasis and is well tolerated. This treatment merits official drug compendium and could avoid amphotericin and/or azoles interruption in patients with AIDS.

Th.B.P.321 ORAL FINDINGS IN PATIENTS WITH ASYMPTOMATIC HIV DISEASE

Schultze, Engelhardt A. H. M.¹; ten Cate, R. W. M.²; van der Wal, J. W.³ ¹ Dept. Oral Pathology and Oral Surgery, ² Dept. Internal Medicine, Free University Hospital, Amsterdam, The Netherlands.

Objective: To determine the prevalence of oral mucosal lesions in patients with asymptomatic HIV disease (OAI-III/IV), and to compare the results with findings in patients with asymptomatic HIV disease (OAI-I/II).

Methods: Oral examination was performed in 70 HIV-positive patients (60 men, 10 women), mean age 38 yr; range: 18-65). Fifty-six patients (80%) were homo/bisexual men. Physical examination, including laboratory evaluation, was completed in all patients. Twenty-two, 31, and 37 patients were classified in group OAI-I, II, and IV, respectively. Of the latter group, 34 patients were classified as having AIDS (OAI, 1987).

Results: In 52 patients (74%) one or more oral mucosal lesions were detected (OAI-III/IV: 35 (70%); OAI-I/II: 17 (79%). Oral candidiasis, hairy leukoplakia, and periodontal diseases were present in all groups.

Conclusion: Our data show, that oral mucosal lesions frequently occur both in asymptomatic and symptomatic HIV disease.

Th.B.P.323 THE IDENTIFICATION AND TRACKING OF CANDIDA ALBICANS ISOLATES FROM ORAL LESIONS IN HIV-SEROPOSITIVE INDIVIDUALS

Miyazaki, Shukui, H.¹, Finkelstein, S.², Hicks, J.³, Greenman, D.³ and Greenman, J.³ ¹ Oral AIDS Center, U.C.S.F., Calif., ² Research Unit, Cedars-Sinai, Los Angeles, Calif., ³ The University of California, San Diego, Calif., U.S.A.

Objective: Candida albicans is recognized as the most frequent cause of oral candidiasis in HIV infection, however, very little data is known regarding these C. albicans biotypes.

Methods: Clinical isolates obtained from 100 HIV-infected individuals with and without oral lesions, plus 8 HIV-seronegative controls. The isolates were hybridized with a number of C. albicans specific DNA probes to assess strain relationships between individuals observed in time. The DNA probes yield a "fingerprint" that can be used to follow individual C. albicans strains for long periods and through repeated re-isolation.

Results: C. albicans has been isolated from all individuals with oral lesions. We have determined that each individual in the study carries a distinct C. albicans strain identifiable by DNA fingerprinting. Furthermore, C. albicans was isolated from a significant fraction of asymptomatic individuals both HIV-seropositive and HIV-seronegative. In two cases so far observed we have now developed following "successful" antifungal treatment, the same strain was found in the same year by the individual during the asymptomatic phase.

Conclusions: The finding of the same strain of C. albicans both before and after standard antifungal therapy raises questions as to effectiveness and sites of correct exposure therapeutic regimen. If in fact C. albicans organisms are altered under selection pressure from the host environment or can adapt to such host uniquely, then it is not surprising that they are such successful opportunistic pathogens. The present finding of a unique C. albicans strain in each individual harboring C. albicans suggests a mechanism for this year's continued presence in a population, immunocompromised and immunocompetent individuals. This work was supported by NIH P01 DE07946.

Th.B.P.330 ORAL MELANOTIC MACULES IN PATIENTS INFECTED WITH HIV-1

FERRAZ, Giuseppe; **Ballino, E.†;** **Adinolfi, M.†;** **Castiglioni, D.†;** **Di Piero, M.†;** **Riccardi, R.†.**
*University of Florence and UNO, Florence, Italy; †University of Texas, Houston, Texas, Houston, USA.

Objective. To describe the features of 9 cases of oral melanotic macule (OMM) in patients (pts) infected with HIV-1.

Methods. Between Dec.87 and March 88, 9 pts developed OMM. Plasma cortisol level was measured. Electron microscopy was done in 5 specimens. In situ hybridization to Epstein-Barr virus (EBV) was done under stringent conditions.

Results. The mean age was 31.6 years. Five pts were men and 4 women. Six pts were IVDA. One pt had the OMM unilateral, 2 had 6 and 8 arcs. In 8 pts the OMM were single and in 1 multiple. None of the pts developed clinical or laboratory evidence of adrenal damage. Six pts received treatment courses of topical imiquimod or systemic isotretinoin. Six pts also had hairy leukoplakia.

Conclusion. Increased melanin deposition in the basal-cell layer and upper lamina propria was observed. In 6 cases leukocytes were present. No ultrastructural alterations were observed. DNA of EBV was found in 2 OMM tissues and in 1 specimen of normal mucosa. In 5 pts the OMM relapsed or recurred after excision.

Conclusion. The etiology of OMM is not known, although several causes should be considered. Subtle adrenal damage, latent viral infection and drug therapy can be involved. OMM might represent a new manifestation of HIV-1 infection.

Th.B.P.332 IMMUNOHISTOCHEMICAL STUDIES OF ORAL SCRATCHES

Langford, Angelita,¹ Kume, R.,² Schepers, S.,¹ Pohle, J.D.,³ Reichart, P.,⁴ Frey, University,¹ Robert Koch Inst.,² Rudolf Virchow Univ.,³ D-1-Berlin-65, FRG

Objective. To examine keratinocytes gained from oral scratches for viral antigens and cytokinin differentiation markers.

Material and methods. Scratch material (lat. border of the tongue) (HIV) patients n=30, HIV- n=20) was filtered, centrifuged onto slides and examined by means of immunohistochemistry (IAPAA) and in situ hybridization (ISH). Applied antibodies: anti-cytokeratin (OK 6.6, K 8.1 and K 4.63 and Ki1; EBV, CMV, HSV 1/2.

Results. Compared to HIV in scratches of HIV- the number of K 8.60 (cornification marker) positive cells was 3.6 times increased, of K 8.1a (fast cell turnover) 1.3 times and of K 4.63 (basal cell marker) 7 times. In scratches of HIV+ patients the number of Ki1 positive cells was 3 times higher than in HIV-. Viral antigens of EBV were not detected in HIV-, but in 1/30 HIV- patients (IAPAA, ISH); 10/15 observed oral hairy leukoplakia (HL), while 3 further patients developed HL during an observation time of 8 months. CMV was observed in 8/30 (ISH) and in 6/30 HIV- patients (IAPAA). In 9/30 (HIV+) patients HSV1/2+ cells were found (ISH). Detection of viral antigens and of immature keratinocytes was highly correlated with AIDS manifestation.

Conclusion. The presented non-invasive technique ("Scratch") is a sensitive aid for regular monitoring of HIV associated oral lesions, such as HL. Proliferation and differentiation of cytokinin in oral epithelium is altered during HIV infection.

1. Detection of EBV in oral scratches seems to be a valuable marker for the later development of HL.

Th.B.P.334 FLUCONAZOLE IN THE TREATMENT OF OROPHARYNGEAL CANDIDIASIS

Just, Gudrun,¹ Schmelz, B. M.,² Böttlinger, C.,² Böttlinger, M.,² Hehl, B. M.,² Gell, W.†
*Universitätsklinik Frankfurt, ZIM, Infektiologie, Theodor-Stern-Kai 7, 6000 Frankfurt, FRG

Objective. To describe efficacy and restrictions of Fluconazole in the treatment of oral candidiasis in HIV-positive patients.

Methods: 104 HIV-positive patients with clinical and cultural signs of Oropharyngeal candidiasis were treated in 112 treatment courses. Initial dosage was 200 mg/die, followed by a daily dosage of 100 mg. Duration of therapy was approximately 3 weeks in approximately 60% of cases. For quantification of colonization, the oral wash-out method was used.

Results: At the end of treatment with Fluconazole, clinical symptoms and candida flora completely disappeared in approximately 50% of patients, although the oral wash-out still showed a remarkable number of candida sp. in the culture. The group of "non-responders" consisted of patients in an advanced stage of disease, patients without cytoretic therapy, or patients with a selection of C. glabrata (12 patients) or C. tropicalis (2 patients). Fluconazole was associated with only a small number of adverse effects even after long term therapy.

Conclusion: Fluconazole is effective in the treatment of oropharyngeal candidiasis. Elimination of clinical symptoms and complaints is not always accompanied by elimination in the culture. The selection of C. glabrata might become a therapeutic problem.

Th.B.P.331 LOCAL DESTRUCTION OF LABIAL SURFACE OF MANDIBULAR TEETH

BY DIRECT APPLICATION OF COCAINE IN DRUG USERS WITH AIDS
Owens, Arthur M.,¹ Swall, C. B.,² and Klein, R. S.,²
North Central State University, Albert Einstein College of Medicine, Scoton, New York, U.S.A.

Objective. To describe a newly recognized oral lesion in drug users with AIDS.

Methods. 92 consecutive drug users with AIDS underwent periodontal and oral examination by a periodontist. Destructive lesions not explainable on the basis of periodontal disease or other recognized oral pathology were noted and photographed. Patients were questioned about direct mucosal application of cocaine.

Results. Five patients had focal destruction of the soft and hard tissue of the labial surface of mandibular anterior teeth. Affected areas could not be attributed to adjacent periodontitis. Subjects included 3 male and 1 female intravenous drug users (IVDU) and 1 female who denied parenteral drug use and whose risk behavior for AIDS was almost contact with an IVDU. All 5 reported at least several weeks of cocaine use by direct application to the affected areas, described as the "freeze" method of cocaine use.

Conclusion. Drug users with AIDS who take cocaine by the "freeze" method are at risk for focal destruction of oral tissue at the site of drug application. Individualized attention is needed in the oral care of drug users with AIDS should recognize this entity.

Th.B.P.333 RECURRENT ORAL APHTHAE IN HIV-INFECTED

HEMIPHAGAL MALES
Lagarde-Nar, François Phang, M. and Silverman, S. J.,
University of California, San Francisco, San Francisco, Ca, U.S.A.

Objective. To develop a profile and assess cofactors in HIV positive homosexual males afflicted with progressive oral aphthae.

Methods: 12 homosexual males, 9 with AIDS and 3 patients with ARC were evaluated and treated. Mean age was 37 (range 27 to 56). Follow-up mean 10 months. Patients were divided into 2 groups -- those with lesions <6 mm (minor), 7/6 mm (major). History of recurrent aphthous ulcerations, frequency, and disease severity prior to 1988 and after HIV test, time of diagnosis of ARC or AIDS and medications were recorded. Tests included HIV by monoclonal Ab, culture (bacterial and fungus) and complete blood counts.

Results. 9/12 patients had a previous history of recurrent aphthae prior to HIV infection. 8 patients presented with major ulcers and 4 with minor ulcers severity and frequency of their oral disease had worsened in 9 patients prior to the onset of ARC or AIDS and in 3 patients after the diagnosis of AIDS. 9/12 patients were negative to HSV 6/8 patients with major ulcers were positive and neutropenic. HIV (mean 2.0), Hb (mean 9.3), WBC (mean 2.3) all patients responded to therapy without systemic (Prednisone) or topical (Clobetasol propionate).

Conclusion. Increased severity and frequency of RAU is a complication of HIV infection. Orbits and neutropenia appear to be cofactors. RAU in HIV positive patients is not HSV related patients with the major type are likely to be orogenic and neutropenic.

Th.B.P.335 CRANIUM OF ORAL CANCER PATIENTS : OBSERVATIONS FROM HIV INFECTION AND CELLULAR IMMUNITY IN BRITISH AREAS.

Das, Kapilraj, R. Datta, S. Ghose, C. Ray, G. Das, S.
Division of General Medicine, Institute of Medical Sciences, University of Calicut, Kerala, India.

Objective. To study the cranium of oral cancer patients in HIV infection and cellular immunity in British areas.

Methods. 104 HIV-positive patients with clinical and cultural signs of Oropharyngeal candidiasis were treated in 112 treatment courses. Initial dosage was 200 mg/die, followed by a daily dosage of 100 mg. Duration of therapy was approximately 3 weeks in approximately 60% of cases. For quantification of colonization, the oral wash-out method was used.

Results: At the end of treatment with Fluconazole, clinical symptoms and candida flora completely disappeared in approximately 50% of patients, although the oral wash-out still showed a remarkable number of candida sp. in the culture. The group of "non-responders" consisted of patients in an advanced stage of disease, patients without cytoretic therapy, or patients with a selection of C. glabrata (12 patients) or C. tropicalis (2 patients). Fluconazole was associated with only a small number of adverse effects even after long term therapy.

Conclusion: Fluconazole is effective in the treatment of oropharyngeal candidiasis. Elimination of clinical symptoms and complaints is not always accompanied by elimination in the culture. The selection of C. glabrata might become a therapeutic problem.

Th.B.P.342 ORAL HYPERTHYMIA ASSOCIATED WITH HIV INFECTION.
Largiadou, Angelika¹; Kounas, R.²; Groh, A.²; Gelderblom, H.²;
Folch, H.²; Hatzigeorgidis, P.²; Raddel-Virchow, U.²; D.-Berlin 65, FRG.
Free University¹, Robert-Koch-Institut², Rudolf-Virchow-Universität, D.-Berlin 65, FRG.

Objective: To characterize the clinical and virological features of hypertymia (h.p.) observed on the oral mucosa of 15 non-smoking HIV-infected patients, biopsies of h.p. (HIV-neg; HIV-neg) and of normal oral mucosa (o.m.) (HIV-neg; HIV-neg) were examined.

Methods: Light microscopy (LM): H&E, Fea and Fei, silverimpregnation. Electron microscopy (EM), immunohistochemistry (DMSAFAP), antibodies against CD4, CD4, CD45, CD45, IgA, TAC and transferrin receptor (ATR).

Results: Localization of h.p. in HIV: gl. buccale, palata, gingiva, tongue, extraoral (face, hands, finger-toe nail). During observation time (avg. 8.2 mths.) the size of h.p. in HIV increased in 1 pat., 2 of them (AIDS) died, 1 pat. developed AIDS. LM/EM of h.p. (HIV-RI) accumulation of melanosomes within keratinocytes/melanocytes of the basal/superficial cell layers, in fibroblasts/phagocytes of the connective tissue (h.p. HIV-RI) and with o.m. (HIV) the number of CD45 (+) times, HLA DR+ (+) times and CD45 (+) times cells was increased within c.HIV-RI. Within c.t. of h.p. (HIV) only single cells stained + for CD45, TAC receptor, ATR and IgA. Compared with h.p. (HIV-RI) and with o.m. (HIV) the number of CD45+ cells within c.t. of h.p. (HIV-RI) was markedly increased, while their number within the epithelium was comparable with o.m. (HIV).

Conclusion: The high imbalance of distribution and status of local immunocytes in h.p. (HIV) may reflect the functional impairment of the oral mucosa. The sudden onset of melanin deposition might be caused by influenza/HIV/postinflammatory reactions and seems to be correlated with the progression of AIDS manifestation.

Th.B.P.344 SALIVARY STAIN AND HIV INFECTION
Sullivan, Alexander D.; Brackbill, D.; Green, D.; Peters, R.; and Neri, G.
University of Iowa, Iowa, U.S.A.

Objective: To determine the salivary stain levels during HIV infection and evaluate their possible role in the seroconversion and AIDS-related lesions (ORL).

Methods: 30 subjects were studied: 7 HIV+, 23 healthy controls (H.C.). 30 HIV+ didn't show ORL, 29 were affected by oral candidiasis and 19 by hairy leukoplakia (HL). Six HIV+ patients, containing a seroconversion and seronegative component, were used to evaluate Stain, IgG and IgM immunoprecipitation allowed to exclude that free secretory component and /or Stain presence could distort our results. Total salivary proteins (T.P.) and albumin were also tested to exclude the albumin influence. Then, values for every patient group are reported in the table.

Results (n=30)	Stain (mg)	T.P. (mg)	IgG/IgM
H.C.	38.0±19.2	382.0±93.3	2.6±0.1
HIV+ without lesions	46.4±22.4	286.7±89.3	3.6±2.3
HIV+ with oral cand.	48.9±17.5	252.4±78.0	3.6±2.3
HIV+ with H.L.	64.5±27.2	279.0±71.7	3.1±1.2

Conclusion: A significant Stain increase appeared in HIV+ compared with H.C. No difference resulted between patients with or without ORL. The lack of significant difference in the Stain synthesis state the minor role of the local immune response in the control of these lesions. On the contrary, the strict relation ship between circulating CD4 decrease and ORL, sustained the cell-mediated immune response importance also in the oral cavity.

Th.B.P.346 ORAL MANIFESTATIONS OF HIV INFECTION IN AFRICAN, COAST DRIVERS
Munishi, M.; Mwangi, J.; De Cock K.M.²; Green T.L.²; Cohen R.²;
Cohen R.²; Greenhouse, J.P.² et al.
CDC/WHO, Oral AIDS Center, University of California, San Francisco, San Francisco, CA, U.S.A.

Objective: To describe oral manifestations associated with HIV infection in hospitalized patients in Nairobi, Cost Driver.

Methods: Two hundred and fifty-six hospitalized patients (Internal Medicine, Pulmonary Medicine, Infectious Disease, Dermatology, Gynecology) had a medical, histological, oral examination, and were tested for HIV-1 and HIV-2 infection. Clinically significant oral lesions were biopsied for histological examination.

Results: Fifty-two percent of men were reportedly reactive to HIV-1 and for HIV-2 ELISA. The seroprevalence for HIV-1 and/or HIV-2 infection was higher in males (60%) than females (36%). Oral candidiasis was more frequent in HIV+ve (64/130) than in HIV-ve (21/113) patients (OR = 4.62, p<0.01). For diagnosing HIV infection, oral candidiasis was 49% sensitive, 83% specific, and had a positive predictive value of 75%. No association was found between oral candidiasis and the taking of antibiotics or corticosteroids. Hairy leukoplakia (HL) was suspected clinically in 18/19 HIV+ve and in 11/12 HIV-ve patients (NS). In 17/19 (90%) biopsies when HL was histologically confirmed. Twelve (68%) of the confirmed HL cases were HIV+ve/ELISA+ve. The predictive value of HL was increased to 71% by histological confirmation.

Conclusions: (1) Oral candidiasis is highly predictive for HIV infection in African patients; (2) HL occurs in African patients with HIV infection.

Th.B.P.343 ORAL HEAVY LEUKOPLAKIA: CLINICAL BEHAVIOR AND TREATMENT RESULTS

Gagliardi, Domenico; Ferrara, D.; Di Pietro, M.; Past, P.; Ravina, A.
University of Florence and USC, 1060, Florence, Italy

Objective: To report on the clinical behavior and treatment results of oral heavy leukoplakia (OHL).

Methods: Appearance of OHL and its clinical behavior were correlated to the T4-cell count in 54 HIV-1 infected patients (pts). In 30 pts treatment response to oral acyclovir was also evaluated. Median follow-up was of 12 months (2-34).
Results: In 54 pts the median T4-cell count, at the appearance of OHL, was of 390 cells/mm³ (16-1634). In 26 pts, OHL appeared after a progressive decline of T4-cell count. In 16 pts, 26 pts received no specific treatment. Of these, 6/26 showed spontaneous remission of OHL, 6/26 cicicic also resolution, 7/26 progression and 11/26 no change. Remission and site variation were associated with incidental biopsy and fluctuation of T4-cell count. Oral acyclovir (1800 mg/d for 14 days) in an open trial determined an objective response (OR=66%) in 14/20 pts. Median duration of response was 6.5 months (2-11).

Conclusion: Declining level of T4-cell influences the appearance and clinical behavior of OHL. Depletion of T4-cells may facilitate the replication of Epstein-Barr virus (EBV) within the lingual epithelium. Oral acyclovir is an effective therapy of OHL. This favors the pathogenetic role of EBV.
This study is supported by a grant from the Regione Toscana-Progetto HIV.

Th.B.P.345 OCCURRENCE OF ORAL PATHOLOGY AMONG DIFFERENT RISK GROUPS OF HIV INFECTED PATIENTS

Loeb, F.¹; Friauf, F.¹; De Wit, S.²; Stegmann, J.; Clumeck, N.²;
Division of *Stomatology and **Infectious Diseases, St Pierre University Hospital, Brussels, Belgium.

In a 6-year period, 700 HIV patients (P) were examined: 73% male and 27% female. Risk factors of acquisition of HIV infection were: homosexual or bisexual (hom) 36.8%, African (Afr): 35%, 10 drug abusers (IDA): 24.4%, heterosexual (hetero): 9.7%, unknown (unk): 1.8%, blood transfusion (blood): 0.7%. Clinical stage and immunological status were comparable in all risk groups. Among those 700 P, 300 (43%) presented at least one oral lesion (1 G), the most frequent findings were: candidiasis (Cand), hairy leukoplakia (HL), periodontal diseases (P.D), Kaposi's sarcoma (KS) and recurrent squamous ulcerations (RU). Occurrence of oral lesions:

Risk Factor	P. No.	C	Cand	HL	P.D	KS	RU
Hom	271	146	5	34	3	13	8
Afr	245	84	54	4	2	8	7
IDA	101	64	21	7	0	1	1
Hetero	68	28	10	3	1	1	1
Unk	10	0	0	0	0	0	0
Blood	5	0	0	0	0	0	0

In conclusion: 1) Prevalence of all oral lesions is significantly greater in the homosexual group (p<0.001). 2) Hairy leukoplakia and periodontal diseases are two oral lesions which appear preferentially in the homosexual group (p<0.001).

Th.B.P.347 NATURAL HISTORY OF HIV-ASSOCIATED SALIVARY GLAND DISEASE Schmitt-Mogensen, G.; Greenstein, D.; Dadd, C.; Chernoff, D.; Wax, D.; Vogel, F.; Hollander, A.; and Greenstein, J.
Oral AIDS Ctr, UCSF, San Francisco, CA, USA, *Univ-Hosp, A Dental Coll, Copenhagen, Denmark.

Objective: To describe the natural history of HIV-associated salivary gland disease (HIV-SGD), i.e. presence of salivary gland enlargement and/or xerostomia in HIV-infected patients in 12 patients with HIV-1 and 12 adults followed for a median of 13 months we assessed symptoms, stage of HIV disease, rearing whole salivary (RWS) flow rate (FR), stained periodontal (PV) FR, and immune status (T4, T4/T8). The salivary FRs of 6 of 9 with periodontal gland enlargement (PGE) were compared with those of a control group of HIV-infected patients without HIV-SGD and with similar degree of immune deficiency.

Results: The symptoms of dry mouth and the periodontal gland enlargement (PGE) were generally unchanged without treatment. PGE disappeared in 3 patients taking various medications (steroids, zidovudine). Acryvof did not change the PGE in 2 patients. Patients with PGE had significantly lower salivary flow than the control group (P<0.01).

HIV-SGD status	FR (ml/min)	Stain
With HIV-SGD	2/12 (17%)	2/12 (44%)
No HIV-SGD	5	6
Mean T4 (ml/min)/T4/T8	283, 0.41	222, 0.28
Mean RWS FR, ml/min	0.46	0.47 (P=0.05)
SP FR, ml/min (n=6)	0.17	0.27 (P<0.01)

Conclusions: HIV-SGD is associated with low T4 counts and a high risk of development of AIDS. Patients with PGE have reduced periodontal disease compared with similar immune deficiency. Unexpectedly, the salivary flow did not decrease with time in spite of further impaired immune status. This effect may partly be due to the given medications. The pathogenesis of this Epstein's syndrome-like disease is unknown. Supported by NIH P01-DE07946, the Danish Med. Res. Council (912-7499,12-8465), and AIDS Fonds, (DK).

Th.B.P.348 TREATMENT OF HIV PATIENTS WITH OROPHARYNGEAL AND/OR DESOXYTHIOSEAL CANDIDIASIS: THE RESULTS OF A R.C. STUDY.

Epappio Roberts, Robert Ferreri, G. and Crivellini, N.
CIVIC OF TRIESTE, ITALY

Objective. To compare in a double blind randomized trial fluconazole and ketoconazole in the treatment of oropharyngeal and/or esophageal candidiasis in patients with HIV infection.

Methods. Fifty patients with clinical and microbiologically documented candidiasis and HIV infection received either fluconazole 50 mg once a day and 1 placebo capsule once a day for 18 days or ketoconazole 200 mg capsule twice a day for 28 days. Clinical and microbiological responses were evaluated at 7, 14, 21 and 28 days together with analysis of safety and tolerance.

Results. At the end of treatment, clinical cure was recorded in 31.5% of patients treated with fluconazole and in 58.2% of patients treated with ketoconazole. A further 4.2% of patients treated with fluconazole and 31.2% of patients treated with ketoconazole was considered clinically improved. The mycological response rate was 44% for fluconazole and 70% for ketoconazole. The incidence of clinical side effects was similar in both groups (5%). The incidence of treatment-related laboratory test abnormalities was higher for the patients treated with ketoconazole (elevated values of SGPT and SGOT in 3 cases vs. 2 cases of elevation of SGPT and 2 cases of elevation of SGOT).

Conclusion. In oropharyngeal and/or esophageal candidiasis associated with HIV infection, fluconazole seems to be clinically more effective than ketoconazole. In the study no significant mycological differences are observed between the two drugs. Ketoconazole seems better tolerated than ketoconazole.

Th.B.P.350 PREDOMINANT MICROFLORA OF HIV-RELATED PERIODONTITIS

T. H. JONES, M. B. HARRIS, D. P. HAY, J. A. MILES,
T. M. McIVER, and J. S. DUNN, University of Pennsylvania
School of Dental Medicine, Philadelphia, PA, USA

Objective. To document the predominant microflora of a rapidly deteriorating form of periodontitis most associated with HIV-infection.

Methods. The subgingival microflora in 12 HIV-infected males with severe periodontitis and no history of recent systemic antibiotic therapy were examined. Also studied were 5 HIV-related periodontitis patients with a history of recent antibiotic therapy. Subgingival plaque specimens were collected with paper points from diseased and normal sites and transported in VMA III. The microbial samples were plated on selective and enriched bacterial blood agar and incubated in 80% R-108, 8% CO₂, and in 10% CO₂.

Results. *Actinomyces viscosus* was the most frequent subgingival isolate in normal periodontal sites. Periodontitis sites revealed higher mean CFUs and a greater number of anaerobic flora. Predominant species included *Actinobaculum actinomycetiforme* (mean 8 of flora in culture-positive patients = 10.4%), *Neisseria* spp. (8.3%), *Peptostreptococcus micros* (2.4%), *Bacteroides intermedius* (15.3%), *Proteobacterium* spp. (9.3%), and microflora (15.2% of microscopic count). Low levels of *Candida* spp. and aerobic gram-negative rods were detected in the subgingival flora of approximately 50% of the patients studied. Patients with recent antibiotic therapy generally had significantly lower proportions of suspected periodontopathic species.

Conclusion. These findings may facilitate clinical management of HIV-related periodontitis and demonstrate that the subgingival flora in HIV-infected persons may serve as a reservoir for pathogenic organisms.

Th.B.P.352 PERIODONTAL DISEASE IN HETEROSEXUAL PATIENTS WITH AIDS

Ward, G. G., and Klein, J. S.
North Central Bronx Hospital, Albert Einstein College of
Medicine, Bronx, New York, U.S.A.

Objective. To determine the prevalence and severity of periodontal disease (PD) in heterosexual patients with AIDS.

Methods. Consecutive pts with AIDS underwent periodontal and oral examination by periodontologists. Periodontal lesions were excluded from analysis. Abnormal findings were photographed.

Results. 101 AIDS pts were studied. Periodontal findings by risk group and gender are shown: (10% antiretroviral drug used).

Extent of PD	Number of subjects (percent)	*Female(=54)
No abnormality	23(23%)	2(3)
Gingivitis only	15(15%)	4(10)
Early PD	19(12%)	1(20)
Moderate PD	15(16%)	4(10)
Advanced PD	19(19%)	1(20)

*PD was significantly more severe in females (odds ratio = 6.1, p<.001). Periodontal lesions were more severe than generally seen in non-AIDS pts. 13 pts with PD had severe alveolar gingival lesions. Additionally 94 pts had periodontitis, 18 had lesions consistent with hairy leukoplakia, 5 lesions suggestive of oral candidiasis, and 9 oral ulcers.

Conclusion. Periodontal disease is common and severe in heterosexual pts with AIDS. Females have significantly more severe disease. Other oral pathology, especially candidiasis, frequently occurs concurrently.

Th.B.P.349 CARBON DIOXIDE LASER TREATMENT OF ORAL KAPOSI'S SARCOMA.

Hedberg, Tom J., Moilan, T.W. van der
Academic Medical Center, University of Amsterdam, the Netherlands.

Objective. The use of the CO₂ laser in the local treatment of oral Kaposi's sarcoma to reduce the morbidity associated with laser treatment with radiotherapy and with the same therapeutic results.

Methods. To avoid the severe mucositis as we have seen after radiotherapy of oral Kaposi's sarcoma we have used the CO₂ laser to remove the tumor of the hard and soft palate as well as from the pharynx and larynx. Until now we treated 9 patients. Five of them had sarcoma on the hard palate, one on the soft palate, two in the pharynx and one in the larynx. The surgery was done under general anaesthesia.

Results. Macroscopically we could remove all tumors but pathological examination made clear that in four cases there was a tumor relapse. The period of patients stay in our clinic was from 2 till 7 days. The patients could drink immediately after the surgery and their diet could be extended in the following days. The postoperative pain was controlled with small doses of minor analgesics during a maximum of 4-5 days. The follow up has been just four months but we haven't seen local tumor recurrences.

Conclusion. The CO₂ laser surgery of oral Kaposi's sarcoma is effective and gives less morbidity, a shorter stay in hospital and less discomfort to the patients than radiotherapy.

Th.B.P.351 IN SITU CHARACTERIZATION OF THE INFLAMMATORY INFILTRATE IN HIV ASSOCIATED PERIODONTITIS

Sera, Michael, Murray, P.A., Winkler, J.R., Williams, C. and
Corenson, J.J.
Oral AIDS Center, University of California, San Francisco, CA, U.S.A.

Objective. The clinical features of HIV associated periodontitis (HIV-P) have been well documented. However, little is known about the immunopathology of this lesion. The purpose of this study is to characterize the mononuclear cell infiltrate in this lesion.

Methods. Thirteen gingival biopsies were obtained from patients with HIV-P. Similarly oriented, serial cryostat sections were stained for MHC subsets using monoclonal antibodies and the indirect immunoperoxidase technique. Antibodies used were specific for anti-T-cells (Leu 4-5), T-helper cells (Leu 3a/b), T-suppressor (Leu 2), B-cells (Leu 14), monocyte/macrophages (Leu M5), Langerhans cells (Leu 6) and cells expressing HLA-Dr. Positive and negative staining cells were counted in corresponding areas of each section for each antibody. The mean percent of each cell subset was then established for all 13 biopsies.

Results. The mean percentage of cells reacting with antibody specific for T-cells was 21.0%, 23.7% and 15.1% of the cells were identified as T-helper and T-suppressor cells respectively. The mean heterogeneity ratio was 2.0. Analysis of B-cell infiltration revealed that 11/13 uniformly distributed dendritic cells were detected within the epithelium using antibody against both HLA-Dr and Langerhans cell markers.

Conclusions. HIV-P is dominated by T-cells, particularly T-helper cells. The majority of the cells express HLA-Dr, thus activated T-cells must represent a substantial proportion of the total T-cells. Monocyte/macrophages are also present in large numbers. There does not appear to be a gross reduction in Langerhans cells. Finally, B-cell infiltration is not a prominent feature of this lesion. Supported by NIH/NIHDC, P01 DE-07946.

Th.B.P.353 SALIVARY INHIBITION OF HIV-1 INFECTIVITY IN SERONEGATIVE

McL. JONES, AND CHILDSSEN AND SERONEGATIVE HIV.
Fox, Philip C., Allright, A., Veb, C.-C., Atkinson, J.C. and
Eism, T.R., CDC, NIH, Bethesda, Md, U.S.A.

Objective. Inhibition of HIV-1 infectivity by saliva from healthy HIV-1 seronegative men and HIV-1 infected men was collected from 25 seronegative men.

Methods. Unstimulated whole saliva was collected from 25 seronegative men (ages 21-42 and 21-42) and 7 children (4 males, ages 4-11 and 3 females, ages 4-9). Samples were obtained also from 9 seronegative males, ages 35-56. Inhibitory activity was assayed on 6 occasions by measurement of infection of stimulated human peripheral blood lymphocytes by HIV-1 which had been incubated first for 60 minutes with saliva samples or control fluids. Preliminary experiments showed that saliva was not toxic to target lymphocytes.

Results. Inhibition of infectivity was observed in all saliva samples. HIV-1 infection was completely inhibited by all salivas from the women and children. Salivas from 6 of the healthy males (65%) completely inhibited infectivity and partial inhibition was found in the remaining 3 samples. The seronegative male salivas had a similar distribution: 7 of 9 (78%) complete and 2 partial inhibition. Dilution of a sample of saliva from a single healthy male showed a dilution-dependent decrease of inhibitory activity, with substantial (>50%) inhibition remaining at a 1:20 dilution.

Conclusion. Salivary HIV-1 inhibitory activity is commonly found in human saliva secretions and may play a role in the low risk of HIV-1 transmission by the oral route.

Th.B.P.360 INTRA LABORATORY EVALUATION OF A CRYPTOPROTECTED DOUBLE LABELED PREPARATION FOR FLOW CYTOMETRY
Meador, M. J., Meador, R. J., and O'Shaughnessy, V. M. * Bureau of Laboratories and Research Services, Health Protection Branch, Ottawa, Ontario, Canada. ** Regional Virus Laboratory, Eastern Ontario Children's Hospital, Smith Rd., Ottawa, Ontario, Canada.

Objective: To establish whether cryptoprotected blood preparations with dual fluorescent labeled monoclonal antibodies against surface antigens (CD4 and CD8) could be useful as an intra laboratory calibration and/or a quality control product. **Methods:** Cryptoprotected preparations were shipped frozen to 15 flow cytometry laboratories (FCL) throughout continental North America. Each package contained two 0.5 ml cell suspension, instructions and data report sheets. **Results:** Twelve institutions returned seventeen laboratory reports. The results were from 18 instruments (8 different models) made by two different manufacturers. All reported values fell within 3 standard deviation (SD). 97% of the results were within 2 SD. Over 82% of the results were within 1 SD. The 3% of data over 2 SD were from one instrument model. **Conclusion:** Cryptoprotected human lymphocyte preparations can be utilized as calibration or quality control material for FCL. For universal applications the cooperation of instrument users and manufacturers is essential.

Th.B.P.362 LEUKOAGGLUTINATION IN PATIENTS WITH HEMOPHILIA
Kiera, M., Pelizzo, M., Niekora, E., Micheli, G., Gilmer, P., Pérez Blanco, E., HEDRA, Academia Nacional de Medicina, Buenos Aires, Argentina.

Objective: a) To evaluate the capability of hemophiliacs (Ho) were to agglutinate normal polymorphonuclear (PMN) leukocytes, since anti-lymphocyte antibodies prevalence is greater in Ho HIV than in Ho HIV-. b) To look for a correlation of leukoagglutination (LA) to circulating immune complexes (CIC) and fibronectin (Fn). **Methods:** One hundred ml of 5×10^6 PMN/wal were incubated with 100 μ l of citrated serum (5% C), diluted 1/10 for 2 hr at 37°C and 18 hr at 4°C, and the percentage of agglutinated PMN was determined. CIC were measured by precipitation with polyethylene glycol 3.3k final concentration. Fn was evaluated by radial immunodiffusion. **Results:** LA was values were significantly higher in Ho HIV+ than in either Ho HIV- or normal controls (0) ($p < 0.07$). LA in Ho HIV+ was 35%, 20% and in Ho HIV- 28.4%, 21.1%, 14.1%, 1%. LA was observed in 94% Ho HIV+, in 34% HIV- and in 78% Ho HIV- values were confirmed for CIC in Ho HIV+ (SD:0.02; 0.05; 0.18) when compared with Ho HIV- and (SD:0.02; 0.05; 0.18) Ho HIV- (SD: 0.03; 0.11; 0.25; 0.1), but there was no statistic correlation between LA and CIC values. Serum Pn concentration was not different in these groups of Ho HIV+ (SD: 0.15) Ho HIV- (SD: 0.10) Ho HIV- (SD: 0.12; 0.14; 0.10). **Conclusions:** The presence of LA in Ho is LA independent of treatment-provoked antigenic stimulation, of CIC and Fn levels. However, LA could be associated with HIV-infection.

Th.B.P.364 INCIDENCE OF AUTOANTIBODIES IN HIV INFECTION.
Quercia, J. F., De Metteis, M. P.; Casanova, C.; Wines, M. S.; Casaccia, P. P.; Dell'Acqua, P. C. et al.

* Laboratoire d'Immunologie, ** Médecine Interne, *** Maladies Infectieuses, CHU St-J. Nice, France.

Objective: Systemic states (e.g. Th lymphopenia and hyperimmunoglobulinemia) in seropositive HIV patients (HIV+) are well known. We have reported the incidence of autoantibodies (AAB) in a series of 87 patients. **Methods:** AAB were detected by indirect immunofluorescence using anti-IRA Ab (microcytopolytoxicity), rheumatoid factor (RF), circulating immune complexes (CIC) (latex immunoprecipitation). **Results:** Anti-mouse monoclonal AAB were observed in 36/76 cases (45%). 37/50 sera react with lymphocytes without anti-IRA specificity (from 3 to 90% of the panel), mean = 41.3% with sd = 27.6%. Anti-nuclear AAB and anti-thyroid microsomal AAB were always absent (0/87). Rheumatoid factor was only found in 3/59 cases (5%). Anti-epidermal AAB were present in 2/26 cases (7%), anti-keratin in 1/15 (7.1%) and anti-actin in one out of 35 cases (2.8%). CIC have been detected in a large percentage of HIV+ patients : 47/66 (71%). **Conclusion:** The polyclonal B-cell activation and diffuse hyperimmunoglobulinemia, well-known features of HIV infection, account for the presence of these autoantibodies and an aberrant B-cell immunoregulation after HIV infection.

Th.B.P.361 A RAPID VERIFICATION OF MONOCLYTE ENRICHMENT/DEPLETION TECHNIQUE UTILIZING FLOW CYTOMETRY
Meador, M. J., Francis, E., Sherratt, A. and O'Shaughnessy, V. M. Bureau of Laboratories and Research Services, Federal Centre for AIDS, Health Protection Branch, Ottawa, Ontario, Canada.

Objective: The adherence-to-plastic techniques have been developed to separate monocytes from peripheral blood mononuclear cells (PBMC). Various solid-phase surface depletion methods have been utilized to either deplete or enrich monocytes from PBMC. A rapid verification of the enriching and depleting methods is possible with flow cytometry. **Method:** The cell suspension containing monocytes was inoculated in plastic dishes of various kinds with and without fetal calf serum coating. Recovered cells were incubated with fluorescent monoclonal antibodies against T4 monocytes (Leu3). The monocyte population was determined by flow cytometry. **Results:** Bacteriological grade plates (BGP) without coating were compared to tissue culture plates (TCP) for efficiency for monocyte enrichment. 75.6% and 81.9% were obtained respectively. For depletion utilizing BGP and TCP the monocyte yields were 5% and 9.8% respectively. **Conclusion:** To enrich monocytes the least expensive method yielded better results. To remove monocytes the more costly plates with fetal calf serum coating is recommended.

Th.B.P.363 INTRA BLOOD-BRAIN-BARRIER TOTAL IgG SYNTHESIS IN PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS INFECTION.

A. Espar, V. Ferrer, J. Sureda, F. Naval, A. Murgades, and E. Franquet, Facultat de Ciències Mèdiques, Centre de Diagnòstic Comunitari, Hospital Curry Cabell, 1100 Lles, Portugal.

Cerebrospinal fluid (CSF) protein profile was studied in 15 patients with human immunodeficiency virus (HIV) infection and clinical evidence of central nervous system (CNS) disorder. Total CSF and serum protein and IgG concentrations were determined and the CSF/serum albumin quotient was measured as an index of blood-brain-barrier function. Results were plotted into a diagram (1) and intra blood-brain-barrier total IgG synthesis was quantified according to three formulas (2, 3, 4). Babier's diagram detected an abnormal protein profile in 14 of 15 (93%) patients and total IgG synthesis within the CSF was present in 11 of 15 (73%) patients. No correlations were found between those CSF abnormalities and the clinical and CT scanning findings. It is concluded that the study of CSF protein profile is a clinically useful and very sensitive way of testing the development of CNS disorder in patients with HIV infection, the acquired immunodeficiency syndrome (AIDS) or AIDS-related complex. Sager, J. Neurol. (1981) 51, 361-370.

Th.B.P.365 LYMPHOCTYTES CD4+, BETA 2 MICROGLOBULINE ET HEPHERINE DANS LE LIQUOR ET LE SANG AU COURS DE L'INFECTION PAR V.I.H.

VERONE A., CALDESI D., BILPIN J., TOURNARE F., LIVOZIT J.M., JOUINCY C.H., TOURNARE L.L. Lab. Neurologique, Hôpital Neurologique 80984 Lyon Cedex 08, FRANCE. *Lab. Radiologie, Centre Méd. Numérique 80984 Lyon Cedex 08, FRANCE. *Purkin (Hôpital Edouard Belin) 69637 Lyon Cedex 08, FRANCE.

Motifs: Prévalence élevée des données, dans le LCS et le sang, pour apprécier une éventuelle étiologie neurologique chez les patients atteints de SIDA.

Méthodes: Etude chez 45 malades V.I.H. (20 SIDA, 10 ARC et 6 Serrypromotiques) dont 20 présentant des manifestations neurologiques. Numération des lymphocytes CD4+ et CD8+ (Cytométrie en flux sur EPICS CB) et dosages de la Bêta 2 microglobuline et de la heparine (RIA).

Résultats: Nous observons une diminution des lymphocytes CD4+, une augmentation progressive de la Bêta 2 microglobuline dans le LCS et le sang, que que soit l'état neurologique. Les taux de heparine sont significativement augmentés quand il y a une atteinte neurologique au stade SIDA.

Conclusions: Chez les malades avec ARC et SIDA, le marqueur le plus performant pour apprécier une atteinte neurologique est le taux de bêta-2-microglobuline; les 2 autres paramètres, CD4+ et SIDA, sont des marqueurs d'évolution de la maladie.

Aspects cliniques Clinical Aspects of AIDS

Th. B.P.372 THROMBOTIC MICROCYTIC COLLAS IN LIVERS OF CHILDREN WITH AIDS.
Thompson, W., Green, R., Hahn, B., Hsi, H., Kasper, M., MacFadden, D., Marmorstein, V., Anderson, W., New York University, NY NY

North Shore Medical Center, Mt. Sinai Medical Center, NY NY
Children's Hospital, LA, CA; Pediatric AIDS Center, USA

Objective: To define the inflammatory cells, especially macrophages and antigen presenting cells (APCs) in livers of children dying of AIDS.

Method: Seventeen livers from autopsies of AIDS children aged 2.1 mo to 7 yrs and sections from 11 non-AIDS controls were studied by immunohistochemistry. All had hepatomegaly and 4 had clinically evident liver disease.

Results: Mild portal inflammation = 9 (53%); moderate = 3 (18%); severe = 3 (18%). 11 with lymphoid aggregates, 2 cases, 1 mild/severe, had KAI granules. Lobular features were seen in 7 (41%) with lymphoid nodules, 2 with granulomas. Antigen expression was as follows (# of cases):

APCs	KAI	CD4	CD8	HLA DR	HLA DE	HLA DQ	HLA DQ	HLA DQ
Lymphocytes	11	11	11	11	11	11	11	11
Macrophages	11	11	11	11	11	11	11	11
APCs	11	11	11	11	11	11	11	11

All Kupfer cells were CD68 (+); rare Kupfer cells (+) for CD10 and HLA-DR. 1 lymphoid aggregate follicle (i.e., distribution of B, T, and APCs), HLA-DR positive and CD45-RO positive. **Conclusion:** 7 cells are the predominant infiltrates in hepatic sinusoids. APCs are present in lymphoid nodules and granulomas; HLA-DR is more sensitive in detecting them. Where lymphoid aggregates are seen, mature follicles are recapitulated.

Neurology Neurology

Th. B.P.374 NEUROLOGICAL MANIFESTATIONS IN PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS INFECTION.
Sohn, Bunn*, Estreich, S*, Forster, G.E.*
*Northwestern University, Chicago, IL, USA
*Whitehead Clinic and *Department of Neurology, The London Hospital, London, England, UNITED KINGDOM

Objective: To determine the prevalence of neurological manifestations in patients infected with HIV.

Methods: 111 patients infected with HIV were analysed retrospectively with respect to age, sex, risk factors, stage of HIV infection, type and cause of neurological manifestations.

Follow-up: was from 6 - 29 months.

Results: 18 neurological episodes were identified in 17 (15%) of 111 patients; from 29 patients with AIDS, two of 19 with AIDS-related complex, one of 28 with persistent generalised convulsions and four of 35 who were otherwise asymptomatic.

Central nervous system involvement included three with HIV-related encephalopathy, three with CMV retinitis, one with grand mal fits associated with toxoplasmosis, one with oculomotor neuropathy, left hemiparesis and Parkinsonism associated with toxoplasmosis, five with Bell's palsy (two in association with herpes zoster) and one with blindness from necrosis of the optic chiasm in association with progressive multifocal leukoencephalopathy. Three patients had peripheral neuropathy.

Conclusions: Neurological manifestations occurred in 15% of patients; cranial neuropathies were common and rare complications such as Parkinsonism and optic chiasm necrosis were seen.

Th. B.P.376 IMPAIRED MOTOR PERFORMANCE OF HIV-1 INFECTED PATIENTS IS NOT DUE TO SIMPLE FATIGUE
Klein, John G., Sadler, AC, Wolf, L, Brown, RJ, Price, RM
Sidits, JJ, Memorial Sloan-Kettering Cancer Center, NY, NY, USA

Objectives: To determine if impaired motor performance (finger tapping) in HIV-1 infected patients is related to the effects of fatigue.

Methods: 123 untreated HIV-1 infected patients at varying AIDS Demographics Composite (ADC) stages with the Neuro-AIDS Study Group. We used neurological history, exam, and neuropsychological battery. Subjects were instructed to rest for 10-second pauses between trials.

Results: Finger tapping performance with dominant (F(2,127)=11.80, p<.001) and non-dominant hands (F(1,127)=30.50, p<.001) declined with increasing severity of ADC-related motor dysfunction, with marked differences among the groups apparent on both hands from the first trial (F(2,127)=13.62, p<.001). Only the normal and mild patients' performance declined on later trials; patients with moderate motor dysfunction showed no change in performance ("fatigue effect") over the five trials (F(4,124)=0.50, p=.75).

Conclusions: With increasing motor dysfunction due to ADC, poor motor performance appears to be related to deterioration of the capacity of the motor system, not simply to susceptibility to fatigue effects.

Th. B.P.373 SERIAL IMMUNOLOGIC STUDIES AS AN INDICATOR OF PROGRESSION TO AIDS IN A COHORT OF MALE SEXUAL PARTNERS OF MEN WITH HIV DISEASE
Riedl, Stanley, Coates, R., Fawcett, W., Klein, M., MacFadden, D.,

Calzavara, L., et al., University of Toronto, Toronto, Canada

Objective: To compare serial immune parameters in men who have developed AIDS with those of men who are seropositive and seronegative controls.

Methods: At recruitment, 143249 men were seropositive and 16 subsequently seroconverted. At the time of this analysis, 24 had developed AIDS. Serial routine hematology, T-lymphocyte subsets, seropositive responses and quantitative immunoglobulins were done on all members of the cohort. Data was analysed based on comparison of values at intervals from estimated time of infection.

Results: There were significant differences in absolute T4 counts, T4/T8 ratios, response to PHA, IgM and IgA levels between seronegatives and seropositives who went on to develop AIDS. Most of these differences did not increase with time but were significant at the time of entry into the study. Only IgA levels showed a significant increase in the last 4 months in the group developing AIDS.

Conclusions: Differences in immune parameters between groups of uninfected, infected and progression to AIDS generally are unchanged on serial determinations. Also, variability in serial test results in an individual makes the use of a single test of limited value in prognosis.

Th. B.P.375 AIDS-RELATED NEUROLOGICAL ILLNESS IN TWO US CITIES: A COMPARISON OF SIMILAR POPULATIONS
Stephen G. Cohen*, Larry B.*; Rosenbaum, M.C.*; Cohen, R.*; Von Roenn, J.L.*; Murphy, R.L.*
*Northwestern University Medical School, Chicago, IL, USA
*University of California, San Francisco, CA, USA

Objective: To address the question of regional and risk group related variations in the incidence of AIDS-related neurological illness, we retrospectively examined the nature and frequency of neurological illness in two similar patient populations treated in University hospitals in San Francisco, California (SF) and Chicago, Illinois (CHI).

Methods: In both SF and CHI, the predominant risk factor for the acquisition of HIV infection was homosexual or bisexual exposure (99% and 79%, respectively), other major risk factors included IV drug abuse (28 SF, 74 CHI) and transfusion (18 SF, 19 CHI). Signs or symptoms of neurological illness were observed in 482 of 1286 (37%) of patients in SF and in 28 of 205 (28%) of patients in CHI.

Peripheral nervous system symptoms were noted in 79 patients in SF (6.1%) and in 20 patients in CHI (9.8%), while CNS dysfunction was observed in 474 patients in SF (37%) and in 41 patients in CHI (28%). Major specific neurologic diagnoses included (SF/CHI): HIV encephalopathy (100, 28); 20, 24); cryptococcal meningitis (68, 14); 4, 7); toxoplasmosis (53, 11); 7, 12); primary CNS lymphoma (25, 5); 2, 3); and PML (8, 5); 3, 3). Less common diagnoses included HSV, CMV or HHV-8 encephalitis (28, 3.8); 1, 1.7%) and rare cases of CNS metastases, and intracerebral hemorrhage secondary to thrombocytopenia.

Conclusions: The data reflect a trend toward increasing neurologic illness with decreased T4 cell counts. The mean T4 cell count in non-neurologically symptomatic patients was 143.5 ± 14.4 while in neurologically symptomatic patients, the mean T4 count was 96.1 ± 14.0. This trend may suggest that immunosuppression is a significant factor in the development of AIDS-related neurologic illness. The data further suggest that populations that are similar with respect to risk group, despite geographical location, may well have similar rates of neurologic disease.

Th. B.P.377 "ANEMIA, LEUCOPENIA, THROMBOCYTOSIS, AND SIDA AU SENEZAL"
D'Amorim, L, Biop A.G., A POVO C.
G.R.U. DE FARM. DAKAR (SENEGAL)

OBJECTIVE: Les divers effets dévastateurs du SIDA imposent la nécessité d'élaborer un approche biomédicale à des données sociales, culturelles par l'étude de des problèmes psychiatriques et neurologiques. Jusqu'ici absent de recherche sur le SIDA au Sénégal.

METHODS: Les 6 cas de 4 patients ont été analysés à partir: - d'un guide d'observation neuropsychiatrique inspiré de L.A.N.E.P. et de la "SIDA".

- d'un examen clinique neurologique;
- d'un examen clinique psychiatrique.

RESULTS: Il a été noté un polymorphisme du tableau neurologique avec divers troubles psychiatriques. Il n'existe pas de manifestations psychiatriques connues au SIDA.

CONCLUSIONS: Ces conclusions ne concernent que la population urbaine. Elles doivent être comparées, dans un an, à une population sénégalaise plus large.

B.507 COMPREHENSIVE OUT-PATIENT CARE OF HIV-INFECTED PATIENTS UTILIZING A PRIMARY CARE MODEL
Anastos, Kathryn; Soloway, B.; Ernst, J.; Bronx-Lebanon Hospital Center, Bronx, New York, USA.

Objective: To meet the total health needs of HIV infected individuals of all ages and all stages of illness in a community with very high HIV seroprevalence.

Method: The establishment of a comprehensive out-patient health care program for HIV-infected individuals.
Results: A community hospital in the South Bronx has developed a program for the out-patient care of HIV infected patients, provided both by primary-care trained physicians practicing in primary-care centers, and by infectious disease sub-specialists in an Infectious Disease Out-patient Center. All sites adhere to uniform, well defined standards of care, specifically designed to meet the health and medical requirements of HIV infected persons in all stages of infection. These include: initial comprehensive evaluation and on-going management of all acute and chronic medical problems, both HIV-related and other (e.g. DM, HTN); evaluation for anti-retroviral and preventive therapies (e.g. PCP prophylaxis); general and HIV-related health maintenance (e.g. immunization, PPD, pap smear, ophthalmologic exam, etc.); patient education; protocols have been developed in detail to cover these and other areas. Provider continuity, including inpatient care, is maintained in all primary care centers. On-going subspecialty input for all patients is provided by the infectious disease team.

Le sang et les produits sanguins Blood and Blood Products

B.509 LONG-TERM FOLLOW-UP OF UNTREATED SEVERE THROMBOCYTOPENIA(STP) IN THREE HIV INFECTED MEN: ADICIT, C. by J. Clotier, G. Sifera, J. Howe, A. Casati, J. Tor, M. Fox. Infectious Disease Unit, Hospital de la Sorbonne, Paris, France. **Objective:** To follow-up the findings and follow-up in three seropositive patients who denied any therapeutic approach during a mean period of 18 months (range 12-15).
Methods: 100 ml of 10% EDTA plasma and 100 ml of serum (chromogranin(1:10)) (platelet count (x1000/mm³) and rich marrow aspirate) related to HIV infection, were of kind of treatment but stopped a follow-up control each 4 months. **Results:** are summarized in table 1

P	Initial Gct	F/mm ³	Follow-up			
			months	2/m ³	F/mm ³	
1	111	9000	540	27	9000	855
2	111	3000	468	13	53000	408
3	111	9000	351	15	54000	-

Discussion: There were only minor hemorrhagic distress manifested by occasional epistaxis in 2 patients and petechia in lower extremities in all three. An increase in platelet count (> 9000/mm³) was observed in the three patients. It was spontaneous in 2 of them and possibly related to a non-opportunistic disease in the third. Only one has relapsed to the initial low count. None of the three patients developed AIDS during the follow-up period. Since we have observed a low response ratio to steroids (only 25% responded) and due to the potential immunosuppressive side effect of prednisone in HIV patients, we argue for enhanced control and expectant attitude, although we propose to assay AT treatment in all of them according to the recent literature. Nevertheless STP is not an unfavorable prognostic sign in AIDS seropositive for HIV.

B.511 HEMOPHILIC POPULATION OF COSTA RICA FROM 1979 to 1989
Taylor, Lisa; Taylor, G.M.; Cordeiro, R.M.; Antua, M.C.; Roy, A.; Lofice, R.M.; Vicens, K.A.

*Louisiana State University/International Center for Medical Research & Training, (LSU-ICMRT), San Jose, Costa Rica; **Neurological Dept., Hospital Mexico, San Jose, Costa Rica; ***US Medical Center, New Haven, Conn.

Objective: To analyze the serological profile in the hemophilic population in Costa Rica.

Methods: Serum samples stored in the LSU-ICMRT serum bank were tested with anti-HIV ELISA (Abbott, HTU-III), Western Blot (LSU-ICMRT), HIV antigen (Vironostika-Organon), IRMA HbAg and anti-Hc (HSA) clinical data were obtained from hospital case files. 1989-1990.

Results: Of the 147 hemophiliacs, 80 (54%) were positive for either HbAg or anti-HIV. 44 (44%) were positive for anti-HIV-1 with the following distribution:

Anti-HIV-1	Hemophilia A	Hemophilia B	Hemophilia C	Von Willebrand
Positive	1	3	2	3
Negative	46	1	2	31
Total	47	4	4	34

Sixteen (36%) of the B hemophiliacs were anti-HIV-1 positive since 1980 or before, while 11 (55%) of the B hemophiliacs were positive since 1986. HIV-1 antigen test of 99 of the 64 anti-HIV-1 positive hemophiliacs whose sera were available. The presence of the HIV-1 antigen was evaluated in correlation with seroconversion, development of AIDS or AIDS and death of the hemophiliac.

Conclusion: The analysis of HIV-1 seropositivity in Costa Rican hemophiliacs provides some new insights into the origin of this disease in Central America.

B.508 AIDS AND PHYSICAL EDUCATION
Favre, S.; Machado, J. . . Centro Corciani. (CUII). Campinas, São Paulo, Brazil.

The human is an integral composition of mind and body represented by pleasure and aesthetic, emotions and reason. The body is the very first human experience moment. The individual senses and lives prior to know-participating through the body of the real life. However the individual are being threatened by the AIDS virus contamination which brings together the feeling of an ending bench mark an impossibility of action. He is not anymore owner of his body which is now controlled by another owner called HIV. In the environment dominated by the AIDS virus, the body is felt through disgust, depression, guilt, revulsion, isolation, tension and death. This conduct the patient to a kind of intense exile, rupturing the life links. The body activity represents at this point in time, an important link with the life since it may be felt through the activity in a conscious way. Specialists are required to help the AIDS patients in an adequate environment which motivates the life. In the same way the specialists need to be helped by the techniques. In our particular case we use relaxation and movement to promote the body awareness. Our real possibility is the creation of an space for the body expression in a awareness way in a reason in the patient when his body represents in the world.

B.510 FULLY AUTOMATED SYSTEM FOR THE DETECTION AND REGISTRATION OF HIV-ANTIBODIES IN DONOR BLOOD
Hessing, Helm.; Koot, A.M.; Schout, N.A.; Platani, A.; Brown, J.M.

* Red Cross Blood Bank, Amsterdam, ** Proton-Witten, Eeten-Leur, *** Wellcome Nederland, Healy, The Netherlands.

Objective: To develop a fully automated system for the detection and registration of anti-HIV in donor blood.

Methods: Anti-HIV tests are done with an ELISA system in microtiter plates (Wellcome, Wellcome, UK). The automated system functions as follows: microtiter plates are provided with barcoded labels and positioned in a pipetting robot (Beck DM, Switzerland). Before the pipetting program for the delivery of serum in the wells starts, the plate's barcode is read by a barcode pen and the barcode of the test tubes is electronically read by the built-in laser scanner of the robot. The position in the plate of each sample is stored in an IBM-PC. After the completion of the tests, the plate is automatically read by a reader (Wellcome diagnostics) and the results are stored on a diskette in the IBM-PC. A special program transfers the test results from the IBM-PC to the SP 3000 mini-computer.

Results: The system now operates under routine conditions and over 100,000 serum samples are tested. No major problems were encountered.

Conclusion: ELISA test systems for anti-HIV detection can be fully automated, which contributes to a safer blood supply by avoiding human errors as well as a reduction of the workload in the bloodbank.

B.512 IMMUNE ACTIVATION IN HIV POSITIVE AND NEGATIVE HEMOPHILIC
Yasuhira, Nobuhiko; Y. Oura; T. Koyama

M. Higuchi and I. Kubota
Department of Internal Medicine, Hyogo College of Medicine, Hyogo, Japan.

Objective: To analyze signs of immune activation observed in hemophilic patients with and without HIV infection.

Methods: The absolute CD4 number, percent CD4/CD8 ratio, is positive cell percent and IgG, IgA, IgM and serum immunoglobulin G (IgG) of hemophilic patients (18 seropositive, 23 seronegative) followed for 5 years in Hyogo prefecture.

Results: Increased levels of serum IgG and is positive cell percent were observed in both seropositive and seronegative groups. And the level of serum IgG in seropositive group was higher than that in seronegative group with statistical significance (P<0.005). Moreover, the correlations between 74/76 and IgG (r=0.546), and between 74/76 and is positive cell percent (r=0.405) were showed only in seropositive group.

Conclusion: Hemophilic patients show some signs of immunostimulation. Increasing levels of IgG and is positive cell percent appear to be correlated with declining immune status in seropositive group.

- B.555** HIV Antigenemia in Patients with AIDS and HIV Infection: A Comparison Between Racial Groups. **Ennis, Edwartz.**
 Serological: C. Faragoles H, Bartlett J, Quinn T, Chaisone R E
 The Johns Hopkins University, Baltimore, Maryland, USA.
 Objective: To determine if HIV p24 antigenemia differs in white and black American patients, as has been suggested in Africa and European patients.
 Methods: 193 consecutive patients with AIDS or HIV infection who presented for clinical trials were studied; 104 had available results. HIV-Ag was measured by the Abbott HIA and verified by neutralization assay. CD4 counts were performed by flow cytometry. Patients were classified by clinical diagnosis and by CD4 counts.
 Results: Overall, 37/132 (24%) of white patients and 7/32 (22%) black patients were HIV-Ag (+ve). Specific results are as follows:

AIDS	White			Black			p value
	Age	Sex	%	Age	Sex	%	
CD4 > 200	27	M	17	0	F	0	0.29
Non-AIDS	15	F	17	0	F	0	0.29
CD4 < 200	12	M	60	6	F	43	0.42
CD4 < 200	12	F	14	14	F	46	0.20

A higher proportion of white non-AIDS patients (30%) were symptomatic than black non-AIDS patients (8% = 0.05).
 Conclusion: The prevalence of serum HIV-Ag does not differ between clinically comparable white and black populations, regardless of clinical status or CD4 number. Prior observed differences cannot be explained by racial variation and suggest that perhaps geographic factors or difficulty in diagnosis of AIDS in developing countries may play a role.

- B.557** ABSENCE DE SEROCONVERSION APRÈS UNE MÉRICITE DE FRENCHINÉTRINE A VIE.
 Biais, J.M., Dubouché, A., Izuel, G.,***
 Sorrenti, D.,*** Lafai, C. *

* Service des maladies infectieuses et tropicales, ** Laboratoire de microbiologie, Villeneuve St Georges - France, *** Laboratoire de virologie et sérologie, CHU, Fontvieille sur Mer - France.
 Objectif: Suivi sérologique et virologique de VIE chez un homme de 26 ans ayant présenté une urticelle aiguë, une ulcération génitale et une méningite de prae-infection à VIE 10 jours après un premier et unique contact heterosexual avec un prostitué.

Méthodes: sérologie ELISA VIH et E. HIA, immunofluorescence, Western Blot, recherche d'anticorps antiprotéine gag, antigénémie EIA, culture rétrovirale à partir de lymphocytes du sang périphérique avec mesure de l'activité transcriptase inverse, PCR (en cours).

Résultats: Tous les examens réalisés sur 10 mois sont restés négatifs hormis une positivité transitoire de Western Blot à J40 après le contact (P18, J25, Op10, Op16) et la culture rétrovirale à 3 reprises (J40, J134, J280). Le patient est asymptomatique et sérologique à 1 an.

Conclusion: Cette observation confirme la possibilité de transmission du VIE après un contact heterosexual unique, favorisée par les maladies associées. L'infection à VIE apparaît dans certaines cas impossible à détecter par les techniques usuelles pendant des périodes prolongées ainsi de favoriser la dissémination du virus. Des études sont actuellement en cours pour caractériser le virus et le statut immunitaire du patient.

- B.559** INTEREST OF COMPUTED TOMOGRAPHY OF THE CHEST (C-CTS) IN 120 HIV-INFECTED PATIENTS (PT) WITH RESPIRATORY SYNDROME (RS).
 M.F. Gerets, Michel Denis, D. Renard, C. Nayat, C. Aboum.

J.M. Hight. Dept. pneumology, radiology - Hôpital Tenon - Paris - France.

Objective: To determine the interest of C-CTS in 120 HIV-infected pts with RS leading to pulmonary infections.

All C-CTS were performed in high resolution (1 mm - 512 x 512) and were studied with knowledge of clinical features; data were compared with final diagnosis. First, we had to consider 2 groups according to normal (G1) or abnormal (G2) chest X-ray.

In G1 (1) Normal C-CTS does not exclude TB, lymphocytic alveolitis or opportunistic infection at an early stage. 2) In some cases, C-CTS showed hilar or mediastinal enlargement, usually associated with tuberculosis. 3) In few cases with suppurative bronchitis and alveolitis due to community-acquired bacteria, C-CTS demonstrated bronchial localizations.

In G2 (1) Pseudocystic cavities (PCC) or a localization of Kaposi sarcoma (KS) were usual. 2) PCC, if appeared as very low intensity diffuse interstitial (and alveolar) opacities, without other abnormalities except cysts. 3) If there was pleural effusion, lymph node enlargement or pulmonary excavation, another diagnosis or an association must be considered. 4) KS appeared as bilateral pleural effusion and peribronchovascular opacities more clearly than in G1. 5) It may also appear as a focus or a diffuse nodular pneumopathy.

Conclusion: C-CTS was of major interest: 1) In G1 when there were hilar or mediastinal abnormalities. 2) In G2 when there was an association of radiological abnormalities.

- B.556** TRANSDUCTION, RIA AND RAPID SCREENING FOR HIV-1 CONFIRMED BY COMBINED TESTING FOR ANTIBODIES AND ANTIGENS
 M. Gagnier, C. Colvert, Y. Pichon and M. Chermak.
 McMaster University Medical Centre, St. Joseph's Hospital, Hamilton, Canada.

Objective: A total of 14 sera from well defined patient infections (5 AIDS, 3 ARC, 4 asymptomatic; 4 negative) were used to evaluate 10 commercial kits for HIV antibodies and another 3 for antigens.
 Methods: Antibody tests included 6 EIAs (Abbott, Organon, Dupont, Diagnostic Systems, Wellcome and Ciba) and 3 Western Blots (Dupont, Vitarin, Bio-Rad), 2 Microscopy tests (Vitarin ImmunoFluorescence, IF and Immunoprecipitation, IP) and 4 rapid assays (Abbott passive hemagglutination (PA) and Testpack; Dupont; HIVCHECK and Chiron; Coaltex and Organon). PA and IP were tested for antigens using tests from Coaltex, Organon and Dupont.

Results: All 6 EIA screening tests were in agreement on 11 sera (8+), 3 discordant results were seen in an antigen positive AIDS patient: an asymptomatic patient with a single p24 band and an HIV2 positive patient. EIA results were confirmed by WB, IP or IF except for these 3 problem sera. The IP and IF tests mimicked WB results closely. Antigen testing which showed no discordance in this series, provided a better understanding of discordant antibody test results. The rapid antibody tests were accurate except for HIVCHECK which demonstrated a problem with sensitivity.

Conclusion: A combination of confirmatory tests such as WB and IP or IF can provide added assurance on interpretation and reporting of discordant sera.

- B.558** LE RETROVIRUS FORME-EXPRIME CHEZ SON PORTEUR EST SEMI-QUANTIFIABLE A PARTIR DES CELLULES MONONUCLEAIRES (CMN)
 Michel Potemkin, Paul D. Smith W. L. Labovitz J.
 INSERM U-393, Centre de Recherches, Centre-Paris-Ouest, France, *ONCO Laboratoire, North Chicago, Etats-Uns; **Institut Pasteur, Paris, France.

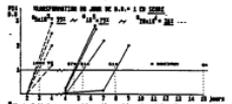

Objectif: Quantifier le rétrovirus présent dans les CMN du patient au moment du prélevement de sang avec leur contenu en VIH génomiques non transcriptés dans une infection chronique.

Méthode: Les CMN (total) contenus de sang VIH séro-négatives, traitées (50000 x) et la même rétrovirus est prélevée dans la culture deux fois par semaine. Les CMN ont été stockés en azote liquide dans la culture deux fois par semaine. Les CMN ont été analysés à l'aide de la méthode de culture de cellules ex vivo.

Résultats: La vitesse de production de rétrovirus par les CMN est transformée en valeur score, qui varie de 0% (D.O.I.) à 100% (1 à 3). La moyenne des vitesses pour un spécimen donné est fonction du temps de culture de cellules.

Les mêmes données de base sont obtenues en CV-293, au moment du prélevement de sang à J12-18 mois après le début de l'infection.

Conclusion: Le niveau d'expression du virus dans un point de mesure biologique peut être mesuré par la vitesse de production de rétrovirus par les CMN. La vitesse de production de rétrovirus par les CMN est semi-quantifiable à partir des cellules infectées.

B.561 QUANTIFICATION DES ANTI-p25 VIH PAR DENSITOMETRIE SUR ANTIPODES DE RECOMBINAISON GENETIQUE (CHIRON, RIA, HIV-1B).

Centre de Transfusion et d'Hématologie, "Laboratoire de Microbiologie, Centre Hospitalier de Versaille".
 M. HANIC, M. C. CHIRON, M.-C. MAISONNEUVE, P. CHIRASSIA, J.-C. DE SAINT-PAUL, B.P.

Objectif: Quantifier par densitométrie les anticorps anti-p25 dans un test de confirmation basé sur des antigènes de recombinaison génétiques sur phase solide avec mise en évidence des anticorps par une antagoniste marquée à la peroxidase de radon (CHIRON RIA HIV-1B, Orho France) et comparer les résultats obtenus sur les séruma séquentiels de patients avec ceux de la technique utilisée en routine (ABSTRACT HIV core recombinaison antigen competitive EIA) calibrée sur un sérum de référence permettant le tirage de 1 à 256.

Méthodes: Les bandelettes RIA CHIRON sont utilisées conformément aux recommandations du fabricant. Elles sont réalisées avec un déterminant SOMODIOM CO-50. Les anti-p25 sont exprimés par rapport au titrom de réactivité IgG. On présente sur chaque bandelette. Des courbes de dilution 10 par 10 (1/1000 de sérum de référence mélangé anti-p25) ont été réalisées à 4 échelonnages. Les conditions sérologiques de 25 patients (84 sérum ont été étudiés).

Résultats: L'évolution du taux des anti-p25 mesurés par densitométrie se conforme aux résultats connus. La sensibilité de la mesure des anti-p25 par RIA CHIRON est supérieure à la technique de référence pour les valeurs basses comme pour les valeurs élevées. Chez certains patients les anti-p25 continuent d'augmenter plusieurs années après la contamination.

Conclusion: Un test destiné à la confirmation massé standardisé par l'utilisation d'antigènes de recombinaison génétiques et de témoins fournit des indications quantitatives d'intérêt pronostic.

B.563 STUDY OF SPREADING IN 36 AIDS PATIENTS FROM 1982 TO 1988 IN RIO DE JANEIRO, BRAZIL.

Belisário-Oliveira, C.A.; Wada, M.A.; Figueira, F.J.; Góes, E.; Pereira, P.; Gomes, A.; Mendes, A.; and Silva, J. Centro de Diagnóstico e Referência Epidemiológica, Fundação de Amparo à Pesquisa do Estado de Rio de Janeiro (FAPERJ-PRONEX-82) - Brazil.

OBJECTIVE: To demonstrate the main infectious aetiologies found among 36 infectious AIDS patients, and compare the findings among time groups.

METHODS: The starting techniques used were: serological (serum, Pw, Smoott) and histology.

DISEASE	1982-85		1986-88	
	n	%	n	%
CMV (+) and (-) bacteria	11	30.6	10	27.8
Herpes B virus	11	30.6	10	27.8
Cryptosporidiosis	12	33.3	6	16.7
Pneumocystis carinii	11	30.6	1	2.8
Parasitosis	11	30.6	1	2.8
Chlamydia	1	2.8	1	2.8
Parasitosis	1	2.8	1	2.8
Cryptosporidium	1	2.8	1	2.8
Parasitosis	1	2.8	1	2.8
Cryptosporidium	1	2.8	1	2.8
Parasitosis	1	2.8	1	2.8
Cryptosporidium	1	2.8	1	2.8
Parasitosis	1	2.8	1	2.8

CONCLUSIONS: 1. Tuberculosis was the most frequent cause of infectious aetiology. 2. Chlamydia was the most frequent aetiological agent associated with gram positive and negative bacteria, pneumocystis and candida albicans. 3. Tuberculosis is frequent cause aetiology of HIV/AIDS patients. 4. Tuberculosis shows a quantitative association with candida albicans, pneumocystis and cryptosporidium.

B.565 PRELIMINARY LABORATORY FINDINGS OF THE CENTRAL NERVOUS SYSTEM IN HIV INFECTION.

Smith, S.M.; Davis, F.P.; Bannister, C.M.; Bassett, R.M.; Falciano, M.J. and Shalton, J. Univ. of California, San Francisco, CA, USA.

100, 3000 Service of Pathology, 1100 Div. of Infectious Diseases, Sausalito Hospital, Sausalito, California, USA.

Objective: to describe the incidence of primary acquired immunodeficiency (AIDS) of the Central Nervous System (CNS) in HIV positive patients.

Methods: The data concern 87 subjects of HIV-like AIDS pts, and 10 stereotaxic biopsies from pts. with extensive nodular lesions with evidence of differential diagnosis in inflammatory and neoplastic lesions. Routine studies were employed. Immunohistochemical analysis and phenotypic cell identification failed for antigenic series of specimens.

Results: post mortem examination of HIV positive-died adult pts. revealed 8 cases of primary acquired AIDS, 6 of CNS. 6 most of neurologic signs 1 patient was group II, 2 pts. group III and 3 cases group IVa (WHO GC classification); none had systemic clinical signs of lymphomatous disease. CNS. 1 infection revealed 8 cases of single deep intracerebral abs. 1 case of double cerebral-cerebellar supratentorial process and 3 cases of multifocal-intracerebral lesions. HISTOPATHOLOGY (H&E) identified 5 cases as lymphomatous with plasmacytoid differentiation. 1 case 1 case as large cell disease cell. 1 case (1 case the stereotaxic biopsy case). Neoplastic lymphoid cells presented thick perivascular cuffs and spread to subarachnoid and Virchow-Robin spaces. **Conclusion:** 1) Primary acquired AIDS. represent 10% of all A.S. series. 2) Prevalence of high CD4 T cell primary acquired AIDS. 3) The positive cerebral localization and therapeutic possibilities are stereotaxic biopsies essential in diagnosing these patients.

B.562 A SENSITIVE AND SPECIFIC ANTI-HEV 2-ELISA USING AN ENVIRONMENTAL SYNTHETIC PEPTIDE.

Knapka, USA; Brust, St.; Behringwerke AG, 3550 Marburg, FRG

Objective: To evaluate the efficiency of an ELISA (Enzygnost-Anti-HV 2), based on a synthetic peptide corresponding to the glycoprotein of HEV 2. **Methods:** 100 µl uncoated samples were pipetted in 50 µl diluent into each well of microtiteration plates coated with 1 synthetic peptide. The incubation over 30' at 37 °C is followed by 4 washings and the addition of 100 µl peroxidase labeled Anti-HV 2. After another incubation for 30' at 37 °C and 4 washings, the colour development is performed over 30' at RT using TMB.

Results: Of 71 Anti-HV 2 sera all specimens reacted clear cut positive. Compared to a commercial assay an improved detection limit of factor 4 was found by testing serial dilutions of Anti-HV 2 sera. Only weak cross-reactivities were observed when HIV 2 Anti-HV 2-sera were tested. From a total number of 1500 negative sera and plasma a specificity of 99,8 % was calculated.

Conclusions: This new ELISA turned out to be highly sensitive. The ELISA 2 showing only weak cross-reactivities with Anti-HV 1, making this assay best suited to differentiate between Anti-HV 1 and -2.

B.564 ROLE OF HIV IN HEMIPARALYSIS. CASE REPORT.

Palazzo, D.; Owen, S.M.; Strydom, H.A.; Adamovich, V.M. and Adelman, D.

MAZD Research Centre, Biomed Canada Inc., ** Faculté de Médecine, Université de Montréal, *** Institut Armand Frappier, Montréal, Québec, Canada

One health status deteriorates drastically in AIDS patients. The present studies aim at correlating the presence of HIV in peripheral blood lymphocytes (PBL) and salivary lymphocytes (SL) with incidences of oral disease.

HIV was searched for in PBL, saliva and SL obtained from 90 patients at different stages of HIV infection by means of immunofluorescence (IF), post-exposed immunogold assay (PIGA) and culturing studies. Quantity of HIV positive cells were electron microscopy (EM) and culturing studies. Quantity of HIV positive cells were compared with the incidences and the evolution of oral disease assessed by monthly over a period of two years. HIV particles and/or antigens were found in PBL, gingival epithelial cells and endothelial cells, lymphocytes involved in plaque, as well as in SL. The incidence and the percentage of HIV-containing cells found in gingiva and saliva was significantly higher than in PBL. Incidences of a variety of oral disease can be positively correlated with the number of infected cells in gingiva and saliva.

These findings suggest that: 1) HIV-positive PBL in gingiva receive antigenic and/or antigenic stimulation by the oral flora resulting in the greater expansion of the virus. This stimulus is supported by our current studies in vitro of stimulation of production of HIV by oral micro-organisms. The presence of HIV in gingiva may be associated with a high stimulation of the local CD4-T cell mediated immunologic reaction associated with a high stimulation of a variety of oral disease behavior.

B.566 NEUROPSYCHOLOGICAL EFFECTS OF EARLY HIV-1 INFECTION: DIAGNOSTIC AND PROGNOSTIC IMPLICATIONS

Isurubaru, Loggia, J., Bridge, P., Janssen, R., Slosser, E., Hwang, R., and Goodwin, J. CDC, Atlanta, GA, USA, **MIMS Intrantel, Bethesda, MD, USA, ***ADAMA, Rockville, MD, USA.

Objective: To recommend a common methodological approach for neuropsychological assessment in HIV-1 infected individuals to foster meaningful comparisons among studies.

Method: Methods used in studies of neuropsychological performance in HIV-1 seropositive individuals were reviewed.

Results: Despite considerable methodological variation observed in studies, investigators generally agree on general domains for assessment. We here recommended specific instruments.

Conclusion: Investigators can optimally contribute to knowledge about neuropsychological effects of HIV-1 by: 1) developing or using markers for disease effects in early HIV-1 infection; 2) applying longitudinal designs; 3) using common instruments when assessing the multiple domains that demonstrate sensitivity to the neurotoxic effects of HIV-1; 4) selecting controls appropriate to the design and research question; 5) evaluating and controlling for co-factors such as knowledge of serostatus, substance abuse, and psychiatric symptomatology; 6) reporting results for both observed change (e.g., 1 SD) as well as impairment (e.g., 1.5 SD) and 7) reporting how impairment affects individuals' daily activities.

B.568 THE INCIDENCE OF A MARKER FOR CHOLINERGIC DYSFUNCTION IN AIDS/ARC.
VALDESKY, W., TULLIN, S., EVANS, C., SATZ, P., FREEMAN, D. and HINKIN, C.
Veteran's Administration West Los Angeles and UCLA School of Medicine, U.S.A.

Objective: A specific pattern on the Wechsler Adult Intelligence Scale-Revised (WAIS-R) associated with cholinergic dysfunction has been reported by Fuld to occur in 50% of patients with Alzheimer's disease and in 20% of younger individuals given scopolamine, while occurring in only 10% of patients with multi-infarct dementia, head injury, depression, and normal elderly individuals. This study sought to determine the incidence of this WAIS-R pattern ("Fuld formula") in patients with AIDS and ARC and the AIDS Dementia Complex.

Methods: The WAIS-R was administered to 116 patients: 40 with AIDS and 76 with ARC. The incidence of the Fuld formula on the WAIS-R was calculated for all patients. **Results:** Of the 116 subjects tested, 11 demonstrated a positive Fuld profile pattern on the WAIS-R (9%), not significantly different from the incidence in non-cholinergically deficient patient groups studied to date. However, 8 of the persons with AIDS (20%) demonstrated the WAIS-R pattern, while only 3 of the ARC patients (4%) demonstrated this pattern.

Conclusions: An increased incidence of a WAIS-R pattern associated with cholinergic dysfunction (scopolamine) and cortical dementia (Alzheimer's disease) was not demonstrated in this sample though a greater number ($p > .05$) of more seriously immunocompromised patients demonstrated the profile compared with less immunocompromised patients. These results support prior reports of the specificity of the Fuld formula for dementia of the Alzheimer's type than in other types of dementia, including the AIDS Dementia Complex.

B.579 THROMBOTIC THROMBOCYTOPENIC PURPURA(TTP) IN AN HIV-INFECTED CHILD: TREATMENT WITH D-SEMPROST-8-D-ARGININE(DSAPV) AND INTERFERON- γ (IFN- γ)

Church, Joseph A.; Marshall, D. and Leung, K. Childrens Hospital of Los Angeles and U.S.C. School of Medicine, Los Angeles, California, U.S.A.
Objective: To describe therapy of TTP in an HIV-infected child.
Methods: Case report. **Results:** After 2 weeks of upper-respiratory infection symptoms, a 44 year old boy with Down Syndrome and transfusion-associated HIV infection presented with acute haemolytic anemia. Previous hemogram and blood chemistries were normal. Immune status was stable with CD4-lymphocytes(520/mm³) and IgGgA(1.193 mg/dl). Laboratory data: Hgb-4.5 g/dl, Hct-11.8%, WBC-10.0 x 10⁹/l(70% neut.), LfL lympho), sedimented rate=10/1000g platelet count=10.2 x 10⁹/l, peripheral smear-consistent with severe microangiopathic hemolytic, schistocytes-2, platelet, 24 seen. Blood urea nitrogen=30 mg/dl, direct and indirect antiglobulin tests-negative. Despite supportive therapy with antibiotics and CO₂ and platelet transfusions, hematology continued, the platelet count dropped to under 5 x 10⁹/l and gross hematuria developed. The patient was given DSAPV(0.3 mg/kg) and began on IFN(300 mg/kg daily for 5 days). Thrombolytic therapy, hemolysis decreased, platelet count improved and hematuria cleared. Three months later his hemogram and blood chemistries were normal. **Conclusions:** This patient's clinical course indicates that, as in adults, HIV-infected children are at risk for TTP. DSAPV and IFN may play a role in the termination of the microangiopathic process characteristic of TTP.

B.581 MUCOCUTANEOUS MAFOSI'S DERMOMY: A MARKER OF PEDIATRIC AIDS.

Edwards, Yolande; Samuels, C. and Kistis A. **Uganda Cancer Institute, (UCI) Uganda.**

Objective: To describe clinical features of childhood Mafosi's syndrome (MS) that is a marker of AIDS.

Methods: Case records of all children admitted to the UCI with diagnosis of MS between June 1987 and January 1989, were reviewed for features that are suggestive of pediatric AIDS. Evaluation of these children included a history and physical examination, investigations including a full hemogram, an ECG, chest X-ray, liver function tests, renal function tests, ultrasound of the abdomen and biopsy of either a skin lesion, lymphnode or both. HIV serology was done using latex-agglutination kit and western blot for confirmation. Patients were staged according to the staging classification by R.L. Mufson et al. (Cancer Treatment Reports 1983; vol. 67, pp. 531-534).
Results: Six children all stage 4 (5 male, 1 female), median 2.5 yrs (range 2-4 yrs) were seen over this 18 mo period. All had histologically confirmed MS and HIV serology with western blot confirmation in 1 case. 4 were HIV +ve, 1 falsely negative, 1 HIV -ve. The 4 HIV +ve children and the one falsely negative child had mucocutaneous MS in addition to lymphnode involvement. The HIV -ve child had only lymphnode MS.
Conclusion: Disseminated aggressive histologically confirmed MS in children should be considered a marker of AIDS as it is in adults.

B.583 RANULA CYSTS IN CHILDREN WITH AIDS

Anderson, Yvonne; Lee, W., N.;; Green, N. A.;; **Arvey, A. Pediatric AIDS Study Group, Mount Sinai Health Science Center, Interfaith Medical Center Brooklyn NY, New York University, NY USA**

Objective: To report the clinicopathologic correlations of ranula cysts in children with AIDS.

Methods: Two cases were reported: 1) Patient 1 had lymphadenopathy and lymphocytic interstitial pneumonitis (LIP) at age 1 year and a 3cm in diameter, sublingual, ranula cyst which was excised at age 2. Within 3 weeks it reoccurred only to spontaneously disappear two months later. 2) Patient 2 had LIP with oral leukoplakia and hypoxia at age 2 years. Following treatment with steroids, a 1cm in diameter ranula cyst disappeared.

Results: The sublingual excisional biopsy of the collapsed cyst revealed a fibrous shell containing lymphocytes and plasma cells that also infiltrate islands of mixed salivary gland tissue containing ectatic ducts lined by pseudostratified epithelium.

Conclusions: Ranula cyst resembles cystic parotid lymphocystic lesions described in adults with AIDS. Ductal obstruction by inflammatory cells is part of the spectrum of steroid-resistant, extraneoplastic, polycystic, polypycystic, 8 wall lymphoproliferation most often presenting as EBV related LIP in children with AIDS.

B.580 GLIANT CELL TRANSFORMATION OF THE LIVER IN PEDIATRIC AIDS

Kahn, R.; Datta, P.; Glick, M.;; Haged, M.;; Harnack, P.;; **Anderson, Yvonne.**

North Shore Univ. Hosp., Massachusetts-General Univ. Med. College, NY, NY; Univ. Hosp., NY, NY; Montefiore Hosp., Univ. of Chicago, Chicago, IL, NY; Albert Einstein Med. College, NY, NY; Montefiore Dept. Health, NY, U.S.A.

Objective: Emphasize that giant cell transformation occurs in the liver of children with HIV infection.

Methods: Review of liver tissue of 46 children with AIDS (Hicopeles =7, subtypes=42).

Results: Giant cell transformation of the liver was seen at autopsy in 4 of 46 children. All had HIV infection in children as their risk factor for AIDS.

IC	Age	Sex	HAI	Inflammation	Cause of death
1	5	M	-	+	sepsis, GAD
2	5	F	+	+	resp. failure
3	6	M	-	-	resp. failure
4	10	M	-	-	resp. failure

Conclusion: Giant cells occur not only in AIDS associated encephalopathy but also in the liver of children with HIV infection. We therefore confirm a previously published report (Williamson - Ann Pediatr 120: 603, 1988) that HIV infection in children may cause giant cell transformation of the liver.

B.582 SIMILAROUS OCCURRENCE OF PAROTID SWELLING & LYMPHOCYTIC INTERSTITIAL PNEUMONITIS IN CHILDREN WITH HIV DISEASE.

Duggal, Asha, Kaul, A., Shah, K., Groth, K., Chow, J. S. & Li, E.

New York Medical College, Valhalla, New York.

Over the last 4 years, 118 children under the age of 13 years have been followed at our affiliated institutions. 25 of these children had clinical and radiological evidence of lymphocytic interstitial pneumonitis (LIP). In three of the cases, the diagnosis was confirmed by biopsy. All of the 25 children also had parotid swelling. There was no child in our series who had either of these two parotid findings as an isolated finding.

It has been postulated that LIP is caused by Epstein Barr virus induced lymphoproliferation. Children who are exposed to HIV in utero handle EB virus infection abnormally leading to the development of LIP. Adults on the other hand acquire EBV infection after primary exposure to EBV and LIP is a rare occurrence in adults. We postulate that parotid swelling may also be caused by EBV infection related lymphoproliferation.

Demonstration of EBV genome in parotid gland will be required to support this hypothesis.

We conclude that the findings of parotid swelling and LIP occur simultaneously in pediatric HIV disease. Children who present with parotid swelling should be observed carefully for the development of LIP and LIP should be a consideration in these children if they develop respiratory symptoms.

B.584 SEVERE REACTIONS TO TRIMETHOPRIM-SULFAMETHOXAZOLE IN CHILDREN INFECTED WITH THE HUMAN IMMUNODEFICIENCY VIRUS

Stephen Charnock; Lugubuhli, L.;; McIntosh, K.;; **"Division of Infectious Diseases, The Children's Hospital, Boston, MA USA.**

Adverse reactions to trimethoprim/sulfamethoxazole (TMP/SMX) therapy occur with greater frequency in patients infected with HIV and commonly occur in all of the following: leukopenia, thrombocytopenia, and rash. Severe reactions, such as Stevens-Johnson syndrome or seizures, have been reported in several adult patients. We report two congenitally infected children who developed severe life-threatening reactions to TMP/SMX therapy. An eight month old male was noted to develop fever of 40°C, vomiting, lethargy, a full dose, and a combination of a maculopapular and urticarial eruption shortly after beginning a second course of TMP/SMX. Laboratory investigation failed to identify an alternate etiology. Later, he was rechallenged with TMP/SMX and developed identical symptoms. A second child, 10 months old, with a history of maculopapular eruption to TMP/SMX therapy, was rechallenged and shortly thereafter developed vomiting, fever of 38.4°C, and respiratory distress (with a negative chest X-ray). Over the next 24 hours, he developed hypotension, acidosis, and a cardio-pulmonary arrest. TMP/SMX was discontinued and the patient recovered over 48 hours. Over the next five days, the following were noted: metabolic, conjunctival, mucous membrane and erythema of the palms, soles, and lips, which led to diffuse, superficial desquamation. Investigation failed to determine an alternate etiology. The occurrence of life-threatening reactions to TMP/SMX therapy should be taken into consideration in the care of children with HIV infection.

- B.591** EFFICACY AND SAFETY OF KETOCONAZOLE IN HIV INFECTED INFANTS WITH MUCOCUTANEOUS CANDIDIASIS: Jeffrey, M.B., Cooper, E.R., Patel, D.K., Patton S.L., Boston City Hospital, Boston University School of Medicine, Boston, Massachusetts, U.S.A.

Mucocutaneous candidiasis is a common opportunistic infection in children with HIV disease and associated with significant morbidity (fever, poor feeding, failure to thrive). Recommended therapies such as Nystatin and nystatin vaginal have not been effective in immunocompromised hosts with moderate to severe candidiasis. We treated 4 infants, ages 1 to 8 mos, with a Ketoconazole suspension (prepared by pharmacy) of 3 mg/kg q 12 h for moderate to severe thrush (3 patients) which involved buccal mucosa, tongue and palate and was associated with poor feeding and weight loss. All had failed a minimum of 7 days of Nystatin a nystatin vaginal. All 3 cleared on Ketoconazole in 3-5 days. 2/3 had recurrence when therapy was discontinued which necessitated "prophylactic" administration of 3 mg/kg/day for 3 and 10 mos, respectively. 1 patient (8 mos.) was treated for seborrheic dermatitis which had failed topical Ketoconazole wash. All children had pre and post treatment evaluation of liver function. No adverse effects were observed. Specifically 1 infant (2 Y1) 4 mos. of age received Ketoconazole and Zidovudine concurrently for 3 mos. Pre therapy LFTs demonstrate moderate hepatocellular injury (SGOT 390, SGPT 104, Billi 7.3). LFTs progressively return to more normal values (SGOT 79, SGPT 50, Billi 1.7) over a 3 mos. course while on both medications. We believe Ketoconazole is a safe and effective therapy of mucocutaneous candidiasis. More information is needed about its concurrent use with Zidovudine and its use in children with evidence of hepatocellular dysfunction.

- B.593** WHICH AIDS PATIENTS NEED STOP DRUG CARE? A PROSPECTIVE STUDY
Muller, Bruce D., Ph.D., University of Washington, Seattle, Wash, R.K.,**
*University of Washington, Seattle VA Medical Center,
**AIDS Prevention Project, Seattle, Washington, USA.

Objective: To assist in discharge planning for hospitalized AIDS patients in need of special AIDS services and about nursing (N) and social work (SW) we carried out a prospective study of 100 persons with AIDS to determine the characteristics of patients in need of such care, and to develop a classification rule to easily identify them at the time of admission. **Methods:** We obtained demographic, medical, and social profiles of patients near the time of admission to the hospital, and concurrently interviewed their doctors, nurses, and social workers regarding appropriateness of stop drug care as a substitute for part of their hospital stay. **Results:** Of the 100 patients (men, mean age 35 yrs), 21 were considered appropriate for stop drug care by their physician and nurse or social worker (or all 3). The appropriate patients were more likely to live alone (58 vs 29%), have poor (<4) Barthel's Activities of Daily Living (ADL) scores (48 vs 63), be impaired in activities of daily living (ADL) (77% vs 17%), or on Medicaid (53 vs 42%) (all, p<.05). In multivariate analysis, three variables contributed significantly to a classification function: living alone, poor ADL score, and impairment in ADL. The function was developed on a 608 random sample of subjects, (83% correct classification, sensitivity 92%, specificity 78%, positive predictive value 73%, negative predictive value 93%, kappa .67) and applied to the remaining 40 (sensitivity 83%, specificity 87%, kappa .62). **Conclusion:** AIDS patients appropriate for various lengths of time from those who are not in several important characteristics identifiable at the time of admission. Knowledge of these factors may aid in discharge planning.

- B.595** AN EARLY INTERVENTION PROGRAM FOR CHILDREN WITH HIV
Morgan, Marjell, Kaplan, M., Sloan, L., Harvell, J., Calver, A., Redell, G., et al.
SRII Health Science Center at Brooklyn, NY, U.S.A.

OBJECTIVE: To describe the program for developmentally delayed (DD), HIV infected children and to evaluate the children's performance. **BACKGROUND:** The Infant and Child Learning Center (ICLC) provides a comprehensive educational, therapeutic and psychosocial program. Each home and caregiver attend a small class several times a week where they participate in activities that address the child's individual needs and strategies. The staff routinely reassesses the goals for each child in order to document developmental skills. A retrospective review was done on 22 children enrolled in the program for various lengths of time (1 mo. to 18 mos., mean 7.5 mos.).

RESULTS: Located in a hospital setting, the ICLC provides a supportive environment where families can freely express their concerns and receive immediate medical consultation and services. The table shows the results of a 3 point criterion rating scale measuring the number of children who progressed, regressed or remained the same during the time spent in program.

	Cognitive	Social/Emotional	Motor	Language
3 progressed	13	31	29	32
4 same	11	24	25	18
4 regressed	22	44	35	30

CONCLUSION: In order to effectively service these children, an interdisciplinary, comprehensive model is necessary.

- B.592** HIV-1 GP 41 ANTIGEN IN THE SERUM OF HIV INFECTED CHILDREN
Hilgart, Madsen; Calveliti, T. and Robinson, A.
Albert Einstein College of Medicine, Bronx, N.Y., U.S.A.

Objective: To detect the presence of HIV-1 gp 41 antigen in the sera of HIV-infected children and correlate with disease activity. **Methods:** HIV-1 gp 41 antigen (Ag) was assayed by an immunoblot assay involving fraction with monoclonal gp 41 antibody followed by peroxidase-conjugated goat anti-mouse IgG. A positive reaction was detected by color development upon addition of substrate, and reactive samples visually graded. **Results:** Eighteen of 100 (18%) patients had gp 41 Ag present in their sera. The concentration of HIV protein p17, p24 and gp 120 in the serum of course and who died. The concentration of serum gp 41 paralleled the concentration of HIV protein p17, p24 and gp 120 in the serum. **Conclusion:** The detection of gp 41 antigen can be of value as an additional marker of disease activity and prognosis and could be potentially useful in monitoring patients on treatment.

B.594

- B.596** CONTROLLED CLINICAL TRIAL OF ANGINICIN, CHINESE HERBAL TONGUE ENHANCER, IN HIV SEROPROFITIVES
Sarkany, Timothy, AIDS Prevention Center,
San Francisco, California, U.S.A.

Objective: To assess the safety and efficacy of a new Chinese herbal immune enhancer developed in the People's Republic of China, which is produced from extracts of angelica, ginseng, and fructus lycium in the treatment of early to mid-HIV infection. **Methods:** 100 HIV seropositive patients with 7 helper lymphocyte counts between 100 and 600/mm³ and no prior HIV-related hospitalizations or ongoing treatments were randomized into double-blind treatment and placebo-controlled groups. The treatment group was given two Anginicin 50 mg capsules three times a day. Diet instructions were to avoid lobster, shrimp, crab, seabird shoots, duck, goose and alcohol. The placebo group received similar-looking capsules and instructions. All patients were followed at biweekly visits and monthly laboratory studies including CBC, chemistry panel, T and B lymphocyte panels and p24 antigen were performed. **Results:** Symptom tabulation, labs, Karnofsky score, frequency of opportunistic infections, and HIV-related hospitalizations are analyzed on a monthly basis over a 6 month period and summary statistics presented with multivariate analysis. **Conclusion:** Promising non-western therapies for HIV infections deserve formal clinical trials in a randomized double-blind controlled fashion to evaluate their usefulness.

 Manifestations cliniques
 Clinical Manifestations

B.609 HIV-INFECTIONS AMONG
IV. DRUGABUSERS IN THE FRG:

Behavioral, differential risks and proportions of
 frequent change of address.

Kalher, Dieter Sozialpädiatrisches Institut Berlin, Berlin (West), FRG.

Our results of a German (nearby) representative differential-epidemiological study (N=630) to estimate the actual HIV-prevalence-rate and the relative riskness of needle-sharing and sexual activities among iv. drugabusers show a much smaller percentage of infected persons than expected (20.1% HIV-positive). A highly significant difference (German rural area 15.7%) and in sub-populations with different social-history (Prison-Prevalence-rates are significantly higher in iv. drug-addicts having prison-experience (63%) compared to those who never have been imprisoned (37%). The important factors to prevent transmission are the frequency of needle-sharing and sex. From a techniques especially anal intercourse and sex-techniques with high risk. From a preventive perspective the amelioration of living conditions of drugabusers (decriminalization: provision of housing opportunities, work opportunities, rehabilitation from illegality; provision of aid; self-help) cannot be stressed enough. In addition, public announcements should be visible in all places where addicts meet to shoot heroin. Acceptance of conditions must be increased and offers of support for drug-dependent prostitutes who want to leave prostitution should be provided.

B.611 RAPID PROGRESSION OF ORGANIC DELUSIONAL SYNDROME TO

DEMENZA IN AIDS
SHIMIZU, Valerie F. State University of New York at Stony Brook; Stony Brook, New York, USA

Objective: To clinically assess the course of Organic Delusional Syndrome in patients with AIDS.

Methods: Hospitalized AIDS patients referred to the Stony Brook University Hospital Psychiatric Consultation Service were assessed by a board certified psychiatrist utilizing medical chart review and semi-structured interview. Diagnoses were made using DSM-III-R criteria.

Results: Case 1: 39 y.o. male IVDA with AIDS on methadone maintenance experienced an acute onset of delusional persecutions. He responded well to phenelzine, but developed akathisia and coprolalia rigidity. These resolved with the addition of diazepam and discontinuation of phenelzine. Within 2 months he became demented. Case 2: 45 y.o. female former IVDA with AIDS (haloperidol), but developed acute dystonia. This resolved with benztropine and discontinuation of haloperidol. Within 1 month she became demented. She died 3 months later.

Conclusion: It is known that some organic mental disorders can progress to dementia and even death. These cases: (1) confirm the increased frequency and severity of adverse reactions to conventional pharmacotherapies noted by other investigators; (2) suggest that the presence of an organic mental disorder, specifically Organic Delusional Syndrome, may be predictive of the dementia process, perhaps hastening its onset or making its course more fulminant; and (3) raise the question of increased vulnerability to organic mental disorders in HIV-infected IVDA's.

B.613 HIV INFECTION - IMMUNOLOGICAL STUDIES IN

BULGARIA

Plochev, Eshan; Tsakov, H.; Vasiliev, Tsh.; Ognjanov, H.; Dikov, I.; Doganov, B.
 Institute for Infectious Diseases, Sofia, Bulgaria.

For a period of three years we have been studying the immunological status of 50 men infected with HIV (proved by ELISA and western blot). 3 of them have AIDS, 7 slight clinical disturbances and 40 are carriers of HIV.

22 out of these 50 men with HIV infection have signs of dysfunction in the immune system: impaired cell-mediated immunity, changes in the T4/20 ratio and negative skin reactivity. In this group 3 men have AIDS, 7 - slight clinical disturbances and 12 are carriers, the latter having no signs of opportunistic infections or neoplasms associated with AIDS.

B.610 INCIDENCE OF AIDS AND OTHER INFECTIONS IN SPANISH DRUG ADDICTS
ANALYSIS OF 8640 CASES AFTER A DECADE OF FOLLOW-UP (1977-1987)
 Spanish Group for the Study of Infections in Drug Addicts.

OBJECTIVE: To study the prevalence and the characteristics of AIDS and other infections in Spanish parenteral drug addicts reported, using a standardized form, all infectious complications in PDM who required hospital admission or hospital control as outpatients. The diagnosis of the infections were made following preestablished criteria and were the same in all participating centers. The PDM number of 8640 infectious complications in PDM have been reported from 1977 to 1987. The number of cases increased abruptly since 1980. The mean age of PDM was 28 years and the male/female ratio 3/1.

RESULTS: A total number of 8640 infectious complications in PDM have been reported from 1977 to 1987. The number of cases increased abruptly since 1980. The mean age of PDM was 28 years and the male/female ratio 3/1. Infective endocarditis was diagnosed in 637 cases (7%); thrombotic and mixed endocarditis in 782; bacterial meningitis or septic arthritis in 501 (5%); skin or soft tissue infections in 418 (5%); tuberculosis in 262 (4%); tetanus in 6. Other infections: chronic hepatitis in 716 (8%); AIDS in 400 (4.5%); systemic candidiasis (skin, ocular and/or chondrocostal involvement) in 671 (8%); malaria in 8 and "other infections" in 1100 (12%). The overall mortality was 3.5%. AIDS in PDM appeared in our country in 1980 and increased abruptly in 1987. Extrapulmonary or disseminated tuberculosis (1274), esophageal candidiasis (184), pneumococcal meningitis (181) and C.N.S. candidiasis (11.5%) were the most common diagnostic presentations. The cumulative mortality of AIDS cases was 26%.

CONCLUSIONS: Infectious complications in PDM have become an emerging and growing problem in Spain since 1980 and AIDS increased abruptly in 1987.

B.612 CLINICAL CHARACTERISATION OF HIV2 DISEASE IN WEST AFRICA

TUNALI COHARIBI, HENOA A.A., WILKINS A.B., GAYE I., WHITTLE R. AND
CHERNOB R.
 MEDICAL RESEARCH COUNCIL, FALAJA, THE GAMBIA.

OBJECTIVES: Particular attention is paid to the pattern of secondary infections in patients with HIV2 disease.

METHODS: All cases suspected of having AIDS, AIDS selected complex on progressive generalized lymphopathy were enrolled in the study. Haematological diagnosis was made by standard methods prior to test in our laboratory. Primary serology using wallocozyme 1 and 2 tests. Positive HIV1 is confirmed using second-generation gel agglutination test (Bio-Rad) and HIV2 by Elansa II. When concordant test for one or both viruses are made.

RESULTS: At the total number of HIV seropositives studied 241 ADE, 11 PGL, 52 Tuberculosis. The main clinical manifestations of HIV2 disease include weight loss 100%, pyrexia 93% and cough 71%, chronic diarrhoea 64%, chronic night sweats and neurological symptoms 43%.

HIV2 cases mortality and morbidity similar to HIV1. There is evidence of vertical transmission.

CONCLUSIONS:

B.614 OBSERVATIONS CLINIQUES SUR LE HIV 2 INFECTION EN

BULGARIE

DIKOV I., DOBOVITKOVA T., CHAKARONITA R., DUB-ROVKA J., KOTCHEVA R., BURCHERT K. et al.
 Clinique des Maladies Infectieuses, Sofia, Bulgarie
 "Hospital Regional, NOVAPAZ, BULGARIE

Pendant la période de 01.01.1986 jusqu'à 31.12.1988 ont été observés 55 personnes de nationalité bulgare avec une sérologie positive pour HIV 2 par ELISA et Western Blot. 14 personnes ont eu des manifestations cliniques, laboratoires et immunologiques au diagnostic un malade avec tableau clinique de SIDA et infections opportunistiques et 3 autres cas de généralisées, qui ont décédé après 15 mois d'évolution, un malade avec polymyélite récidivante isolée, 5 personnes avec infections indolentes / candidoses, dermatoses subchroniques, complications otologiques et etc., 7 personnes avec ségnes laboratoires / TS élevés, leucopénie et lymphopénie / sans signes cliniques.

B.615 PULMONARY HEMORRHAGE IN PNEUMONITIS OF HIV-INFECTED PATIENTS

Bridhat, Jeanne-Marie¹; Doré, M.F.²; Capron, F.²;
Veked, M.¹; Schmeure, J.¹

¹Department of Pathology, ²Laboratory of Anatomy and Pathologic Cytology; Hôtel Dieu; Paris; France.

Objective: Study the frequency of pulmonary hemorrhage (PH) in pneumonitis of HIV-infected patients by scoring alveolar macrophage hemoferritin load as described by Golse (Golse's score GS).
Results: On 16 of the consecutive 136 bronchoalveolar lavage (BAL) by 20 we diagnosed with a GS greater than 100 (mean value=125) and was occult in 14 cases. In one, a severe thrombocytopenia was concomitant (13,10⁹/l).

PH was associated with bacterial pneumonia (2 cases), opportunistic pneumonia (11 cases) and bronchopulmonary Kaposi sarcoma (3 cases).

A fatal outcome occurred in 2 cases (GS: 117 and 126). In 2 patients with an initial GS of 118 and 113, GS of control BAL performed 1 and 3 months later were respectively 35 and 0. In 3 patients, GS remained greater than 100 in a delay of 1 to 10 months, associated with persistent pulmonary multiple opportunistic infections.

Conclusion: Hemoferritin score is a semi-quantitative approach for the diagnosis of PH. However, in our series, this diagnosis was always associated with either bacterial or opportunistic infections or Kaposi sarcoma.

Diagnosis**
B.617 ETUDE DE LA SPECIFICITE DES ANTICORPS DETECTES CHEZ DES SUIJETS EN COURS DE SEROCONVERSION L'AIDE DE PROTEINES RECOMBINANTES

GAGLLE S., CHABOT C., LESTIER C., **HELANDER, Jean-François**,
Diagnostique Pasteur, Paris, France

Objectif : Montrer la prévalence d'anticorps directs préférentiellement contre la protéine interne p25 ou contre la glycoprotéine d'enveloppe gp120 lors de séroconversion.

Méthode : Les prélèvements sérologiques de sujets en cours de séroconversion ont été analysés par Western Blot et par un test ELISA fondé sur l'utilisation de protéines recombinantes (TRANSEPI, France). Les protéines prévalentes (p25) ont été testées par un ELISA indirect gp120 dirigé dans les cellules NK4 infectées par un virus recombinant de la coxécipier un ELISA indirect p25 (protéine sous forme native avec une souche EL-Cell transfected) et par un ELISA mixte gp120/p25.

Resultat :	ELISA	p25	gp	p25 + gp
100 sulfor. séro.	0,258	0,398	0,258	
Nombre de positivité (%)		2	0	
Nombre de négativité	(100/111)	(100/111)		

CONCLUSION : La majorité des séroconversions présentent des anticorps directs préférentiellement contre la gp120. Cependant la prévalence d'anticorps anti p25 chez certains sujets confirme l'intérêt de l'utilisation de deux protéines p25 et gp120 dans les tests de seconde génération afin de garantir le dépistage de toutes les séroconversions.

B.619 EFFICACY OF ADHESION RECOMBINANT HIV-1 gp120 ELA FOR EARLY DETECTION OF HIV INFECTION

LEUNG, P., ABRAHAM, P., HENDER, J., BRADY, V., PHELPS,
Laboratoire de Bactériologie, Hôpital St-Jacques, Paris, France

The greatest difficulty in HIV diagnosis in Europe is to trace at one's disposal an ELISA test sensitive enough to detect the levels of HIV-2 as well as HIV-1 antibodies in the seroconversion phase. The recombinant HIV-1 gp120 ELA by studying sequential sera from one HIV-2 and seven HIV-1 seroconversion patients.

B.616 HEMOPTYSIS COMPLICATING PNEUMOCYSTIS CARINITI PNEUMONIA

YALOW, K.P. and LOMATSKY, E.
Dept. of Pathology, Mount Sinai Medical & Mental Health Center, Brooklyn, New York USA

Objective: To describe pulmonary destruction with hemorrhage associated with Pneumocystis carinii (PC) pneumonia.

Case Report: A 54 year old Hispanic female intravenous drug addict presented with hemoptysis of two days duration, fever, chills and productive cough. She had diabetes, lymphoma, generalized lymphadenopathy, oral candidiasis and bilateral rales. Radiograph revealed interstitial infiltrates in the right upper and left lower lobes, which subsequently became diffuse, and strongly suggestive of PC pneumonia. Bronchoscopic examination detected active bleeding from the right upper lobe bronchus, anterior segment. Bleeding persisted for five days. The patient's condition deteriorated to respiratory distress, right side pneumothorax, and she expired ten days after admission. At autopsy all lobes showed diffuse hyaline membrane formation, masses of PC in the alveoli and aggregates of foamy macrophages. In addition, the right upper lobe contained a few cavity lesions (0.3 to 1.0 cm) lined by granulation tissue, small remnants of bronchial epithelium, and dilated engorged blood vessels lined with the neovascular. Few PC organisms were demonstrated within the cavities but no other infectious agents were noted in spite of prolonged search with various special stains. It is noteworthy that the patient had survived an episode of PC pneumonia seven months earlier.

Conclusion: Hemoptysis in an AIDS patient may be a sign of PC pneumonia.

B.618 EVALUATION OF AN ULTRASENSITIVE ELISA FOR SPECIFIC DETECTION OF ANTI HIV 1

Bruhl, Stefan; Knapka, U.; Behringwerke AG, 3550 Marburg, FRG

Objective: To evaluate an improved competitive ELISA for the detection of antiHIV1 against HIV 1.

Methods: 100 µl undiluted specimens are diluted to 25 µl diluent buffer in each well of microtiteration plates coated with cell culture propagated HIV 1 antigens. The first incubation step over 60 min at 37 °C is directly followed by addition of ready to use conjugate (peroxidase labelled human Anti HIV 1). After 30 min (37 °C) and 5 washings H₂O, the chromogen TMB is added. The enzymatic reaction is stopped after 20 min (RT) with 0.5 N H₂SO₄ and readings are made at 450 nm. The cut off value is defined as 50 % of the negative control.

Results: The results on screening 643 Anti HIV 1 samples refer to a sensitivity of 100 % with clear cut positive inhibited O.D. values. The detection limit of Enzygnost anti-HIV 1 ultra was found to exceed that of western blot analysis by Factor 8. A panel of 13 sera derived from early stages of HIV 1 infections were found positive, even those which were negative in the Western blot and in commercial 2nd generation ELISA. A paired serum and plasma specimen.

Conclusions: In view of the fact, that Anti HIV 2-sera were found negative or weak positive, this ELISA in combination with a specific Anti HIV 2-test will help discriminating HIV infections.

B.620 DETECTION OF SERUM ANTIBODIES AGAINST THE GAG PROTEIN: A LATEST OF AN ADHESIVE INFECTION WITH AN HIV VARIANT

M. Theodoropoulos, R. Malherain, E. Spanakis, E. Antoniadou, V. Georgakopoulos
Reference Center of Crete, Venetian Hospital, Iraklio, Greece and School of Medicine, University of Athens, 11527 Athens, Greece.

Objective: To determine whether heterosubunit glycoprotein antigens apply the gag protein are highly HIV-related.

Methods: Peripheral blood lymphocytes (PBL) were co-cultured with the HIV-1 permissive CD4+ T-cells and the virus replication was evaluated by the reverse transcription activity (RT) and the p24 antigen and the culture supernatant (SN). However, the ultra centrifuged pellet of SN was tested for HIV by an RNA blot and also using specific cDNA probes. The membrane expression of p24 protein on PBL was evaluated by immunofluorescence using monoclonal integrated viral reagent were detected by Southern blot.

Results: PBL of 7/19 subjects expressed the p24 molecule (range 3-160) whereas p24 protein was detected on adherent cell but not PBL in an additional subject. gp120 was also expressed in the supernatant of the HIV-1 infected cell. The membrane expression of p24 protein on PBL was evaluated by immunofluorescence using monoclonal integrated viral reagent were detected by Southern blot.

Conclusions: These findings indicate that the HIV-1 variant is highly HIV-related and that the HIV-1 variant is highly HIV-related.

B.633 NATURAL HISTORY OF HTLV-I INFECTION
Shibuya Tachibana*, K. Tsuda*, M. Yoshida*, M. Esse****,
N. Noel-Huet**

*Miyazaki Medical School, Miyazaki, Japan. **Cancer Institute, Tokyo, Japan.
Harvard School of Public Health, Boston, MA. *Harvard School of Public Health, Boston, MA.

Objective: To describe the natural history of HTLV-I infection within an endemic area of Kyushu, Japan.

Methods: A population based cohort established of approximately 1600 adult residents of two villages, of whom 505 are HTLV-I positive. HTLV-I antibody titer was determined by MA and proviral DNA in carriers lymphocytes was investigated.

Results: Antibody titers of sixty percent of carriers ranged between 512 and 2048. Of 78 consecutively determined for four years, 63 kept the same titer. During this period 7 seroconversions have been observed. No HTLV-I case has been observed, however among 40 carriers tested for proviral DNA in the lymphocytes, a sample from a healthy woman presented the pattern of serological interpretation. Thirty-six percent of her lymphocytes was tit positive but the abnormal lymphocyte count was less than one percent, suggesting to be in the preclinical stage.

Conclusions: Continuing the surveillance on carriers in association with preclinical stage is important in understanding of natural history and may provide a lead to elucidate the factors in leukemogenesis of the virus.

B.635 IDEAL ASSAY OF HIV-1 AND HIV-2 ANTIBODY USING ANTI-PC-E2A WITH RECOMBINANT HIV-1 AND HIV-2 ANTIGENS - CHANGING HANDS
J. Zhou, M. Beigel, R.M. Thoen, G.A. Balis, D.J. Anderson, et al. Cambridge Biotechnology Corporation, Worcester, MA, USA.

Objective: To develop a recombinant antigen immunoassay (RIA) that has the capacity to detect both HIV-1 and HIV-2 antibodies in human sera. Virus specific antibodies were then detected by peroxidase-labeled recombinant HIV-1 and HIV-2 antigens using individual antigen conjugates or mixtures. 200 HIV-1 positive, 80 HIV-2 positive, 2 HIV-1 and HIV-2 co-infections, 1027 HIV-2 negative blood donors, and a seroconversion panel were evaluated. In addition, dilutions of positives were also tested.

Results: The assay identified all the positive samples tested using individual antigen conjugates. No significant change in positive signals were observed when both antigen conjugates were used. The HIV-1 and HIV-2 antigened samples produced additive signals. This assay could detect HIV antibody as early or earlier than current viral lysate RIA's using an HIV-1 seroconversion panel.

Conclusion: In this RIA test, each antigen conjugate reacted with their respective target antibodies independently. This RIA system can be used to detect both HIV-1 and HIV-2 antibodies in one test without significant loss of sensitivity for antibodies to either virus.

B.637 FOCUS OF HIV-1 ASSOCIATED TROPICAL SPASTIC PARAPARESIS IN EQUATORIAL ZAIRE
Rasani, K., Deamter, Jan*, Goubeau, P., Curtin, H.,**
University Hospital, Kinshasa, Zaire; ** Sage Institute and University Hospital, Leavenworth, Kansas.

Objective: To present the first focus of HIV-1 associated tropical spastic paraparesis (TSP) in Africa. Only 5 sporadic cases are known in Africa, although Africa has the largest world reservoir of HIV-1.

Methods: Search among chronic paraparesis patients from Lissala, population 50,000, Equateur Province, Zaire, by HC and KK. Elisas and immunoblots by PA and WB.

Results: 39 cases (11 men, 28 women) of HIV-1 associated TSP were identified: 21 by direct examination, and 18 in close blood relatives of 10 of the above, as derived from typical history and confirmed in all 4 examined. 7 mothers but no fathers or spouses of TSP patients had TSP; 3 familial cases were in paternal relatives. Half of the patients were Wandungu who represent 10% of the population (p<0.01). Presentation, history, serology and spinal fluid findings were as seen elsewhere.

50% of healthy close relatives had anti-HIV-1. Patients were anti-HIV negative.

Conclusions: This first African focus is probably the largest in a population of similar size worldwide. The familial clustering observed can only be explained by cofactors in addition to HIV-1. Some epidemiological definitions of the disease would have missed many true cases and they should be revised.

B.634 PREVALENCE OF HTLV I/II INFECTION IN BLOOD DONORS AND HIGH RISK GROUPS IN THE U.S.
Szaferan, J., Falker, L.,** Krommel, E.,** Mann, T.,**
Osake, M.,** and Lane Huet** *Molbiol Laboratories, North Beach, IL, USA
** Duke University Medical Center, Durham, NC, USA ** Kagoshima University, Kagoshima, Japan

Objective: To determine the prevalence of HTLV I exposure among HTLV seropositive donors and high risk populations in the U.S. METHODS. Specimens from 11 drug abusers (IVDA), blood donors and high risk groups such as hemophiliacs and homosexual were collected between 5/87 and 10/88 and tested for antibodies to HTLV I by EIA. Repeat EIA positive samples were confirmed by Western blot and SCS-RT-PCR.

CATEGORY	NO. TESTED	EIA +	CONFIRMED
IVDA	1032	226	0.04
Volunteer Blood Donors	6612	24	0.23
Plasmapheresis Donors	6200	14	0.23
Hemophiliacs	145	2	0.00
Homosexuals	152	2	1.30
ITP/IMW	41	39	95.12
Contacts of IAL	40	15	36.2
TP/SMW	12	5	41.7

CONCLUSION: TSP occurred in the USA seropositive for HTLV I/II infection in 100 U.S., 112.5% of HIV-1 alone and a further 8.26 HTLV I coinfected with HIV-1. Unlike HIV, hemophiliacs and homosexuals are not risk groups. Plasmapheresis donors show five times higher seroprevalence rates when compared with volunteer donors.

B.636 DETECTION OF EARLY HTLV-I SEROCONVERSION (SC) BY ELISA
Rasani, K.,** Murphy, E.,** Wilks, R.,** Blanchard, B.,**
Drummond, J.,** Waters, D.,** Swanson, P.,** Lee, H.,**
Blattner, W.,** MCI, Bethesda, MD, **CSF, San Francisco, CA, **Min. of Health and Welfare, Jamaica, **F. Frederick, MD, Chicago, IL.

Objective: Evaluate sensitivity of HTLV-I screening and confirmatory assays during SC among transfusion recipients (TRC).

Methods: Pre-transfusion exposed TRC from Jamaica, followed at monthly intervals, were tested by WB (DuPont and Abbott) and recombinant envelope (rev) (Cambridge Biotech.) EIA, Western blot (WB) and radioimmuno-precipitation (RIPA) using IOT-105/03/02/03 cell lines. Receiver's test was used to detect differences in sensitivity.

Results: 12 of 58 TRC, 9 with >1000 copies of follow-up, and 8 with persistently positive SC patterns were analyzed. 58/93 samples were WB p24+24 positive. WB was used as reference for comparing test performance.

EIA	EIA2	WB	RIPA	*one sample not tested
40/58	44/57	58/58	48/58	+fwd criteria

(96%) (77%) (100%) (81%) 2 case seropositive (WB, WB) WB was more sensitive than EIA and EIA2; WB was as sensitive as WB, but specificity was not evaluated. WB detected antibody earlier than other methods; early gag protein patterns preceding TSP SC were either p19 only, p24 only, or p19p24 +/- other bands. Sensitivities between the two W EIA's were not significantly different (p=35).

Conclusion: Two W EIA's had comparable sensitivities in this population of exposed transfusion recipients. Patterns showing either p19 or p24 only preceded FDA seroconversion criteria via WB determination. EIA or EIA2 may be an alternative to RIPA as a confirmatory test.

B.638 HIV P24 ANTIBODY IN ASYMPTOMATIC, PA, AND AIDS PATIENTS AT GATHINI: A CLINIC OF UNIVERSITY HOSPITAL, HUS IN AMERICA
Meyer, Ramona, Sams*, Salazar-Gonzalez, M.,** Dubreuil, E.,** Grace, M.,**
** P. Meyer, M.D., C.A. Collins, L.D., M.D.,
* Gathini & Gathini University, HUS in America University (HUS) - Brazil.
** F200A2

Objective: To determine the presence of p24 antigen in patients with different clinical status of HIV infection.

Methods: Serum HIV p24 antigen measured by antigen capture ELISA (Abcoat**). Laboratories, North Chicago, IL. USA) was performed in 125 patients who met the Surveillance case definition of not infection by Centers for Disease Control (CDC), 100(21), 100% distributed as ORP 2+ = 4), ORP 1+ = 30 and ORP 0 = 10.

For statistical analysis we used the statistic χ^2 (2x1-square), matching for the linear tendency (Spearman, ρ - Statistical Methods in Medical Research, John Wiley and Sons - N.Y., 1971).

Results: Overall, 52 of 125 patients tested for antigenemia were positive (41, 8%). The distribution of these patients according to CDC's criteria is shown in following table:

CDC'S GROUPS	TOTAL NUMBER	ANTIGENEMIA	
		NUMBER	%
II	41	22	53.7
III	30	10	33.3
IV	54	10	18.5

$\chi^2 = 39.10$, $P < 0.001$ χ^2 for departure from linear trend = 2.08 $P < 0.05$
Conclusions: There is a clear evidence of association between antigenemia and clinical status. There is also a definite trend which results in progressively small increases in the proportion of p24 antigen as it changes successively to lower categories.

Clinical Aspects of AIDS

- B.639** INTRACUTANEOUS TESTS WITH HERPETOUS ANTIGENS AND CD4-CD8 DETERMINATIONS IN AIDS
 FERRAZ ROBERTO, CAVALLINHO, M. J. FREIRE, C. J. LEVI, P. J. AGOSTINI, C. J. MENDES, N. et al.
 Escola Paulista de Medicina, São Paulo, Brazil.

Objectif: To correlate simple immunological parameters with the clinical classification of AIDS.
Méthode: A total of 172 AIDS patients classified according to CDC criteria were tested in vivo with HIV, candidin, trichophyton and streptococcus-*streptococcus* test. Absolute numbers of CD4 and CD8 lymphocytes were also determined.
Résultats:

	2 or more positive cutaneous tests	mean of 3 CD4 cells/mm ³	mean of 3 CD8 cells/mm ³
Group II and III (n=61)	694	760	1067
Group IVa (n=3)	308	279	796
Group IVb and IVc (n=3)	178	379	481

Conclusion: A progressive decrease in the reactivity to intracutaneous tests with ubiquitous antigens and in the absolute numbers of CD4 and CD8 cells was observed across the clinical spectrum of AIDS, emphasizing the value of these procedures.

- B.641** ASPECTS CLINIQUES HIV1 ET HIV2 ET CLASSIFICATION DE BANGUI
 Sow Ah. A., Coll. Ang. Marika*, Fay/Miso M.A., Drouf G. J., Feller-Sandhu L. J., Dip B. A. et al.
 * Service des Maladies Infectieuses, C.H.U. de Dakar.

Objectif: Evaluer la sensibilité et la spécificité des critères de diagnostic clinique du SIDA HIV1 définis à Bangui et proposer leur élargissement éventuel au SIDA HIV2.
Méthodes: Etude rétrospective de 73 cas de SIDA HIV1-HIV2 hospitalisés de Janvier 1986 à décembre 1988 au Service des Maladies Infectieuses du C.H.U. de Dakar. Une cohorte de témoin (patients suspects mais sérologiques) a été étudiée. Les critères de la classification de Bangui ont été recheckés pour chaque cas et une étude comparative statistique a été effectuée.
Résultats: Sur 73 cas de SIDA.
 49 HIV1
 22 HIV2
 3 douteux

Le sero-test est de 2-4. Le grand majorité des malades HIV1 comme HIV2 présentent les signes majeurs de la classification de Bangui: amaigrissement > 10%, diarrhée > 1 mois et fièvre > 1 mois. Les manifestations cliniques HIV1 et HIV2 sont comparables dans notre série. Un pourcentage non négligeable de suspects ont eu une sérologie négative (sensibilité 0).
Conclusion: L'élargissement à HIV2 de la classification de Bangui est proposé mais une validation est possible.

- B.643** DETECTION OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) DNA SEQUENCES IN SEROPOSITIVE PATIENTS AND SERONEGATIVE AT RISK SUBJECTS BY POLYMERASE CHAIN REACTION (PCR)
 Fabrizio Enoli, V. Fiorelli, L. Mezzarona, F. Aiuti

Dept. of Allergy and Clinical Immunology, University of Rome, Rome, Italy
Objective: To investigate the earlier stage of the infection we detected HIV-1 DNA sequences in seronegative people at high risk as drug addicts and partners of seropositive subjects and seropositive patients classified according to CDC criteria. Normal blood donors were employed as controls.
Methods: Genomic DNA's collected from PCR of seropositive and seronegative people were subjected to forty cycles of amplification. Two primer pairs for different conserved regions of the env gene were used. Specificity of amplification products was confirmed by Southern Blot. Serology was assessed by Western Blot; antigenemia by an Elisa system.

Results: Almost all seronegative people at high risk were confirmed negative by DNA amplification; individuals that resulted positive for HIV sequences also seroconverted after a few weeks. On the other hand no HIV sequences were detected with these primer pairs in a small percentage of seropositive but antigenemia negative individuals.
Conclusion: PCR coupled with serological techniques is very useful to investigate the HIV infection especially in those cases in which serology remains silent or unclear. Studies are in progress with primer pairs for different regions of HIV genome to better characterize the integrated sequences during the disease.

- B.640** PREDICTIVE VALUE OF THE DETERMINATION OF HIV-1 Ag IN SERUM
 Leal, M., Pineda, Juan A., Calderon, E., Navarro, M., Roy, G., Lissen, E., et al.
 University of Seville, Seville, SPAIN.

OBJECTIVE: To assess the predictive value of the determination of HIV-1 Ag in Serum.
METHODS: We have tested for HIV-1 Ag by EIA E12 serum samples sequentially collected from 51 Anti-HIV-1 positive patients. On an average, they had been followed during 42.10 (range 24-73) and 4.15 (range 1-11) (range 1-2) serum samples had been taken from each patient. All of the subjects were at the stage II or III of the current CDC classification for AIDS related diseases at the beginning of the study.

RESULTS: The overall follow-up time and the number of samples taken from each patient were similar for those developed AIDS and those that did not. 316 patients were found to be antigenic at entry. Eight of the remaining 44 seroconverted during the follow-up. Seven of the 14 (50%) (range 1-2) serum samples had been taken from each patient. All of the subjects were found to be antigenic in some time developed AIDS (stage IVc). The passage of time from the first evidence of HIV-1 Ag to the diagnosis of AIDS ranged from 1 to 73 months. All of the remaining 37 patients are still at the same clinical stage.

CONCLUSION: These results show a close association between the presence of HIV-1 Ag in serum and poor prognosis of HIV-1 infection. On the other hand, the rate of AIDS developing among antigenic patients observed by us is one of the highest reported so far.

- B.642** ETUDE DE LA VALEUR DIAGNOSTIQUE DU WESTERN BLOT CHEZ 113 SIDAIS
 M. Boreau*, D. Kervadec*, P. H'Pajot*, N. Copin*, F. Vallet*, A. Itou-Agopost*, M. Gentilini*

*Unit of Médecine Tropicale, Hôpital Pasteur et Unité INSERM 313, 47 Bd de l'Hôpital, Paris, France. **Médical Général de Brézillac, Gironde, France.

Méthode: L'usage d'un échantillon de type rétrospectif. Les cas sont les patients répondant à la définition clinique du SIDA (effectifs). Les sérotests sont les durures de sang considérées (effectifs). Les sérotests ont été répétés en cas de doute ou trace, et bande nette.

Résultats: Les valeurs ont plus souvent des Ac gp41 : chiz 1:625 p 0,02, odds ratio (OR) = 2,17. La même constatation a été faite pour les Ac gp120 : chiz 1:640, p 0,0003, OR = 3,36.

Il n'a pas été trouvé de valeur sur Ac gp25. Les sérotests ont été répétés en présence d'au moins un des deux Ac anti-gp d'une part, et absence des deux Ac d'autre part : une liaison a été également trouvée (chiz = 13,2, p = 0,028, OR = 5,36). La liaison persiste pour la gp120 lorsque l'on mesure l'OR de la gp41, elle disparaît pour la gp41 lorsque la gp120 est négative. Cependant, la liaison persiste pour la gp41 dans le groupe absence de gp120.

Discussion: Nous n'avons pas trouvé au Congo de liaison statistique entre le stade clinique et la présence d'Ac gp25. Nous avons montré qu'est associée à un mauvais pronostic la présence d'Ac gp120, la présence d'Ac gp41 chez les patients n'avait pas la gp120.

- B.644** CONTROL DE QUALITE DES TESTS DE DETECTION ET DE CONFIRMATION DES ANTICORPS ANTIVIRUS (WESTERN BLOT) DES ANTICORPS ANTIVIRUS - 160
 MULLIGAN L. J., FRANCOIS E. J., CHERRY J. J., COORNEAU A. M., et al.
 Le Service de Sérologie.

1 Laboratoire National de la Santé - Département de Biologie Médicale Paris France.
 2 Société Nationale de Transfusion Sanguine.

Objectif: Contrôle de qualité national des laboratoires déclarant pratiquer le test de confirmation (Western Blot) des anticorps anti HIV - 160 laboratoires.

Méthode: Les laboratoires ont reçu 3 séries de 8chantillons de plasma, sur lesquels ils effectuent conformément à la circulaire du 24-02-87, deux tests de dépistage et un test de confirmation. Les 12 plasma correspondent à : 6 HIV1 dans 3 débuts de séroconversion et un cas de séide, 3 non sérologiques 2 p25, 1 p18, 2 négatifs, 1 HIV2.
Résultats: 5 résultats de dépistage et 3 résultats de confirmation ont été utilisés. Au total : 90 erreurs sur 1472 dépistages ont été faites par les laboratoires (taux réactifs confus (soit 6,3 %).

	HIV1	HIV2	non spécifique	négatif
% d'erreurs de diagnostic	8,2 %	4,1 %	7 %	0,6 %

Les résultats des laboratoires en fonction des réactifs utilisés seront détaillés.
Conclusion: Ce contrôle a permis une amélioration des performances des laboratoires et des réactifs.

Aspects cliniques
Clinical Aspects of AIDS**B.645** THE USE OF GRAPHIC ART TO MEASURE NEUROPSYCHOLOGICAL FUNCTION IN HIV-INFECTED PERSONS

Spachis, Phyllis* and Peabody, B.**
*USCD Medical Center, **AIDS ART Project, San Diego, CA, USA.

Objective. To measure neuropsychological function in people with HIV infection through their artwork.
Methods. Twice-weekly, 3 hour sessions for HIV-infected persons for ART therapy/instruction generated written and photographic observations of artwork and behavior of 75 patients over 44 years. In an unstructured, group setting, an AIDS-sensitive therapist familiar with multiple art media (water-based paints on paper, oil and chalk pastels, ink, oil paint on canvas, markers, collage using art tissue and "found" objects) developed close relationships with patients leading to verbalization of problems and evidence of patient's physical and neurological deficits.

Results. Illustrative case studies of 5 AIDS patients demonstrated that changes in composition, subject matter, and color selection correlated with 1) progressive cognitive and affective deterioration (2 pts), 2) improved physical and cognitive status during ART therapy (1 pt), and 3) incipient seizures (2 pts). For example, within hours to days of first painting characteristic, red, vertical stripes, 2 patients had generalized seizures.

Conclusion. In addition to its therapeutic value, artwork may provide a useful diagnostic approach to neuropsychological dysfunction in AIDS by illustrating changes in cognitive function and affect and by predicting seizures.

B.647 ADVERSE EFFECTS TO ZIDOVUDINE-ALFAMANDOPROL (ZAP-90) TREATMENT OF PRESYMPTOMATIC DANGEROUS PRENATAL (DPP) IN AIDS

Spagnoli-Ferraz, J., Alvarez, V., Polo, R., Herreros, J., Alvarez, R., Agudo, J., G.

Instituto de Salud Carlos III, Hospital del Rey - Servicio de Medicina Intensiva -

Toxic effects of ZAP-90 treatment of FDP are frequent in American-AIDS patients with AIDS.

Higher tolerance to this treatment has been reported in Non-American AIDS patients. Our experience is reported here.

Methods: 43 patients with HIV infection and a first episode of FDP diagnosed by serology with histological evidence. Sample were retrospectively evaluated. Patients received ZAP 20 mg/kg/day and 500-1000 mg/kg/day ZV for at least 7 days. Mean age was 30.2 years (SD=6). 26 patients were male. 12 patients had previous drug abuse (10A), 9 non-smokers, 3 behavioral partner of 10A - and 2 had no recognizable risk factor.

Results: Adverse effects were identified in 20 patients (46.5%).

- Nausea/vomiting: 11 (25.3%) <50% ZV - Nausea: moderate: 3 (6.9%)

- Headache: moderate/severe: 5 (11.6%) severe: 1 (2.3%)

- Rash: moderate: 1 (2.3%) - Vomiting: 8 (18.6%)

> 3 mg/kg/day ZV

- Discontinuation of treatment because of severe toxicity: 6 (13.9%)

- Creatinine: 1.5-3 mg/dl: 1

- Neutropenia <500: 2

- Neutropenia (100-500)-vomiting severe: 1

- Rash severe: 1

Conclusion: Although toxicity is frequent, discontinuation of ZAP-90 treatment is needed in a minority (13.9%) of patients. Modified differences in renal frequency between our patients and American-AIDS patients are observed.

B.646 OUTCOME OF ADVANCED MATERNAL AIDS IN OFFSPRING

*Mweshi, Farzin, *Kabona, M.
Department of Pediatrics, Mwaneta Hospital, Kinshasa, Zaïre.

Objective: To define the outcome of advanced maternal AIDS in offspring.
Methods: We followed 20 infants born to mothers with advanced clinical AIDS.
Results: Eighteen mothers had produced 7 twins and 16 singletons. Mothers were all ill at the time of delivery. Four died within 4 weeks of giving birth. Two had tuberculosis and one had Kaposi's Sarcoma. The others were hospitalized for AIDS. All 20 babies were born small for age. Six babies were born at term weighing from 1830-2500 grams. Fourteen were born at 30-38 weeks of gestation, weighing from 1000-2000 grams. All newborns were doing poorly at birth and manifesting the following clinical signs after birth: 20 (100%) with asthenia, 13 (65%) with diarrhoea, 13 (65%) with respiratory infections, 9 (45%) with fever, 9 (45%) with anaemia, 6 (40%) with oral candidiasis, 6 (30%) with vomiting, 3 (15%) with neurological complications, 3 (15%) with physiological jaundice, 2 (10%) with pyrexemia and 1 (5%) with splenomegaly. In the course of hospitalization, one term infant was sent home to a stable condition. A second infant, who weighed 1340 grams at birth, gained 280 grams and was discharged in satisfactory condition. Of the remaining 18 newborns, 6 died within the first week of life and 12 died within 2 months of birth.
Conclusion: HIV seropositive mothers infect 30-40% of their offspring, however. In our series, advanced maternal AIDS was associated with a significantly higher maternal and neonatal morbidity and mortality. There was 2/8 maternal and 9/28 neonatal demise shortly after delivery.

B.648 ADVERSE EFFECTS OF LIDARTINE (LID) IN PATIENTS WITH HIV INFECTION

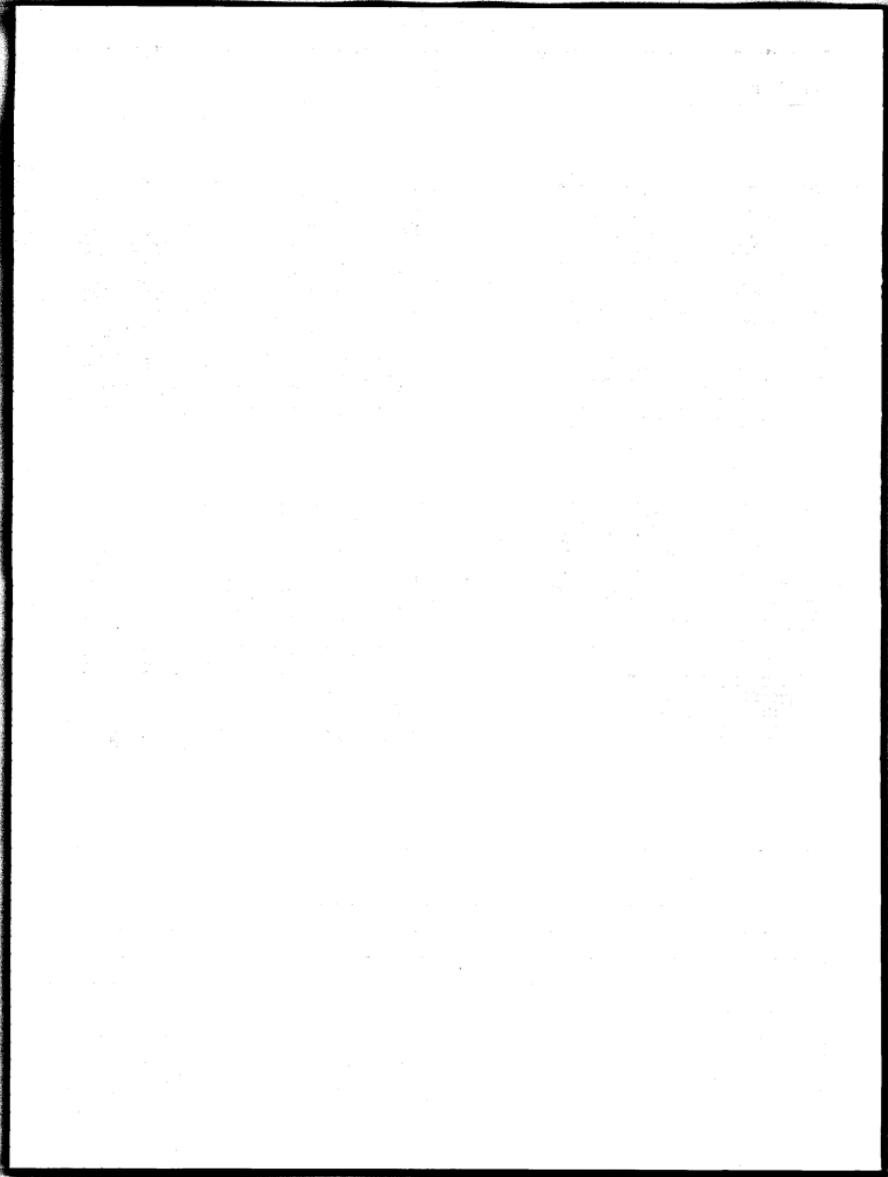

MC VALENTIN, V. PINTADO, M. FRANCIS, P. LAVILLA, OML DUPLA, A. OIL
Hospital La Paz, Madrid, Spain.

OBJECTIVE: Assessment of adverse effects (AE) to lidartine in patients with HIV infection in an intensive pharmacologic surveillance program.

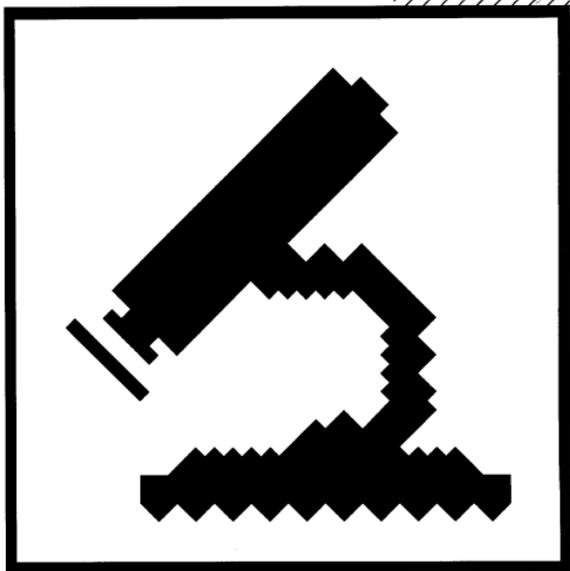

MATERIAL AND METHODS: 33 patients were entered. 22 patients fulfilled AIDS criteria, 3 patients had a group III (IG) infection, 3 group IV-A infection, 2 group IV-B infection. 11 patients were drug abusers, 4 were homosexuals, 1 bisexual, and one was a heterosexual partner of an HIV carrier. Mean age was 39 years (range: 11-61). 23 were males. LID dose was 1200 mg/day. This dose was modified upon hematologic parameters. An intensive pharmacologic surveillance program for detection of AE, with toxic a watch exhibited during first three months, and thereafter monthly was begun.

RESULTS: 1) Hematological toxicity. 11 patients showed anemia (IG). In 9 it was severe (23) (hemoglobin < 11 g/dl). Anemia usually began between 7th and 17th week of treatment. It was recurrent, unstable, and required transfusion of 1 unit of erythrocyte concentration per patient. In one case, neutropenia was observed in 6th of case, neutropenia in 10th. 3 patients showed granulocytopenia. 2) Gastrointestinal toxicity. In 5 patients (15) severe nausea and vomiting required symptom of therapy. 3) Neurologic toxicity. 4 patients showed blue-colored nails (IG), and one patient showed diffuse cutaneous hyperpigmentation. 4) Renal toxicity. In one case there was a transient increase in serum creatinine that subsided after withdrawal of therapy. 5) In total, no toxicologic toxicity was observed.

CONCLUSIONS: 1) Hematologic toxicity was the most severe AE observed, requiring modification of therapy, but not cessation. 2) Gastrointestinal toxicity, although common, was the severe tolerated. 3) Changes in cutaneous and regional pigmentation are a new contribution to the AE constellation of LID.

Mechanisms of Pathogenesis of HIV

M.C.O.1 VIRAL AND HOST FACTORS INFLUENCING THE PROGRESSION TO AIDS. **Jay L. Liebo, Cheng-Mayer, C. Walker, C. and Honey, J.**
Dept. Medicine and the Cancer Research Institute, University of California, School of Medicine, San Francisco, CA 94143.

A basic question in AIDS is why the time to development of clinical symptoms and progression to disease differs widely among HIV infected individuals. The vast heterogeneity in the biologic, serologic, and molecular responses among HIV strains offers one explanation. In particular, their differential ability to infect different cell types (both CD4+ and CD4-) to replicate rapidly in these cells, to cause cytopathic changes, and to be neutralized by various sera has been demonstrated. Moreover, certain isolates appear more sensitive to serum enhancement. Furthermore, the interaction of the HIV *env* gene product with the viral LTR, a state of latency can be induced that may delay or prevent disease in the infected individual. Our studies have indicated, for example, that individuals with a rapid progression to disease have viruses that replicate rapidly and are more cytopathic with a wide cellular host range. Moreover, brain and blood isolates can be distinguished by their relative ability to grow in macrophages and lymphocytes, to modulate the CD4 antigen on T cells, and by their serologic properties. Molecular and protein studies have indicated a relationship of some of these biologic activities with changes in protein and genetic structures.

The host immune response also plays a substantial role in determining the HIV pathogenic process. Antibodies that enhance virus infection can permit HIV spread to several different cell types including lymphocytes, macrophages and fibroblasts. Cellular immune responses can destroy virus-infected cells or suppress virus release, via the production of antiviral cytokines or mechanisms involving cellular interaction. Thus, the dynamics of a quickly changing replicating virus and an active immune system provides an important "key" to whether an individual has a long asymptomatic course or a rapid progression to AIDS.

M.C.O.3 ROLE OF N-LINKED GLYCOSYLATION IN HIV INFECTION. **Guickman, Jean-Claude*, Farnoulet, E., Garreau, L.,***, Ciergel-Rastain, B., Montagner, L.,***, Bahroui, E.,*****
*CERVI, Hôpital de la Pitié, Paris ; ** Laboratoire de Biologie Cellulaire, Faculté de Médecine Paris-Nord ; *** Unité d'Oncologie Virale, Institut Pasteur, Paris, France.

N-linked glycans represent 50% of the MW of HIV *env* gene product, and glycosylation sites are well conserved among different isolates. Carbohydrate oligosaccharides (CHO) are likely to be prominent structures on the virus surface, although their precise role is still poorly understood. We have demonstrated that complete enzymatic removal of glycans from recombinant gp120 or gp160 (gp120/160) in the absence of denaturing agents does not significantly modify *in vitro* interaction with its CD4 receptor : deglycosylated gp120/160 attached to soluble or membrane-bound CD4 with comparable affinity and inhibited fusion of HIV-infected and non-infected cells to the same extent than glycosylated gp120/160. This apparently contradicts a previous observation that deglycosylated native viral gp120 (gp120) displayed markedly reduced binding capacity to CD4. Differences between these observations may stem from technical conditions, or they may be related with differences in the glycosylation patterns of gp120 and gp160 that could result in functional differences of the glycan moieties. In addition, experiments conducted with glycosidase inhibitors that interfere with early oligosaccharide processing indicate that CHO may play a role at a post-translational level and be involved in other functions of gp120/160 in relation with post-binding events. *Env* glycoproteins may also interact with extra-cellular or cell-membrane lectins, especially on mononuclear phagocytes. On the other hand, our recent data suggest that gp120 behaves as a lectin, binding D-2-N-acetylglucosamine. These properties might be used by HIV to attach to cell membranes independently of CD4 and be one of the explanations that HIV can infect CD4+ cells under some circumstances. Finally, CHO chains may intervene in the immune response to HIV either by directing responsiveness to certain sites or by masking part of gp120/160 epitopes.

M.C.O.2 IMMUNE RESPONSE TO HIV
John Lullman, University of Massachusetts,
Dept. of Pediatrics, MA, USA.

M.C.O.4 NEW APPROACH TO THE STUDY OF OLIGOSACCHARIDES AS DETERMINANTS OF THE TISSUE TROPISM OF HIV-1.

Tom Felix
MRC Clinical Research Centre, Watford Road, Harrow, Middlesex, United Kingdom

The envelope glycoprotein, gp120, of the human immunodeficiency virus (HIV-1) is highly glycosylated with a diverse array of N-glycosidically linked oligosaccharides^{1,2,3}. We have proposed⁴ that these oligosaccharides which are likely to be prominent structures on the virus surface, are candidate attachment and addressing factors in the host at various stages of the virus cycle. This communication will be concerned with the molecular dissection of oligosaccharide-mediated interactions by a novel approach involving the generation of oligosaccharide probes from the envelope glycoprotein.

M.C.C.0.5 GENETIC ANALYSIS OF HIV DERIVED FROM MANDELLI (SI)_{MAN}
Teujimoto, H.*; Hasegawa, A.**; Cooper, R.V.**; Fukasawa, K.*;
Mura, T.**; Hasegami, H.**;*** et al.
*Institute of Microbiology, University of Tsukuba, Japan, **Toyo Nenryo
Kogyo K.K. Japan, ***Centre International de Recherches Médicales de
Francoville, Gabon, ****Institute for Virus Research, Kyoto University,
Japan.

Objective: To understand genetical relationship and phylogenetic epidemiology of HIV/SIV group.
Methods: Two isolates of SIV were obtained from apparently healthy mandrill in Gabon. One of them was molecularly cloned from the circular replicative intermediate DNA by linearization with one-sam. restriction enzyme, and totally sequenced by the methods of Sanger et al.
Results: Gene structure of SIV_{MAN} is almost equal to other HIV/SIV, but the open reading frames such as gag and pol were uncertain. The amino acid sequence homologies of each open reading frame to other HIV/SIV (GIV-1, HIV-2, SIV_{MAC} and SIV_{PAO}) were almost equal, about 80% in gag, 80-60% in pol, and about 20% in env regions.
Conclusion: The SIV_{MAN} was totally sequenced and was considered to be a new member of HIV/SIV group, equally distant from other HIV/SIV including SIV_{MAC}. It suggests the species-specificity of SIV group and unlikelyness of recent interspecies transmission among primates.

M.C.C.0.7 PROSPECTIVE CLINICAL, IMMUNOLOGICAL, AND VIROLOGIC FOLLOW-UP OF AN INFECTED LAB WORKER (LV)
Ballinger, M.*; Hara, P.*; Shaw, G.*; Hahn, B.*; Kemp, L.*; J.C. Newman, F.*; Williams, D.*; Gallo, R.* National Cancer Institute, Bethesda, MD; #U of Alabama, Birmingham, AL; *Duke Univ., Durham, NC; **FRI, Durham, NC.

Objective: Follow natural history of accidental laboratory acquired infection with HIV-1LV-11lg strain.
Methods: Sequential isolations (SI) obtained by cocultivation (Science 235:16, 1986). Neutralizing antibodies (NA) measured by virus infectivity syncytium inhibition assay (AIDS Res. and Hum. Retro. 3:228, 1987). Nucleotide and deduced amino acid sequences of the viral envelope gp120 immunodominant loop region (a 302-327) determined for Cloned SI. CD4 counts by FACS.
Results: LV is clinically healthy. CD4 counts show an initial lymphopenia (CD4 (375) and CD8 (426) 11 months after initial sample), rising over the next six months to a currently stable value at 28 months of CD4 (860) and CD8 (470). NA responses show an initial low titer type specific immune response which broadened over time. Heterologous hyperimmune glob anti HIV-1LV-11lg are used to block infection by SI in a syncytium inhibition assay demonstrated a shift in neutralization profile away from parent virus. Sequential point mutations representing a total of 9 amino acid substitutions over a 28 month period in the immunodominant loop were detected.
Conclusion: Cumulative changes in immunologically relevant domain of the HIV-1 envelope may reflect serial mutations of the virus or selection of coincidentally present substrates as part of a repertoire to avoid the host immune response.

M.C.C.0.9 REPLICATIVE CAPACITY OF SEQUENTIAL VIRUS ISOLATES FROM HIV-1 INFECTED SUBJECTS AND RELATIONSHIP TO CLINICAL PROGRESSION
Eva M. Fegans*, Albert J.**, Manfredi-Mansueti, L.* and Asjö, B.* Departments of Virology, Karolinska Institute* and National Bacteriological Laboratory**, Stockholm, Sweden.

Objective: To study changes in the replicative capacity of HIV-1 that occur in the same individual over time.
Methods: High passives were followed with sequential virus isolations during a 30-month observation period.
Results: Patients with stable lymphocyte nadir (LAS) yielded slow/low viruses on repeated isolations. Viruses isolated from patients during the period of clinical progression from LAS to AIDS-related complex (ARC) showed increasing replicative potential. In sequential virus isolates from patients with ARC, the replicative potential of sequential virus isolates fluctuated during the observation period. Accordingly, changes from slow/low to rapid/high and back to slow/low replicative potential, could be observed. One patient showed a rapid development of severe immunodeficiency, progressing from LAS to AIDS within one year. Viruses isolated during this period replicated with increasing efficiency in vitro.
Conclusions: The results show that HIV-1 isolates with distinct replicative capacity may be obtained from the same individual over time. Rapid clinical progression is often accompanied by the emergence of variant viruses with increased replicative capacity.

M.C.C.0.6 GENOMIC DIVERSITY OF SIV GROUP OF VIRUS.

Objective: To estimate the genomic diversity among various isolates of simian immunodeficiency virus from African green monkey (SIV).
Methods: The full- or partial-length of viral DNA of 4 HIV₁ isolates from African green monkey originated from different places, SIV_{MAC} (T9-2), (T9-5) and (T9-7) and (K1) were molecularly cloned from their virus infected cell lines and were compared with previous reported isolate, SIV_{PAO} (T9-1) by restriction endonuclease mapping.
Results: All the isolates are strongly hybridized with SIV_{MAC} (T9-1) probe. The gel end probes of HIV-1, HIV-2, SIV_{MAC} and SIV_{PAO} (T9-2) and (T9-5) and (T9-7) are as long as (T9-1) and once digested by EcoRI, NotI, SmaI, their restriction sites (including EcoRI, HindIII, Bam I, Sac I, Sma I etc.) were great divergence not only for their region but also in other regions. The genome sizes of SIV_{MAC} (T9-1) and (K1) are shorter than those of others, and are divergent from SIV_{PAO} (T9-1).
Conclusion: The genomic diversity of SIV_{MAC} group might be as well as (or greater than) those of other HIV/SIV groups although all the isolates belong to the one group. HIV-1 heterogeneity was also observed in the virus isolated from one animal as seen in HIV-1 infected person.

M.C.C.0.8 EVOLUTION OF THE BIOLOGICAL PHENOTYPE OF SEQUENTIAL HIVAN IMMUNODEFICIENT VIRUS (HIV) ISOLATES IN SUBOCULTURING MONOCULTURE MD4, M. Tarmann, R.H.T. de Gooze, F. de Wolf, J. Goudaert*, J.C. Newman, F. Williams, G. van Nieuwen, B. van den Broek, J. van der Meer, H. van de Loo, and G. van der Grinten, National Institute of Health and Public Health, Bilthoven, The Netherlands.

The type of HIV isolates used in diathesis-induced syncytium-inducing (SI), high-replicating isolates with a broad host range and non-syncytium-inducing (NSI) isolates only replicating in peripheral blood mononuclear cells (PBMC) (Tarmann et al., J. Virol. (1988) 62:2028-2032). From stable asymptomatic seropositive persons only HIV isolates were recovered. SI isolates were not recovered from persons progressing to ARC or AIDS. To investigate whether syncytium-inducing (SI) HIV isolates, associated with CD4+ cell depletion and disease, are present from seroconversion onwards or emerge in the course of HIV infection, and to account for the paradox that apparently transmission of HIV by an SI isolate carrier does not generally result in an infection with an SI isolate in the recipient, we analyzed the biological phenotype of sequential HIV isolates obtained from a cohort of seroconverting homosexual men. The results of this study allow for the following conclusions: 1) Early after seroconversion only non-syncytium-inducing (NSI) isolates are recovered; 2) SI isolates, if detectable, emerge in the course of HIV infection; 3) Upon transmission, SI isolates are presumably suppressed in the host. The results of this study support a model for AIDS pathogenesis in which the duration of the latency period between seroconversion and AIDS is determined by the capacity of the host immune system to suppress the emergence of virulent, CD4+ cell-depleting HIV variants.

M.C.C.0.10 CD4+ T LYMPHOCYTES FROM THE PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) OF HEALTHY SEROPOSITIVE INDIVIDUALS MARKER THE HIV-1 PROVIRAL SEQUENCES

Panlidopoulos-Mitilias*, Schmittman, S.*; Baseler, N.W.; Fouci, A.S.*; Lane, S.C.* and Ismailov, S.P.* *University of Washington, Washington, DC USA; #FRI, Frederick, MD USA; and *NIAID, National Institutes of Health, MD USA

Objective: To demonstrate the presence of integrated proviral HIV-1 in PBMC of healthy seropositive individuals and determine viral load and the specific subset of PBMC that harbors the HIV-1 at early stages of the disease.
Methods: PCR amplification was performed on the subsets of PBMC obtained by fluorescence activated cell sorting from ten healthy, seropositive individuals using primers from 12R, gag and envelope conserved regions.
Results: HIV-1 proviral sequences were found in all subjects studied and the CD4+ T cell subpopulation which retains the CD4 surface molecule is the predominant cell that harbors HIV-1. In two cases (1/10) CD4low (monocyto/macrophage) subsets also harbor HIV-1 but at a significantly lower level. Serial dilutions of sorted CD4+ T cells show that at least 1,000 - 1/10,000 cells are infected.
Conclusions: The cell populations that harbor HIV-1 are CD4+ T cells that continue to express the CD4 surface molecule. Healthy seropositive individuals have a 100 fold lower viral load than AIDS patients. Their immune system may be able to maintain a chronic, T latent infection for extended periods of time when there are low levels of virus.

M.C.O.11 THE MURINE ACQUIRED IMMUNODEFICIENCY DISEASE (MAIDS) IS CAUSED BY A DEFECTIVE RETROVIRUS
Huang, Hing*, Honna, Z**, Aziz, D**, Simerd, C* and
Jolicoeur, P.*

*Clinical Research Institute of Montreal, Montreal, Quebec, Canada;
**Université de Montréal, Montreal, Quebec, Canada.

The Duplan strain of murine leukemia virus (MuLV) induces MAIDS, a disease showing striking similarities with human AIDS. We identified the etiologic agent of this disease as being a defective retrovirus having a 4.8 kbp genome. Sequencing of this DNA showed that the pol and env genes have been deleted and that the complete gag region has been conserved and harbors a novel p12 sequence. Using a cell-free translation system, the genome has been shown to encode a 50 kd gag fusion protein. The same protein was detected in non-producer cells harboring the defective genome and is not cleaved. In-tripic pseudotypes have been constructed with this virus and the role of helper virus in the disease is also being investigated using the W2 encapsidation-negative system. This mouse model emphasizes the need to search for pathogenic defective retroviruses in AIDS.

M.C.O.13 ROLE OF ANTIBODIES, CYTOKINES, AND VIRUS VARIATION IN SIV/SIM INDUCED DISEASE.
Falls, Patricia J, Stricker, R**, Montagnier, L***, Sonigo, P***, McClure, H., and Anderson, D. *

*Kierkes Primate Research Center and Department of Pathology, Emory University, Atlanta, GA, **Cancer Research Institute, University of California, San Francisco, CA, USA, ***Institut Pasteur, INSERM, Paris, France.

Objective. To identify the role of antibodies, cytokines, and biologic and genetic variation in disease associated with different isolates of SIV/SIM.
Methods. Antibody responses, including neutralization and autoantibodies, and cytokine levels in serum from mangabeys and macaques were compared. SIV-9 and SIV-PS114, a variant that causes rapid death, were analyzed for phenotypic and genotypic properties which included the ability to replicate in and their effects on PBMC from various species as well as cloning and sequencing.
Results. Comparison of humoral immune responses to SIV/SIM in mangabeys and macaques showed that disease in macaques was associated with the presence of autoantibodies but not with total or neutralizing antibody titers. In contrast to SIV-9, the lethal SIV-PS114 strain, which was associated with the presence of high levels of TNF- α in serum, induced PBMC from macaques and mangabeys to proliferate, replicated in resting PBMC in the absence of exogenous IL-2, formed syncytia with Sup-T1 cells and had a transmembrane protein of 45-46,000 daltons that lacked a premature stop codon.
Conclusions. Humoral immunity does not appear to be a major factor in the pathogenesis of SIV/SIM for macaques and mangabeys. Autoantibodies and TNF- α , however, may play a role in disease induction by SIV-9 and SIV-PS114, respectively. SIV-PS114 appears to have multiple mutations, some of which affect env-encoded proteins and perhaps regulatory proteins. (IRH 80-0165)

M.C.O.12 INDUCTION OF IMMUNODEFICIENCY DISEASE BY PALV AND RELIFANCE TO SIV AND HIV-DISEASE
Mullis, James L*, Hoover, E.A**, Murphy-Corb, M***, Donohue, P.R*, Overbaugh, J*, Pom, M.L**, Edmonson, P.P*, Hirsch, V*, Martin, L***, ***Delta Regional Primate Research Center, Covington, LA

*Harvard School of Public Health, Boston, MA, **Colorado State University, Ft. Collins, CO

Objective. We are developing animal models for AIDS using a feline leukemia oncovirus (FeLV-PAIDS) and a simian immunodeficiency lentivirus (SIVmac-8323). FeLV results have led to questions now being addressed in both the SIV-macaque model and in HIV-infected primate.

Methods. Establish disease models and relevant in vitro correlates using molecularly cloned viruses, and identify viral genetic and biochemical factors which determine pathogenesis.
Results. Molecular clones of pathogenic FeLV-PAIDS genomes, isolated directly from tissue vivo (see Overbaugh et al). Defective genomes, isolated directly from tissue vivo since a replication competent pathogen could be created in vitro. Similarly, a molecular clone of SIVmac-8323 derived from consistently culture-passaged virus was highly replicative in vivo and only weakly pathogenic in vitro. However, passage of SIVmac-8323 through a macrophage that eventually died from SIV-disease resulted in evolution of a more acute pathogen. The length of the transmembrane gene did not influence virus pathogenicity significantly, although the TM was altered by the type of selection imposed - a shorter coding region was selected for in vivo, and a longer glycosylation was selected in vivo (see Edmonson et al). The T-cell killing determinants of an FeLV-PAIDS clone were mapped to the envelope glycoprotein gene and were correlated with several biochemical features of the envelope glycoprotein. Killing is also prevented by exposure of infected cells to neutralizing antisera (see Donohue et al).
Conclusions. Strong viral genome selection occurs in vivo as well as in vitro, and in vivo propagation may obscure viral gene coding capacity as well as select against acute pathogens. T-cell killing, at least in the FeLV-PAIDS system, likely occurs from a failure or delay in the establishment of superinfection interference.

M.C.O.14 NEW CONCEPTS IN HUMAN AIDS PATHOGENESIS

M.C.O.21 THE IMMUNODOMINANT NEUTRALIZATION LOOP OF HIV-1: BIOLOGICAL AND IMMUNOLOGICAL SIGNIFICANCE. Ignotz, D.; Ivancoff, J.; Rusche, J.R.; Nixie, J.; Redfield, R.; and Wong-Staal, F. Walter Reed Biomedical Research Group, WRAIR, Washington, D.C. 20307. Smith, Kling, and French Laboratories, King of Prussia, PA 19406. Regpligen Corporation, One Kendall Square, Cambridge, MA 02139. Monop, of the U. of Pennsylvania, Philadelphia, PA 19104. Laboratory of Tumor Cell Biology, NCI, NIH, Bethesda, MD, U.S.A.

Objectives: We described blocking of neutralizing activity (NA) of type-specific heterologous anti-viruses by synthetic oligo-peptides from the RPI35/136 region (a.a. 298-320) of gp120. The change of residue within this epitope loop reduced blocking of NA. To further investigate the functional and immunological significance of this area of HIV-1 env, a panel of mutants were constructed. **Methods:** Mutants were constructed in H13 containing a 9gIII - PvuII-BglII segment of HIV-1 envelope, inserted back into a phage clone containing the SalI-BamHI HIV-1 envelope insert, and the entire envelope cassette substituted for the corresponding region of pROD202. **Results:** The characteristics of mutant clones suggests that the integrity of the RPI35 loop is important in viral infectivity, cell range, and syncytium formation, as well as determination of neutralizing phenotype. This area does not appear to be involved in viral binding to CD4.

M.C.O.23 Three-dimensional Structure of the HIV-1 Protease and Its Role in Virus Maturation. Nara, P.A., Fitzgerald, P.M.D., McKeever, R.M., Liu, C.-T., Heideck, J.C., Murphy, W.K., Stal, I.S., Darke, P.L., and Springer, J.P. Merck Sharp & Dohme Research Laboratories, Rahway, NJ 07065 & West Point, PA 19380, USA.

The structure of the HIV-1 protease has been solved by X-ray diffraction analysis, and is shown to be a dimer. Large regions of the HIV-1 protease monomer can be roughly matched to the N- and C-terminal domains respectively of the peptin-like aspartyl proteases of known three dimensional structure, although significant differences do exist. The immediate active site region is assembled around the dimer interface with one characteristic Asp-Thr-Gly site sequence contributed by each monomer. An examination of the structure immediately suggests a mechanism for the auto-proteolytic activation of the protease from the gag-pol polyprotein fusion product on which it is synthesized. Further, an explanation for the control role of the protease in the control of the final assembly and maturation of the HIV-1 virus particle is suggested.

M.C.O.25 CONSTRUCTION OF AN INFECTION MOLECULAR CLONE OF HIV-1 AND GENETIC COMPLEMENTATION WITH A REPLICATION-DEFECTIVE HIV MUTANT. Mura, T. and POI MUTANT OF HIV-1. Mura, T.; Aochi, A.; Shibata, R.; Fukunaga, M.; HAZUKI MASARU. *Institute for Virus Research, Ryojo University, Japan. **Institute of Medical Science, University of Tokyo, Japan.

Objective: To set a basic information for making a recombinant HIV-1 which can infect African monkeys as an useful animal model system for AIDS. **Methods:** Some full-length HIV-1 DNAs were cloned from the circular replicative intermediate DNA by linearization with one-cutting restriction enzyme. These clones were reconstructed to generate provirus form (pSAD1). The env defective mutant of HIV-1 (pNL-Ep) and pol defective mutant of HIV-1 (pSA-Bp) were constructed respectively. These constructs were transfected to COS-1 cell line. After 24 hr, the supernatants were inoculated to HeLa/C18 cell line.

Results: Remarkable cytopathic effect (CPE) was observed and HIV-1 antigen was detected in inoculated HeLa/C18 about a week after transfection with pSAD1. Weak CPE was observed when pSA-Ba and pNL-Ep were co-transfected, while no CPE was observed at all when pSA-Ba or pNL-Ep was used individually.

Conclusion: An infectious HIV-1 molecular clone was obtained and the genetic complementation with a replication-defective env mutant of HIV-1 and pol mutant of HIV-1 was suggested.

M.C.O.22 MOLECULAR ANALYSIS OF SINGLE CELL LYSIS BY HIV-1. Sedláček, J.; Kowalski, E.; Dostálek, T.; Bergman, L.; Wilkowsky, M.; Haseltine, V. Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA U.S.A.

Objective: To define regions of the HIV-1 envelope glycoproteins important for the cytopathic effects of the virus.

Methods: Mutations were introduced into the amino terminus of the gp120 transmembrane glycoprotein. The effects of the mutations on virus replication and cytopathic effect were determined.

Results: Mutations in the gp120 amino terminus revealed in either replication defective viruses or in viruses that replicated at levels approximately that of the wild-type virus. The latter viruses exhibited significant reductions in cytopathic effect in established human lymphocyte lines and in primary peripheral blood lymphocytes. Both syncytium formation and the lysis of single cells were attenuated in these mutants.

Conclusion: The amino terminus of the gp120 transmembrane glycoprotein, which has been previously shown to be important for the fusion of cell membranes during syncytium formation, is also involved in the lysis of single cells accompanying HIV-1 infection in vitro.

M.C.O.24 STRUCTURAL PATTERNS IN REGULATORY SEQUENCES OF HIV-1. HERSH, Gerald; Linzer, C.F. and Tsang, C.-S. Theoretical Division, Los Alamos National Laboratory, Los Alamos, N.M. U.S.A.

Objective: To define DNA sequence-dependent structures for the TAR and RRE cis-acting regulatory elements.

Methods: Computer-assisted nucleotide sequence analysis-alignment and modeling of DNA tertiary structure--is correlated with mutational and biochemical results pertaining to the sequences for TAR and RRE. **Results:** Two sequence-dependent consensus structures are identified for the HIV-1 TAR regulatory element at positions +18 and +37; hexanucleotide sequences corresponding to these structures have been shown by mutational and biochemical (i.e., footprinting) analyses to subsume the core of TAR. Different sequences yielding equivalent DNA structures are in HIV-2s at +18 and +33 and in HIV-1 at +17 and +39. The second of these two structures, responsive to cellular U73 protein, is found in all lentiviral IRNs (EIAV, CAEV, VADV, FIV) at ca. +35 while the first of these structures is found only in HIV-1 and HIV-2. Extension of this analysis to the RRE region of the ZTR, now thought to be the cis-acting element for the RRE regulatory function, again reveals the role of DNA tertiary structure in HIV-1 regulation. Sequence-dictated microconvolution of the DNA may be essential to this region of the ZTR.

Conclusion: Transactivation of HIV-1 and HIV-2 partly entails indirect (reverse direct) reading of the DNA by proteins; site-directed mutagenesis of HIV-1 and related retroviruses should have this phenomenon in mind. The results suggest ways to manipulate the RNA effects and DNA effects pertinent to transactivation.

M.C.O.26 EXPERIENCE WITH HIV-1 VACCINE TRIALS IN CHIMPANZEES

Flachy, J. and R. Sambrook. Institute for Biomedical Research, San Antonio, Texas, USA.

Objective: To test the efficacy of various HIV-1 vaccines in chimpanzees. **Methods:** The following HIV-1 vaccine candidates were employed to actively or passively vaccinate 27 chimpanzees: 1. synthetic peptide (175-752). 2. vaccinia-env recombinant, 3. recombinant gp120 expressed in mammalian cells. 4. HIV-immune globulin (HIV-IG) prepared from HIV-1 positive asymptomatic people, 5. recombinant gp120 peptide (358-574), 6. vaccinia-gp recombinant, 7. a combination of vaccinia gag and env recombinants 8. Idiocyctic antibodies (local of anti-gp120). **Results:** Cell-mediated immunity in immunized animals, as assayed by specific lymphocyte blastogenesis or cytotoxicity, was only detected in vaccinee trials 2,3,5,7. While all vaccinees induced humoral antibodies as detected by ELISA and/or Western blotting, only passive immunization (trial 4) conferred significant neutralizing antibodies. All immunized and control chimpanzees that were challenged (trials 1-4) were not protected, i.e. HIV CPE could be isolated and/or seroconversion was documented. Due to the experience gained in trials 1-4 and the poor neutralizing antibody response it was decided that vaccine candidates 5-7 did not warrant a challenge with live HIV. The experiment with vaccine candidate 8 is still in progress. **Conclusion:** Eight HIV vaccinee consisted of 27 chimpanzees did either not confer protection or did not warrant challenge with live HIV or in progress.

T.C.0.1 DESIGN AND ACTIVITY OF A NOVEL CLASS OF NUCLEOSIDE ANALOGS EFFECTIVE AGAINST HIV-1.
Belleau, Bernard*, Dixit, D.*; Nguyen-Nh, H.**; Kraus, J.-L.*
*Institut Armand-Frappier, Université du Québec, Laval, Qué., Can.; **IAF BioChem International Inc., Laval, Qué., Can.

Objectives: To replace the pentose of nucleoside analogs by isosteric rings in which the 3'-carbon is an S or O atom and to test these opds. to block HIV replication *in vitro*.

Methods: Synthetic strategies were used to make intermediates with a 5'-hydroxyethyl group in the desired steric relationship with base substitution. The *de novo* syntheses led to mixtures of *cis*- (natural) and *trans*- (unnatural) isomers which were separated and fully characterized. **Results:** Two opds, both carrying a *cis* substitution, were generated on a scale which allowed extensive biological evaluation. The best analog, NUPP-21, having the "natural" *cis*-configuration was very effective *in vitro* as an anti-HIV-1. Its potency equivalent to AZT in all assays, as well as an improved therapeutic index. Another analog, DOTTI-10A (unnatural *trans*-configuration), had a surprisingly good *in vitro* profile. Some structure-activity relationships will be discussed briefly.

Conclusion: Novel compound NUPP-21 is a drug candidate for AIDS and is less toxic than AZT. Supported by an NBRCC/IAF BioChem-Industrial Research Chair (Bernard Belleau).

T.C.0.3 INHIBITION OF HIV-1 INDUCED SYNTHESIS FORMATION BY MONOCLONAL ANTIBODIES TO THE MEMBRANE ADHESION PROTEIN CD13.

Yalcinli, A.I.; Paterson, M.P.; Azzh B (1).

1. Department of Virology, Hamilton Institute, Stranmillis, DUBLIN, IRELAND

Objective: To study the participation of the membrane adhesion glycoprotein CD13 in HIV induced syncytia formation.

Methods: U937 clone 16 cells were pretreated with monoclonal antibodies (Ab) to CD13 and directed to the CD13 on M6e in major histocompatibility complex class I (MHC-I). Treated and control cells were infected with the HIV-1183 strain of HIV and grown in presence or absence of the reactive Ab. Viral replication was monitored by reverse transcriptase (RT) activity, immunofluorescence (IF) and syncytia formation.

Results: HIV infection of U937 clone 16 cells resulted in extensive viral replication and syncytia formation leading to cell death. In contrast, cells pretreated with Ab to CD13 yielded cell cultures with no signs of cell aggregation or syncytia formation, an percentage of infected cells, low RT activity and high cell viability for several weeks. The sensitivity of the inhibition of HIV induced syncytia formation was demonstrated by addition of MHC-I Ab. No difference in cytopathic effect was observed between this culture in the control.

Conclusion: We directed to the membrane adhesion glycoprotein CD13 effectively block HIV induced syncytia formation and cell death. Our results also suggest that intercellular adhesion contributes to and enhances spreading of the virus infection *in vitro* and possibly *in vivo*.

T.C.0.5 IDENTIFICATION OF SEVERAL SPECIES OF HIV-1 MAJOR CORE PROTEIN PRODUCTION AND CELL-SURFACE EXPRESSION

Laurin, A.C.; Krusi, B.; Rey, M.A.; Monseigneur, L.M. and Hébert, A.C.

Unité d'Oncologie Virale, Institut Pasteur, Paris 15, France.

Objectives: Characterisation of HIV-1 gag gene product p25 by two dimensional gel electrophoresis analysis.

Results: The p25 detectable in HIV-1 infected cells is composed of four gel species designated as a, b, c and d with isoelectric points: 6.8, 6.6, 6.5 and 6.3, respectively. Species b and d are the phosphorylated forms of species a and c, respectively. The two most acidic species c and d have a slightly slower electrophoretic mobility in polyacrylamide gels compared to the species a and b. All four species of p25 could be immunoprecipitated by polyclonal and monoclonal antibodies but only species a and b could be identified by electrophoretic transfer-immobiline assay using these same antibodies. Thus once p25 is denatured, then species c and d cannot be identified by polyclonal or monoclonal antibodies.

Pulse chase experiments indicated that all four species of p25 are produced at the same time after the synthesis of p55 but their subcellular localisation is different. Only species a and b are recovered with the virus particles whereas species c and d are a proportion of species a and b are secreted by virus producing cells. In addition to these results, heteropolymerase catalyzed iodination of the cell surface was employed to show that the four species of p25 are expressed on HIV-1 infected cells.

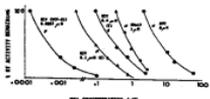

Conclusion: These different observations suggest that there might be distinct processing pathways for the production of species a,b compared to species c,d.

T.C.0.2 DIFFERENTIAL SENSITIVITY OF WILDTYPE AND RECOMBINANT HIV-1 REVERSE TRANSCRIPTASE TO INHIBITION BY FOZACARIN.

Malhotra M. Lightfoot and J. Murray Bailey,
The George Washington University School of Medicine and Health Sciences
Washington, DC 20037

The recombinant reverse transcriptase from HIV-1 cloned into the vaccinia virus VCF-21 (Moe) was expressed in monkey kidney cells and purified from cultures supernatants by conventional chromatographic procedures. The kinetic characteristics for inhibition of the recombinant enzyme by phenothiazine/ornithine acid (Fozacarin) were compared to that of the wild type HIV-RT and RTs of other retroviruses. Incorporation of ³H-TTP directed by poly(A) RTs, purified from cultures supernatants, was inhibited with an IC₅₀ of only 0.0007 μM compared to 0.001 μM for the wild type HIV-RT (Figure). K_i for TTP incorporation were also measured to identify differences. Sensitivity of a recombinant HIV-RT to Fozacarin was also determined. The results indicate that Fozacarin is more effective in the sense as that of wild type RT. Properties of the VCF-21 RTs were compared to those of the wild type RT. RTs from different mammalian cells were compared. The results indicate that different transcriptional processing of the vaccinia RT construct may give rise to different enzymatic activities and can give rise to HIV-RT variants with markedly enhanced sensitivity to Fozacarin.

SENSITIVITY OF VIRAL REVERSE TRANSCRIPTASES TO INHIBITION BY PROPYDINOFANATE

T.C.0.4 STRUCTURE AND FUNCTION OF HIV-1 REVERSE TRANSCRIPTASE (RT)

S.A. Lander, D. Lowe, Dorothy J.B. Purifoy, M. Tiedals, S. Darby, D.K. Staemers, et al. UNITED KINGDOM

Objective: To determine important structural features of the HIV-RT.

Methods: A variety of genetic manipulation techniques including site directed mutagenesis has been used to create a large number of variants of the HIV RT. These include enzymes with modified amino-acid sequences, with portions of the enzyme deleted (at N or C terminus or internally), or with additional amino-acid added. These mutant enzymes have been used to delineate the function of specific regions of the enzyme.

Results: Deletion of the C Terminal region of the enzyme has previously been shown to remove part but not all of the enzymes activity. We further define this region and further delineate a region of the enzyme that can be deleted without major loss of enzyme activity. Site specific mutants have been generated which alter the sensitivity of the enzyme to the anti-HIV drugs AZT and PPA, to determine the effect of such mutations on the ability of HIV to replicate proviral constructs were made encoding the mutant RT genes. On transfection of these constructs into HeLa cells they were found to replicate. These viruses showed decreased sensitivity to PPA, suggesting that infectious PPA resistant virus can arise *in vitro*. Finally, we have attempted to crystallise each of the variants to get better ordered crystals of RT. An up-to-date progress report on how the mutant enzymes crystallise will be given.

Conclusion: Mutational analyses have been successfully applied to determine functionally important regions of the HIV RT.

T.C.0.6 GAG AND GAG-POL PROTEIN PRECURSORS MADE FROM A SV40 LATE REPLACEMENT VECTOR ARE PROPERLY PROCESSED AND ASSEMBLED INTO PARTICLES

Smith, Alan J.; Hammarshild, M.L.; and Fawcett, D., Departments of Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

The expression of the HIV-1 gag and pol genes has been studied using fragments of the BH10 clone of HIV inserted into a SV40 late replacement vector. An initial construct containing the entire coding regions of gag, pol and vif produced only minute amounts of the gag precursor (p55). However, high level expression was obtained when an additional sequence from the *env* gene (the rev-responsive element) was inserted 3' of vif in the correct orientation, and rev was provided in trans from a second vector. Western blot analysis of transfected cells showed the presence of large amounts of both gag and gag-pol precursors as well as all of the expected cleavage products. In addition analysis of the culture medium showed the presence of particle-associated reverse transcriptase activity. Experiments are presently underway to determine whether envelope proteins, expressed from a separate vector, and virus-specific RNA are associated with these particles.

T.C.0.7

VARIANTS OF HIV RESISTANT TO ZIDOVUDINE (AZT)

Larder, Susan A.; Kemp, S.D.*; Darby, C.* and Richman, D.D.**

*Molecular Sciences Dept., Wellcome Research Laboratories, Beckenham, Kent, U.K. **Infectious Diseases Dept., V.A. Medical Center, San Diego, U.S.A.

Objective. To investigate whether prolonged exposure of HIV to zidovudine in patients leads to selection of resistant variants.**Methods.** HIV was isolated from PBMC prepared from untreated and zidovudine-treated individuals and propagated in MT-2 cells. Zidovudine sensitivity was assessed by plaque-reduction in a beta cell line (ST2-6C) expressing the human CD4 gene.**Results.** Infection of ST2-6C cells with HIV results in formation of plaques (foci of multinucleated giant cells) allowing precise determination of drug-sensitivity. Isolates from untreated individuals showed very similar sensitivity to zidovudine (mean ID₅₀ 0.03nM, range 0.01-0.04nM). However, most isolates from patients with AIDS or ARC treated for 6 months or more showed decreased sensitivity characterized by increase in ID₅₀ or ID₉₀ values (or both). Several isolates showed 100-fold increases in ID₅₀. Although these were sensitive to all other drugs tested except AZDT, TMP resistance mechanism is being investigated by analysis of cloned reverse transcriptase genes. The sensitivity of HIV isolated from asymptomatic individuals during therapy is also being determined.**Conclusion.** Zidovudine-resistant variants of HIV can be isolated from patients with AIDS or ARC after prolonged therapy. At present the clinical significance of this observation is unclear.

T.C.0.8

SURFACE STRUCTURES INVOLVED IN HIV RECOGNITION

Madon, Paul A., Progenics Pharmaceuticals, New York, N.Y., USA.

T.C.0.9

TRANS-REGULATION OF HIV-1 GENE EXPRESSION

Michael E. Malin and Bryan E. Collins

Howard Hughes Medical Institute, Departments of Medicine and Microbiology and Immunology, Duke University Medical Center, Durham, NC 27710 USA.

This presentation will briefly address the physiological role of the regulatory proteins encoded within the genome of HIV-1, focusing particularly on the viral *tat* gene product. The *tat* protein is required for expression of the viral structural gene products and, hence, for viral replication. I will review data demonstrating that *tat* functions post-transcriptionally to modulate the transport of HIV-1 mRNAs from the infected cell nucleus to the cytoplasm, where translation into viral proteins occurs. In addition, I will review recent data demonstrating that the *tat* protein contains two discrete functional domains. One of these is required for the specific interaction of *tat* with its viral RNA target sequence. The second is required for the subsequent activation of viral RNA expression. These results will be discussed with reference to possible targets for therapeutic intervention into AIDS.

T.C.0.11 EXPRESSION, PURIFICATION, SPECIFICITY, ACTIVITY AND SUBSTRATE SPECIFICITY OF THE HIV-1 PROTEINASE

Debnick, Christine, Beckman, J., Malinowski, J., Meak, T., Moore, H., Strickler, J., et al. Smith Kline French Laboratories, King of Prussia, PA 19406, USA.

Objective: The gag and pol coding region of HIV-1 is translated into large precursors that are cleaved by a protease encoded by the virus and that is unique and essential. Our goal is to develop specific inhibitors of this enzyme that will block the maturation and infectivity of the virus without interfering with the host physiology.

Methods/Results: The HIV-1 protease was expressed as a precursor and in its mature form in various E. coli strains and shown to specifically cleave its own gag-pol substrate in vivo as well as heterologous substrates containing appropriate cleavage sites. This system was used to identify residues in the enzyme that are essential for its activity. The enzyme was purified to homogeneity and its structure and enzymatic activity characterized.

A simple peptidic in vitro assay was developed to be used to screen natural products and rationally designed compounds for inhibitory activity.

Conclusion: Asp-29 and Gln-66 are residues critical for the HIV-1 protease activity. The enzyme is an aspartyl-protease and behaves as a dimer in vitro assay for the

T.C.0.12 TUMOR NECROSIS FACTOR-ALPHA ACTIVATES HIV EXPRESSION IN A CHRONICALLY INFECTED T CELL CLONE THROUGH INDUCTION OF NUCLEAR FACTOR BINDING TO NF- κ B SEQUENCES

Ela, J. Duf*, Wendy J. Masry*, Thomas M. Folks*, Anthony S. Fauci*, and Anne B. Resanz* MDACC, NIH, Bethesda, MD, *CCDC, Atlanta, GA USA

Objective: To describe the molecular events by which TNF- α activates HIV expression. **Methods:** The AC20 cell line is a clone cell line derived following infection of A3.01 T cells with HIV-1. AC20 cells are chronically infected with HIV and contain a single integrated HIV provirus whose expression can be augmented by TNF- α treatment. Steady state HIV RNA levels were studied by dot blot hybridization, and activation of HIV transcription was analyzed by nuclear run-on assays. GAT retardation assays employing P-32 labeled oligonucleotides were used to study the induction of nuclear proteins binding to the HIV long terminal repeat. Transfection of wild type and mutant HIV LTR-GAT plasmids into A3.01 T cells were performed to identify LTR sequence responsible for activation.

Results: TNF- α treatment of AC20 cells resulted in an increase in steady state levels of HIV RNA and HIV transcription. GAT mobility shift assays demonstrated that the transcriptional activation of the HIV LTR by TNF- α was associated with the induction of a nuclear factor binding to the NF- κ B sites in the LTR. Deletion of the NF- κ B sites from the LTR eliminated activation by TNF- α in T cells transfected with plasmids in which the HIV-LTR directed the expression of the CAT gene.

Conclusion: TNF- α appears to activate HIV RNA and vice production by AC20 cells through the induction of transcription activating factors that bind to the NF- κ B sequences in the HIV LTR.

T.C.0.13 RNA SPLICING EVENTS DETECTED IN EARLY IN VITRO HIV INFECTION USING THE POLYMERASE CHAIN REACTION (PCR)

Klugman, Marc E., DeRoos, A., Buchsinder, A. and Wong-Saal, P., Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Md, U.S.A.

Objective: The HIV genome codes for at least six additional regulatory gene products along with the gag, pol and env products. The complexity of this 9 kb virus are in part due to the regulation of a series of splicing events during the production of these gene products. We studied the early splicing events that occur after infection of H9 cells with purified HIV to determine the sequence of events.

Methods: RNA was extracted from infected cells at a series of time points ranging from one hour after viral absorption to forty-eight hours. Antisense primers and AAV reverse transcriptase were used to make cDNA which was amplified by PCR using sets of oligonucleotide primers designed to detect specific splicing events. The regulatory primers were chosen from within the 2nd and 3rd exon flanking the splice donor-acceptor sites at nucleotides 6044 and 8378. The envelope primers were from within the first and second exon and flanked the splice donor-acceptor sites at nucleotides 703 and 5973 respectively.

Results: The splicing between the first and second coding exons of the regulatory genes *rev* and *nef* could be detected within hours after infection and appeared before splicing of the envelope genes which occurred within six hours of infection. Standard Northern blotting did not detect these mRNAs at the early time points.

Conclusions: mRNA splicing occurs very early in infection of H9 cells with HIV. Splicing of regulatory exons precedes splicing of mRNA coding for structural gene products.

T.C.0.14 POTENTIAL BIOLOGICAL SIGNIFICANCE OF A SECONDARY RNA START SITE WITHIN THE HIVLTR

Mason, J.L., Bednar, D.P., *The Henry M. Jackson Foundation, Biotechnology Laboratory, Rockville, MD, *The Johns Hopkins Oncology Center and Dept. of Immunology and Infectious Diseases, Baltimore, MD, USA.

Objective: The aim of the present study was to determine the biological significance of a secondary RNA start site within the HIVLTR.

Methods: S1 nuclease mapping has localized the site of the secondary RNA start to 80 base pairs downstream from the primary RNA start site. RNA analyses show that whereas the HIVLTR contains 167 nucleotides 5' from the primary RNA start site results in RNA expression from both start sites, an HIVLTR deletion containing only 65 nucleotides results in RNA expression only at the secondary start site. Provirus transfections and HIV infections suggest the existence of more than one RNA transcript for the HIV-enclosed *tat* gene product, possibly due to RNA initiation at the secondary site. We are using PCR analysis to attempt to further map and to ascertain the biological significance of a secondary start site in HIV regulation.

Conclusions: These data support the possibility that the existence of a secondary RNA start site could play a significant role in HIV gene expression and replication.

T.C.0.15 REGULATORY ELEMENTS IN THE LTR (HIV-1) RESPONSIVE TO GLUCOCORTICOID STIMULATION

Stachurski, M., Wang, J., Zeng, J.F., & DeGruy I.D. *Université Pierre et Marie Curie, Paris, France. **University Hamburg DDR

Within the LTR of HIV-1 provirus we have identified two hormone responsive elements (HREs) corresponding to the TGTCT sequence identified as the glucocorticoid receptor binding element within the LTR or HIV1T (responsible for the transcriptional activation of the provirus). We have used an LTR (HIV-1)-CAT construct to transfer, infect (H9)3 and non infected H9 cells. Four hours before harvest the two cell types were divided into two and one half treated with dexamethasone (1.0-70). The cells were harvested, and the CAT activity measured in eight repeat experiments on increased (50%) expression of the CAT gene in the presence of the glucocorticoid cells has always been observed in H93, but no effect of the steroid has been measured in the non infected cells. Double transfection of LTR (HIV-1)-TAT and LTR (HIV-1)-CAT into non infected H9 cells results in a cell population in which the CAT gene was responsive to glucocorticoid stimulation. We have further shown, using cells transfected with a mutant LTR (HIV-1) promoter CAT that only one of the steroid HREs is required for the glucocorticoid response. Our results are discussed in relation to the well characterized HIV1T-LTR system and to the well established role of glucocorticoids in HIV-1 virus activation.

T.C.0.16 MECHANISM OF HIV-1 INFECTION OF MONONUCLEAR PHAGOCYTES

O'Brien, William A.; Koyanagi, Y. and Chen, I.S.-Y. UCLA School of Medicine, University of California, Los Angeles, CA, USA

Objective: To investigate mechanisms of mononuclear phagocyte infection by macrophage-tropic strains of HIV-1.

Methods: Two distinct HIV isolates with differing ability to productively infect mononuclear phagocytes *in vitro* were molecularly cloned and compared at the sequence level. Kinetics of virus infection were measured in mononuclear phagocytes following treatment with granulocyte-macrophage colony-stimulating factor (GM-CSF). Fragments of the HIV-1 LTR linked to the indicator gene, CAT (chloramphenicol acetyltransferase), were transfected into primary blood-derived mononuclear phagocytes of GM-CSF to identify sequences necessary for GM-CSF activation.

Results: The complete nucleotide sequence of two HIV-1 isolates from the same individual having different tropism for mononuclear phagocytes show a sequence difference of 38. The macrophage-tropic virus replicates to high titers in these cells, and its production is further enhanced by GM-CSF treatment. Sequences in the HIV-1 transcriptional enhancer region necessary for GM-CSF activation were identified. These sequences are distinct from the NF- κ B binding sequences of the LTR.

Conclusion: Related viruses may have biologic differences. Sequences in the HIV-1 LTR necessary for GM-CSF activation in mononuclear phagocytes are distinct from those necessary for virus replication following T-cell activation.

Biologie moléculaire : les mécanismes de régulation de type tat des gènes viraux Molecular Biology: TAT-Mediated Regulation of Viral Genes

T.C.0.27 THE TAR REGION OF HIV-1 BINDS AND ACTIVATES THE DOUBLE-STRANDED RNA DEPENDENT KINASE (dsR) *Ray, Soubrier, Mary, I., Perkin, K.M., Nersisyan, L.M., Kato, M.M., and Sonnenberg, R.J., McGill University, Montreal, Canada; *The University of New York, Syracuse, New York, USA; **Washington University, Seattle, Washington, USA.*

Objective: To elucidate the mechanism by which the tat-responsive element (TAR) within the 5' non-coding region of HIV-1 mRNA activates the double-stranded RNA dependent kinase (dsR), resulting in inhibition of protein synthesis, as observed in HIV-1 retroviral infection.

Methods: An RNA mobility shift assay was devised to study nucleoprotein complex formation between dal purified from retroviral lysate and small RNAs comprising the TAR region (HIV-1 RNA) (1 to 400).

Results: We show specific RNA-protein complex formation between dal and TAR RNAs. Mutant TAR RNAs with retained secondary structure lose their ability to bind dal and are considerably less potent in activating the kinase. The introduction of compensatory mutations designed to restore the secondary structure of the TAR region restored the RNA's ability to complex with and activate dal. An excess of the double-stranded RNAs poly(U) and reovirus dsRNA complex and inhibit dsR activation.

Conclusion: The double stranded nature of the TAR region present at the 5' end of all HIV-1 mRNAs renders it capable of activating dal, a protein involved in the activation of protein synthesis by interferon. Activation of dsR correlates with the ability of the TAR RNA to bind to purified dal. These studies may have important implications for the regulation of HIV-1 replication.

T.C.0.28 PROGRESSIVE GENETIC CHANGES IN HIV-1 TAT GENE COINCIDENT WITH DISEASE

Neirameh, Andras, Chernier, R.*, Saurin, M.**, Kwak, S.**, Seinsky, J.**, Williams, J.**, Adju, B.*** and Kahn-Neirameh, M.***. The University of *Institut Pasteur, Paris, France; **Cetus Corporation, Emeryville, USA; ***Karolinska Institute, Stockholm, Sweden.*

Objective: 1) Analysis of the HIV-1 proviral population of four virus isolates taken from the same individual as he progressed towards AIDS (CD4 - ARC - AIDS).

Methods: 1) tat gene sequences were amplified by PCR and cloned into an expression vector. Inertly plasmid clones of each isolate were sequenced. **Results and conclusions:** 1) Comparing viral populations after short term culture, significant changes in the distal viral species were observed during disease progression. This effect is less prominent with tat variants obtained directly from lymphocytes. 2) In vitro cultivation of the virus population present in blood lymphocytes, whereas long term cultivation does not constitute a further selective pressure. 3) On the protein level, single and multiple amino acid changes as well as defective genomes were observed. Functional studies complementing the structural analysis underway will allow us to interpret better these data.

T.C.0.29 BINDING OF THE HIV-1 TAT PROTEIN TO TAR SEQUENCES IN VITRO.

Dingwall, C., Emberg, I., Heaphy, S., Blomer, M. A., Gall, M. J. & Karn, J. MRC Laboratory of Molecular Biology, Hills Road, Cambridge, CB2 2QH, UK.

Objective: To investigate the binding in vitro of HIV tat protein and cellular factors to TAR sequences.

Methods: A synthetic tar gene has been expressed both in an E. coli expression system and in a number of eukaryotic cell lines. The binding of expressed tat protein to nucleic acid representing the TAR sequence has been investigated in vitro using gel retardation assays.

Results: The tat protein produced from both the E. coli and from the eukaryotic expression systems has been shown to be biologically active. The binding of tat, synthesized in E. coli, to TAR nucleic acid has been examined both in the presence and absence of host cellular proteins. Binding of tat expressed in eukaryotic cells gives a different pattern, suggesting that host proteins interact with the tat/TAR complex. The specificity of binding has been examined using a number of different nucleic acids, including mutant TAR sequences.

Conclusion: Direct interactions between tat protein and TAR sequences are involved in trans-activation.

T.C.0.30 HIV-1 NCER HAS THE CAPACITY TO ENCODE BIFUNCTIONAL TAT AND REV PROTEINS THROUGH ALTERNATE splicing

Visually, Georges, A. and Mullins, J. J.

Harvard School of Public Health, Boston, Massachusetts, USA

Objective: We previously demonstrated that, in contrast to HIV-1, coding exon 2 of SIVmac (SIVmac) tat is required for significant tat activity and the dispensing of the proximal tat sequence at the 5' end of tat mRNA activates a downstream splice acceptor site and results in the formation of a functional tat protein. We now seek to characterize the structure and functional coding capacity of mRNA molecules which encode the SIVmac tat and rev proteins.

Methods: Polymerase chain reaction was used to specifically amplify cDNAs corresponding to either tat or rev mRNAs from SIVmac (SIVmac) infected HeLaT cells and the different spliced forms were characterized by oligonucleotide probe hybridization and DNA sequencing.

Results: We found that tat and rev mRNAs use different splice acceptor sites at the beginning of their respective first coding exons. Three different splice acceptor sites are used at the beginning of the coding exon. The two 3' most splice acceptor sites have the capacity to encode proteins which differ by single amino acid substitutions and the deletion of either 1 or 6 amino acids. The two 3' most splice acceptor sites, which facilitate them the step between the 5' end reading frame (see abstract by Edmonson et al.), were used at frequencies of 54% and 43%, while the 3' most site was used at a frequency of 2%. Similar splicing events which join non-coding exon 1 and 2 were also identified. They were used at frequencies of 61%, 37% and 17%, respectively. Finally, rev mRNAs fall into 3 classes with respect to their 5' structure. These classes are approximately equivalent in frequency and differ by the presence or absence of 144 nucleotide bases located within the 5' region of the 5' LTR. The biological activity of clones of each of the tat and rev cDNAs are currently under investigation.

Conclusion: SIVmac uses alternative splicing to generate mRNAs with the capacity to encode isoforms of the tat and rev proteins.

T.C.0.31 BINDING OF HIV-1 TAT TO THE 5' REGION OF mRNA

Rappoport, J.-E., Joseph, S., Kloman, M., Kang, C.Y., Daifler, S., Rench, J., and Wong-Staal, F. Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Md., U.S.A.

Objective: HIV-1 gene expression is positively regulated by the viral transactivating protein, tat. Evidence suggests that the structure of the RNA stem loop within the TAR region is critical for transactivation therefore we proposed that the tat protein binds directly to this RNA structure.

Methods: Recombinant tat protein produced in both E. coli and baculovirus expression systems were tested for their ability to bind directly to gel-purified 32P-labeled transcripts from the initial 5' nucleotides of the HIV-1 mRNA that were synthesized from constructs using the heterologous T7 polymerase. RNA gel mobility shift assays were performed using the wild type as well as a mutant transcript (ΔS) generated by a four base pair deletion (+35-38) at the RNTI site, known to lack transactivation potential.

Results: Introduction of the recombinant tat protein by the "scraper-loading" procedure into HeLa cells stably integrated with the HIV-1 LTR linked to the bacterial chloramphenicol acetyl transferase gene confirmed the activity of the protein. Wild-type TAR transcripts formed a stable complex with the recombinant tat protein resulting in retarded gel migration. The deleted transcript (ΔS) did not form a stable complex.

Conclusion: The data suggest that tat protein of HIV-1 specifically and stably binds to TAR RNA which may be a required step in vivo in the transactivation pathway.

T.C.0.32 CD4+ LYMPHOCYTES CAN CONTROL ACUTE HIV INFECTION OF CD4+ T-CELLS

Wain, Christopher M., Thomson-Horvath, G., Hsieh, J. & Finlay, J. A. Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To determine if peripheral blood CD4+ T cells from HIV-infected subjects can suppress the growth of HIV in acutely infected CD4+ T cells.

Methods: Peripheral blood mononuclear cells from HIV-infected and uninfected subjects were stimulated with PHA for three days, and T lymphocyte subsets expressing the CD4+ and CD8+ antigens were enriched. CD4+ cells were cocultured with CD4+ cells infected with HIV isolates, and then cultured with the CD8+ T lymphocytes. Culture supernatants were assayed three days for HIV RNA.

Results: CD4+ T cells from HIV-1 seropositive subjects, but not seronegative controls, were able to prevent replication of HIV in acutely infected CD4+ T cells. Suppression of virus growth required the continuous presence of CD8+ T cells, and was not HLA-restricted. Monoclonal antibodies to antigens on these cells (i.e. CD4 and CD8 proteins), but not cells that can mediate antibody-dependent cellular cytotoxicity of normal killing (i.e. CD8) positively blocked suppression.

Conclusion: Cytotoxic suppressor T lymphocytes can prevent the growth of HIV after acute infection and are present in the peripheral blood of HIV-infected individuals. The mechanism of action of these CD8+ T cells remains to be determined.

T.C.0.33 IDENTIFICATION OF SITES WITH WHICH SERVIC AS TARGETS FOR ADCC USING HUMAN MONOCLONAL ANTIBODIES

Titre: D'Amico, Zola-Pazner, B... Gomy, M... Banway, D...
Bolognesi, D. and Wainwright, W. *Coriell* University Medical Center, Durham, NC, USA. *New York University Medical Center and *New York VA Medical Center, NY, NY, USA.

Objectif: To utilize human anti-HIV-1 monoclonal antibodies (mAb) to define target epitopes for antibody-dependent cellular cytotoxicity (ADCC).
Méthodes: PE800 from HIV-1 infected individuals were EBV transformed, screened for mAb production, cloned and maintained in long term culture. Six cell lines made mAb to gp41 and five made mAb to gp24. These mAb were tested in a ⁵¹Cr release ADCC assay using virally infected and gp120 adsorbed CEM/CMR targets.

Résultats: None of the anti-gp120 mAb mediated ADCC. However, five of the 6 mAb directed at regions within gp 41 mediated significant lysis of HEp, RF and MN infected targets, at dilutions in the range of 1:640 to 1:4. No lysis of gp20 adsorbed targets was seen. The specific lysis of the three most effective mAb at two dilutions is shown in the table. Interestingly, the scope

mAb	HEp	RF	MN
10A10 (gp20)	28.2	16.0	22.7
10B10 (gp20)	22.5	10.1	19.4
9B4 (gp20)	20.8	6.7	20.0
10A10 (gp41)	20.8	6.7	20.0
10B10 (gp41)	20.8	6.7	20.0
9B4 (gp41)	20.8	6.7	20.0

of all ADCC directed against gp41 mAb was not significantly different from that of antibodies directed against the immunodominant region of gp41. The purity, potency and broad specificity of these human mAb makes them ideal for passive immunotherapy. Current work on the identification of the specific epitopes to which these mAb are directed will facilitate the design and development of a future vaccine.

T.C.0.35 PUTATIVE INTERACTION SITE BETWEEN HIV gp120 AND gp41 : ANTIVIRAL ACTION OF SYNTHETIC PEPTIDES.

Méthodes: DeLor, F., Favau, B., Le, C., Cumings, S., Stapleton, D.,**
Doherty, R.* and Kemp, R.*
*HARC Special Unit for AIDS Virology, Fairfield Hospital, and
**McC. Vincent's Institute, Melbourne, Victoria, Australia.

Objectif: To determine the antiviral action of synthetic peptide analogues corresponding to a putative interaction site between envelope glycoprotein, gp120 and gp41, of HIV.

Résultats: Purified synthetic peptides of 8 to 23 residues were tested (at 10⁻⁶ to 10⁻¹⁰M) for their ability to inhibit HIV replication "in vitro" at mol of 0.0002-0.01 µg/ml/assay.

Conclusion: We have identified a region in gp120 (89-119) and a complementary sequence in gp41 (371-591) with four matched charge residues conserved for all HIV isolates which has a propensity to form amphiphilic helices with charged residue contacts and complementary hydrophobic residues. Synthetic peptide analogues partially suppress the in vitro infection inhibited virus replication as measured by reverse transcriptase activity and delayed syncytial formation.

Conclusion: Our results illustrate that it is possible to reduce HIV infectivity with synthetic peptides that mimic structures involved in the contact region between gp120 and gp41.

T.C.0.37 DEFINITION OF SEVERAL ALONG A HOMOLOGY-DOMINANT REGION OF THE HIV-1 GP41 AND THE IMPACT OF CONSERVATIVE AND NONCONSERVATIVE AMINO ACID SUBSTITUTIONS ON HIV-1 REPLICATION

Méthodes: Pappas, S., Benveniste, B., Ryms, L., Vukob, A.,
Dimitrova, P., *Medical Biophysics, University of Chicago, Illinois.*

Objectif: To determine protein sequence variations for maintenance epitopes along a region of the HIV-1 gp41, previously shown to be immunodominant, and to study the impact of amino acid substitutions on HIV-1 replication. The amino acid sequence of the gp41 region 371-591 was determined for 100 HIV-1 strains. Regions heterologous to the amino acid (aa) sequence of 371-591 were synthesized and used to immunize mice. The immunized mice were then challenged with a recombinant HIV-1 strain expressing the gp41 region 371-591.

Résultats: Four amino acid substitutions (Glu to Asp, Asp to Asn, Asn to Lys, and Lys to Arg) were found to be conserved in all 100 HIV-1 strains. The other amino acid substitutions were found to be non-conserved. The non-conserved amino acid substitutions were found to be conserved in all 100 HIV-1 strains.

Conclusion: Within a small set of (24) immunodominant epitopes as many as 10 substitutions in the gp41 region were found to be conserved in all 100 HIV-1 strains. The conserved amino acid substitutions were found to be conserved in all 100 HIV-1 strains. The non-conserved amino acid substitutions were found to be conserved in all 100 HIV-1 strains.

T.C.0.34 FUNCTIONAL DOMAINS OF THE HIV-1 ENVELOPE PROTEIN

Titre: Feliciano, D. and Moss, B.
Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD 20892, USA

Objectif: To examine the functional domains on the HIV-1 envelope (env) glycoprotein. **Méthodes:** Recombinant vesicular viruses containing intact or mutated forms of the HIV-1 env gene were constructed. **Résultats:** Cells, infected with a recombinant virus that contains the entire env gene, synthesized glycosylated gp120 which was cleaved to gp120 and gp41 and inserted into the plasma membrane, leading to CD4 binding and syncytium formation. When the DNA encoding the pro-membrane cleavage site was deleted, gp120 was no longer cleaved and inserted into the plasma membrane, but no syncytium was formed. Inserted gp120 was still able to bind soluble CD4.

A family of recombinant vesicular viruses that express N-terminal overlapping env proteins of 204, 287, 393, 504 (gp120), 435, 747, and 821 (gp120) amino acids (aa) was constructed. Only the 747 aa and the full-length protein mediated syncytium formation. The remaining proteins were all present in intracellular and secreted forms which differed in extent of glycosylation. Curiously, the 393 aa protein also was anchored in the plasma membrane but neither its full-length protein bound to CD4. In contrast, an N-terminally spliced env protein (gp120) was not inserted into the plasma membrane and did not bind to CD4. (2) cleavage of gp120 is required for fusion to CD4-bearing cells; (3) the pathway of gp120 cleavage is an act dependent process; (4) the transmembrane domain is cleaved at 835 and 747; (5) the CD4 binding domain is between aa 393 and 504; (6) a cryptic membrane anchor sequence lies between aa 387 and 393.

T.C.0.36 CHARACTERIZATION OF THE HIV-2 ENVELOPE GLYCOPROTEIN: THE TRANSMEMBRANE GLYCOPROTEIN IS A HOMODIMER

Titre: Maiti-Agnon, A., Laurent, A.G., McClure, J., Kravitz, B., Mosselman, L., and Hovanessian, A. G.
Institut Pasteur, Paris 15, France ; *Gene Systems, Seattle, Washington, USA.

Objectif: Identification of HIV-2 envelope external and transmembrane glycoproteins (EOP and TMP) by polyclonal and monoclonal antibodies.

Résultats: A 80-kD glycoprotein (gp80) is produced in HIV-2 infected cells along with three other glycoproteins that we have recently reported : the external glycoprotein (gp125), the envelope glycoprotein precursor (gp140) and the transient dimeric form of gp140 (gp300). The gp125 and gp300 are detectable after the synthesis of gp140 and the formation of gp300. Among these four glycoproteins, only gp80 and gp125 are associated with HIV-2 viruses. As the other glycoproteins, gp80 can be recognized by all HIV-2 positive sera. As a murine polyclonal antibody raised against the purified gp300 recognizes all four glycoproteins. On the other hand, a monoclonal antibody raised against a synthetic polypeptide deduced from the sequence of TMP of HIV-2 recognizes gp140, gp300 and gp80; thus indicating that gp80 should be related to TMP of the envelope. Heating (50°C, 5 min) of cellular or viral extracts in 1% SDS results in the dissociation of gp80 into the monomer gp36. These results suggest that during the processing of the HIV-2 envelope glycoprotein gp140, the dimer is produced which when cleaved by the cellular protease gives the EOP gp125 and TMP dimer gp80. **Conclusion:** Dissociation of envelope glycoprotein precursor and the TMP is a specific property of HIV-2 and HIV gene expression. Dissociation of the precursor might be required for its processing to give the mature envelope products whereas the TMP dimer might be essential for optimal structures of the virion.

T.C.0.38 gp160 IS ENDOPEPTIDOLYTICALLY CLEAVED IN A PREFUSIONLYMPHOCYTE CONTAINING COMPARTMENT OF THE GOLGI COMPLEX.

Titre: Barry, S., Smith, K.S., Switzer, S., and E.G. Engstrom*, Stanford University School of Medicine, Palo Alto, CA 94304, USA. *Chico State University, Chico, CA 95909, USA.

Objectif: To identify the intracellular site of endoproteolytic cleavage of the HIV-1 gp160 envelope precursor.

Méthodes: HIV-1 envelope glycoprotein transcripts were immunoprecipitated from an actively infected CD4+ T cell line (VB) radiolabelled with [³⁵S]methionine and [³⁵S]threonine and subjected to one- and two-dimensional SDS-PAGE. **Résultats:** gp160 contains 70 kD of endo-H sensitive N-glycanase (N-gly) high mannose carbohydrate side chains, is devoid of fucose and is neuraminidase resistant (pI = 7.0 to 7.5). gp160 is not transported to the cell surface, but binds to CD4. gp120 has approximately 20 kD of endo-H sensitive and 55 kD of N-glycanase sensitive N-glycanase linked oligosaccharides signifying both high mannose and complex side chains. gp120 is rich in fucose and sialic acid, with a broad pI of 5.0 to 7.5 that shifts up to 7.0 upon neuraminidase treatment. N-glycanase shifts the pI of gp120 toward the acidic range (5.5 to 6.5) suggesting the presence of abundant sialylated N-glycans. Pulse chase studies with 1-deoxy-mannosyloligosaccharide indicates that gp160 has a transit time of approximately 2 hours to the site of action of Golgi α -mannosidase I and that its endoproteolytic cleavage occurs before processing by Golgi α -mannosidase I. gp160 cleavage is achieved by a non-act dependent process. **Conclusions:** gp160 is endoproteolytically cleaved in a pre-fusionlymphocyte compartment of the Golgi complex, likely before processing by Golgi α -mannosidase I, which is consistent with localization to the RER-to Golgi interface.

W.C.O.5 CD4⁺ LYMPHOCYTES ARE THE CRITICAL CELLS MEDIATING SUPPRESSION OF HIV RELEASE BY CD4⁺ CELLS
D. Weiss, J. Wheeler, C.M. and Leo, J.A. Cancer Research Institute, University of California, San Diego, San Francisco CA 94143 USA

Objective: To determine the critical cell type responsible for the suppression of HIV replication in CD4⁺ lymphocytes, and define whether cell killing is a major mechanism of this suppression.
Methods: Purified CD4⁺ and CD8⁺ lymphocytes from HIV seropositive donors were prepared by the panning technique. CD4⁺ cells were cultured alone or with the addition of either CD8⁺ cells or cells prepared by CD4-depletion. Reverse transcriptase assays were done on culture supernatants at 2-3 day intervals. Cell viability counts were assessed by trypan blue exclusion. Expression of HIV proteins by the CD4⁺ cells was measured by indirect immunofluorescence (IFA) assay.

Results: Panned CD4⁺ and CD8⁺ lymphocyte populations were 85-90% pure by FACS analysis. Cells prepared by CD4-depletion contained 95% CD8⁺ cells, as well as B-cells and non-T lymphocytes. The suppressive activity of purified CD4⁺ cells was markedly greater than that of the CD4-depleted cells added in most number to the CD4⁺ cell cultures. Neither autologous macrophages nor cells depleted of both CD4⁺ and CD8⁺ cells demonstrated suppression of HIV release.

Conclusions: Cell counts and FACS analysis done at the end of 3 experiments showed no decline in the number of CD4⁺ cells remaining viable in cultures where suppression of HIV release had occurred. When CD4⁺ cells were removed by panning after exposure to HIV suppressing CD8⁺ cells, the percentage of cells remaining viable after IFA did not decline. Subsequent cocultivation of these CD4⁺ cells with HIV-1-stimulated lymphocytes from a seropositive donor resulted in rapid release of infectious HIV.
Conclusion: The CD4⁺ lymphocyte is the critical cell mediating suppression of HIV replication by autologous CD4⁺ cells. Killing of the infected cells does not seem to be a major mechanism of this suppressive effect.

W.C.O.7 Activation and infection of T cells by HIV-1 Infected Antigen Presenting Monocyte/Macrophage: **Mann, Isani*, Gardner, R., Appelo, A.**, National Cancer Inst., Frederick*, Bethesda****, MD, USA

Objective: To investigate T cell infection and antigen presentation by HIV-1 infected monocyte/macrophage (M/M).

Methods: M/M were isolated from peripheral blood lymphocytes (PBL) from HIV-1 seropositive individuals by surface adherence and infected with HIV-1. Infected and uninfected M/M were exposed to tetanus toxin (TT) and streptolysin (S3) for 24 hours washed, and autologous M/M depleted PBL added. After 18 hours of exposure to M/M, T cells were prepared and cultured with uninfected T and SX free autologous M/M. ³H thymidine incorporation was determined in the T cells to assess antigen stimulation and reverse transcriptase activity measured in supernatant to monitor infection.
Results: Maximal T cell infection by HIV-1 infected M/M occurred at 7 days. HIV-1 infected M/M presented TT and SX to autologous T cells with activation comparable to uninfected M/M. HIV-1 infected M/M stimulated and infected T cells without TT. Stimulation and infection of T cells were increased when T was presented by HIV-1 infected M/M. M/M to some MHC class II antigens (HLA-DR, DP) blocked T cell infection by HIV-1 infected M/M with and without TT.
Conclusion: HIV-1 infected M/M present TT and SX to autologous T cells not unlike that seen with uninfected M/M. Activation of T cells appears to be an important component of T cell infection as antibodies that block antigen activation also block infection.

W.C.O.9 PATTERN OF HIV REPLICATION DURING *IN VITRO* MATURATION OF MONOCYTES INTO MACROPHAGES

Glinde, Rana*, Chapuis P., Josell T.**, Paravincini C.***, Gluckman J.C.***, Monongeyer L. ***

* Unité d'Oncologie Virale, Institut Pasteur, Paris, France.

** UFR Fédérative, Paris, France.

*** V. Can. Am. Pa. Univ. in Milano, Ospedale L. Sacco, Italy.

Objective: Does macrophage activation control HIV replication?

Methods: HIV replication was observed in peripheral blood monocytes and monocyte cells (THP1) cultured under various conditions to induce macrophage activation (different concentrations of human serum, phorbol ester or cytokines). Expression of differentiation cell markers: Leu M1 (monocyte specific), Pam 1 (macrophage specific), and expression of cytoplasmic viral antigens: constitutive and regulatory proteins (gp110, gp41, p18, p25, p55, p68 and nef), viral RNA, were detected at different time points after infection.

Results: HIV replication is correlated with differentiation of monocytes into macrophages and with activation of the macrophages (a study of the cell cycle indicated a high synthesis of nucleic acids). If HIV infected cultures are stimulated with heat-inactivated HIV, there is increased viral replication.

Conclusions: Expression of cell markers is correlated with monocyte differentiation. Our results suggest that a second round of viral infection could induce macrophage activation and by this way, stimulate productive HIV infection.

W.C.O.6 Infection by HIV-1 of purified NK cells with a

CD3⁺-CD2⁺-CD56⁺-CD16⁺-phenotype.
Basile, Scott*, Virelizier*, Favier*, Francoise Vuillier*, Denise Gherard*, Leo Montagnier* and Guillaume Ullrich* Immunology Institute, Pasteur Institute, 251, Boulevard Pasteur de l'Institut Pasteur 75724 Paris Cedex 15 - FRANCE
In a previous work, we demonstrated a significant depletion of CD3⁺, CD16⁺ NK cells in HIV infected patients (AIDS seropositive and retroviruses #: 121, 1988). These results prompted us to investigate the possibility that HIV could infect NK cells in vitro. Highly purified CD3⁺, CD4⁺ and CD3⁺-CD2⁺-CD56⁺-CD16⁺ cell lines were obtained from peripheral blood of a patient displaying a large granular lymphocytosis; and were infected with the human immunodeficiency virus (HIV) strain HTLV-III. Cell lines displayed the well known pattern of infectivity after exposure to HIV: in the case of CD3⁺-CD2⁺-CD56⁺-CD16⁺ cell line, no increase of reverse transcriptase expression without increase of p-25 antigen was observed. On day 23 of culture, non-infected autologous CD3⁺-CD2⁺-CD56⁺-CD16⁺ cells were added to HIV infected CD3⁺-CD2⁺-CD56⁺-CD16⁺. An important and sustained increase of p-25 antigen was observed 4 days after coculture, whereas in the case of reverse transcriptase, no increase in expression was observed. These results suggest that NK cells can be directly infected by HIV, in the presence of relatively little cytopathicity and can propagate the virus to autologous CD4 cells.

W.C.O.8 MACROPHAGE-ACTIVATING FACTORS (MAF) ALTER HIV-1 PRODUCTION FROM PRIMARY MONOCULAR PHAGOCYTES

John Mellors, M. Orian, N. Ashkin, R. C. Smith, M. Landay, J. Ryan, Yale School of Medicine and VA Medical Center, West Haven, CT, USA.

Infection of mononuclear phagocytes by HIV-1 is believed to be a central event in the pathogenesis of AIDS. It is not clear, however, whether activating signals alter HIV production from these key target cells. We have studied the effects of several MAFs including recombinant tumor necrosis factor- α (TNF- α), interferon- γ (IFN- γ) and lipopolysaccharide (LPS), on HIV-1 production from blood monocyte-derived macrophages (MDM). MDM were purified (99% esterase) from normal donors by density-gradient centrifugation and adherence to plastic in 10% human serum. After 1-2 weeks of culture, MDM were infected with HIV-1 (strain HTLV-IIIB) at a multiplicity of infection of approximately 5. Virus production was determined by ELISA of culture supernatants and cell lysates for HIV p24 antigens. Treatment of MDM with TNF (10⁻⁶ U/ml), starting either 2 days before or 7 days after HIV-1 infection, increased virus production 3-fold over control. Treatment with LPS (10⁻⁶ ng/ml) starting 7 days after infection increased virus production 4-10 fold over control. In contrast, IFN- γ (1 U/ml) inhibited HIV-1 replication (38-59% inhibition). Viral inhibition was observed irrespective of the timing of IFN- γ treatment in relation to HIV-1 infection. Similar inhibition was produced by recombinant interferon- α or native interferon- β , indicating that anti-HIV activity was not specific for IFN- γ . These studies indicate that proinflammatory inhibit HIV-1 replication in MDM, but that IFN- γ and LPS enhance virus production from these cells. These observations, combined with clinical evidence that T-cell IFN- γ production declines and circulating TNF levels rise with progression of HIV-1 infection to AIDS, suggest that certain MAFs may be important modulators of HIV-1 replication *in vivo*.

W.C.O.10 ADHERENT LINGERING-ACTIVATED KILLER CELL (A-LAK) CYTOTOXIC ACTIVITY AGAINST HIV INFECTED MONOCYTES

Melby, Robert J. **, Gault, R. S. **, Gupta, R. **, Rinaldo, C.R. **, Weissfeld, T. S. **, and Herberman, R.B. **, University of Pittsburgh* and Pittsburgh Cancer Institute, Pittsburgh, PA, USA**

Objective: To characterize non-MHC restricted killing of HIV infected monocytes by a highly cytotoxic and homogeneous recombinant-interleukin-2 (rIL-2) activated killer cell (AK) population. **Methods:** Monocytes were infected with HIV-1 strain IIIB (IB strain) and a monocyte-derived strain and incubated at 37°C for 1 to 7 days. Autologous and allogeneic A-LAK cultures were prepared by stimulating monocyte-depleted PBL from normal HIV-seronegative donors with rIL-2 for 24h at 1000 U/ml and expanding the plastic-adherent population. Cytotoxicity of A-LAK cells towards HIV-infected and rIL-2-infected monocytes as well as tumor cell lines was evaluated in an ⁵¹Cr-release assay. **Results:** A-LAK cytotoxicity against the infected and rIL-2-infected monocytes after 3 days of infection was 83 lytic units (LU)/10⁶ cells (strain IIIB), 364 LU/10⁶ cells (monocyte-derived strain) and 17 LU/10⁶ cells (uninfected monocytes). Killing of K562 and Daudi cells resulted in 8,584 and 2,008 LU/10⁶ cells respectively. A-LAK killing of HIV-infected monocytes was at least 20-fold greater than from rIL-2-stimulated monocyte-depleted PBL from normal infected monocytes (23 LU/10⁶ allogeneic cells) was as effective as killing by autologous cells (74 LU/10⁶ cells). One culture of A-LAK cells expressed high levels of non-MHC restricted cytotoxic activity against monocytes infected with both strain IIIB and a monocyte-derived HIV strain.

Vaccine Developments In AIDSW.C.O.17 CURRENT TRENDS IN HIV VACCINE PREPARATION
Marc Girard, Pasteur Vaccins and Institut Pasteur, Paris, France.

The development of a vaccine against AIDS has met with considerable difficulties. Not only does the virus remain latent in the body for long periods of time, probably persisting as an integrated provirus in the genome of the host cell, but it also shows considerable genetic variability. For an HIV vaccine to be able to prevent infection, quick neutralization of the virus would be of crucial importance. However, neutralizing antibodies raised against an HIV-1 isolate do not usually cross-neutralize other HIV-1 isolates. Work on a vaccine is further hampered by the fact that the only animal model system available so far for HIV-1 uses the chimpanzee. Following infection the animals replicate the virus and become asymptomatic carriers with no signs of disease. Finally, the HIV envelope glycoprotein appears to be poorly immunogenic: it elicits only weak neutralizing anti-viral antibody titers, perhaps due to epitopic suppression. In our hands, vaccinia virus HIV recombinants elicited a T-cell immune response but only a weak humoral response, an inactivated virus vaccine elicited a good humoral immune response but no T-cell response. Purified HIV antigens added with a MDP-base adjuvant showed however high immunogenic potency. Finding the appropriate presentation of HIV antigens able to elicit high neutralizing antibody titers of broad reactivity is a requisite for the successful development of an HIV vaccine.

W.C.O.19 IMMUNISATION EXPERIMENTALE ANTI HIV CHEZ L'HOMME

Zaïre, Denis

Dans le cadre d'une collaboration de recherche Franco-Zairoise, des essais d'immunisation active anti HIV, destinés à préparer un vaccin anti-SIDA, par l'inoculation d'une immunisante à médiation cellulaire, ont été réalisés depuis novembre 1986 chez des volontaires séro-négatifs. Des essais (1-2), préalable d'une sélection chez l'animal qui a montré l'innocuité et l'immunogénéité des préparations utilisées, ont comporté une primo-injection de vaccine recombinante (Vr) exprimant le protéoglycane 160 du HIV et un rappel variant suivant les individus (Vr + agencement de protéines membranaires endogènes isolées ou non du virus) et/ou le protocole d'immunisation Vr + cellules autologues infectées et l'huile peut être considéré comme un candidat vaccin polyvalent induit une réaction anti HIV immunisante et spécifique de groupe (2-3) avec des cellules lésées et des autours qui sont protecteurs - et non facilitants - vis à vis de l'infection par le HIV; des macrophages/mesophages in vitro (4).

Nous recherchons actuellement un protocole d'immunisation reproduisant le même état d'innocuité anti HIV que le protocole et plus simple à administrer à un grand nombre d'individus. Cette étape dans le développement d'un vaccin anti SIDA est indispensable avant d'engager un essai clinique à plus grande échelle (phase 2) susceptible d'évaluer le niveau de protection vis à vis de l'infection naturelle du candidat vaccin.

W.C.O.18 DEVELOPMENT OF AN HIV SUBUNIT VACCINE
Faulkner, Scott, R.*; LaRosa, G.; Javaherian, K.*; Emini, S***; Biogenesis, D.**; and Matthews, T.***; *Repligen Corporation, Cambridge, MA, USA, **Duke University Medical School, Durham, NC, USA, ***Herch, Sharp and Dohme Research Laboratories, West Point, PA, USA.

We have mapped the principal HIV neutralization determinant to a disulfide loop in a variable region of the outer envelope (aa 303-338). Antibodies elicited by peptides as small as eight amino acids from the center of this determinant neutralize free HIV and prevent fusion of HIV infected cells with uninfected CD4 cells. These antibodies are type-specific in that antibodies elicited by a peptide of the sequence from one isolate do not neutralize a panel of divergent HIV-1 isolates.

Using PCR amplification and sequencing of this determinant from independent HIV-1 isolates, we have found that over 40 of 100 randomly isolated viruses have identical or very similar amino acid sequences. In addition, over 80 of 100 sera from randomly selected HIV-1 infected people react with a peptide of this sequence. This indicates that viruses with this amino acid sequence are prevalent. This data, taken along with data that antibodies to this determinant delay HIV infection of chimpanzees, (E. Emini, et al.) suggests that a broadly protective HIV subunit vaccine can be developed.

W.C.O.20 EVALUATION OF A RECOMBINANT HIV-1 ENVELOPE PROTEIN AS AN IMMUNOGEN IN HUMANS

EVALUATION BY PCR OF HIV-1 STATUS OF CHIMPANZEES CHALLENGED WITH HIV AFTER RECEIVING HUMAN HIVIC
Maziarz, J., Indira, A., Sperelak, J.S., Newthorne, C.A.,
Tishler, M., and FRISCH, A.S.,
Food and Drug Administration, * Bethesda, MD, 20892, New York Blood Center
HIV* and Southwest Foundation, TX, *** U.S.A.

Objective: To determine the status of HIV after virus challenge in chimpanzees previously immunized with HIVIC.
Methods: Five chimpanzees were passively immunized with HIVIC prepared from plasma of HIV seropositive, seronegative donors whose serum contained high titres of neutralizing antibodies (Frisch et al. PNAS, Vol 85 p. 6944-6948). Virus isolation was performed on peripheral blood mononuclear cells (PBMC) by coculture. PCR was performed on DNA isolated from lymphocytes, using the gag and env primers for confirmatory detection.
Results: HIV-1 DNA sequence was detected by PCR in lymphocytes of all 5 animals after virus challenge although virus cultures were not all positive until 3-9 weeks after challenge.
Conclusion: Administration of HIVIC to chimpanzees was unable to prevent HIV infection. Virus expression (RNA-PCR in PBMC) and release of assembled virus in culture (PCR in serum) are being performed to assess virus activity in these animals.

W.C.O.29

EFFECTS OF SPERM AND AUTOMUNEMITY ON MERKRE AIDS (MAIDS)
Steinlich, Zvi H., Weissman, Z., Moshier, A.,**
*Hebrew University of Jerusalem, Jerusalem, Israel
R. Ben Ari Institute of Clinical Immunology, Kaplan Hospital, Hebrew University Medical School, *Experimental Animal Unit, ***Department of Cellular Immunology, Weizmann Institute of Science, Rehovot, Israel.

Objective: To determine the effect of sperm and induced autoimmune disease on the generation and course of MAIDS.
Methods: Disease was induced by viruses obtained from cell line LP-BMS-571 (SIV CP126), B19A, A19 and A19 strains. Autologous sperm cells (1-3 x 10⁷) were injected intravenously prior to and following the viral inoculations. Antispermic SIV-like disease was induced by a human monoclonal antibody. Experimental SLE-like disease was induced by a human monoclonal proliferation and histopathological examinations were performed.
Results: Spermogeny in several animals and prolonged suppression of sperm-PCR proliferation to mitogens and allogeneic stimulation were observed following single sperm injection into normal animals. Sperm enhanced significantly the induction of MAIDS by the viral preparations, which was more evident when using sublethal doses of virus.
Table:

Saline	Sperm	Virus	Sperm + Virus
MAIDS	0/19	7/19	10/19

10% antibody injection to virus inoculated animals increased serum levels of Ig, anti DNA and anti idiotypic antibodies and immunopathology.
Conclusion: Immunomodulation by sperm and autoimmune disease influences the course of MAIDS. This may have direct relevance to their role in the pathogenesis of human AIDS.

W.C.O.31

T-CELL KILLING BY THE POLY-P-FAIDS IMMUNODEFICIENCY VIRUS
Emswiler, R., Dombas, E. A., Hovav, C.M.C. deLoraine, S.L.,
Garcas-Barria, J., Overbaugh, J., and J. Mullins, (DH) Harvard
School of Public Health, *O'Connell Base University, N. Collins, CO.
**Present Address: Univ. of Washington, Seattle, WA, U.S.A.

OBJECTIVE: Locate the genetic determinant and elucidate some aspects of the mechanisms of T-cell killing by a genetically cloned feline leukemia virus that induces fatal immunodeficiency disease in outbred specific-pathogen-free cats.
METHODS: Chromosomal variants were generated in vitro using the replicative defective assay immunosuppressive 616 provirus. To assess their pathogenicity, an *in vivo* assay using a feline T-cell line was developed.
RESULTS: Replication competent chimeres were obtained that were T-cell cytotoxic *in vivo* and induced immunodeficiency disease *in vivo*. Analysis of 22 chimeres revealed that the essential determinant for T-cell killing resides within chimera 23 (a 2 base pair (2 amino acid) stretch within the extracellular glycoprotein gene (gp70), corresponding to a single amino acid change and a 6 amino acid insertion in the protein. Other changes within gp70 and the viral LTR enhance the efficiency and rate of T-cell killing *in vitro* and pathogenicity *in vivo*. T-cell killing occurs along with production of high levels of integrated viral DNA and viral mRNA, and can be blocked by exposing newly infected cells to antisera from cats exposed to the virus.
CONCLUSION: These results suggest that T-cell killing occurs as a result of massive superinfection and that the critical mutations in gp70 cause a failure or delay in the establishment of superinfection interference, possibly through altered interactions with p15E and/or its cellular receptor.

W.C.O.28

THE MARINE ACQUIRED IMMUNODEFICIENCY SYNDROME (MAIDS) IS CAUSED BY A DEFECTIVE RETROVIRUS
Hanna, Mings*, Hanna, Z., Atz, D. P., Simard, C. and
Jullouwer, P. et al.

*Clinical Research Institute of Montreal, Montreal, Quebec, Canada;
**Université de Montréal, Montreal, Quebec, Canada.

The Duplan strain of marine leukemic virus (MLV) induces MAIDS, a disease showing striking similarities with human AIDS. We identified the etiologic agent of the disease as being a defective retrovirus having a 4.8 kb genome. Sequencing of this DNA showed that the pol and env genes have been deleted and that the complete gag region has been conserved and harbors a novel p12 sequence. Using a cell-free translation system, the genome has been shown to encode a 50 kd gag fusion protein. The same protein was detected in non-producer cells harboring the defective genome and is not cleaved. N-tropic pseudotypes have been constructed with this virus and the role of helper virus in the disease is also being investigated using the W2 encapsidation-negative system. This mouse model emphasizes the need to search for pathogenic defective retroviruses in AIDS.

W.C.O.30

MOLECULAR CLONING AND SEQUENCE ANALYSIS OF FELINE IMMUNODEFICIENCY VIRUS (FIV)
Ginsburg, Robert, A., Barnes, A.S., Yessierli, J.K.,** Hirsch, V.V.,
Purohit, R.H.,** and Johnson, F.R.* Georgetown Univ., Rockville, MD, *NIH, NIH, Bethesda, MD, **Univ. of California-Davis, U.S.A.

Objective: FIV is a T-lymphotropic retrovirus that is associated with immunodeficiency and opportunistic infections in cats and provides an excellent opportunity for the development of a small animal model for AIDS. To isolate these viruses, we isolated a proviral clone of FIV for molecular and biological characterization.
Methods/Results: FIV-1/2 provirus cDNA clones were synthesized and used to isolate the proviral molecular clone, FIV-14. Molecular cross-hybridization analysis of FIV-14 with 5 feline viruses revealed that nucleotide sequence similarities exist between FIV and these viruses in the gag-pol gene. Significant nucleotide sequence identity was observed between the 3' LTR of the FIV-14 pol gene and the pol gene of FIV, HIV-1, HIV-1, EAV, vira virus and CAEV (59%, 69% identity). Sequence similarities were not observed upon comparison of the FIV LTR sequence with known viral sequences. Common antigenic determinants appear to be shared by FIV, CAEV, and vira virus as shown by serological cross-reactivity of rabbit antibodies to CAEV and vira virus with the proviral FIV ones protein, p24. Importantly, proviral viruses of FIV-14 were infectious for experimentally inoculated cats.
Conclusion: These studies demonstrated that FIV is a member of the lentivirus subfamily and is distantly related to the AIDS lentiviruses of primates. The availability of an infectious molecular clone will make possible a detailed dissection of the molecular pathogenesis of FIV, which may facilitate the development of vaccine and therapeutic strategies for AIDS.

W.C.O.32

INFECTION OF THE NEW ZEALAND WHITE LABORATORY RABBIT (OTOCYCLOPSA CUNICULUS) WITH HIV-1
Beland, E.***, Haxhaxhiu, E.***, Gard, E.A.**, Ford, G.**, Buchbinder, A.**, Gallo, R.C.**, et al.
*National Cancer Inst., NIH, Bethesda, MD, **NIH, Bethesda, MD, ***Bionomics Research, Inc., Rockville, MD, U.S.A.

Objective: To develop a laboratory model for HIV infection of New Zealand White rabbits.
Methods: NZW rabbits were injected intraperitoneally with HIV-1 or HIV-2-infected cells after thymoglycinate-induced pancytopenia. Animals were monitored for physical and hematological abnormalities, infectious virus, viral nucleic acids, and antibodies to viral proteins.
Results: Three rabbits inoculated twice at 60 day intervals with HIV-1 produced continuously rising titers to both gag and env proteins. Virus, detected as viral antigens, was also periodically recovered from peripheral blood leukocytes by cocultivation with susceptible cells. Persistent infection was also suggested by detection of proviral DNA in multiple tissues. Physical abnormalities included lymphadenopathy and pancytopenia. Histopathology revealed a disruption of follicular architecture of lymph nodes.
Conclusion: NZW rabbits appear to be infectable with HIV-1 and demonstrate a pathological effect. However, much work remains in characterizing this potential animal model.

W.C.O.33 ANALYSES OF T CELL HILLAR FACTORS WHICH BIND TO THE NEGATIVE REGULATORY ELEMENTS (NRE) OF THE HIV LTR
 CRY, Bruno, A. Acres, D. and Klay, K.F.
 TRANSCORP S.A., 6705 Scribblewood Circle, FRANCE

Objective: To analyze the nuclear factors binding to the NRE sequence of the HIV LTR and to investigate the influence of nef on these factors. Gel retardation assays and methylation interference techniques have been used.
Results and Conclusion: Nuclear extracts from human T-rossette positive peripheral blood cells and from T cell clones were analyzed using gel retardation assays. NRE binding factors were detected and their appearance and binding factors in nuclear extracts prepared from cells stimulated with PHA 17k appear to be different from that (those) which appear in response to 12-O-tetradecanoyl phorbol-13-acetate 12-myristate 13-acetate (TPA) as expressed in cells using a vaccinia virus expression system. The evidence will be presented which demonstrates associations between the appearance of HIV NRE binding factors and genetic elements involved in T cell activation.

W.C.O.35 EFFECTS OF MUTATIONS IN THE *gag* GENE ON THE GROWTH OF HIV.
 Kim, Sunyoung*, Bensch, K.W., Byers, K.A., Greenway, J.P., and Baltimore, D.*

* Whithead Institute, and Dept. Biology, MIT, Cambridge, MA, USA.
 ** New England Deaconess Hospital, Harvard Medical School, Boston, MA, USA.

HIV contains the open reading frame called *gag* at the 3' end of its genome which was reported to be dispensable for viral growth but to reduce viral gene expression. We have compared two different HIV-1 strains with the same genetic background, except for a lesion in *gag* (one containing the complete coding region, and the other null for *gag*). The effects of *gag* on various stages of HIV infections were examined. We have tested effects on viral DNA and RNA after infection. Comparable results were obtained from both *gag*⁺ and *gag*⁻ strains. The effects on viral growth were also tested by following changes in reverse transcriptase activity in cell cultures supernatant and the fraction of infected cells (determined by indirect immunofluorescence) during the course of infection. The presence of the *gag* gene product fails to slow down viral growth in many different cell types tested, including human T lymphocyte cell lines, B9 and CEM, human primary T cells, and human monocytic cell lines such as U937 and THP-1. These results were reproducible with the use of a different virus isolate. Our data suggest that *gag* does not act as a negative factor, at least in the experimental system we employ.

W.C.O.37 EFFECTS OF NEF EXPRESSION ON HIV REPLICATION AND CELLULAR FUNCTIONS

Chakrabarti, Goolbsy, Imerets, P. Luce, P.A. and Levy, J.A.
 Cancer Research Institute, University of California, San Francisco, CA 94143 USA, *Department of Medical Pathology, University of California, Davis, CA 95618 USA

Objective: To determine the effects of stable *gag* expression on HIV replication and cellular functions.

Methods: Stably transfected cell lines expressing the *gag* protein were obtained by transfection of HUT-78, RD (Ruman rhabdomyosarcoma) and COG-7 (monocytic cells with plasmid constructs of *gag*) under the SV-40 or HIV-1 promoters. Expression of *gag* was monitored by an immunofluorescence assay (IFA) and immunoblot analysis. Effects of *gag* expression on HIV replication were assessed by transfection and infection of these stable cell lines. Effects on cellular function were monitored by cell growth and modulation of cell surface markers.

Results: Stable cell lines expressing the *gag* gene product, *gag*⁺ were obtained in HUT-78, RD and COG cells. Expression of *gag* in HUT-78 results in the down-modulation of the CD4 receptor molecule. This down-modulation appears to be specific since other cell surface markers, e.g. CD3, were not affected. Expression of *gag* in COG cells also leads to the suppression of HIV COG upon transfection or infection with HIV. In some stably transfected cell clones, the expression of *gag* appears to retard cell growth. This is similar to that observed for expression in yeast. Current studies are directed at elucidating the mechanisms by which *gag* regulates HIV replication and cellular function. Its interaction with other HIV regulatory proteins is also being examined.

Conclusion: Expression of *gag* in stably transfected cell lines has been shown to suppress HIV replication and affect cellular functions. These cell lines will be used to understand the mechanism by which the *gag* protein exerts its effects, and the interactions it has with the other HIV regulatory proteins.

W.C.O.34 FUNCTIONAL ROLE OF HIV-1 VPU

Gilman, Rick A.; Terwilliger, E.; Sodroski, J.; Haseltine, W. Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA U.S.A.

Objective: Determination of the effect of the *vpu* gene of HIV-1 upon the viral life cycle.

Methods: Isogenic HIV-1 proviruses identical except for possessing a functional *vpu* were constructed and transfected into CD4⁺ Jurkat cells. Parameters of virus infection quantitated included cell number, syncytia formation, supernatant reverse transcriptase activity, and both cell and virion associated viral protein levels.

Results: Cells infected with *vpu*-expressing virus demonstrated a marked increase in the ratio of virion associated versus cell associated viral protein compared to cultures infected with *vpu*-negative virus. The *vpu*-positive cultures exhibited lags in syncytium formation, cell death and accumulation of intracellular viral proteins, despite possessing higher levels of supernatant reverse transcriptase activity.

Conclusion: The product of *vpu* acts to accelerate virus export.

W.C.O.36 VPU - A PROTEIN UNIQUE FOR HIV-1 IS REQUIRED FOR EFFICIENT VIRUS REPLICATION AND RELEASE

Kirkland, Thomas*, Strabel, S., Owsenstein, J.M., Martin, M.A.*
 *Laboratory of Molecular Microbiology, MILD, NIH, Bethesda, MD, USA
 **George Washington University Medical School, Washington, DC, USA

Objective: To determine the role of HIV-1 *vpu* and its intracellular location during productive viral infection of human T-cells.

Methods: Infections of T-lymphocytes with virus particles derived from an infectious molecular clone of HIV-1 or a deletion mutant lacking the *vpu* gene were compared. A nonspecific *vpu* antiserum was used in indirect immunofluorescence assays for the cellular localization of *vpu*. Morphological changes associated with wild type or *vpu* mutant infections were examined by electron microscopy.

Results: Wild type or *vpu* mutant viruses have similar infectivity in human T-cells. However, infections with the *vpu* mutant resulted in earlier cell fusion and cell death, both of which paralleled the intracellular accumulation of viral proteins. Using indirect immunofluorescence assays, *vpu* was localized to the cytoplasm of infected cells; no *vpu* was detected in the nucleus or on the outer surface of the plasma membrane of virus producing T-cells. Electronmicroscopic analysis of cells infected with the *vpu* mutant revealed the presence of virus-like particles in the cytoplasm, intracellular budding, and an accumulation of immature particles at the cell surface; these features were not observed in cells producing wild type viruses.

Conclusions: *vpu* is required for the efficient release of HIV-1 particles from productively infected lymphocytes. The absence of *vpu* results in an intracellular accumulation of virus particles and inefficient virus maturation.

W.C.O.38 IN VITRO GENERATION OF NEUTRALIZATION-RESISTANT HEMAGGLUTININ DEFICIENCY VIRUS (HDV)

Takatsuki, K., Harada, Shinji*, Masuda, T., Kamogi, K., Hatemachi, S., and Institute for Virus Research, Kyoto University, Kyoto, Kyoto, 606 Japan. **Kumamoto University Medical School, Kumamoto, 860 Japan.

Objective: To prove that HIV produces antigenic variation in the presence of neutralizing monoclonal antibody (0.5).

Methods: Plaque-cloned HIVs and monoclonal antibody (0.5) which shows type-specific neutralization were used. The virus-infected MT-4 cells were cultured with or without 0.5 for 1 month to obtain variants of the virus. To know the antigenic changes of the viral envelope, we performed plaque assay for neutralization and radioimmunoassay. Restriction enzyme assay analyses were used to show the genetic changes.

Results: After 1 month of culture, we obtained variant viruses which showed cytotoxic effects even in the presence of 0.5. Neutralization test by 0.5 revealed that antigenic differences between control and variant were marked. Also, 0.5M precipitated gD2 of control but not of variant. Restriction enzyme assay analyses showed that there were no differences among them.

Conclusion: We showed that the alteration in virus neutralizability was observed in the presence of neutralizing monoclonal antibody, suggesting that this antibody may exert selective pressure. Restriction enzyme assay analyses indicate that genetic shift might be a minor one. Probably a point mutation was proposed.

W.C.O.45 NEUROPATHOLOGICAL STUDY OF HIV-INFECTED MACAQUES

Anderson, Daniel C., McClure, J.M., Silva, J.L., Anstair, A., Pulla, P., and Mirra, J.R.
*Yerkes Regional Center and Department of Pathology, Emory University, Atlanta, GA, *Armed Forces Institute of Pathology and Walter Reed Army Institute of Research, Washington, D.C., and *VA Medical Center, Atlanta, GA, U.S.A.

Objective: To determine the pathologic changes in the CNS of macaques acutely or chronically infected with HIV isolates P91-10 or 800-9. Methods: Brains and spinal cords from macaque animals were examined histologically at various intervals post-SIV infection. Included were brain animals that died 0-8 days post-infection (P.I.), brains from 2 from 17 macaques that died 9 months P.I., and brains from 2 chronically infected macaques that died 14-43 months P.I.

Results: Lesions were seen in the brain as early as 8 days P.I. Changes seen in animals dying shortly after infection include: (1) choroid plexitis and meningeal cell and occasional multinucleated giant cell inflammation unaccompanied by a T-lymphocyte infiltrate, and (2) astrocytosis with predominantly mononuclear cell inflammation. Parenchymal lesions were rare in animals dying shortly after infection; infected animals showed a less striking choroid plexitis and more frequent parenchymal granulomatous lesions comparable to HIV infection in humans produce CNS lesions with features reminiscent of HIV infection in man (immunopositivity with multilobar giant cells and macrophages). Continued study of the pathogenesis of SIV infection should provide important information related to the pathogenesis of CNS involvement in AIDS. (Supported by NIH grant RR0145).

W.C.O.47 MONKEYS WITH SIMIAN AIDS PRODUCE AN ANTIBODY DIRECTED AGAINST A HISTONE-LIKE PROTEIN ON CD4+ T-CELLS

Sticker, Raphael M., Fultz, P.N., Haslip, A.M.,
*University of California, San Francisco, CA, *Yerkes Regional Primate Research Center, Emory University, Atlanta, GA, U.S.A.

Previously it was shown that patients with AIDS and AIDS-related conditions produce a cytotoxic antibody that binds to lectin-stimulated or virally-infected CD4+ T-cells (Namer 207, T10-713, 1987). Subsequently it was discovered that the target antigen resembles a histone protein, H2B. We have now investigated the production of this antibody in monkeys infected with simian immunodeficiency virus (SIV). When macaques are infected with SIV, these monkeys develop symptoms of immunosuppression that characteristic of simian AIDS (SAIDS). In contrast, when mangabeys are infected with SIV, they remain healthy. Sera from 10 mangabeys and 10 macaques infected with SIV were tested for the presence of antibody against histone H2B by immunoblotting. The ten mangabeys (all healthy) did not have antibody against histone H2B detected in their sera. Four of the macaques were healthy at the time of testing, and some of their sera contained antibody against the histone protein. In contrast, the other six macaques had symptoms of SAIDS, and all six had antibody against histone H2B. When sera from these animals were tested sequentially, detection of antibody against the histone protein appeared to coincide with the onset of disease. The histone-like antigen was also detected on macaque lymphocytes, as determined by immunoblotting using monoclonal antibody against histone H2B. We conclude that monkeys with SAIDS produce an antibody that reacts with a histone-like protein expressed on CD4+ T-cells. This antibody may play a key role in the destruction of CD4+ T-cells in both AIDS and SAIDS.

W.C.O.49 EVIDENCE FOR PROGRESSION TO DISEASE IN CHIMPANZEES CHRONICALLY INFECTED WITH HIV-1

Dine, D., Davis, F., Fildes, R., Siegel, R., McClure, R., Steiner, K.W.,
*Yerkes Regional Primate Research Center and Department of Pathology, Emory University, Atlanta, GA, USA; *Yerkes Regional Primate Research Center, Emory, GA, USA

Objective: To assess the virologic, immunologic and clinical status of chimpanzees after long-term infection and immunization with HIV-1.
Methods: Following inoculation of HIV-1 and later therapeutic immunization with purified HIV antigens, chimpanzees were evaluated for hematologic status; vitreous status, including cell-free and cell-associated HIV and p24 antigenemia; and immune responses, including antibodies that neutralized virus infectivity, inhibited cell-to-cell transmission, asymptomatic formation, or RT activity.
Results: Of six chimpanzees infected for 45 to 54 months, three developed changes in antibody profiles or abnormalities in hematologic parameters. Two animals, one of which was persistently hypergammaglobulinemic for more than 6 years, lost antibodies to gag-antigenic epitopes. The third animal has been lymphopenic, with loss of CD4+ cells, and thymocyteopenic for more than 1 year, and recently became viremic, as evidenced by isolation of cell-free HIV from plasma. Therapeutic immunization had little effect on HIV-specific immune responses or clinical status.
Conclusions: Long-term infection of chimpanzees are developing abnormalities analogous to those that are predictive of AIDS in HIV-infected persons. If HIV-induced disease in chimpanzees is a function of length of time of infection, then HIV-infected chimpanzees may yet develop AIDS. (GR grant RR-00145 and CDC Contract 200-80-0667).

W.C.O.46 CLINICAL, IMMUNOLOGICAL, AND VIROLOGICAL FOLLOW UP OF HIV-1

INFECTED BRISIAN MONKEYS.
Dumont, Dominique, L'Orange, Y., Chavrier, S.O., Oustan, D., Ozi, Roudot, J., Maber, E.U., and Monod, J.P.,
*Centre de Recherches de l'Institut Pasteur, 213 Avenue de la Chimie, Pasteur, 91190, Fontaine aux Rues, FRANCE; *Institut Pasteur, Paris, FRANCE; *CEA, Bruyères le Châtel, FRANCE.

Objective: To establish an animal model of human HIV infection and/or clinical manifestations of AIDS, in order to understand pathogenesis of HIV infection, to test therapeutic protocols, and vaccine strategies. 10 rhesus monkeys have been inoculated with 2 different strains of HIV (89BR, 89RD) which were being "adapted" in vitro to monkey cells (fibroblasts, macrophages, T-cells). Monkeys were infected both by IV route and intracerebrally. Follow-up consisted in clinical survey, serological tests (RPA, mainly lymphocyte culture, CD4+CD8+ cells count and conventional blood chemistry tests). HIV-1 isolated in monkey lymphocyte culture and CSF have been compared to starting virus material by restriction map and by Southern blot analysis. A second, in vivo passage of HIV-1 in monkey, which exhibited in vivo biological properties in cell culture, is in progress.

Results: 2 animals inoculated (D10-230, earlier with the HIV-89RD strain adapted on cynomolgus cells than the other strain, HIV-79) was detectable in lymphocyte culture supernatants in 6 of the 7 animals who were observed in cell culture. Significant lymphopeny and decrease of CD4+ cells count were observed in 6 animals. Two animals exhibited clinical symptoms which might be related to HIV-1 infection: acute orchitis, dyspnea, serologic symptoms related to anticomplexon typhoid of the lungs of the monkey, for one animal, and weight loss, lymphadenopathy, and proctopyria for the other one. HIV-1 isolated from these monkeys behave differently in cell culture than the starting virus.
Conclusions: HIV-1 able to replicate in rhesus monkeys, and may induce clinical symptoms in some animals. This model has to be reproducible before being considered as a model for AIDS or for HIV infection. Molecular and biological markers of in vivo adaptation have to be investigated, and may help in understanding HIV infection pathogenesis and variability of clinical manifestations.

W.C.O.48 VACCINE PROTECTION AGAINST SIMIAN IMMUNODEFICIENCY VIRUS INFECTION

Daniel, Muthiah D., Sehgal, P., Wyand, M., Ringler, D.,
King, H., and Drenth, R.A.,
New England Regional Primate Research Center, Harvard Medical School, Southborough, MA, USA

Objective: To test the efficacy of inactivated simian immunodeficiency virus (SIV) (SIVmac) as a vaccine.
Methods: Rhesus macaques were immunized by multiple inoculations with purified, disrupted, non-infectious SIV in adjuvant (chromyl selenyl dipalmitate adjuvant formulation of SIVmac).
Results: Immunized animals developed anti-SIV antibodies detectable by Western blots and by Western blot; these antibodies had weak neutralizing activity. These macaques were challenged with 200 to 1000 animal infectious doses of live, cell-free SIV one week after the last immunization. SIV recovery from peripheral blood and anamnestic antibody responses were used to monitor infection. Two of six vaccinated macaques showed no evidence of infection after challenge with live virus. Four of four unvaccinated macaques became infected with these doses and three have died with AIDS 118-208 days after challenge. Only one of six vaccinated-challenged macaques has died to date.
Conclusions: These results suggest that inactivated whole virus vaccination can protect macaques against SIV challenge. The SIV animal model appears useful for comparison of AIDS vaccine strategies.

W.C.O.50 GENETIC VARIATION OF SIV IN EXPERIMENTALLY INFECTED MACAQUES: TISSUE VERSUS TISSUE CULTURE

Chakravorty, Venkatesh, Kulkarni, M.L., *MADANI, Bethesda, MD, U.S.A.,
Johnston, J.M.B., Orosz, R.A., Purcell, R.H.,** and Hirsch, V.M.,
*Chattanooga University, Knoxville, TN, **NIH/NIH, Bethesda, MD, U.S.A.

Objective: Lentiviruses have the potential for significant genetic variation during natural course. Viruses isolated from infected animals with 2 different strains of certain variants in tissue culture; and, (ii) the presence of replicating and non-replicating variants. To address these issues, we have begun to analyze and compare SIV proviral DNA in tissues from SIV-infected macaques and in cell lines from the same macaques. We have identified 2 main **Mac/Man/Repl** strains. Three groups of macaques were infected with SIV from a sooty mangabey (SIVsmm) group 1 received unselected SIV; group 2 received SIVsmm (sm1-3), derived from a biologically active molecular clone; and, group C received sm1-4, derived from a second SIVsmm molecular clone. One macaque in group A died 7 weeks after inoculation from disseminated CMV infection. On Southern blot analysis, skin origin Southern blot contained one detectable proviral form. Portions of proviral DNA isolated from cultured with CEM cells or processed for genomic DNA isolation. Comparative Southern blots revealed that 1) multiple proviruses were present in the acutely infected CEM cell line and the splenic tissue; and, (ii) a major proviral form present in the splenic tissue (equivalent with the original form) was not detected in the CEM cell line. Furthermore, this proviral form was also detected (at varying levels) in liver, kidney, and lymph nodes. This cloning and molecular characterization of these proviral variants are underway.
Conclusions: Multiple proviral forms of SIV arise during infection of macaques. Certain variants may not be recovered in tissue culture despite a high integrated proviral copy number. The importance of these variants is unclear, but they may play a role in the pathogenesis of SIV infection.

Aspects pathologiques de l'infection par le VIH Pathological Aspects of HIV Infection

Th.C.0.7 DISTINCT HISTOLOGIC LYMPH NODE CHANGES FOLLOWING HIV INFECTION IN ADULTS

Berlin, Nancy L., Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114, U.S.A.
Objective: To develop a clinically relevant classification of lymph node histopathology in HIV infection.

Methods: This report is a review of histopathologic and immunohistologic findings in lymph node biopsy and autopsy specimens from patients with HIV infection seen at Massachusetts General Hospital since 1982, as well as a review of the recent literature.

- Results:** At least 6 major types of lymph node histopathology are seen in HIV infected patients, either alone or in combination with other types:
1. Florid reactive follicular hyperplasia ± follicle-lysis
 2. Follicular involution
 3. Diffuse pattern (± lymphocyte depletion ± neoplasmoembolic changes.)
 4. Atypical follicular hyperplasia (Gonorrhea-like lesion)
 5. Tumors: a. Malignant lymphoma (Burkitt-like or immunoblastic) b. Kaposi's sarcoma (primary or secondary)
 6. Specific infections

Types 3-6 are usually associated with one or more diagnostic criteria for AIDS. While Types 1 and 2 may be associated with POAGC, and are not specific for HIV infection. Types 1 and 2 may be associated with normal lymph node CD4/CD8 populations or with CD4 depletion; CD4 depletion is often pronounced in type 3. Type 4 pattern is strongly correlated with lymphadenopathy Kaposi's sarcoma.
Conclusion: Lymph nodes in HIV infected patients may show a variety of patterns with important prognostic implications.

Th.C.0.9

IN SITU HYBRIDIZATION FOR DETECTION OF HIV GENOME

Peter Biberfeld, Carlo Perruccio*, Marianne Ekman*, Anne Magnusson*, Anna Forsvar*, Robert C. Gallo*, Immunovirology Lab, Karolinska Institute, Stockholm, Sweden, *Chair Pathology, Milano University, Milano, Italy, **ATCC, MD, NIH, Bethesda, Maryland, U.S.A.

The pathogenic mechanisms of HIV have been studied by *in situ* hybridization and immunohistochemistry in lymph nodes of various stages of HIV infection and in lymph nodes from AIDS patients. *In situ* hybridization was made of 30 labeled (P. Biberfeld, M. Perruccio et al., *AIDS* 1985;4:104-110) as well as unlabeled (Magnusson, HIV DNA: From Cells, LaFont and Engvallsson, *Journal of Cellular Biochemistry* 1985;24:1-10) probes (p24, p27, p28, p29, p30, p31, p32, p33, p34, p35, p36, p37, p38, p39, p40, p41, p42, p43, p44, p45, p46, p47, p48, p49, p50, p51, p52, p53, p54, p55, p56, p57, p58, p59, p60, p61, p62, p63, p64, p65, p66, p67, p68, p69, p70, p71, p72, p73, p74, p75, p76, p77, p78, p79, p80, p81, p82, p83, p84, p85, p86, p87, p88, p89, p90, p91, p92, p93, p94, p95, p96, p97, p98, p99, p100) as well as anti-HIV antibodies. The results of the hybridization and immunohistochemistry were compared with the results of immunohistochemistry for screening of lymph material and cells and also combined simultaneous detection of viral antigens and RNA.

Th.C.0.8 DETECTION OF HIV IN LYMPH NODES

Bissegger, Hermann-Horst-Johanna for Tropical Medicine, Hamburg, West Germany.

In lymph nodes (LN) of HIV-infected persons the causative agent can be detected using electron microscope (EM), immunocytochemistry (IC) or *in situ* hybridization. Applying immunostaining on frozen sections gag proteins of HIV can be visualized in germinal centers (GC) of LN. This reaction is highly sensitive and specific, therefore, it can be used for diagnostic purposes. Concordant staining with gag proteins and antibody to follicular dendritic cells (FDC) shows the association of viral antigen to FDC. In correlation with these findings, EM shows that HIV-particles along the processes of FDC. Results of *in situ* hybridization have also shown the presence of cells expressing viral RNA inside the GC. HIV enters the GC early during the course of infection. We have demonstrated the infection of GC both with EM and IC 4 weeks after seroconversion. Once gained access to GC, HIV can persist here for long time periods. On repeated biopsy specimens we have detected HIV up to 2 year intervals. Not only GC of LN but also those in gut associated lymphoid tissue contain HIV-proteins associated with FDC. Thus, it is very important that FDC as antigen trapping and retaining cells are very important in the pathogenesis of HIV-infection. FDC probably capture HIV transported by lymphatics. Using EM, IC and *in situ* hybridization we have found evidence for spreading of HIV via lymphatics. We feel that this way of dissemination is especially important when HIV enters the body through a mucous membrane.

Th.C.0.10 BIOLOGICAL FUNCTIONS OF HUMAN MONOCLONAL ANTIBODIES TO HIV.

Sollitt-Hamer, G., Reardon, M., West, Victoria Elic and Hershfield, R.W. Veterans Admin. Hosp., New York, NY, *Wadsworth Univ., Hawthorne, NY, Univ. of Texas Southwestern Med. Ctr., Dallas, TX & *Duke Univ. Med. Ctr., Durham, NC.

OBJECTIVE: To characterize the biological functions of human monoclonal anti-lysozyme (mAb) to HIV.
RESULTS: Monoclonal cells from peripheral blood of HIV-infected subjects were infected with Epstein-Barr virus and cultured in microtitre plates for one month. Wells making anti-HIV were expanded and cloned at limiting dilution. mAb from each clone were tested for specificity by ELISA, radio-immunoprecipitation, and Western blot and assayed for function as described in abstracts 2022, 4331 and 4473.

RESULTS: Of 11 lymphoblastoid lines producing mAb to HIV, mAb from 5 lines react with gp41. Five react with p24. mAb to gp41 mediate antibody-dependent cell-mediated cytotoxicity requiring 1-5 µg mAb/ml. Of the 11 mAb, only one, specific for gp41, mediates complement- and antibody-dependent enhancement of HIV infection requiring 1 µg mAb/ml. Two mAb to gp41 were capable of the depolymerized chain of ricin. 50% killing of the HIV-infected T cell line, HT-1080, occurs at 500 µg/ml. 50% killing of the HIV-infected U937 myelocyte cell line is achieved at 1000 µg/ml in the absence of chloroquine and at 10 µg/ml in the presence of chloroquine. None of the mAb to gp41 are neutralizing or mediate opsonic inhibition. None of the mAb to p24 are active in any of the described functional assays.

CONCLUSIONS: Human mAb to gp41 mediate a variety of biological functions. No biological functions here, as yet, been ascribed to human mAb to p24.

Mise au point de médicaments : utilisation de l'AZT et d'autres oligonucleotides dans le traitement du SIDA Drug Development: Use of AZT and Other Oligonucleotides in AIDS Therapy

Th.C.0.17 Differential modulation of HIV replication and AZT activity in monocyte/macrophages by Gm-CSF, M-CSF, and G-CSF.
Johns, D., Broder, National Cancer Institute, Bethesda, MD, USA.

Objective: To study the ability of granulocyte-macrophage colony stimulating factor (Gm-CSF), macrophage-colony stimulating factor (M-CSF), and granulocyte colony stimulating factor (G-CSF) to modulate HIV replication and/or the antiviral activity of AZT in monocyte/macrophages (MΦ).
Methods: Elutriated MΦ were exposed to 100 U/ml Gm-CSF, 1,000 U/ml M-CSF, or 100 U/ml G-CSF for 5 days before challenge with HIV-1 (genenotypic strain NL4-3) or lymphotropic strain HTLV-IIIa) with/without AZT. Analogous phosphorylation of AZT was also studied in MΦ with/without Gm-CSF, M-CSF, or G-CSF. AZT enhances replication (up to 1,000x) of both HTLV-IIIa) and HTLV-IIIg in MΦ, and reduces >100x the minimum viral dose required to productively infect the MΦ. MΦ also enhance HIV replication (not less than Gm-CSF), while G-CSF had no effect. Despite increasing HIV infection, Gm-CSF activates the antiviral activity of AZT and related thymidine and uridine congeners in MΦ. 0.01 nM AZT reduces 250x viral titration in Gm-CSF-stimulated MΦ, while 1 nM AZT is required to achieve the same effect in MΦ without G-CSF. The effect of other dideoxynucleosides not related to AZT is not enhanced by Gm-CSF. Neither M-CSF nor G-CSF modulated AZT activity in MΦ. G-CSF increases the intracellular level of AZT and its triphosphorylated form in MΦ, but only induces a minimal increase of thymidine 5'-triphosphate (dTPP). Thus the ratio of AZT/dTPP is substantially increased in MΦ exposed to Gm-CSF, and this may explain its enhancement of AZT activity.
Conclusion: A combination of Gm-CSF plus AZT (or a related congener) may be worth exploring in patients with HIV-related disease.

Th.C.0.19 INHIBITION OF HIV EXPRESSION: ENHANCEMENT OF ACTIVITY OF PHOSPHOROTHIOLATE OLIGONUCLEOTIDES BY CHEMICAL MODIFICATION.
Natsuguro Makiyoshi, Hori K., Sato S., Cohen J.S.,**
*Mitsubishi Kagaku Iryo, **Medical Research, National Cancer Institute, National Institutes of Health, Bethesda MD and ***Applied BioSystems Inc., Foster City CA, U.S.A.*

Objective: Phosphorothiolate oligonucleotides in an antisense configuration against the HIV *env* mRNA showed significant inhibition against HIV-1 viral expression in chronically infected cells (Proc. Natl. Acad. Sci. 1989, in press). However, relatively high concentrations were required to inhibit viral expression. Therefore, it is reasonable to explore chemical modifications of the phosphorothiolate oligomer to enhance such anti-HIV activity.
Methods: We synthesized a series of compounds by linking intercalating moieties or by modifying the bases. Compounds were tested in the viral expression inhibition assay using chronically HIV-1 infected SP cells.
Results: Anthracylene-conjugated and acridine-conjugated antisense phosphorothiolate oligomers against *env* showed more potent inhibitory activities against the viral expression in chronically infected cells in comparison to unmodified phosphorothiolate antisense by approximately 10 fold and 5 fold, respectively. Another modification, the use of allyl-methoxy derivatives on thymidine bases, also showed an enhancement of the antiviral activity by approximately 2 fold. These modifications in these modified phosphorothiolate oligomers are at least comparable to that in the unmodified antisense phosphorothiolate oligomer.
Conclusion: Certain modifications of antisense phosphorothiolate oligomers could result in advantages to potential therapeutic intervention against AIDS and related diseases.

Th.C.0.21 CONFORMATIONAL PREFERENCE OF ANTI-HIV NUCLEOSIDES AND DRUG DESIGN

*P. Van Roye¹, L. Dierckx², E.W. Taylor¹, R.F. Schmitz¹
¹Medical Foundation York, ²UDBrno, ³University of Georgia
College of Pharmacy, Athens, Georgia 30602, ⁴Henry University School of Medicine/VA Medical Center, Athens, Georgia 30603, U.S.A.*

Objective: To study the molecular conformations of anti-HIV nucleosides for drug design.

Methods: Molecular conformations of active as well as inactive nucleosides against HIV have been determined by X-ray crystallography.

Results: Active anti-HIV nucleosides show several conformational features in the glycosyl link geometry and sugar ring puckering. The active nucleosides have the extreme end of the range of observed anti-conformations. Ten of the eleven observations of active compounds have exceptional C2'-endo sugar conformations. The inactive nucleosides on the other hand, have C3'-endo conformations. The correlation between the extreme glycosyl link conformation and sugar ring puckering is significant.

Conclusion: These differences in conformations between active and inactive nucleosides result in a significant difference in the position and orientation of the 5'-hydroxy group. Because the phosphorylation at 3'-position of the carboxamide moiety is the initial and essential activation step in the nucleoside compounds, these conformational differences may account for the activity difference. Furthermore, this information may allow us to design new anti-HIV agents.
(Supported by USPHS Grants AI 20055, AI 25899, DA 34789 and Veterans Administration)

Th.C.0.18 INHIBITION OF HIV REPLICATION BY NOVEL PHOSPHORYLATED DERIVATIVES OF AZT AND OTHER DIDEOXYNUCLEOSIDES INCORPORATED IN VIRION
*Rezaglar, Kazu Y.,** and Richman, Douglas D.,**
**Vical Inc., San Diego, California and *University of California, San Diego and the VA Medical Center, San Diego.*

Monocyte/macrophage represent an important reservoir of HIV infection. Specific therapies to target these cells might halt HIV infection more effectively. Consequently, we synthesized phosphorylated AZT (P-AZT) and AZT diphosphate diphosphate (AZTDP), new phosphorylated AZT with a phosphate group on their polar head groups. Liposomal P-AZT and AZTDP (Pro-AZT) were incubated with CD4 cells infected with HIV-1. The amount of drug required to reduce by 50% the release of p24 antigen into the culture medium after 24 hours was determined. The IC₅₀ values for P-AZT and AZTDP were 1.0-2.0 and 1.0-2.0 μM, respectively. No cell toxicity was observed at liposomal concentrations of 100 to 200 nM or greater. Liposome with no liposomal phospholipid was ineffective. P-AZT was also effective to protect CD4 cells lacking thymidine kinase (TK), demonstrating that the new AZT compound can be metabolized directly to AZT-monophosphate. AZT has no antiviral activity in these cells. Phospholipid derivatives of AZT, AZT and dCTP were also effective in a plaque inhibition assay in CD4+ cells and in p24 reduction assays. P-AZT and AZTDP were also effective in reducing HIV p24 production and plaque formation. These compounds are relatively non-toxic, bypass phosphatase inhibition by calciferol and appear to be promising candidate compounds for treatment of the monocyte/macrophage reservoir of HIV infection.

Th.C.0.20 3-HALOGENO-2'-FLUORO-3'-DEOXYNUCLEOSIDES ARE POTENT INHIBITORS OF HIV REPLICATION IN VITRO AND IN VIVO
*Jan Balzarik, A. Van Aerchele, C. Roelants, R. Pauwels, M. Bala, D. Schrijn, R. De Clercq,
Radboud Institute for Medical Research and Biotechnology, X.U.Leuven, B-3000 Leuven, Belgium*

The 3-halogeno (i.e., 3-Fluoro-, 3-chloro-, 3-bromo- and 3-Iodo) derivatives of 2'-fluoro-3'-deoxythymidine (FdTID), designated PdFtdP, PdClFtdP, PdBrFtdP and PdIFtdP, respectively, were synthesized and evaluated for their activity against human immunodeficiency virus (HIV) and simian AIDS related virus (SRV). PdFtdP did not show any appreciable antiviral activity at subtoxic concentrations. In contrast, all three other 3-halogeno PdFtdP derivatives inhibited HIV-1 and HIV-2 replication in H9-cells at an effective dose (ED₅₀) of about 0.2-0.7 μM. Also, HIV-1-induced antigen expression in H9-T8 cells was suppressed by the three 3-halogeno PdFtdP derivatives. PdClFtdP was markedly more selective in its anti-HIV activity in MT-4 cells than PdBrFtdP and PdIFtdP. Its selectivity index was similar to that of 3'-azido-2',3'-dideoxycytidine (AZT, ddC). PdClFtdP was also effective in inhibiting SRV-induced giant cell formation in Raji cell cultures (ED₅₀ 1 μM) but not in thymidine kinase (TK)-deficient H9 cells (ED₅₀ > 200 μM), pointing to a structural role of cellular TK in the metabolic activation of PdClFtdP. Unlike AZT, PdClFtdP did not cause a blockage of thymidylate kinase. PdClFtdP was also less toxic to mouse marrow cells than AZT. In conclusion, the 3-halogeno PdFtdP derivatives, and in particular PdClFtdP, should be further pursued for their potential in the treatment of AIDS.

Th.C.0.22 SYNTHESIS AND *IN VITRO* FUNCTION OF RIBOSYMS TARGETED TO HIV-1 SPECIFIC RNA
*Rossi, J., Chang, P., Stephens, D.,** Lunde, P.,**
Cantle, C.,** and John, S.,**
**City of Hope Medical Center, Duarte, Calif., U.S.A.*

Objective: To design and test catalytic RNA specific for HIV-1. **Methods:** We have utilized two classes of catalytic ribozymes targeted to HIV-1 RNA: one class (RRZ) is targeted to the 5' RNA gene containing part of the required autocleavage site (GAAC...GGG). The remainder of the required sequence (CGAGG...), supplied *in trans* along with flanking sequences, is provided specifically by the second class of ribozyme (GUR-RZ). It is patterned from Haseloff and Gerlach (Nature 25: 119, 1985) and contains the required sequence for autocleavage (except the target site GUR) along with appropriate flanking sequences to promote hybridization to a specific GUA site in the HIV-1 RNA. RRZ and GUR-RZ were synthesized by *in vitro* transcription, purified by PAGE, incubated under varying conditions with the target HIV-1 RNA transcripts, and analyzed by PAGE and autoradiography.

Results: GUR-RZ targeted to cag cleaved the HIV-1 RNA more efficiently than RRZ. The GUR-RZ cleavage reaction is entirely magnesium dependent (10 mM) 20mM KCl. The cleavage is pH dependent (optimal range from 7.2 to 8.0) and completely cleaves large molar excesses of substrate. GUR-RZ can be designed which can potentially target any GUA site in the HIV-1 genome and deserve evaluation as potential antiviral agents.

Th.C.0.29 EPITOPES RECOGNIZED BY THE NEUTRALIZING ANTIBODIES OF AN HIV-1 INFECTED INDIVIDUAL

Ernst, Albert L.; Sellins, P. T.; Eckler, L. J.; Nara, P. M.; Matthews, L. M., et al. **at al.** **Regen** Corporation, Cambridge, MA, USA. **National Cancer Institute, Frederick, MD, USA.** **Duke University Medical School, Durham, NC, USA.**

Objective: To determine the extent to which broadly neutralizing antibodies raised by an HIV-1-infected individual recognize the principal neutralizing epitope of the envelope protein gp120 amino acids 296-331.

Methods: Broadly neutralizing serum from an antibody-positive, HIV-infected donor was subjected to affinity chromatography on immobilized peptides corresponding to the neutralizing epitope of three viral isolates. Effluent and eluate fractions were assayed for inhibition of HIV-1 infection of cell fusion and neutralization of each of the three isolates.

Results: Most of the antibodies that neutralize one isolate were absorbed by peptides corresponding to its 296-331 envelope sequence. By contrast, most of the antibodies that neutralize the other two isolates were not absorbed by the immobilized peptides.

Conclusions: Infected humans seem to raise a type-specific neutralizing response against the principal neutralizing epitope of one isolate. Broad neutralization appears to result from the recognition of other epitopes as yet unidentified.

Th.C.0.30 NEUTRALIZATION OF IN VIVO HIV-1 INFECTIVITY MEDIATED BY IN VITRO NEUTRALIZING ANTIBODY

Thairu, Shigehiko A.; Eickbush, J. M.; Nara, P. L.; Lewis, J. M.; Matsushita, T.; Kelley, J. D., et al. **Regen** Corp., **W.A.R.C. Japan and Dohme Research Laboratories, Inc.,** **NIH** Natl. P.H. **Southwest Foundation for Biomedical Research, San Antonio, TX.** **NIH-CDC-Frederick Cancer Research Facility, Frederick, MD.** **University Medical School, Japan.** **Regen Corporation, Cambridge, MA, U.S.A.**

Objective: To determine if an association exists between the ability of antibody to neutralize HIV infectivity *in vitro* and its ability to prevent HIV infection *in vivo*.

Methods: HIV-1RT⁺ challenge challenge inocula of HIV-1 (isolate HTLV-IIIB) were individually incubated *in vitro* with (1) virus-neutralizing IgG from an HIV-seropositive challengee, (2) a specific neutralizing monoclonal antibody (0.56), (3) non-neutralizing IgG from an HIV-seropositive human, (4) IgG from an uninfected control. Both neutralizing IgG preparations were directed against the gp120 major neutralizing determinant.

Results and Conclusions: The polyclonal neutralizing IgG inhibited *in vivo* HIV infection by the criterion of specific anti-HIV antibody development in the challengee animal. Similarly, the monoclonal neutralizing antibody decreased the infectiousness of the challenge virus. No effect was noted when the non-neutralizing anti-HIV IgG or the control IgG. Correlation appears to exist between the ability of antibody to neutralize HIV infectivity *in vitro* and its ability to inhibit HIV infection *in vivo*.

Th.C.0.31 STUDIES OF HYPERVARIABLE REGION DELETION MUTANTS OF HIV-1

Steiner, K. S. et al. Chino, E.; Moore, G. C.; Mann, K. A.; Proyas, P. T.; Skiles, P. V. **University of California, Los Angeles, California, U.S.A.**

Objective: To determine the role of hypervariable regions in the structure, function, and immunogenicity of HIV-1 gp120.

Methods: Sequences encoding the five major hypervariable domains of the gp120 region of the envelope gene were deleted using standard mutagenesis. These domains encompassed amino acids 131-154 (V1), 161-198 (V2), 300-332 (V3), 388-414 (V4), and 457-463 (V5). The resulting variants were produced in recombinant cells as nonglycosylated soluble CD4 or secreted, glycosylated proteins in mammalian cells. CD4 binding of each gp120 variant was measured by radioimmune precipitation of gp120 variants and recombinant, antibody CD4. Purified virus-derived variants were used by hyperimmune mice animals. ELISA titers versus the immunizing antigen and virus neutralization titers against HIV-92 and HIV-83U were determined using standard techniques.

Results: Deleted, nonglycosylated virus-derived wild type gp120 did not bind to CD4 while purified or supported mammalian cell-derived glycosylated gp120 bound CD4 as well as gp120 from virus-infected cells. Mammalian cell-derived gp120 variants of any or all of the three hypervariable regions in the C-terminal half of gp120 (V3, V4, V5) resulted in CD4 binding that was at least 10-fold reduced relative to wild type gp120. In contrast, deletion of the variable regions in the N-terminal half of the protein (V1, V2) did not perturb CD4 binding. In immunogenicity studies, deleted, nonglycosylated gp120 polypeptides deleted in one to three hypervariable regions, including deletion of V3, elicited type-specific neutralization in guinea pigs and mice. However, the nonglycosylated protein with deletion of all five hypervariable regions failed to generate neutralizing activity, although it elicited high titer antibody responses.

Conclusions: Hypervariable regions play a major role in the immunogenicity of nonglycosylated versions of gp120 and may influence the structure of glycosylated gp120 and its binding to CD4.

Th.C.0.32 ANTIBODY DEPENDENT CELLULAR CYTOTOXICITY (ADCC) FOLLOWING VACCINATION WITH A RECOMBINANT HIV-1 GP120 VACCINE

Corse, Geoffrey; Newman, P. J.; Balash, R. B.; and MIAID. **Merrell University, Fremont, W.A.** **Method, WA, USA.**

Background: Sera from asymptomatic HIV-1 infected patients are more likely to mediate ADCC than sera from AIDS patients. Thus, stimulation of serum ADCC activity may be a desirable goal in the development of an AIDS vaccine. **Objective:** To measure ADCC activity in sera obtained from persons in an HIV-10 (Microsome) vaccine trial.

Methods: We tested sera from four adult vaccinees who developed antibody to gp120 on Western Blot after three doses of 40ug or 80ug of gp120, and one placebo recipient whose Western Blot remained negative for anti-HIV-1 antibody. Target cells were HIV-1 infected and uninfected T20 cells (a variant of the CD4 T-cell line) which were labeled with ⁵¹Cr and incubated with vaccinee sera and control Western Blot positive sera from HIV-1 infected patients at dilutions of 1:5 to 1:40. PMA from normal healthy adults served as an effector cells at an E/T ratio of 50:1. Percent ADCC was measured as antibody dependent minus antibody independent lysis. **Results:** Sera from one vaccinee demonstrated a transient increase in percent ADCC. The vaccinee received 80ug doses of gp120. None of 3 other vaccinees nor the placebo vaccinee manifested significant percent ADCC during the study.

Conclusion: We conclude that gp120 at the two dose levels tested did not induce significant persisting antibody which mediated ADCC.

Th.C.0.33 SAFETY AND IMMUNOGENICITY OF HIV-1 RECOMBINANT GP 120 VACCINE CANDIDATE IN NORMAL VOLUNTEERS.

Belish, R. A.; Chinn, S. S.; Stahler, D. A.; Smith, C. M.; and Krets W. **University of Rochester, Rochester, NY.** **NIH AIDS Vaccine Program, and *Microbiology, West Haven, CT, U.S.A.**

Objective: To assess the safety and immunogenicity of two dosages of an HIV envelope glycoprotein (gp120) vaccine in normal volunteers.

Methods: Recombinant HIV-1 glycoprotein (gp120), prepared using a baculovirus vector (MicroGeneSys) was studied in 72 normal volunteers in a multicenter study, employing a double-blind, controlled experimental design. 18 subjects received 40 ug of gp120, 18 received 80 ug of gp120, 18 received hepatitis B vaccine, and 18 received placebo. 3 intramuscular injections were employed (Days 0, 30, 180). Subjects were followed for clinical and laboratory toxicities for up to 1 year. Serum antibody responses were determined by Western blot (WB), ELISA, and neutralization (NI) assays. **Results:** 39 females and 33 males participated, and 67 subjects received all three immunizations. gp120 was well tolerated, and there were no differences in acute or chronic toxicity between the groups. There were also no differences in WB, T4, T8, blast counts or Hb levels among the groups. Serum antibodies to gp120 detected by WB were first noted at day 18 in 8/17 subjects at the 40ug dose, and in 8/17 at 80ug. At day 180, 10/17 at the 40 ug dose and 15/17 at the 80ug dose were seroreactive by WB. Antibody response to gp120 was less than 1:1000. Antibodies appeared generally later and less frequently than WB antibodies. Studies of NI antibodies are currently underway.

Conclusions: This gp120 vaccine candidate is well tolerated and non-toxic in normal volunteers, and induced high rates of serum antibody responses as detected by WB.

Th.C.0.34 T CELL RESPONSES TO HIV IN HUMANS IMMUNIZED WITH RECOMBINANT VACCINES

Conry, Elizabeth M.; Ziering, J. M.; Hu, S. L.; Wasson, A. M.; Conry, L. G.; and Greenberg, M. L. **NIH** and Washington University, St. Louis, MO, USA.

Objective: To study T cell responses to HIV antigens and vaccines (VAc) using a Phase I vaccine trial with a recombinant VAc containing the HIV gp160 gene (HIVAc-1c).

Methods: 30 subjects were vaccinated and then boosted with either wild-type VAc or HIVAc-1c. T cell in vitro proliferative responses to a panel of antigens were determined pre- and 4-week intervals post-vaccination. **Results:** In vitro stimuli were several HIV antigens preparations including UV-irradiated inactivated HIV, live HIV, and gp160, immunogens including VAc, HIV, CMV, and a non-HIV antigen including Pfla, Cln A and Pfla.

Results: T cell responses and serum neutralizing antibody to VAc were detectable pre-vaccination in all 26/30 subjects previously immunized to VAc, including 13/15 recipients of HIVAc-1c. Association with HIVAc-1c significantly boosted the T cell response to VAc in 7/13 and this correlated with a 4-fold rise in the serum antibody titer. The 2 HIVAc-1c recipients with no detectable T cell responses to VAc following priming, *in vitro* proliferative responses to VAc at week 8 stimulus augmented the proliferative T cell responses of the 30 subjects to VAc. Of the 13/15 HIVAc-1c recipients with pre-existing immunity to VAc, 5 developed low and/or transient responses to one of the HIV antigen preparations. By contrast, the 2 HIVAc-1c recipients with no detectable T cell responses pre-vaccination to HIV antigens post-vaccination. No significant HIV antigen responses were detected in the 2 HIVAc-1c recipients who were not affected by vaccination with either VAc or HIVAc-1c. **Conclusions:** Vaccination of individuals lacking cellular immunity to VAc, with a recombinant VAc expressing gp160 elicits strong T cell proliferative responses to HIV, and stimulates in progress to define the CTL response in these individuals. Individuals previously vaccinated demonstrate persistent immunity to VAc and are variably primed to HIV antigens by vaccination, and studies to further characterize and augment these responses are being performed.

ENTRY OF HIV INTO CELLS
Montagnier, L., Sureau, P., J., Grolloff, G.,
 Clapham, P.R., Gajjar, S., J., Grolloff, G.,
 Kennedy, N.S., Grolloff, G., J., Grolloff, G., J., Grolloff, G.,
 National Center for Disease Control, Atlanta, GA, USA, *Columbia University, New York, NY, USA, **Charat, Beatty Laboratories, London, UK.

Objective. To determine whether the CD4 molecule, which serves as an attachment protein (receptor) for HIV, also functions in the HIV internalization event.
Methods. Conditions for saturating cells with HIV and for synchronizing the penetration event were developed as were assays to detect CD4 internalization and HIV penetration. Mutations were introduced into the cytoplasmic segment of CD4 rendering cells that express these mutant CD4 molecules incapable of phosphokinase C-induced CD4 internalization.
Results. Tracking CD4 during HIV penetration failed to detect CD4 internalization. Induction of CD4 internalization did not enhance HIV infectivity nor did inhibition of CD4 internalization prevent HIV infection. Cells expressing CD4 mutant molecules that are incapable of internalization were, nevertheless, infectible by HIV.
Conclusion. HIV penetration does not require internalization of its receptor, CD4.

Th.C.0.43

SURFACE RECOGNITION STRUCTURE FOR HIV
A.G. Deligdis

MRC Clinical Research Centre, Harrow, HA1 3UH, U.K.

The surface recognition structure for HIV is the CD4 molecules which binds to the gp120 component of the HIV envelope with a high affinity (10^{10}). This property is conserved amongst all isolates of HIV-1, HIV and HIV-2, although the affinity may be lower in the latter. This remarkable attraction of the envelope for such an important immunological ligand as CD4 may well explain the development of an acquired immunodeficiency without involving direct cytotoxic effect by the complete virus. Masking of the CD4 epitopes by envelope may prevent antigen presentation and other CD4 dependent immunological functions, as well as leading to clonal deletion of activated CD4 cells by cytotoxic cells. These hypotheses may be investigated using soluble CD4 and soluble gp120. The detrimental effect of soluble gp120 in immunological responses assays, and the beneficial effect of soluble CD4 *in vitro* and *in vivo* virological systems suggests that soluble CD4 may have beneficial therapeutic effects even at doses much less than those required to have an antiviral effect *per se*, simply by inactivating soluble gp120 and free virus. Vaccine strategies based on gp120/CD4 have been examined using anti-CD4 monoclonal antibodies which may induce an internal image resembling the gp120 binding site on CD4 and therefore bind and neutralise a broad range of HIV isolates. These studies have now been extended to further characterize the anti-idiotypic response, the role of adjuvants and the response of the human immune system to anti-CD4 monoclonal antibodies.

Th.C.0.42

ROLE OF MACROPHAGES IN PATHOGENESIS OF HIV
Sarkar, Suman, and Popovici, M.
 *New Mexico State University Health Research Institute,
 Las Alamos, New Mexico, USA, *National Cancer Institute,
 National Institutes of Health, Bethesda, Maryland, USA.

Both *in vivo* and *in vitro* studies clearly indicate that cells of the monoclonal phagocyte lineage play a key role in the pathogenesis of AIDS. To facilitate a more detailed analysis of HIV-1 interactions with cell types of this lineage, a cell culture system using normal monocytes/macrophages (MΦ) from peripheral blood has been developed. We have previously shown that MΦ are highly susceptible and permissive hosts for "fresh" HIV-1 isolates recovered from various tissues of virus-positive individuals. Utilizing this MΦ cell culture system, we will present data demonstrating that (a) cells of the monoclonal phagocyte lineage are principal sites of HIV-1 replication early in the course of the virus infection, (b) "freshly" recovered (not propagated in permanent cell lines) HIV-1 isolates are dual (MΦ and T cell) tropic, (c) in HIV-1 infected MΦ exhibit functional alterations similar to those observed in AIDS patients and (d) the most efficient HIV-1 transmission from MΦ to T cells occurs during specific antigen presentation.

Th.C.0.44

CYTOKINE INDUCTION OF HIV EXPRESSION
Fazel, Anthony, A. National Institutes of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland, USA.

We have previously established an *in vitro* model system for the study of the induction of expression of HIV in latently or chronically infected promonocytic (U-1) and T lymphocyte (ACH-2) cell clones. We have used these systems to demonstrate the induction of HIV expression in these cell lines by certain cytokines. Specifically, tumor necrosis factor (TNF)-alpha was capable of inducing HIV expression in both U-1 and ACH-2 cells. Other cytokines such as interleukin (IL)-6 and granulocyte-macrophage colony stimulating factor (GM-CSF) were able to induce HIV expression in U-1 but not in ACH-2 cells. In addition, there was significant synergy between TNF-alpha and IL-6, and TNF-alpha and GM-CSF in the induction of HIV expression in the U-1 cell line. The pathways of induction consisted of a transactivating mechanism whereby a DNA-binding protein was shown to selectively bind to the NFkB site of the HIV LTR. Most recent experiments have demonstrated an autocrine/paracrine loop involving the induction of HIV expression by TNF-alpha which in synergy with TNF can regulate its own expression. Furthermore, we have demonstrated that cytokine induction of HIV expression involves the direct or indirect activation of phosphokinase C (PKC) and that inhibitors of PKC can inhibit HIV expression. These model systems will be used to further delineate the precise mechanisms of HIV expression and, perhaps, the control of expression of HIV in infected cells.

Th.C.0.45 Immunization of Rhesus Monkeys with Inactivated HIV Fails to Protect Against Mucosal or IV Challenge
Rappaport, J., Pedersen, E., Gardner, J., Hanson, C.V., Miller, C., Gottlie, A., Jennings, M., Ripstein, J. and Marx, P.A. University of California, Davis, Davis, CA, U.S.A.

Objective: To determine if immunization of rhesus monkeys with an inactivated whole virus live (SIV) vaccine protects against mucosal or IV challenge with live HIV.
Methods: Eight juvenile rhesus received 4 immunizations (2 by total viral protein) of penicillin IV light inactivated SIV_{mac} with HCP adjuvant. Eight controls received solvent only, the humoral immune response before and after challenge was monitored by western blot and neutralization assays. The animals were challenged IV and by genital mucosa with 10-1000 the animal animal infectious dose (ID₅₀) of live SIV. Viremia was assayed by co-cultivation of PBMC with CD4 + T4 cells and the number of infected cells was roughly quantitated by limiting dilution assay.
Results: The vaccinated animals made an adequate immune response as judged by immunoblot and neutralization assays and by comparison to our previous results with heterologous vaccines. However, at 2 and 6 weeks after challenge with live SIV, by either IV or genital mucosal routes, virus was readily isolated from the PBMC of all 8 vaccinated rhesus and all controls. The results were not significantly different in the two groups.
Conclusions: Immunization of rhesus monkeys with an inactivated SIV_{mac}-HCP vaccine failed to protect against viremia following challenge with live SIV_{mac} by the IV and genital mucosal routes.

Th.C.0.46 HIV IMMUNIZATION AND CHALLENGE OF HIV SEROPOSITIVE AND SERONEGATIVE CHIMPANZES.
E.L. Gilber¹, C. Mon, J. R. Peters², H. C. Jansen, J. D. Miller, J. S. G. J. Nijh, Bethesda, MD², The Immune Response Corporation, San Diego, CA; ¹The Salk Institute, San Diego, CA, U.S.A.

Objective: To determine the characteristics of the serologic response of HIV seropositive and seronegative chimpanzees to HIV immunization and to viral challenge.
Methods: Three adult chimpanzees (two seropositive and one seronegative) were inoculated 1M (primary and 2 booster doses) with a genome irradiated non-infectious HIV immunogen reformulated in incomplete Freund's adjuvant (IFA). Approximately 13-15 months after the initial immunization, these chimpanzees and an untreated control animal were challenged IV with 10 chimpanzee infectious doses of HIV. Western blots, ELISAs and tests for neutralizing antibody and for virus by co-cultivation of PBMC were performed.

Results: The two previously HIV infected seropositive chimpanzees, A-86C and A-3, exhibited an anamnestic response to the first dose of immunogen; the initially seronegative chimpanzee, A-36, manifested a primary and secondary response after the first and second doses, respectively. After challenge, A-86C and A-3 exhibited no evidence of infection, while A-36 became infected. In contrast, A-36 became virus positive and exhibited only a reformed anamnestic response to the viral infection (anti-p24 that fell negative 1.8000).

Conclusions: 1) The resistance to reinfection observed in A-86C and A-3 suggests that primary-type antibody response to the viral infection (anti-p24 that fell negative 1.8000) may be an amenable goal. 2) The anamnestic response following challenge observed in A-36, in contrast to the primary-type response to infection observed in A-189, raises the possibility that induction of immunity to disease through vaccine-induced immunologic memory may be achieved even if infection is not prevented.

Th.C.0.47 IMMUNOGENICITY OF POTENTIAL HIV VACCINES IN CHIMPANZES
Girard, Marc ; Kley, M.P., and Lecco, J.P. ; Taglioli, M., and Guzman, C. ; Bressan, F., and Montelari, C. ; L. ; Muzarelli, E. ; and Fultz, P. - Pasteur Institute, Marne-la-Coquette, France, Strasbourg, CNRS, Institut Pasteur, Paris, Institut Pasteur, Paris France ; ICMIP, Toulouse and Overseas Primate Center, Atlanta, GA, USA.

Objective: To test the safety, immunogenicity and efficacy of potential HIV vaccines in chimpanzees.
Methods: Chimpanzees were immunized with multiple injections of vaccinia virus recombinants expressing gp160 and p24, followed by inactivated HIV formulated with Syntex adjuvant (SAR). Humoral and cellular HIV specific immunity was assessed.
Results: One animal, that had antibody (Ab) titers in the range of 1:200,000 (western blot and ELISA) and sustained T cell proliferative responses to purified HIV gp160, was challenged with 3E TCID₅₀ of the LVI-103 isolate (injected IV). Infectious virus was recovered from the animal's PBAs starting at 2 weeks after challenge, thus demonstrating lack of protection. A ten-fold anamnestic response was observed in ELISA titer, followed by progressive appearance of Ab to gp120, gp120, and HIV. Neutralizing Ab titers, however, remained low or below detection, even during 7 subsequent months. Two unchallenged animals that had undergone a parallel immunization course were repeatedly boosted with gp160 IN SAR, with no significant increases in ELISA or neutralizing Ab titers.
Conclusion: A vaccination regimen involving a live recombinant vaccine, inactivated HIV and gp160 emul induced good cell-mediated and humoral immunity, but only poor neutralizing activity, indicating that better presentations of virus neutralization epitopes must be devised to elicit protective immunity.

Th.C.0.49 VACCINATION WITH LIVE RETROVIRUS: THE NATURE OF THE PROTECTIVE IMMUNE RESPONSE
Rappaport, Ruth M., Horn, J., Garza-Sosa, M., and Finberg, R. *Dana-Farber Cancer Institute, and Harvard Medical School, Boston, Massachusetts, USA.

Objective: To determine the nature of the protective immune response in animals vaccinated with a live pathogenic virus.
Methods: Adult female BALB/c mice were inoculated with the Reuscher Murine Leukemia virus (RLV) at time 0. Four hours after virus exposure, the animals were given post-exposure prophylactic therapy with 3'-azido-2'-deoxythymidine (AZT or Zalcitabine) in combination with recombinant human interferon- α (to 20 x ED₅₀). At time 1, the animals were given a second recombinant human interferon- α (to 20 x ED₅₀) and the live RLV in the absence of antiviral therapy. Three weeks later, > 80% of these animals were found to be free of viremia and disease. On day 26, they were challenged with the RLV in the presence of antiviral therapy. One hour after challenge, the recipients were sacrificed or after removing B cells or monocytes by passage through nylon wool columns, or after removal of vaccine - cell subsets. One hour after adoptive cell transfer, the recipients were challenged with the live virus and left untreated for 3 weeks at which time they were sacrificed. Their spleens were weighed and analyzed for the presence of virus by immunoblot analysis.
Results: A dose of 4×10^6 unfractinated interferon α cells was sufficient to protect naive recipient mice from virus infection and disease. Removal of cytotoxic immune T cells led to a drastic reduction in the number of recipient animals resistant to viral challenge. Passive transfer was not protective.
Conclusions: Immunologically attenuated by combination therapy with AZT and recombinant human interferon- α , can elicit a protective immune response which is most likely due to the action of immune cytotoxic T cells.

Th.C.0.48 Simian Immunity to HIV-1 Candidate Vaccines
Wainman, Robert N., D'Amico, Bernard, Bureau of Laboratories
Zentral, American Health Services, Federal Center for AIDS, Detroit MI
C. Smith and M. Cochran, MicroGenetics, Inc., West Haven, CT

The first HIV vaccine approved for clinical trial status by the U.S. FDA was that produced in a baculovirus-insect cell expression system by MicroGenetics. We have studied the antibody response of 12 rhesus monkeys initially inoculated with various doses of the gp160 recombinant envelope protein. Immunoblot and neutralization assays on these monkey sera have shown a persistent, albeit, attenuated response one year after the final gp160 boost of 500 μ g dose. A final boost of gp160 to two monkeys showed a characteristic anamnestic response as measured by immunoblot and neutralization assays. Ten animals had received boosters with a 1 dose regimen of a new p24 (gp2) recombinant protein. This induced the anticipated immunoblot reactivity and also complemented the *in vitro* neutralizing capability due to gp160. The monitoring of the long term persistence of antibody (including neutralizing) is ongoing.

Th.C.0.50 DEVELOPMENT OF AN HIV SUBUNIT VACCINE
Wainman, Robert N., D'Amico, Bernard, Prof. A. A. Ruschke, J. J. Matthews, T. M. Y. and Wolinsky, D. M. *Appligen Corporation, Cambridge, MA, USA, *Duke University Medical School, Durham, NC

Objective: To develop an effective HIV subunit vaccine able to protect against infection by diverse HIV isolates.
Methods: Recombinant HIV vaccine candidates including the entire envelope, gp160, have been prepared from several different HIV-1 isolates in E. coli and in insect cells and synthetic peptides of the envelope have been made. Animals including chimpanzees were immunized and the neutralizing antibody response was measured.
Results: The principal neutralizing epitope within gp160 was mapped to a hypervariable region of gp120 residues 308-311. Antibodies to this region neutralize Free HIV and prevent CD4 cell fusion. Antibodies to this epitope delay HIV infection of chimpanzees (E. A. Binal, et al.). Antibodies to this epitope do not prevent binding of gp120 to CD4 and therefore neutralize HIV via a post-binding step. We are PCR sequencing this region from several isolates to uncover common elements. Chimpanzees immunized with gp160 formulated in ISCOM particles including neutralizing virus-like particles comparable to those elicited by infectious HIV.
Conclusion: An immunogen, composed of either a cocktail or a hybrid polypeptide, incorporating this epitope from several HIV-1 strains may elicit protective immunity to many isolates. The ISCOM may be a useful adjuvant to present these immunogens.

M.C.P.1 DIFFERENTIAL VIRAL GENE EXPRESSION AND THEIR EFFECT ON THE BIOLOGICAL PROPERTIES OF CLONES OF AN HIV-1 INFECTED CELL LINE
 Kalyanaraman, V.G., Rodriguez, V., Joseph, S., Gallo, R.C., Sargadharan, M.G., *Biometrics Research, Inc., Rockville, MD, *National Cancer Institute, NIH, Bethesda, MD, USA.
Objective: Analyze the biochemical and biological properties of HIV-1_{IIIB} (805/451) which secretes both gp120 and gp160 in the extracellular medium.
Methods: Obtain single cell clones of 805/451 cells and examine their morphology by electron microscopy and ability to form syncytia with CD4 positive cells. Using metabolically labeled cells the expression of viral proteins was also analyzed.
Results: Three interesting clones secreting functional gp120 and gp160 in the medium were obtained. The first clone expressed viral reverse transcriptase (RT) and had both mature and immature virus particles. The second clone had only immature virus, expressed no RT or p24 and had only PrP₂₅ in the cells. Both the clones formed syncytium when mixed with CD4 positive cells. The third clone expressed only gp120 and gp160 but did not form syncytium with CD4+ cells. All three clones had intact viral lengths when examined by restriction enzyme analysis.
Conclusion: Even minor changes in the genome of HIV-1 can lead to a preferential expression of the viral gene products which influence the biological properties of the infected cells.

M.C.P.3 CLINICAL EVALUATION OF EXPERIMENTAL AIDS VACCINES
 Koff, Wayne C., Westot, S.L., Novak, J., Stables, D., Ferlinz, R., and Gerin, J. for the AIDS Vaccine Evaluation Group, Bethesda, Maryland, U.S.A.
 The process of conducting clinical trials of AIDS vaccines poses significant scientific and logistical challenges including strategies for recruitment of volunteers, experimentally induced seroconversion, and other difficult ethical dilemmas. In order to accelerate the development of a safe and effective AIDS vaccine, the Vaccine Research and Development Branch of the AIDS Program, NIAID has established a multi-center cooperative clinical trials network. The AIDS Vaccine Clinical Trials Network consists of an AIDS Vaccine Selection Committee, and the AIDS AIDS Vaccine Evaluation Group (composed of AIDS Vaccine Evaluation Units, Data Coordinating and Analysis Center, Data and Safety Monitoring Board, Core Immunology Laboratory, and Central Repository). The capacity to clinically evaluate multiple AIDS vaccine approaches simultaneously has been instituted, and two candidate AIDS vaccines are currently being tested utilizing comprehensive core protocols. Ancillary research studies are also being done to ensure that maximum safety and immunogenicity data on each candidate vaccine is obtained. Guidelines and outcome criteria for candidate vaccines entering into Phase 1 and 2 clinical trials will be discussed, along with a detailed review of approaches developed to address the issues unique to the clinical evaluation of AIDS vaccines.

M.C.P.5 PRODUCTION AND CHARACTERIZATION OF A HUMAN-MOUSE CHIMERIC MONOCLONAL ANTIBODY (C81) AGAINST HIV
 Hasegawa, Naoko, Hasegawa, Y., Takayoshi, S., Hattori, T., and TAKAHASHI, K. et al. *The Second Division of Internal Medicine, Kumamoto University Medical School, Kumamoto, Japan. **Osaka-Sera-Institute, Osaka, Kumamoto, Japan.
Objective: To determine the anti-HIV functions of a human-mouse chimeric monoclonal antibody (C81) *in vitro*.
Methods: Murine hybridoma 3T5 cells which produced a type specific anti-HIV chimeric monoclonal antibody (0.58) were used to produce human-mouse chimeric antibody. Both V_H and V_L genes were cloned from 54'CB1 cells and linked to human I_H and I_L genes respectively. These chimeric genes were transfected with Fc- β 28 cells. After appropriate selection chimeric antibody producing clone (C81) was obtained. Chimeric C81 antibody was purified from culture supernatant by Sepharose Protein A-Sepharose.
Results: The binding and neutralizing activities of C81 antibodies were similar to those detected with 0.58. No antibody dependent enhancement of HIV-infection was detected with 0.58 and C81 when U87 cells were used as target cells in an HIV infectivity assay. Complement dependent cytotoxicity of HIV-infected cells and antibody dependent cellular cytotoxicity against HIV-infected cells were observed in the presence of chimeric C81. By contrast, murine 0.58 did not possess these activities.
Conclusion: These results may facilitate the use of human-mouse chimeric monoclonal antibodies against HIV-infections.

M.C.P.2 RECOMBINANT VACCINE AGAINST FELINE LEUKAEMIA VIRUS USING A RECOMBINANT ANTIGEN
 Chakrabarti, B., Srinivas, G., A. Bhatia, C.H. Ganguly, A. Akhtar, and D.J. Pantalone, *Central Biotechnology Corporation, Morarjee, MA, USA, **Virac Laboratories, 06316 Carver, France.
Objective: To produce a feline leukaemia virus (FLeV) recombinant subunit vaccine.
Methods: The genetic information coding for the polypeptide portion of subgroup A FLeV glycoprotein gp70 was cloned into a P₆-based expression vector. This polypeptide (200-250) was expressed in *E. coli* and purified. Kittens were immunized three times with 100 μ g 200-250, 20 μ g purified adjuvant adjuvant, and aluminum hydroxide and challenged with 1 X infectious FLeV particles.
Results: Vaccination induced neutralization titers ranging from 32-64 for subgroup A FLeV as well as cross-neutralization of subgroup B and C. anti-FOCA titers of 128, and antibody affinity maturation during the course of vaccination. A secondary response was observed in vaccinated upon challenge. Control animals developed chronic viraemia and protracted lymphocytopenia within a month of challenge whereas vaccinated animals were seroconvalescent or developed a low transient viraemia and were protected against disease.
Conclusion: Recombinant subunit vaccine based on subgroup A gp70 induces protection against FLeV.

M.C.P.4 HUMORAL AND CELLULAR IMMUNE RESPONSE TO RECOMBINANT HIV-FE/PATITIS B SURFACE ANTIGEN PARTICLES
 Michel, M.L., Margline, Margline, Vogt, G., Hemlin, Y., Riviere, Y., Dormont, D., and Toulon, P., *Unité de Reconnaissance et Expression Génétique INSERM U163, CNRS U4 271, Institut Pasteur, 28 rue du Docteur Roux - 75726 Paris Cedex 15, *Unité d'OncoVirologie Virale, Institut Pasteur, 28 rue du Docteur Roux - 75726 Paris Cedex 15, **Commissariat à l'Energie Atomique, Fontenay aux Roses, France.
Objective: To evaluate the immunogenicity of H5Ag particles carrying HIV envelope determinants.
Methods: Rhesus macaques were immunized with recombinant HIV-H5Ag particles purified from transfected mammalian cells.
Results: Serum from vaccinated animals was evaluated for antigenic potency and for the ability to neutralize HIV infectivity *in vitro*. Peripheral blood lymphocytes were tested for their ability to proliferate in response to stimulation with purified, non disrupted HIV.
Results: Using a H5Ag particle carrying a fragment of HIV gp120 envelope protein (AA338-472) comprising the CD4 binding site, we obtained neutralizing activity against HIV and a T cell response against both parts of the fusion protein O5Ag and HIV.
Conclusion: H5Ag particles seem to be a good carrier for the presentation of HIV epitopes and enable us to induce in vaccinated macaques neutralizing antibodies and an helper T cell response against a functional domain of gp120 envelope protein.

M.C.P.6 MAPPING THE NEUTRALIZING EPITOPES OF HIV-1 ENVELOPE PROTEIN
 Mammalian, Sakai, Ross, R., Profy, A., Langlois, T., Pitney, S. et al. *Wepigen Corporation, Cambridge, MA, USA, **Duke University Medical School, Durham, NC, USA.
Objective: We showed previously that the principal neutralizing domain of HIV-1 envelope protein of IIIB isolate represented by a 24 amino acid peptide called RP125 is located within a disulfide loop (amino acids 295-331). We have attempted to locate the neutralizing epitope more precisely inside the loop.
Methods: A series of small peptides corresponding to different parts of the loop were synthesized. Sera were raised against these peptides and each was tested for fusion inhibition and neutralization activities.
Results: Only peptides related to the "tip" of the loop containing the sequence glycine-proline-glycine were capable of raising neutralizing antibodies. We show peptides of the size of 8-10 amino acids are sufficient in size to elicit neutralizing antibodies. We have also raised antibodies against a hybrid peptide of 15 amino acids which was shown to neutralize two viral isolates.
Conclusion: Sera raised against small peptides (8-10 amino acids) corresponding to the tip of the principal neutralizing domain of gp160 are capable of neutralizing the virus.

M.C.P.7 IN VIVO IMMUNIZATION AGAINST HIV PROTEINS USING GAU SYNTHETIC PEPTIDES: PRELIMINARY RESULTS

Yukita, Mitsuo **, Chervin, J.M. **, Bann-Stinson, F.C. **, Kourilsky, P. ** and
Dormann, D. **

** CERSA-CEA (DPSPSE), Fontenay-aux-Roses, France. ** Institut Pasteur, Paris, France.

Objective: As T immunocytes have been shown to be constant of sera self motifs, we tried to boost the immune response to HIV 1 proteins with live of them, located in conserved regions of HIV GAU glycoprotein.

Methods: Five GAU synthetic peptides, selected for their absence in Self-protein sequences data bank, and which are conserved among 13 HIV isolates, have been inoculated into three animal species (Mouse, Rabbit, Baboon). The animals received two successive injections of granulocyte polymorphonuclear product the first was performed in complete Freund adjuvant emulsion, and the second in a calcium phosphate precipitate. They were then challenged with live inactivated HIV 1 protein (ELA-1) in saline solution in 10% in vivo in Baboons and Rabbits. Clinical observations were performed (weight loss) before and compared to those of controls, which had only received HIV protein injections.

Results: Mice presented clinical signs, mice developed thrombocytopenic toxemia as back, as did of guinea-pig inoculation, which was different than the HIV protein injection toxics. Controls behaved with no abnormal clinical signs.

Conclusions: Four of the five peptides have been reported elsewhere to be recognized in vivo by HELA 4.2 restricted T cytotoxic cell line specific for HIV. Considering the pathology observed we then operated on the activation of T cell population in the presence. If the accurate observations established in this case may be as reproducible, mice could provide a model for T lymphocyte selection, on the assumption that they do stimulate T cell populations. These peptides could thus be used as immune response boosters in vaccine development aimed AIDS.

M.C.P.9

USE OF POLYMERASE CHAIN REACTION FOR DIRECT DETECTION OF HIV-1 IN CLINICAL SPECIMENS

Mark, Richard, O. Keller, D.R. Haack, M. Fisher and D. Fraser.

Biotech Research, Inc. 2000 15th St.

Objective: The Polymerase Chain Reaction assay was used for the direct detection of HIV-1 nucleic acid sequences in peripheral blood lymphocytes (PBL's) from high risk male homosexuals, blood donors, patients positive for HIV-1 by ELISA, babies born to HIV seropositive mothers, and from normal control individuals.

Methods: The DNA was extracted and HIV-1 specific sequences were amplified by PCR using specific primers for the gag and tat regions. Current amplifications were performed using cycling primers for ELISA. All samples were tested by ELISA and Western Blot assays. From samples were also tested by co-cultivation with PHA stimulated PHA-2 from normal controls.

Results: All culture positive samples tested (400 patient samples) were also PCR positive. However, 10 out of 31 high risk individuals who were antibody and culture negative were positive by PCR. Six of these 10 individuals subsequently seroconverted to HIV-1.

Almost all (240/243) antibody positive adult individuals tested were also PCR positive. Three samples, however, (4) of which belonged to the high risk male homosexual group were repeatedly negative or only positive positive by PCR for both gag and tat. All babies born to seropositive mothers were HIV-1 antibody positive, presumably due to the presence of maternal antibody. Approximately 60% (26/44) of these babies were PCR positive, while the rest were negative. All of normal donors were negative by PCR. **Conclusion:** PCR provides an extremely sensitive test for the direct examination of HIV-1 in PBLs. This assay is capable of detecting HIV infection in high risk individuals, even before they seroconvert, and of confirming Western Blot indeterminate samples. In addition, PCR may be a useful tool for monitoring babies born to seropositive mothers, where the presence of antibody does not necessarily imply infection. The PCR method is much faster, cheaper and far more sensitive than conventional for the direct detection of HIV in clinical samples.

M.C.P.11

CLINICAL AND VIROLOGIC RESPONSES TO A RECOMBINANT VACCINE HIV-1 GP160 VACCINE (BIVAC)

Collins, Alan **, Hill, S.L. **, Coombs, R. **, Ardito, G. **, Coey, L. **, University of Washington, Seattle, WA, USA.

Objective: To describe and compare the clinical and virologic responses of healthy HIV-negative sera after receipt of recombinant HIV-1 gp160 vaccine (BIVAC) and nonvaccine controls.

Methods: 29 men (age 24-46) with history of intravenous (IV) drug use (19) and 10 (36%) were vaccinated with BIVAC-1 or V (10) by 0.5 ml (total) in 4 weekly doses of 0.5 (week 1), 0.5 (week 2), 0.5 (week 3) and 0.5 (week 4) plus one booster (0.5) at 11 weeks later; 17 men gave good HIV-1 CA at 10⁷ (1) and at 1.1 x 10⁷ units later.

Results: HIV-1 CA in V sera was isolated from the 1 vaccination site in 1/17 vaccine, and 5/10 (9/10) and 7/11 (6/11) in 2 dose subjects. In 8 and 11 recipients, mean duration of isolation was 6.5 days for HIV-1 CA and 4.7 days for VEP=NS. After 8, 8(30%) of HIV-1 CA and 4(30%) of V recipients also virus from the site for 1.0 and 0.2 days, respectively (P<0.01 for 8 vs 11). Restriction enzyme analysis of 17 and 14 dose HIV-1 CA isolates obtained from 1 subjects showed them to be identical to the vaccine strain. 26 of the 29 persons with a history of previous V and V neutralizing antibody titres at seroconversion. The baseline GMT for HIV-1 CA recipients was 3.2, 8.2 and rose to 12.1 after 1 and 10.8 after 8. For V recipients, the respective GMTs were 3.2, 8.2 and 8.2. 65% of subjects had a 4-fold rise in V neutralizing titre after 1 dose to 0 after 8. V seronegatives also virus began to V seropositive. No toxicity was seen with either vaccine. As in HIV seronegatives, responses were detected in 1/16 HIV-1 CA recipients, 2 V seronegatives and 1 V seropositive developed Ab to gag and gp120. Three of 4 HIV-1 CA subjects who shed virus for 1.0 day developed VEP=NS after 10 weeks and 1/12 who shed for <1 day.

Conclusion: This trial demonstrates the safety and genetic stability of this HIV-1 gp160 vaccine recombinant vaccine. The clinical and virologic responses to vaccination were similar between HIV-1 CA and V. The development of early Ab appears related to the duration of HIV-1 CA replication in skin, which is inversely related to the presence of pre-existing V neutralizing antibodies. The lack of local viral replication after 8 suggests that other forms of actual vaccines should be evaluated for boosting.

M.C.P.8 HIV-1 RECOMBINANT GP160 VACCINE RECEPTORS DEMONSTRATE gp160-SPECIFIC LYMPHOCYTE PROLIFERATION PRIOR TO WESTERN BLOT REACTIVITY.

Kear, Michael C., Smeets, W., Roberts, N.C.L., de Wit, J., van der Schueren, R.C., University of Rochester School of Medicine, Rochester, NY, USA

Objective: To characterize cellular responses to HIV gp160 vaccine.

Methods: As part of the NIAID multicentered AIDS vaccine evaluation program, we enrolled 12 volunteers in a phase 1 randomized, double-blind, placebo-controlled trial of baculovirus-expressed recombinant HIV-1 envelope glycoprotein gp160 (GP160) (Genzyme Synt). Six subjects received GP160, 3 a Hep-B vaccine, and 3 placebo at 0, 1, 4 and 6 months. We performed lymphocyte proliferation assay (LPA) using cryopreserved peripheral blood mononuclear lymphocytes obtained at day 56 (28 days post first booster). The GP160 and a control consisting primarily of the major contaminating baculovirus glycoprotein were used as antigens.

Results: Background baculovirus proliferation was eliminated in 11/12 subjects at 0, 1, 4, and 6 months. At 1.0 ml (mg/ml) in dose response assays. Higher antigen concentrations produced generalized stimulation and did not distinguish the vaccine recipients from controls. At 0.1 mg/ml, all 6 GP160 recipients had stimulation indices (SI) of 2.1 (SI < 1.0 = no response). The SI was <2.0 in all 6 subjects who did not receive GP160. Western blot (WB) assays were performed on day 56 and were positive for only one GP160 recipient at that time. Sequential LPA on this subject disclosed SI > 2.0 prior to vaccination, SI < 2.0 at day 23 (Immediately pre-booster) and two weeks prior to receipt of the 6-month booster. At day 56, three months post-first booster, the other 5 GP160 recipients also developed WB reactivity 2-4 months after demonstrated reactivity in LPA.

Conclusion: The HIV-1 GP160 vaccine induces cellular immune recognition, illustrated by lymphocyte proliferation, prior to detection of antibodies by Western blot.

M.C.P.10 GP160 ISOCYTES: A CANDIDATE HIV VACCINE.

Amstrong, L. **, Williams, M. **, Larkin, R. **, Ljunggren, J., K-9113

Upstate, Sweden. **Karolinska Institute, Box 6000, S-14186, Stockholm, Sweden

Objective: To formulate a candidate HIV vaccine for the prevention of AIDS.

Methods: Isocytes were formed using gp160 (vaccinia) and gp160 (baculo) according to Martin et al. (1984). Immune response was analyzed in an indirect ELISA using defined recombinant nucleocapsid proteins and peptide as antigens. These antigens were gp160 (vaccinia), gp160 (part of gp120) and gp120 (a synthetic peptide). Neutralization tests were done according to Nara et al. (1987). AOC was done according to Ljunggren et al. (1987).

Results: Isocytes containing gp160 from HIV, elicited high antibody titres in mice, rabbits and guinea pigs after two immunizations. The animal sera were tested for serological reactivity, AOC, activity and for CD4 binding capacity. All sera were negative in AOC. Blocking of gp120 binding to CD4 positive HeLa cells was shown by mouse sera at a range of serial dilutions of 1/50 to 1/1250. Syncytial inhibition titres against the homologous isolate IIIIB were in the order of 1/4 to 1/120 and cross neutralization titres were in the range of 1/4 to 1/16 using the heterologous isolate 89.

Conclusion: The gp160 isocyte gave rise to high antibody titres in mice, rabbits and guinea pigs. These isocytes elicited neutralizing antibodies in mice towards the homologous isolate IIIIB as well as for the distantly related HIV isolate 89 indicating the possibility of inducing group specific neutralization.

M.C.P.12

GENETIC MAGNITUDE AND DURATION OF ANTIBODY RESPONSES IN HIV-1 GP160 VACCINE

Shannon, Leslie **, Hadden, K., O'Keefe, R., Nelson, G., Whittet, R. **, The NIAID AIDS Vaccine Evaluation Group, Bethesda, MD, USA

**MicroGenetics, Inc. West Haven, Connecticut, USA.

Objective: To characterize the kinetics, magnitude and duration of serum antibody responses of recipients vaccinated in a multicenter phase 1 randomized trial with recombinant baculovirus expressed gp160 (gp160) of HIV-1 (vaccine HIV-1 MicroGenetics, Inc.)

Methods: 24 HIV seronegative individuals were vaccinated with 0.5 ml of 10⁷ (1) or 10⁸ (2) gp160 (N-24) or a control preparation (N-0). Coded blood specimens obtained from 24 recipients were analyzed for antibody response 1 and 2 months after vaccination using for IgG antibody responses by Bio-Rad/Orion Western blot (WB), Abbott HIV EA, and conceptually similar enzyme immunoassay (EIA) using gp160 as antigen. The specificity of gp160 EIA was confirmed by a blocking assay.

Results: The mean time interval for detecting serum antibody responses in gp160 vaccinees, of 23 vaccinees with antibody responses by any assay, 98% were detected by gp160 EIA by WB and 100% were detected by gp160 EIA by Abbott HIV EA. The mean time to detect serum antibody responses by WB and gp160 EIA and WB results were 91% compared to 80% for the gp160 EIA and Abbott HIV EA.

The kinetics and magnitude of antibody responses in sera of vaccinees were characterized by the antibody EIA. Of 23 vaccinees detected by gp160 EIA, 17% were detected by gp160 EIA and WB after the first, 72% after the second, and 100% after the third vaccination. After the second and third vaccinations, the level of antibody increased 3.6-fold and 3.3-fold above the pre-vaccination level. By 2 months after the initial vaccination, 12 months after the third, the level of antibody had declined but remained elevated above pre-vaccination levels.

Conclusion: The gp160 EIA was more sensitive than WB or Abbott HIV EA and detected serum IgG antibody responses to gp160 in 22 of 24 vaccinees. The EIA makes it possible to quantitate the magnitude of antibody response to the second and third doses of vaccine and to determine the duration of responses over the 6-month period after vaccination.

VALIDATION OF A SYNTHETIC HIV-1 P-17-BASED CANDIDATE AIDS VACCINE, HOP-30

Allan, S., Edinger, R., Paul, M., Boyler, J., E. Kinkley, C. W. Boyler, C. J. Gibney, and J. S. Tom. The George Washington University Medical Center, Washington, D.C., National Institutes of Health, Bethesda, MD, U.S.A.

Objectives: To evaluate neutralizing and immunogenicity of a synthetic subunit vaccine based on an HIV p17 peptide analogue (HOP-30)

Methods: The synthetic peptide HOP-30 (Boyer et al, PNAS, 86, 1991, 1997) was conjugated to keyhole limpet hemocyanin (KLH) and injected with various adjuvants at different doses in a variety of animal species. The presence of antibodies was detected by ELISA (HOP-30 specific) and Western blot (p17 specific). Neutralization activity was evaluated as inhibition of ID₅₀ virus replication and/or virus induced syncytium formation with different HIV-1 strains.

Results: Immunization of animals with HOP-30-KLH gave antibodies to HOP-30 as detected by ELISA, but not to the recombinant HIV-1 strains with whole or disrupted virus enhanced the production of antibodies to p17. High titer antibodies to p17 effectively neutralized various strains of HIV-1 in ELISA assays. Similar results were obtained with monoclonal antibodies which recognize HOP-30. The proposed candidate subunit vaccine, has proven safe in a number of animal species.

Conclusions: A synthetic subunit vaccine based on HOP-30 representing immunodominant epitope HIV-1 p17 produces antibodies in animals which recognize HIV p17, neutralize HIV infection *in vitro* and prime the animal to respond to natural HIV p17. Based on these studies a phase-I clinical trial will soon be initiated in England.

M.C.P.15 DISPLAY OF RECOMBINANT PARTICLES WHICH EXPRESS AN HIVP24 T-CELL EPITOPES PURIFIED TO THE HIVP24 ANTIGEN

McGee, J.L., Letour, D., Mlich, G.M., Thomson, G.B., and Montary, A.M., *R.W. Johnson Pharmaceutical Research and Development, La Jolla, CA, U.S.A., **Schuylkill County Research Foundation, La Jolla, CA, U.S.A.

Objective: The importance of viral internal core or gag proteins in regulating the immune response to envelope epitopes has recently been demonstrated with hepatitis B virus (Mlich et al., Nature, 1987). Based on these studies we have sought to evaluate the role of the gag related antigen of HIV in the regulation of the immune response (T-dependent and T-independent) to themselves and to HIV gp120/60. In order to pursue these studies, we designed and expressed recombinant particles expressing both HIV gag and HIV-1 determinants.

Methods: A proposed T and B cell epitopes from the C-terminus of the HIV P24 gag region (Coles et al., Nature 1987) was selected for insertion upstream from a recombinant core expressing HIV core antigen in the form of particles. The HIV gag sequence was prepared as a synthetic oligonucleotide sequence and inserted upstream from the HIV sequence in the Pst-SmaI region of the multiplying site within the HIV construct.

Results: The recombinant fusion protein was expressed in E. coli and the antigenic specificity determined by ELISA using Western blot analysis. These analyses revealed a single protein species at 24,000 n.w. the size predicted for the P24/HIV fusion protein. This protein was reactive with anti-HIV and anti-P24 antibodies, generated in rabbits. **Conclusions:** Recombinant vaccines have been engineered capable of expressing a fusion protein which contains HIV and HIV P24 antigens. The fusion protein forms particles which, by electron microscopic examination, are similar to HIV particles. These HIV/HIV particles are being used to evaluate the role of gag T-cell determinants in the immune response to HIV.

M.C.P.17 TYPE-SPECIFIC NEUTRALIZING ANTIBODIES TO HIV-1 IN RABBITS IMMUNIZED WITH RECOMBINANT HIV-1 ENVELOPE PROTEINS

G.M., Day, R., and Sullivan, J., *University of Massachusetts Medical School, Worcester, Massachusetts, USA, **Applied Biotechnology, Cambridge, Massachusetts, USA.

Objective: To analyze humoral immune responses in rabbits immunized with vaccinia vectors expressing envelope gene from two strains of HIV-1. **Methods:** Two vaccines were produced: intramuscularly with 500³ pfu of vaccinia vectors which expressed either HIV-1 envelope genes (HIV-III B or HIV-III B) or the gag gene of equine herpes virus as a control. Rabbits were bled with 500³ pfu of the same vector 6 weeks after the initial inoculation. Antibody titers were determined by Western blot analysis (HIV) or ELISA (Vaccinia). Neutralizing activities were determined using a syncytium inhibition assay with both III B and R9 strains of HIV.

Results: All rabbits developed strong antibodies to both Vaccinia virus (titers to 1:409,600 by week 2) and to HIV-1 envelope antigens (titers to 1:10,240 by week 6). No major antibody response was to gp120 and gp120 with antibodies to gp41 appearing later and at lesser titers. Significant levels of neutralizing antibodies to HIV-1 (p146) developed by week 5 post inoculation. These neutralizing antibodies were type-specific and remained so even after boosting. Previous studies using vaccinia/HIV-1 env recombinant viruses had failed to demonstrate neutralizing antibody response (Hu et al., Nature 338:721), though antibody responses in these studies were mainly directed to gp1.

Conclusion: Rabbits immunized with recombinant vaccinia/HIV-1 viruses develop significant type-specific neutralizing antibodies to HIV-1.

M.C.P.14

CELLULAR IMMUNITY IN HIV-1 RESPONSE VACCINES.

Milby, S.G., Carlson, L., Graham, M., Clements, M.E., Miller, M., and Adler, W.H., *The George Washington University Medical Center, Washington, DC, USA, **Montefiore, City, USA, ***NIAH, NIH, Bethesda, MD, USA.

Objective: To evaluate cell mediated immune responses in healthy adults who participated in a phase I safety and immunogenicity trial of recombinant gp120 (rgp120) of HIV-1 (HivSyn HIV-1). **Methods:** Twelve volunteers at low risk and without evidence of HIV-1 infection were vaccinated at 0, 1 and 3 months with one of the following: 40 µg rgp120 (R-2), Recombinase HB (R-3), or placebo (N-3). All 8 rgp120 vaccinees had detectable antibody to gp120 or HB by Western blot after their vaccination. Blood drawn before and at 0, 1, 1.5, 2, 4, 6, 8, and 7 months after their vaccination was tested by ELISA for blood assays of cellular immune function: lymphocyte subset analysis, natural killer (NK) cell lysis activity, antibody dependent cellular cytotoxicity (ADCC), proliferative response of peripheral blood mononuclear cells to HIV-1 and to mitogens PHA, Con A, PWM, and pokeweed mitogen-induced B lymphocyte. Responses of the gp120 vaccinee group were compared to those of the placebo and Recombinase HB or placebo.

Results: The rgp120 group had higher absolute lymphocyte counts, but there was no difference in the percent representation of lymphocyte subsets (CD4, CD8, CD19) between the two groups. Proliferative responses to all mitogens were normal but lower in the rgp120 group. Spontaneous Ig synthesis in vivo was not different between the groups while PWM induced IgG and IgM synthesis was higher in cells from the rgp120 group. High titers of IgM were shown that individuals from both groups could be stimulated into proliferative cycles without any exogenous mitogens. Proliferative responses to each major protein dose, NK and ADCC activity were similar in the two groups. **Conclusions:** The rgp120 induced specific antibody formation in vivo to gp120 or HB, appeared to have no adverse effects on GM. Cells from the rgp120 vaccinees responded to mitogens with similar amounts of Ig. The rgp120 antigen caused a small degree of normal lymphocyte activation.

M.C.P.16 RECOMBINANT VACCINIA VIRUSES THAT COEXPRESS HIV OR SIV ENV AND GAG-ENCODED PROTEINS PRODUCE RETROVIRAL PARTICLES

G. Hestera*, Dennis Franciga*, R. Corlier*, R. Desrosiers**, M. Hestera**, R. Kiplinger**, M. Applin**, J. Hestera**, J. Hestera**, Cambridge, MA and *New England Regional Primate Research Center, Southborough, MA, USA

Objective: To evaluate the formation of retroviral particles by vaccinia recombinants that express gag, env*, gag*, env* or gag + env* genes from HIV-1 or SIV.

Methods and results: The formation of free, defective, retroviral particles produced by monovalent and multivalent vaccinia recombinants that express HIV-1 or SIV polypeptides was assayed by several techniques, including electron microscopy and sucrose gradient centrifugation. We have demonstrated that vaccinia recombinants that coexpress gag and env genes give rise to the formation of enveloped retroviral particles that are secreted into the growth medium, while recombinants that express gag proteins alone yield immature, non-enveloped particles.

Conclusions: Recombinant vaccinia viruses that express one or more HIV-1 antigens have been proposed as candidate vaccines against AIDS. The production of enveloped retroviral particles by multivalent vaccinia recombinants suggests that they may have greater potential for eliciting an immune response effective against early events in HIV-1 infection.

M.C.P.18 HYPERIC EFFICACY OF A NEW AGENT AGAINST HIV IN VITRO

Valentin, Fran., Hestera, D.V., Tré, V., Lavia, G., Desrosiers, R., *Montefiore, Philadelphia, *New York University Medical Center, New York, USA.

Objective: To examine the effect of hypericin (HY), an aromatic polycyclic dione, against HIV in vitro.

Methods: 40 different concentrations of HY were incubated overnight with U800 to 10 tissue culture infective doses (TCID₅₀) of H9 isolates of HIV-1 and phytohemagglutinin activated human mononuclear cells (PHA-MNC). Cells were cultured with Interleukin 1 and monitored for the production of particulate reverse transcriptase (RT) by immunoblotting. In titration assays, 10⁵ cells were infected first and then treated with HY for 1, 2 and 6 hours, and (6) PHA-MNC were pretreated with HY, washed, infected and monitored for (6) free HIV was exposed to HY, and examined for infectivity and particulate RT.

Results: HY inhibited the production of HIV by PHA-MNC as assessed by RT and pH₂ when 4) HY and HIV were added together, 3) cells were preinfected and then treated with HY, 4) cells pretreated and then cultured with HIV in the absence of free HY, 5) free HIV was incubated with HY for 1 hr, and then added to PHA-MNC. This inhibition was most marked with 10⁵ TCID₅₀ or less, and at 10⁵ PHA-MNC. Only reduced to complete inhibition of RT and pH₂ through 10 days of culture. These concentrations of HY do not inhibit antigen-antibody complexes of normal HIV.

Conclusions: Short exposures of cells or 10⁵ HY at nontoxic levels inhibit the formation of infectious HIV by mechanisms that are not yet clear. This data on HY and HIV, together with our observation that HY inhibits latent retroviral infections in mice at levels nontoxic in vivo, indicates that HY should be developed as a potential anti-HIV agent for humans.

M.C.P.19

FUNCTIONAL ANTIBODY RESPONSE IN PERSONS IMMUNIZED WITH RAGULOVIRUS-DERIVED GP120 CANDIDATE AIDS VACCINE

Graham Barron, Rowland J. Robshaw, E. Montefiori, D. Mitchell, W. Wright, P. and the NIAID Vaccine Evaluation Group - Vanderbilt University School of Medicine, Nashville, TN, USA.

Objective: To determine the functional serological response of vaccinees in the circumvent NIAID sponsored trial of the MicroCousby baculovirus-derived gp120 candidate AIDS vaccine.

Methods: Neutralization (NT), complement-mediated antibody dependent enhancement (C-ADE), and anti-fusion activity were measured in a cytopathic effect assay system based on natural red spots by viable MT8 target cells. NT is a measure of cell-free virus inactivation by serum; C-ADE, done in parallel with the NT assay by adding complement to the HIV, measures the reduction in NT activity and is verified by detecting more rapid HIV cytopathic effects. C-ADE, done in parallel with the NT assay by adding complement to the HIV, measures the reduction in NT activity and is verified by detecting more rapid HIV cytopathic effects. HIV specific proteins, and srycrine formation, anti-fusion assays serum inhibition of cytopathic effect resulting from infected more rapid HIV-to-target cell fusion *in vitro*. Volunteers were immunized on days 0, 30, and 180 with either 40 mcg or 80 mcg of gp120. Sera from all vaccinees at day 0 and sera from Vanderbilt vaccinees at days 30 and 180 had no evidence of NT, C-ADE, or anti-fusion activity at any time point despite waning HIV positivity in many of the sera.

Conclusion: It is not known whether the inability to measure functional antibody activity in the sera of vaccinees is a function of the magnitude or quality of the antibody response.

M.C.P.20

HLA DR PEPTIDE IMMUNITIS BY HIV 1 IMMUNODOMINANT PEPTIDES

Wanda Rosenthal¹, Ulrich, E.P., Anand, N.P., Asare, H.Z.,^{2,3} Howard Hughes Medical Inst., and Dept. ¹Microbiol. and Immunol., and ²Immunol., Baylor College of Medicine, Houston, TX 77030 USA.

The binding of human immunodeficiency virus (HIV) to CD4 cells might be enhanced if the envelope bound to several sites on the same molecule or to several different molecules. Because class II molecules are important in the presentation of antigens and bind both the T cell receptor (TCR) and CD4 molecules, we determined whether the HIV-1 envelope protein exhibited sequence similarity with DR molecules. Five regions with sequence similarity were found and examined for their ability to inhibit cytopathic formation between HIV/HIV cells and uninfected CD4 cells. Peptide 141-155 inhibited the release of ³H-T from HIV/HIV cells after addition of uninfected CD4 cells. The inhibition was dose of a dimeric. This region, 204-248 in gp120, is highly conserved among HIV isolates and the region, 141-155, in the gp120 molecule is also highly conserved between haplotypes. Mutation of this region in HIV-1 has been previously associated with loss of infectivity (Willey et al., J. Virol. 62:139, 1988) and rabbit antibodies directed toward this region have neutralized HIV infectivity (De et al., Science 239:1021, 1988). We were infected with HIV apparently fail to respond to this region in HIV-1. In addition, both anti-CD4 and anti-HIV sera are unresponsive to this region when immunized with intact DR2. Immunization with the peptide, however, does induce a response. This region may, therefore, be essential in the design of an HIV vaccine, but caution is suggested because of the possibility of induction of harmful anti-self DR responses.

M.C.P.21

RECOMBINANT ADENOVIRUS INDUCES ANTIBODY RESPONSE TO HIV GP120 IN MICE

Rosemary Bennett, L. Graham, F.L. and Provo, L. McMaster University, Hamilton, Ontario, Canada

Objective: Construction of recombinant adenovirus vectors capable of expressing individual human immunodeficiency virus (HIV) polypeptides in infected cells and their use to assess antigenicity and as potential vaccines.

Methods: Recombinant adenovirus vectors capable of expressing HIV gp120 (p55 and gp160), and env (gp160) were constructed by inserting HIV structural genes into human adenovirus type 5 wild or without foreign promoters. Expression of recombinant vectors was assessed using immunoprecipitation and western blotting. Mice were infected with these vectors and examined for the production of antibody and the generation of cytotoxic T lymphocytes (CTL) to HIV proteins.

Results: Recombinant adenovirus vectors expressed HIV gp120 in a variety of human cells including 293-transfected human cell lines. Infection of mice with Adgp120 resulted in the production of antibody to HIV gp120. We are currently using these vectors to determine the role of individual HIV gene products in induction and serving as targets for both murine and human antiviral CTL.

Conclusion: We have successfully constructed recombinant adenovirus vectors capable of expressing HIV gp120 and generating immune responses in mice.

M.C.P.22

HUMAN T-CELL CLONES DEFINE DISTINCT EPITOPES WITHIN THE V3 REGION OF HIV-1 GP120

Wainhold, Kent¹, Stanley, D., Jawahars, K.M., Scott, C.M., Putney, S.W. and Holmgren, M.E., ¹Shiga University Medical Center, Durham, NC, USA; ²Wageningen, The Netherlands, ³Ma, The Netherlands

Objective: To identify epitopes within the HIV-1 envelope which are recognized by T-cells from seropositive individuals.

Methods: Peptides representing the V3 region of HIV-1 gp120 were used to stimulate T-cell reactivity in primary cultures of peripheral blood mononuclear cells (PBMC) from seropositive donors. T-cell clones were derived, phenotyped, and assayed for specificity against a panel of peptide constructs. Clones were analyzed for cytolytic activity against autologous target bearing peptide antigens.

Results: The HIV-1₁₁₁ gp120 peptide was found to be a potent stimulator of primary T-cell reactivity *in vitro* whereas the HIV-1₁₁₁ analogue (gp139) was far less stimulatory and the HIV-1₁₁₁ peptide (gp145) lagged only detectable activity. Using hybrid peptides, the multiple CD4 T-cell clones were found to belong to 3 different specificity groups, each capable of recognizing a subdomain within the V3 region of gp120. Representative clones from each of these groups had demonstrable cytolytic activity.

Conclusion: T-cells from HIV-1 seropositive donors recognize determinants within the V3 region of gp120. Unlike the single epitope recognized by mice, human T-cells appear capable of distinguishing multiple sites. Lastly, the V3 region of gp120 may be important not only for production of neutralizing antibodies, but also for eliciting virus-specific T-cell reactivity in potential vaccinees.

M.C.P.23

PLAQUE REDUCTION ASSAY TO DETECT HIV NEUTRALIZING ANTIBODIES IN SERA FROM HIV VACCINEE

Fengzi, Terry W., Seaman, T. and Balise S. and NIAID AIDS Vaccine Program - ¹Marshall Univ. Sch. Med., Ht., Wv., ²Bethesda, Md, USA

Objective: To describe a neutralization (Nt) assay which employs vaccinia virus recombinant (VVR) infected CD4⁺ HeLa cell monolayers.

Methods: HeLa cell monolayers 4-6 hr. for HIV CD4⁺ receptors were established in multi-well plates and upon reaching confluency (24 hrs) were infected at 100 PFU/10⁶ cells with 1) VVR expressing GP140 env protein, 2) VV, 3) VVR or 4) VV treated with sera from individuals vaccinated with recombinant GP140 (rGP140) vaccine (Microgen) and 4) VVR or VV treated with primum sera from vaccinees. Consistently sera were assayed for neutralizing antibodies using inhibition of cytopathic formation induced by HIV strain 89 in MOLT 3 cells.

Results: Infection with VVR but not VV produced plaques by day 3 in CD4⁺ HeLa cell monolayers but not in CD4⁻ cell monolayers. Plaques resulted from cytopathic formation and subsequent sloughing of HeLa cells. HIV membrane antigens were demonstrated on the surface of cells at the periphery of plaques by immunofluorescence. In both assays sera from vaccinees demonstrated with 3 10⁶ dose of rGP140 did not exhibit neutralizing activity. In spite of the fact that post vaccine sera exhibited positive ELISA and reactivity to GP140 in Western blots.

Conclusion: A plaque assay employing VVR and CD4⁺ HeLa cells has been used to examine sera for neutralizing antibodies among rGP140 vaccinees.

M.C.P.24

QUANTITATIVE ASSESSMENT OF SERA INHIBITION OF HIV/RECEPTOR BINDING

Janis V. Girard¹, Nishanian, P.G., Ho, D.H. and Schmid I. UCLA School of Medicine and the Jonsson Comprehensive Cancer Center, Los Angeles, CA, USA

Objective: Vaccination against HIV is expected to induce antibodies with a variety of biological activities. Antibodies that inhibit HIV/receptor binding, as well as those that neutralize HIV, are expected to be protective. We have developed a method to design a sensitive assay to assess sera inhibition of HIV/receptor binding.

Methods: Using an EPICS C flow cytometer (EPICS Division of Coulter Electronics, Becton Dickinson) we have established a sensitive fluorescence intensity of the 256 channels of the 3-decade log scale of our instrument. Using beta-2-microglobulin-labeled HIV (Nishanian, et al., J. Immunological Methods 103:261, 1983), virus binding to T-cells was detected using an anti-HIV serum and FITC-conj anti-human IgG.

Results: When antibodies to gp120 were incubated with the HIV prior to adding the HIV to the T-cells, inhibition of HIV binding was observed with some sera, while enhancement of HIV binding was observed with other. This activity could be precisely quantitated, permitting accurate assessment of minor differences in the biological properties of different sera.

Conclusion: This method will be valuable for assessing the immune response of vaccinated persons, and is being used to evaluate the virus that are involved in binding (see abstract by David Ho, et al., this Conference).

M.C.P.25 CROSS REACTIVITY OF GOAT SERA GENERATED AGAINST FIVE HIV-DERIVED OF 120 RECOMBINANTS AND SYNTHETIC PEPTIDES

Yair Duvshil, Koshi Ishwaran, Albert T. Profy, and James Krause
Repligen Corp., Cambridge, MA 02137, USA
Present Address: E. I. Du Pont Co., Diagnostic Division, Glasgow, DE 19110, USA
Objective: To determine the binding specificity of goat sera generated against C-terminal fragment of p120 (PB-1) and amino acid 301-324 loci sequences derived from five HIV isolates (HIV, MN, WML2, and SC).
Methods: Three different ELISA formats (peptide antisera/peptide antigens, peptide antisera/PB antigen, and PB-1 antisera/PB-1 antigens) were utilized to determine the cross reactivity patterns of the sera with the antigens.
Results: Antisera generated against MN and SC were highly cross reactive. This cross reactivity pattern was unique to the amino acid antigens and antisera used and could not be predicted from the amino acid sequences of the five variants. Furthermore, it was established that the PB-1 fusion domain and the peptide KLH-carrier protein does not contribute to the cross reactivity.
Conclusions: The study demonstrates a strong cross reactivity of MN and SC. The cross reactivity could not be predicted from the linear sequences of the five peptides and the five PB-1's. Correlations of this cross reactivity with that of HIV-infected human sera and virus neutralization is discussed.

M.C.P.26 IMMUNOGENICITY OF HIV-1 GLYCOPROTEIN IS DEPENDENT ON PROPERTIES OF THE GLYCOPOLYMER HEAVY

Herman, Yanna Malm, K. Eriksson, S. Fridberg, T. Alsterlund, L. and M. Virelizier
Dept. Vascular Virology, Biomedical Center, Uppsala, Sweden.

Objective: Recombinant glycoproteins derived from the HIV-_{env} gene are under evaluation as antigens in vaccines against AIDS. The importance of the structure and size of the glycoproteins for eliciting a protective immune response is obscure. As a first approach to elucidate this matter we present data on the immunogenicity of mice of two env glycoproteins, which have been modified by treatment with glycosidases.

Methods: Gp120 (A), purified from HIV-1_{HT89} infected 293 cell culture medium (7yle STW et al. AIDS Res 1987;3:387-400) and gp160 (B), expressed in Vero cells from the HIV-1_{HT89} env gene in a vaccinia virus vector, were incorporated into ISCOEM and treated with 1) buffer (non-modified control), 2) serratostatinase, 3) endoglycosidase H or 4) glycosylphosphatidase-F. The 8 antigen preparations were analyzed by EM, SDS-PAGE and immunoblot and injected, at a dose of 1µg (antigen group A1-A4, B1-B4) or 0.1µg (group B1-B4) into mice (16 animals per antigen and dose) at two occasions, 4 weeks apart. Blood was withdrawn from the tail vein at intervals up to 8 months after the first immunization and the serum individually analyzed by ELISA for HIV-1 gp160 and several related peptides.

Results: The serological immune response to the non-modified and modified glycoproteins differ with respect to relative antibody titer, timing and type of ELISA. As a general rule the modified proteins gave rise to a lower total titre than the non-modified glycoprotein.

Conclusions: The carbohydrate residues are important for defining antigenic epitopes. It remains to be shown whether this has bearing on protective efficacy.

M.C.P.27 STV VACCINE DEVELOPMENT SURVEILLANCE Schultz, A. R. and Glass, R.

Vaccine Research and Development Branch, AIDS Program, NIAID, National Institutes of Health, Bethesda, MD, USA 20892

Use of vaccines infected with STV has become an important disease model for the development of a vaccine for human AIDS. A proliferating variety of approaches (synthetic peptides, recombinant peptide regions, subunit approaches, live expression vectors with different gene products, killed and live attenuated STV) are under development and being utilized by numerous groups, all destined for evaluation of safety and immunogenicity in the animal and, ultimately, for protection from STV challenge. To further complicate the picture, immunologically distinct isolates of STV are being used, some biologically cloned, some genetically cloned, and others uncloned. Some projects are in early stages, while others are well underway. As an aid to information dissemination, facilitation and coordination of these efforts, the Vaccine Branch of the NIAID AIDS Program maintains surveillance of initiation and overall progress in these experiments. A summary of research approaches and findings will be presented.

M.C.P.28 ZARIAN HIV-1 VARIABLE AND HYPERVARIABLE ENVELOPE FRAGMENTS

André, Gérard, Smer, R., Kolontzakis, V., Zagury, J.F. and Zagury D
Université Pierre et Marie Curie, Paris, France

Objective: To compare the heterogeneity, in Zairian asymptomatic carriers and physically asymptomatic individuals, of amplified DNA fragments from envelope gag regions.

Methods and results: DNA extracted from paraffin block mononuclear cells has been used for PCR amplification of envelope and gag regions. We have found that the PCR, if carried out under condition designed to avoid non-specific amplification, results in a large number of false negatives.

PCR results (empirical efficiency):

Isolation amplification sequence	21	22	23	24	25	26	27	28
env 30-368	+	+	+	+	+	+	+	+
env 682-1021	+	+	+	+	+	+	+	+
env 1760-2293	+	+	+	+	+	+	+	+
gag 1551-1665	+	+	+	+	+	+	+	+
gag 856-1046	+	+	+	+	+	+	+	+

A modified PCR technique, involving lower annealing temperature, has successfully amplified fragments of these variable envelope regions. The DNA fragments have been purified and reamplified using the PCR technique and enough DNA obtained for direct sequencing/sequencing of cloned fragments. The results are important in relation to the development of envelope based vaccines.

M.C.P.29 COMPARISON OF IMMUNE RESPONSES IN MICE IMMUNIZED WITH NATIVE HIV-1 ENVELOPE GLYCOPROTEIN OR CORRESPONDING IMMUNOGENE

Lise Thibodeau, L. Flamand,* D. Oth,* L. Lachapelle,* and L. Montagnier**
*Institut Armand-Frappier, Montréal, P.Q., Canada, **Bacteriologist, Paris, France.

Objective: Investigate the role of HIV antigen presentation on the first step of immune reaction (macrophages activation) as well as on later events such as T-lymphocytes proliferation and antibody synthesis.

Methods: HIV-2-immunosome (HIV-2-IMS) was prepared by anchoring purified envelope glycoprotein into the phospholipid bilayer of liposomes. The immune responses to HIV-2 purified gp140/125, or corresponding immunosome, have been determined by the level of Interleukin-1 (IL-1) production by adherent peritoneal exudate cells (PEC), T-lymphocyte proliferation upon *in vitro* restimulation with the immunizing antigen, and by antibody synthesis evaluated by ELISA, IFA, neutralization of cell-free viruses and syncytia formation inhibition.

Results: Mice immunized with HIV-2-IMS developed both higher antibody response and neutralizing titers against HIV-2 than mice immunized with equal amounts of envelope glycoprotein. Similarly, IL-1 production was higher in mice immunized with HIV-2-IMS. In addition, upon *in vitro* restimulation, enhanced IL-1 production was observed only in mice primed and restimulated with immunosomes. T-lymphocyte proliferation, determined by 3H TdR incorporation, followed the pattern of IL-1 production.

Conclusion: These observations indicate that the physical presentation of an antigen may be critical not only for their uptake by macrophages, and simultaneous release of IL-1, but also for the subsequent events in the cascade of immune responses, suggesting the potential application of liposomes as carrier for purified HIV antigen in designing an AIDS vaccine.

M.C.P.30 AN IMMUNODOMINANT EPITOPE OF THE HIV GP160 ENVELOPE GLYCOPROTEIN RECOGNIZED BY CLASS I MHC-INDUCED HUMANS

André, Annie,* Fossati, I.,* Margerite, C.,* Berzanji, J.A.,, Gello, R.C.*** and Zagury, D.***
*Université P. M. Curie, Paris, France, **Metabolism Branch, NCI, Bethesda, USA, ***NCI, Bethesda, USA.

Objective: A single peptide corresponding to residues 308-322 of Rattner et al. (1) sequence accounted for the murine CTL activity (2) measured using stimulator cells expressing the entire gp160 protein. Because CTL may be important for preventing direct cell to cell transmission of HIV we investigated the peptide specificity of the anti-HIV CTL in immunized humans.

Methods: Volunteers, primed by 7⁰ expressing gp160 proteins, received boosters constituted by gp160 hetero-oligomers. These PBs were stimulated *in vitro* by irradiated autologous cells carrying gp160 signals in a mouse lymphocyte culture. Effector PBs were screened for specific cell mediated cytotoxicity by chromium release test, using EBV transformed B cells initially infected with rV or purified p18.

Results: Our results show that immunized populations are CTL responders. Our data found that the peptide p18 may represent a good antigenic signal for specific CTL recognition. However, the response to a single epitope represented by a 15 residue synthetic peptide of T cell epitope and are seen by CD 8 CTL in association with class I (MHC) molecules.

Conclusion: This epitope which occurs in a highly variable segment of the envelope protein may be immunodominant in humans and of clinical importance in vaccine development.

M.C.P.31

MAPPING OF T- AND B-CELL EPITOPES OF HIV-1 NP PROTEIN IN HUMANIZED CHIMPANZES.

Okamoto, M., Chaudhri, V., Yipko, M.; Sabater, J.M.; Gay, R.M.; Girard, M.; Bahraoui, E. et al.
*Pitié-Salpêtrière Medical Center, Paris; **CNRS U4179 INSERM U172, Marseille; ***Transgene SA, Strasbourg; ****Pasteur Vaccine, France.

Objective: As an approach to vaccination, the immunogenicity and fine specificity of HIV-1 p27^{NP} regulatory protein for T and B cells were assessed using synthetic peptides.
Methods: Chimpantests were repeatedly immunized with soluble purified p27 produced in E. Coli, associated with other recombinant HIV-1 proteins (gp120, p18), and mixed with MDP as an adjuvant. Four animals had been previously inoculated with recombinant vaccines expressing different HIV-1 proteins, 2 of them having that received p27. Two were naive. PBL proliferative specific responses (PFR) (Thymidine incorporation) and serum antibody reactivity (ELISA) were sequentially tested against p27 and a set of synthetic peptides spanning the entire NP sequence.

Results: Independently of immunizations, PFR to p27 was strong and sustained in 1 animal (mean SI = 2), moderate in 2 (mean SI = 5.7 and 5.9), weak in 2 (mean SI = 2.7 and 2.1), and negative in 1 (mean SI = 1). Anti-p27 antibody titres ranged from 1:100 to 1:8400 in the sera of the 3 animals whose lymphocytes had the strongest PFR. The dominant epitope recognized by PFR of these chimpanzees was located in the C-terminal region of p27 whose peptides were compared for their capacity to induce PFR. In parallel, one of the 3 major linear epitopes recognized by ELISA was located distally, indicating that the test of 40 amino-acids of p27 covers both T- and B-cell epitopes.

Conclusion: Besides demonstrating that p27^{NP} presents dominant epitopes recognized by T and B cells on a C-terminal region, these data provide a means to explore the pathophysiological value of the immune response to NP product, and its possible usefulness for vaccination purposes.

M.C.P.33 AN AUTOMATED MICROTITER TEST SYSTEM FOR THE DETECTION OF HIV-1 AND HIV-2 NEUTRALIZING ANTIBODIES

Melzer, W., Kleinschmidt, A., and Edle-Vollmer.
*DSF-Abteilung für Molekulare Zellphysiologie, D-6042 Neuherberg; **Medizinische Poliklinik der Universität München, D-8050 München, West-Germany.
Mark Richardson; Adams, S.E.; Griffiths, J.M.; Burns, N.

Objective: Establishment of a microassay for the measurement of HIV-neutralizing antibodies using monoclonal cells.

Methods: Inoculation of human fetal lung cells (clone LCE5) with HIV-1 or HIV-2 in microtitre plates and demonstration of cytoplasmic viral proteins after two to three days using the indirect immunoperoxidase staining (IP). Demonstration of neutralizing capacity of sera in an enzyme-reduction assay. Use of an automated workstation (BIO-MEX 1000) for the performance of the neutralization assay.

Results: The incubation of LCE cells with HIV results in the formation of IP-positive colonies two to three days after infection. The colonies are counted very easily and their number corresponds to the amount of infective units in the inoculum. Pronunciation of HIV with neutralizing sera prior to infection results in a distinct reduction of colonies, in comparison to endpoint test systems. This assay is more sensitive and the neutralizing capacity of sera can easily be quantified (after determination).
Conclusion: The use of monoclonal cells in combination with IP represents a reliable and easy to quantify test system for the detection of HIV neutralizing antibodies, which can be completely automated. This test system is fast, very sensitive, requires minimal handling of infectious virus and is thus suitable for the screening of large numbers of sera.

M.C.P.35

HIV VACCINE DESIGN: EXPLOITATION OF TY VIRUS-LIKE PARTICLES

Mark Richardson; Adams, S.E.; Griffiths, J.M.; Burns, N.*
Senior, J.M.* and Kingman, A.J.*
*British Biotechnology, Oxford, U.K. and *Department of Microbiology, University of Oxford, Oxford, U.K.

A protein encoded by the yeast retrotransposon Ty can be used as a carrier for recombinant antigens. HIV antigens (gp120, gp41, p24, p17, reverse transcriptase, Tat) have been incorporated into specialized expression vectors for high level production in yeast. These antigen coding sequences include those for complete proteins and selected regions.

All of the Ty-HIV fusion genes were transcribed and translated into fusion proteins that assemble into hybrid virus-like particles (VLPs). The formation of VLPs is conferred by the self-assembly properties of the Ty protein. The hybrid VLPs contain about 300 copies of the fusion protein and hence about 300 copies of the added antigen. The non-Ty component is presented on the outer surface of the particles and induces the production of HIV-specific antibodies.

The ability of various of these polyvalent antigens to induce virus neutralizing antibodies and cellular responses is currently being evaluated in rodents and non-human primates.

M.C.P.32

DEMOGRAPHIC CHARACTERISTICS AND FREQUENCY OF EXCLUSIONARY CRITERIA IN A POPULATION VOLUNTEERING FOR HIV IDENTIFICATION.

Maschke, E. Ulf; Melzer, W.; Giese, G.-J.; Anderson, K.R.; Berry, C.F.* and the ELIAS AIDS Vaccine Program*.
*University, Huntington, W.V., USA; **Bethesda, Md., USA.

Objective: To define the population volunteering for an AIDS vaccine study (ELIAS MicroStudy) and to determine the frequency of occurrence of exclusionary criteria in such a population.

Methods: 156 volunteers were interviewed and examined. Blood was collected for routine laboratory testing as well as cell counts, HIV ELISA (EIA), Western Blot (WB) and p24 Ag.

Results: 85 males (mean age 22.2, range 18-42) and 81 females (mean age 23.9, range 17-50) volunteered. 130/166 (78%) were university students. Most had less than 1 year of study from news media (50%), Friends/relatives (17%). The most common causes for exclusion were the presence of indeterminate WB (26.9%) or a change of mind after the initial interview (24%). Other causes were abnormal CBC and DIFF (7.2%), elevated ALT (3.8%), HbA1c (3.6%), abnormal UA (3.4%), recent STDs (3.0%), 74 (400 (1.9%); abnormal CD4 (1.7%); recognized high risk behavior (1.7%); SWE (1.2%), premenstruity (1.2%), failure to meet age criteria (1.2%), unable to be available for entire study (1.2%), abnormal physical exam (0.5%) and split up (0.4%). No volunteers had AIDS. 14.5% had more than one reason for exclusion.

Conclusion: Even in a community with low prevalence for HIV, a large number of healthy heterosexual volunteers can be expected to be ineligible for enrollment in HIV vaccine trials. An average of 4.8 volunteers were screened for each of 12 vaccinees chosen.

M.C.P.34

NOVEL APPROACH TO PURIFICATION OF HIV p24 PROTEIN BY CLEAVAGE FROM HYBRID TY VIRUS-LIKE PARTICLES

Jacqueline E.H. Gilmore; Burns, N.R.; Kingman, S.N.; Kingman, A.J.* and Adams, S.E.*
*British Biotechnology Limited, Cowley, Oxford, U.K. *Department of Microbiology, University of Oxford, Oxford, U.K.

Objective: To develop a rapid method of purifying a component of a fusion protein

Method and Results: The coding sequence for HIV-1 p24 was cloned into a TyVLP vector. The resulting fusion protein assembles into virus-like particles due to the presence of the yeast Ty p1 protein. This is linked to p24 via the recognition sequence of the blood clotting factor Xa. The VLPs can be readily purified in milligram quantities. The p24 component can then be cleaved from the particles with activated factor Xa. A rapid method has been developed for the subsequent purification of p24 from the cleavage mixture. This technology has also been used for the purification of other proteins including HIV TAT and RTF.
Conclusion: A simple and effective method has been developed for the purification of the p24 component of a fusion protein. This is a generic method applicable potentially to any protein of interest.

M.C.P.36

BREAST MONKEYS IMMUNIZED WITH RECOMBINANT VACCINA VIRUSES

CONTAINING HIV-1 ENVELOPE GENES INDUCE ANTIBODIES REACTIVE WITH ENVELOPES OF DIFFERENT HIV-1 STRAINS. Mital, Ales; Wala, M.; Hendry, B.R.; Carrow, S.E.; Mose, B.; Quinn, Q.; El, M.; Wala, W.; PFA. Inst. for Biological Control, Research, and Eval. REAID, Heli, Bethesda, Md., U.S.A.

Objective: To study HIV-1 specific antibody (Ab) responses in rhesus monkeys immunized with recombinant vaccinia viruses containing the gp160 envelope genes of HIV-1 strains IIIIB or SF.

Methods: Groups of 4 rhesus (R) monkeys were immunized with either ZVid⁰ FFP of a 7% deletion mutant of vaccinia virus (VAC) or recombinant vaccinia virus containing the HIV-1 IIIIB (VAC-IIIIB) or HIV-1 SF (VAC-SF) gp160 envelope genes, at weeks 0 and 9. Sera were collected at three week intervals for measurement of HIV-1 envelope reactive Ab. Serological assays were performed by Western blotting (WB) 1:10 dilutions of sera against recombinant HIV-1 (strain IIIIB) strips, and by whole virus (IIIIB) ELISA and recombinant HIV-1 (LAV) gp160 ELISA serum dilutions of 1:5 to 1:40.

Results: All AB strain primary but not secondary tests. As results were:

ASSAY	AB STRAIN OF ORIGIN	VAC-IIIIB	VAC-SF
HIV-IIIIB WB gp120/160	0/4	0/4	3/4
HIV-IIIIB WB gp41	0/4	0/4	3/4
HIV-IIIIB ELISA (GMT)	0/4	3/4 (20.0)	3/4 (23.2)
WFA-IVF-p160 ELISA (GMT)	0/4	4/4 (24.0)	3/4 (15.8)

Concluding: VAC-IIIIB or VAC-SF induced broadly reactive Ab to HIV. Only VAC-SF induced Ab to gp41, suggesting greater expression of the complete gp160 by VAC-SF or the immunodominance of HIV-SF gp41 heptamer sequence. Testing for Ab at 1:100 would have failed to detect Bb seroconversion.

M.C.P.37 SALIVARY ANTIBODIES TO HIV ANTIGENS IN AN AEROSOL VACCINE TRIAL

Archibald, David, Ambrin, C., Sun, D., Tacker, C.
University of Maryland at Baltimore, U.S.A.

The development of HIV-specific secretory antibodies may be a desirable outcome in individuals receiving AIDS vaccines. We investigated carotid and whole saliva samples from 5 volunteers who received a recombinant HIV-1 envelope glycoprotein (gp120) vaccine (Aerovax) and the presence of HIV-specific antibodies. Ten healthy adult volunteers received intramuscularly either 3 doses of gp120, (reactions B vaccines) or a placebo preparation on days 0, 30, and 180. Individuals receiving the gp120 received either 40 or 80 µg at each vaccination. Saliva samples were collected one day from the volunteers on days 0, 24, 50, 120, 194, and 270. HIV-specific antibodies were assayed using immunoblots (Epitope) which were incubated with the saliva samples, then with a biotinylated anti-human immunoglobulin antibody with a streptavidin-biotin horseradish peroxidase complex. To date, all volunteers were negative for HIV antibodies by ELISA (Abbott) in their serum. By Western analysis, secretions in gp120 in HIV envelope were demonstrated in 2 individuals, one who received the low dose vaccine and one who received the high dose. We tested antibodies to gp120 in whole saliva samples collected from one of these individuals. Stimulated prostatic saliva collected on this date and all others was not detectable HIV-specific antibodies. Mean total IgA levels of the volunteers with stimulated flow were 55 mg% g/l and 3.0 mg% s/l for whole and parotid saliva respectively, as detected by ELISA. The finding of HIV-specific antibodies in whole saliva following vaccination may indicate that development of secretory immunity is possible.

M.C.P.39 REPLICATION OF HIV UNDER SIMULATED GROWTH CYCLE CONDITIONS: A MODEL FOR STUDYING THE EFFECT OF ANTIVIRAL DRUGS.

Diazand, Fernando, Anderson, S., Capobianchi N.R., Anelli, P., Di Marco, P., Turzillo, J. The Institute of Urology, University "La Sapienza", Rome, Italy.
Objectives: To describe an experimental model of HIV infection for testing antiviral drugs. **Methods:** C8166 cells were infected with 2x10⁶ TCID₅₀/cell and then seeded in the presence or absence of antiviral drugs. At various time points cultures were collected and intracellular or extracellular virus was back titrated in fresh C8166 cells by standard limiting dilution method (0.5 Log ratio, 4 replicates per dilution). Replication is completed in 20 hr and at each time point, the effect of intracellular virus is 2 Logs higher than the extracellular one. This model allows us to determine directly the killer of antiviral drugs in terms of infectious virus yield reduction rather than of production of indirect parameters of viral growth (RT, p24, or C.p.e.). **Conclusions:** HIV replication is not as slow as previously established. Availability of a simple and dependable test to directly measure infectious virus may overcome uncertainties and ambiguities connected with indirect evaluation of viral growth by RT or p24 antigen determination. By using this model we have been able to show synergism between zidovudine and didanosine.

M.C.P.41 T CELL EPITOPES IN A CHEMICALLY SYNTHESIZED 104-MER CORE PROTEIN (p24) OF HUMAN IMMUNODEFICIENCY VIRUS (HIV-1)

Shibata, H., *Mocagni, P., *Torchio, G., *Gibbons, W.A., * and

*Dept. Med. Microbiol., London Hosp. Med. Coll., Turner Street, London E1 2AD, U.K. *School of Pharmacy, London, U.K.

Objective: To locate T cell epitopes of the terminal half of p24 of HIV-1. **Methods:** A 104-mer peptide corresponding to the amino acid sequence of the C-terminal half of p24 of HIV-1 was synthesized using an automated ABI 430A peptide synthesizer and an NBOO chemistry. The long peptide was used to generate murine peptide-specific T cell lines. The lines were then tested for their ability to proliferate to whole virus and native core proteins of HIV-1. A set of 14-23 mer peptides containing predicted T cell areas and a second set of 15 residues overlapping peptides were then individually tested to stimulate proliferation of the 104-mer specific T cell lines in order to locate the T epitopes. Peptides that induced *in vitro* proliferation of the lines were also tested to generate *in vivo* help in the production of antibody reactive to synthetic peptide, recombinant and natural core proteins. **Results:** The murine 104-mer specific T cell lines were of the helper phenotype and proliferated to the antigen in a MHC-restricted manner. The lines also responded to the whole virus and native p24. Five T epitope containing regions were defined in the 104-mer. Murine antipeptide raised against the T epitopes contained the synthetic protein, recombinant core proteins and viral p24 of HIV-1. **Conclusion:** The 104-mer peptide contains both T and B epitopes with viral core protein and is therefore suitable for studies in HIV vaccine.

M.C.P.38

REACTIVITY OF PURIFIED HIV-1 GP120 BY ALHYDRAL.

Hess, J., Miller M., Ziv, E., Pyle, H. W., Brummond, J. L., and Arthur, L. O. Program Resources, Inc.

NI-Frederick Cancer Research Facility, Frederick, Md. 21701. **Objectives:** The duration of the humoral immune response in chimpanzees vaccinated with HIV-1 gp120 formulated in Alhydrogel suggests that HIV-1 gp120/Alhydrogel complexes may be short-lived *in vivo*. In order to explore this possibility, we determined the effect of serum on gp120/Alhydrogel complexes. **Method:** Radiolabelled HIV-1 gp120 was adsorbed to Alhydrogel and the resulting complexes were separated from non-adsorbed gp120 by centrifugation. The gp120/Alhydrogel complexes were resuspended in distilled water and aliquots were added to normal human serum or gp120/Alhydrogel complexes. Incubation of gp120 was determined by pulling aliquots at various times and determining the amount of radioactivity in the pellets and supernatants. **Results:** HIV-1 gp120 is readily adsorbed by Alhydrogel and is stable for long periods of time when resuspended in distilled water. However, soon after 24 hours, approximately half of the complexes immediately dissociate, and less than 20 percent of the gp120 remains complexed after 96 hours. **Conclusion:** HIV-1 gp120/Alhydrogel complexes in serum are short-lived, *in vitro*, and may explain the short-lived humoral responses in chimpanzees. Additional studies need to be evaluated for use in HIV-1 gp120 AIDS vaccine experiments.

M.C.P.40

INDUCTION OF ANTIBODY TO HIV-1 ENVELOPE PROTEINS BY p24 CORE T EPITOPES

Coates, Anthony R.M.,* Slin, D.Y.,* Macagnani, P.,* Torch, G.E.,* Haselton, J.R.,* and Gibbons, W.A.,**
*The London Hospital Medical College, London, U.K. **The School of Pharmacy, London, U.K.

Objective: To investigate the possible involvement of HIV-1 p24 T epitopes in helping the generation of antibody responses to viral envelope proteins. **Methods:** Previously we have located 5 T epitope-containing regions in a synthetic 104 residue long peptide corresponding to the sequence of the C-terminal half of HIV-1 p24. Groups of Balb/c mice were individually primed subcutaneously with 50 µg of each of these 5 T epitope-containing peptides in Freund's incomplete adjuvant and boosted with 50 µg of a synthetic chimeric peptide. Chimeric molecules used were a 138 mer peptide consisting of the 104 residue peptide linked to an envelope peptide which has been demonstrated to contain at least one T epitope, and another 43 residue peptide containing a selected p24 T epitope linked to the same envelope sequence. Antisera were collected 14 days post challenge and assayed for their reactivity against HIV protein using Western blotting. **Results:** Antibody against envelope proteins was detected in mice primed with the 104 mer or individual T epitope-containing peptides and boosted with the 138 mer. Anti-envelope responses were also found in T epitope primed mice which were boosted with the 43 mer chimeric peptide containing the same T epitope. **Conclusion:** It appears that some T epitopes of p24 core protein can regulate antibody responses to the envelope protein.

M.C.P.42

DIPYRIDAMOLE HAS ACTIVITY AGAINST HIV-1 AND POTENTIATES THE ANTIVIRAL EFFECTS OF AZT AND OTHER DIDEHYDROXYLICOSIDES IN MONOCYTE/MACROPHAGES

Szabon, Janna*, Wahl, S.M.,* Popovic, M.*, Wahl, L.M.C.*, Garas, S.*, Fine, R.L.,* Skarlov, U.A.* and Weisand, J.N.*

*National Cancer Institute, *National Institute of Dental Research, National Institutes of Health, Bethesda, Maryland, USA

Objective: To report: 1) an inhibitory effect of dipyridamole (DPM) on HIV-1 replication in monocyte/macrophage (M/M) cultures and 2) a potentiation by DPM of the anti-HIV effects of zidovudine (AZT) and didanosine (ddC) in M/M. **Methods:** M/M cultures were prepared from peripheral blood monocytes purified either by adherence to plastic or by centrifugal elutriation. The cells were infected with HIV(HIV-1_{IIIB}/H89) and p24 antigen production was measured at intervals by ELISA. **Results:** The ID₅₀ values of AZT and ddC decreased by at least 5-fold in the presence of 2.10 µM DPM. With 0.4-0.8 µM DPM, the ID₅₀ of AZT appeared to decrease by about 2- to 3-fold. No toxicity of DPM for M/M was seen at concentrations of 10⁻² to 10⁻⁴ M, as assessed by cell counts and by the functional criterion of superoxide generation with or without stimulation by PMA. DPM did not potentiate AZT toxicity for human bone marrow promotor cells in a CFU₂ assay. **Conclusions:** DPM is widely used in the treatment of vascular diseases because of its platelet anti-aggregant and vasodilator activities. Since M/M are major reservoirs for HIV-1 *in vivo*, our findings suggest the possible utility of DPM in combination chemotherapy of HIV infections. However, clinical efficacy cannot be predicted on the basis of *in vitro* studies such as these.

Session d'attachage Poster Session

M.C.P. 49 Inhibition of *de novo* HIV infection in monocytes/macrophages by Agents which block the binding of HIV-1 gp120 to CD4. **Ferns, Carlo-Federico, Varsano, R., and Broder, S.** National Cancer Institute, Bethesda, MD, USA.

Objective: To evaluate the ability of ORTAs or recombinant soluble CD4 (rCD4) to inhibit HIV replication in cells of monocyte/macrophage (M/M) lineage. **Methods:** Peripheral blood M/M prepared by various separation techniques (in some cases cultivated in medium with 100 ng/ml GM-CSF) and U937, a monoclonal line, were exposed to HIV-1 (monocytotropic strains HTLV-III₈₉ or HTLV-III₉) in the presence or absence of ORTAs or rCD4 (produced by Genentech).

Results: Fresh M/M had relatively low amount of surface CD4 (10-15% weakly CD4⁺ by FACS). In most cases the amount of CD4 increased as the cells were permitted to mature for 3 days (GM-CSF). U937 cells were 20% CD4⁺. Despite these differences among M/M populations, ORTAs inhibited HIV replication in all M/M by 20% for up to 30 days after viral challenge, even at the lowest concentrations tested (0.01 μg/ml). rCD4 at 3 μg/ml inhibited HIV replication in all M/M populations by 20%. Also, 1 μg/ml rCD4 inhibited HIV by 75% in mature M/M and in GM-CSF-treated M/M, while somewhat less inhibition was achieved in fresh M/M. HTLV-III₉ replication was 20% inhibited in U937 by 0.1 μg/ml rCD4 and 1 μg/ml ORTAs. No consistent HIV suppression was found with ORTAs in cocultures to a different extent on CD4⁺ or with a control murine IgG1a. rCD4 inhibited HIV replication by 90% if added to M/M within 2 hours of viral challenge, while ORTAs lost its antiviral effect if added 24 hours after viral exposure.

Conclusions: ORTAs and soluble CD4, which block CD4-gp120 binding, are highly effective inhibitors of infection of blood-derived M/M by HIV, providing evidence that CD4 is the principal if not sole receptor for HIV in M/M.

M.C.P. 51 HELA CELLS STABLY EXPRESSING HIV ENV AND AIDS TOOLS FOR STUDY OF STRUCTURE, FUNCTION AND CANDIDATE GENES OF THESE HIV ENV PROTEIN PRODUCTS.

Gama Sosa, M., DeGasperis, R., Fahey, F. and Bannard, D.M.
Dana-Farber Cancer Institute, Boston, MA
and Harvard Medical School, Boston, Massachusetts, USA.

Objective: To stably express the *env* and *gag* gene products of HIV in HeLa cells, and to use such expression cell lines to isolate these gene products for structure/function analysis. **Methods:** A DNA fragment containing the *gag*, *env* and *gag* genes from the HIV-1 infectious clone pHR232 was cloned into the neomycin shuttle vector pRShCMV3. The resulting plasmid pHR232 was transfected into human cells, and transfectants (HeLa *gag/env* cell clones) were selected in G418 containing medium.

Results: Stable expression of HIV *env* was demonstrated by immunoprecipitation with AIDS patient antisera which showed only bands of molecular weights 120, 120 and 41 kD after lentil lectin chromatography. HIV *gag* expression in these HeLa cell transfectants was demonstrated for over 6 months. An indirect assay for *gag* based on synovium formation was performed as follows: HeLa *gag/env* cells were cocultured with indicator HeLa T4 containing the chromosomal source of synovial (CAT) gene under the transcriptional control of the HIV LTR (kindly provided by Drs. B. Fether and G. Fawcett). Transactivation of the CAT gene was observed after cocultivation of indicator cells with HeLa *gag/env* but not with wild type HeLa cells. This transactivation was inhibited by ORTAs and, likewise, inhibition of glycoprotein processing such as castanospermin or its analogues inhibited CAT transactivation.

Conclusions: The virus-free expression of the HIV *gag* and *env* will allow analysis of structure, function and inhibition of these gene products in a bioassay-free system.

M.C.P. 53 USE OF AZT AS A CHEMOPREVENTIVE AGENT: EFFICACY AND TOXICITY IN MURINE RENOVATED DEFICIENT (RND) MICE.
Billie, John, S., Mackley, C., Yetter, R.A., Shepko, S., Friederickson, T., Bell, W. and Riegman, J.L.
VA Medical Center, and University of Maryland, Baltimore, MD, U.S.A.

Objective: To determine if AZT therapy can protect susceptible populations from retroviral infection.

Methods: AZT was administered to C57BL/6 or NFS-1/N mice prior to challenge with LP-10MS or Cas-B-R-M M/J or retrovirus.

Results: 1) Treatment with AZT (100 mg/kg) for 2 weeks (4 weeks) protected newborn NFS-1/N mice from a single challenge with Cas-B-R-M but was not able to prevent maternal-fetal transfer of LP-10MS M/J to infected C57BL/6 mothers.

2) AZT treatment of adult C57BL/6 mice suppressed LP-10MS replication upon removal of AZT, viral replication and disease was observed in a significant percentage of the mice.

3) Mastocytosis fell dramatically in mice treated with high levels of AZT. 4) The hematopoietic toxicity was dose dependent, hyperplasia and elevations in spleen and bone marrow WBC were observed in mice treated by continuous infusion, indicating that AZT alters erythropoiesis in the absence of detectable retroviral infection.

Conclusion: The effectiveness of AZT as a chemopreventive agent depends upon the elimination of reservoirs of infection and the management of hematopoietic toxicity.

Recherche fondamentale (biomédicale) Basic Research (Biomedical)

M.C.P. 50 USE OF NUCLEIC ACID HYBRIDIZATION FOR HIV SUSCEPTIBILITY TESTING.
Robert Stewart, H., *Gibball, D., *Wilson, V., *Lentzfeld, M., *Kerning, M., *Carlson J.
University of California, Davis, California, USA and *Molecular Hybrids Inc, (MHI) Alhambra, CA, USA

Objective: Many antiviral compounds for Human Immunodeficiency Virus (HIV) infection are being studied using time consuming and tedious *in vitro* methods. We have developed and evaluated a new technological approach for antiviral susceptibility testing using a rapid and simple method for specimen processing known as "hybridizing". This technology has been adapted to successfully test the susceptibility of HIV to zidovudine (AZT).

Methods: CD4 cells (2×10^6) were infected with HIV (HIV-1) at approximately 850,000 average transcopies units (ATU). After 3 hr adsorption the cells were washed 3 x and RPMI 1640 + 10% calf serum with AZT (10⁻⁶-0.1 μM) was added. Cells were incubated for 6 days, at which time the media was removed and cells were lysed with the RNA lysis agent (RLT). Hybridization of the virus was carried out at 47°C for 2 hrs with an Ligated as an AZT probe containing 3.0 kb of the HIV genes p90-95. After a 1 hr wash at 50°C the vials were counted in a gamma counter.

Results: The inhibitory *IC*50 (ATU) for AZT by this method was <0.01 μM. This result was reproducible and paralleled RT assays and p24 Ag assays. **Conclusions:** This technology is a rapid and simple method for screening HIV. This technique should prove very useful for the rapid screening of antivirals and the study of resistance in clinical isolates.

M.C.P. 52 RECOMBINANT GRANULOCYTE COLONY STIMULATING FACTOR (r-met-HGF-CSF) AND RECOMBINANT BIRTHPOINTE (r-HSP90) MAY ABROGATE THE NEUTROPENIA AND ANEMIA OF AZT AND MAY ALLOW FOR RESUMPTION OF ZIDOVUDINE (AZT) IN PATIENTS WITH AIDS.

Mill, Steven, Minoura, S., Fink, N., McCarthy, S., Allen, K., Sosa, L., and Clerp, J.
*ADA AIDS Center, Los Angeles, CA, USA and *Angene, Inc., Thousand Oaks, CA, USA.

Objective: To see if combined AZT-CSF/HSP90 can correct neutropenia and anemia in patients with AIDS and allow for the resumption of full or higher doses of AZT.

Methods: Phase I/II Open Label Trial of r-met-HGF-CSF/HSP90 AZT in patients with AIDS/ANEMIA. Patients with absolute neutrophil counts (ANC) < 500/mm³ and hemoglobin (Hb) < 11.5 g/dl (all *g* marrow suppressive drugs including AZT = 3 weeks) were treated with r-met-HGF-CSF one daily 1000 mg until ANC of 5000 was achieved and maintained for 2 weeks. r-HSP90 (TW) was added and increased until an increase of 1.5 g/dl of Hb, over baseline was observed. Patient groups were then given 1000 mg, 1500 mg or 2000 mg of AZT per day.

Results: Eleven of 24 patients have completed. Of these, eight have completed the r-met-HGF-CSF alone phase with mean, 1500 mg, 20,449 ± 9130 neutrophils. Four have completed the combined r-met-HGF-CSF/HSP90 phase with normalization of their hemoglobin values (13.0 ± 0.8) and have resumed full dose AZT (1000 mg/d). One patient died unexpectedly and another was withdrawn for neurologic decline during this phase. Both r-met-HGF-CSF and r-HSP90 have been well tolerated. Toxicities were mild transient pain responsive to ibuprofen (2 sp), and hypokalemia and/or hypophosphatemia in 9 sp, with poor nutritional status and chronic diarrhea. Analysis of limiting dilution plasmids and lymphocyte cocultures for HIV and p24 antigens showed no significant alterations in viral expression prior to resuming AZT.

Conclusions: Recombinant-met-HGF-CSF and r-HSP90 may alter the neutropenia and anemia of AZT, is well tolerated and may allow the resumption of full dose AZT in AIDS patients without stopping HIV expression. This combined therapy may be benefit to AZT intolerant AIDS pts.

M.C.P. 54 PHOSPHORYLATION OF 3'-AZIDO-2',3'-DIDEOXYTHYMIDINE, AZIDO-2'-DEOXYADENOSINE AND AZIDO-2'-DEOXYGUANOSINE IN UNINFECTED AND HIV-1 INFECTED GENOME CELLS.
Edman, R. L., Oswald, S. J., Sommadossi, J. P., Chu, C. K., Williams, G. and Salzman, N. P.

Veterans Administration Medical Center and Emory University School of Medicine, Atlanta, Ga, USA
University of Alabama, Birmingham, AL, University of Georgia, Athens, Ga, and *Ticon Bioscience Inc., Amesbury, MA, USA.

Objective: To compare the antibiotic phosphorylation of 3'-azido-2',3'-dideoxythymine (AZido-CTB), 3'-azido-2'-deoxyadenosine (AZido-CTD), and 3'-azido-2'-deoxyguanosine (AZido-CTG) in cell culture.

Methods: Uninfected and HIV-1 infected cells were treated with Propylthiouracil (PTU), AZT, or AZido-CTB. AZido-CTB and AZido-CTD were prepared and HPLC-analyzed using a Symyxmodel 8000 detector. AZido-CTB and AZido-CTD were also analyzed to determine the amount of drug incorporated into RNA and DNA.

Results: A 3-hour pulse-labeling of uninfected GenomE cells indicated that AZT may be more rapidly phosphorylated than AZido-CTB. No such difference was seen at 24 h incubation. Both AZido-CTB and AZT accumulated 1 fold of either drug, however, generated 5-10 times lower levels of phosphorylation than did AZido-CTB. AZido-CTB and AZido-CTD were also analyzed to determine the amount of drug incorporated into RNA and DNA.

Conclusions: The observed differences in HIV-antiviral effects in cell culture, have been linked with 1 fold of either drug, however, generated 5-10 times lower levels of phosphorylation than did AZido-CTB. AZido-CTB and AZT, over 50% of total radioactivity was found in the RNA fraction. In contrast, AZido-CTD and AZido-CTG, over 90% of total radioactivity was found in the DNA fraction. These results indicate that AZido-CTB and AZT, over 50% of total radioactivity was found in the RNA fraction, while AZido-CTD and AZido-CTG, over 90% of total radioactivity was found in the DNA fraction. This indicates that AZido-CTB and AZT, over 50% of total radioactivity was found in the RNA fraction, while AZido-CTD and AZido-CTG, over 90% of total radioactivity was found in the DNA fraction.

Conclusions: Although AZT and AZT produced similar phosphorylation patterns, significantly lower levels of mono- and diphosphate of AZido-CTB were found which may explain its lower activity and toxicity in vivo.

M.C.P.67 NEUTRALIZATION OF HIV-1 BY ANTI-IDIOTYPIC ANTIBODIES

Lundl, D., Wain, B., & Johnson, P.*, and Thompson, T.*
*Mc Johnson Pharmaceutical Research Institute La Jolla, CA, USA,
**Cincinnati University

Objective: To evaluate the ability of anti-CD4 monoclonal antibodies to block anti-idiotype antibodies that are capable of binding and neutralizing HIV. **Methods:** Monoclonal antibodies (mAb) with purified OKT4A MAb and 4 weeks later with OKT4F (10 day injection protocol). The anti-CD4 antisera were assayed for anti-idiotype antibody by competition ELISA and for internal image (CD4-like reactivity, i.e. binding to HIV) using a commercial HIV antibody detection kit. To determine HIV neutralizing titres in vitro, MT-4 cells, pretreated with serially diluted antisera in 96-well microtitre plates, were exposed to HIV-1 (clarified supernatant for 2 hrs at 37°C. Cultures were incubated for 7 days and developed colorimetrically with MTT. At the end of the 7 day incubation period, supernatants were harvested and neutralization assayed immediately. Neutralizing antibody titres were detected 5-14 days post immunization. Following OKT4F, anti-CD4 and neutralizing titres were found to be slightly higher.

SERIA	ANTI-CD4		ANTI-OKT4F		NEUTRALIZING	
	ITITER	ITITER	ITITER	ITITER	ITITER	ITITER
Prebnd	<1100	<1100	<1100	<1100	<110	<110
2wk post OKT4A	ND	ND	1400	1400	ND	ND
6mo post OKT4A	11200	ND	1100	ND	ND	ND
2wk post OKT4F	ND	ND	1900	1800	ND	ND

Conclusions: Anti-idiotype antibodies were raised in response to anti-CD4 monoclonal antibodies which were able to bind and neutralize HIV, in vivo.

M.C.P.69 PHARMACOKINETICS, TOXICITY AND PROPHYLACTIC ANTIVIRAL ACTIVITY OF PMA IN FELINE RETROVIRUS INFECTED CATS

Nathans, Lawrence E., Semson, C.L., Polas, P.A., Sans, R., Hayes, K. and Kitchin, J.
The Ohio State University, Columbus, Ohio, U.S.A.

Objective: To determine the pharmacokinetics, toxicity and prophylactic antiviral activity of 9-(2-(phosphorinethoxyethyl)adenine (PMEA) in feline infectious viral infective cat. **Methods:** Pharmacokinetics and bioavailability of PMEA was determined in 6 cats at three doses. In prophylactic studies, 3 different dosage regimens of PMEA (100, 25 or 12.5 mg/kg/day) were evaluated for toxicity and antiviral activity *in vivo*. In all prophylactic studies PMEA was administered by continuous IV infusion beginning one day prior to FeLV challenge. Toxicity was evaluated as part of the prophylactic testing.

Results: PMEA administered at doses greater than 12.5 mg/kg/day continuous IV infusion were toxic to severely toxic, causing death in 3 of 7 animals treated. The most prominent clinical feature in these animals was hemolytic anemia. A dosage of 12.5 mg/kg/day PMEA administered by continuous IV infusion for 3 was prevented or delayed the onset of infection in 6 of 6 challenged animals. Moderate anemia was evident in these animals at the end of 3 wks of treatment. By comparison 7 of 7 control cats developed chronic viremia by 3 wks post challenge. All PEA treated cats remain FeLV negative after 5 wks post challenge. **Conclusion:** Though moderately toxic in cats at a dose of 12.5 mg/kg/day continuous IV infusion for 3 wks, PMEA was highly effective as a prophylactic treatment for preventing FeLV infection of cats for the period so far observed. Lower dosage regimens are currently being evaluated.

M.C.P.71 FLUORAZOLIDONE TREATMENT OF ESOPHAGEAL CANDIDIASIS IN AIDS PATIENTS.

A Gil, Z. LERJILLA, A. SANCHEZ, H. VALERIO, JL. DELA, JO. VAZQUEZ, B. Lopez, L. Mas, Madrid, Spain.

Aims of the study: To assess the efficacy and safety of Fluorazolidone in the treatment of esophageal candidiasis in AIDS patients. **Methods:** 18 patients (15 male and 3 female) were included. Mean age was 28 years (range: 19-41). There were 10 (55%) with CD4 counts < 200/mm³ and 8 (45%) with CD4 counts > 200/mm³. Esophageal candidiasis was confirmed by endoscopy, biopsy and/or culture. Therapeutic regimen: 200 mg (100 mg) followed by 100 mg orally p.o. for 4 weeks. Endoscopic control was carried out at the end of the treatment. A follow up visit 1 month after treatment was scheduled. General drug surveillance was performed in all patients. Therapeutic evaluation was performed in 32 patients, although only 20 completed treatment. The study was carried out over a 14 month period (February-December 1985). During this time 8 patients died, 4 in the protocol stage and a further 4 after completing treatment, all of these due to other opportunistic infections. **Clinical and endoscopic cure** was achieved in all patients; in most, clinical picture resolved within a week. In 2 patients an esophageal relapse occurred 1 month after treatment. Re-treatment with Fluorazolidone achieved cure again. In a further 3 patients esophageal relapse occurred 1 month after treatment. In 1 patient, relapse occurred 2 months after treatment. In all cases, relapse was observed. Elevations of liver enzymes: discrete (19 patients), moderate (5 patient) and severe (1 patient), the latter leading to drug discontinuation, were reported. Increases of alkaline phosphatase without hyperbilirubinemia (23) was the most commonly observed adverse effect; however, it has to be taken into account that most patients had coexisting opportunistic infections and/or received antipneumocystis carinii chemoprophylaxis. **Conclusions:** 1) Fluorazolidone has been shown to be an effective and safe treatment of esophageal candidiasis in AIDS patients. 2) A 4 week treatment may be sufficient in this condition. 3) An effective prophylactic regime with Fluorazolidone in these patients needs to be desirable.

M.C.P.68 PHOSPHONATE INHIBITS FELINE RETROVIRUS INFECTION IN CATS

Shannon, Cheryl L., Weisbrod, S.E., Sans, R., Nagode, L., Hayes, K., Malins, L.L., & Johnson, P.*
The Ohio State University, Columbus, Ohio, USA.

Objective: To determine *in vitro* and *in vivo* efficacy and toxicity of phosphonate (PPA) against feline leukemia virus (FeLV). **Methods:** PPA-induced inhibition of FeLV infection feline lymphoid cells (3201) was determined by reverse transcriptase (RT) assay. Pharmacokinetic studies were performed in young and adult cats. For prophylactic studies, six cats received 1000 mg/kg/day PPA as a continuous IV infusion for 1 day prior to and 4 weeks post-FeLV challenge. Six control cats received 120 U/kg/day heparin in saline. Six cats served as challenge control. **Results:** Histometric determinations were performed on the distal radius of young and adult cats given 1000 mg/kg/day PPA and on age-matched controls. **Conclusions:** FeLV infection of 3201 cells was inhibited by >90% at 64 nM PPA as measured by RT activity. Young cats exhibited a higher (2x) plasma clearance of PPA than adult cats, which was attributed to enhanced bone accumulation. Mean oral bioavailability was 35%. Continuous IV infusion of PPA (1000 mg/kg/day) prevented FeLV viremia in 4 of 6 cats. Six of 6 untreated challenge cats demonstrated FeLV viremia by 3 weeks post-inoculation. Plasma biochemical changes prevented in PPA treated cats compared with sham-operated controls included: increases in calcium and decreases in phosphorus, alkaline phosphatase and calcitriol. Bone histomorphometry revealed rickets-like lesions in young cats and osteomalacia in adult cats given 1000 mg/kg/day PPA for 14 days. **Conclusion:** PPA prevents FeLV infection *in vitro* and *in vivo*. High doses of PPA induce rickets in young cats and osteomalacia in adult cats.

M.C.P.70 PHOSPHATE TRIESTER DERIVATIVES OF AZT AS INHIBITORS OF HIV

McDonnell, Chris J., Devine, K., O'Connor, S.M., Galpin, B.H., Williamson, J.B., Kitchin, D.,
*University College, London, UK, **St Mary's Hospital Medical School, London, UK.

Introduction: A series of 20 phosphate triester derivatives of AZT have been tested against HIV-1 (SF115 III, RP strain) in the C8662 CEM-7 cell line. These compounds have been designed as more suitable substrates in order to overcome some of the limitations shown by AZT and other nucleoside analogues; such as kinase dependence, metabolic instability and poor membrane penetration. It has been found that asymmetrically substituted phosphates of AZT are active antiviral agents especially when one phosphate moiety is an amino-linked amino-acid, and the other is an aliphatic chain. **Results:** Depending upon the nature of the substituents large differences in the antiviral effect are observed. In the compounds below changes in the aliphatic chain (X) and the amino acid (Y) gives a range of activities (IC₅₀) from 3 - 100 nM. Studies to investigate the nature of the block in HIV replication was in progress.

UCL No	X	Y	Z	IC ₅₀ (nM)
UCL 11	MeO	MeVal	Et	300
UCL 12	MeO	MeVal	Me	10
UCL 23	MeO	MeVal	Me	30
UCL 24	EtO	MeVal	Me	100

M.C.P.72 RECOMBINANT SOLUBLE CD4 AS A VEHICLE TO DELIVER RIBICIN TO HIV-ENVELOPE EXPRESSING CELLS

Cochran, Nancy A., Collinson, A.H., Liu, L., Miller, C.,
V.**, Ross, N.D.,** Golsharif, V.S.,** Tamura, S.,** Cambridge, UK, *Biogen, Inc., Cambridge, MA, USA.

Objective: To assess the effectiveness of recombinant soluble CD4-blocked ribicicin conjugate (cd4-rib) as a potential drug for the elimination of HIV-envelope expressing cells, *in vitro*. **Methods:** Intact ricin was covalently modified such that it retains ricin's ability to efficiently penetrate intracellular and plasma membranes but can no longer bind to cells through its natural binding sites. Blocked ricin (rib) was then covalently linked to rH8 and the conjugate was tested in a number of *in vitro* assays. Cytotoxicity and specificity of killing were tested on CD4 cells and HIV-infected human T cells. Binding efficiency of rH8-r8 to gp120 was assessed in an RIA using recombinant gp120 (rgp120). **Results:** rH8-rib conjugate retained the capacity to bind to gp120 in an RIA. The cytotoxicity of the rH8-r8 conjugate was specific to HIV-envelope expressing cells. gp120-expressing CD4 cells were effectively killed between 10⁻⁶ and 10⁻¹⁰ M rH8-rib. Unmodified rH8 completely blocked the rH8-rib mediated killing. Uninfected CD4 cells and CD4 cells expressing a non-related recombinant protein were not affected at these concentrations. Experiments with HIV-infected human T cells confirmed these observations. **Conclusions:** We demonstrate that blocked ricin conjugated to recombinant soluble CD4 selectively kills HIV-envelope expressing cells, *in vitro*, at concentrations that are achievable *in vivo*.

M.C.P.79 INHIBITORY EFFECT OF SULFATED AMPHOTERICIN B ON THE REPLICATION OF HIV IN VITRO

Yoko Otake, K. Miyase, H. Shimokawa, M. Kasai, H. Ohsa, H. Kimita and T. Kurimaru*
Osaka Prefectural Institute of Public Health, Osaka, Japan,
* Yottori University, School of Medicine, Yonago, Yottori, Japan.

Amphotericin B methyl ester (AME), a water-soluble derivative of amphotericin B, showed inhibitory effect on HIV. However, the cytotoxicity of AME was relatively high. Newly synthesized sulfated amphotericin (SA), which was expected to show low toxicity and anti-HIV effect, was examined in vitro.

SA at the concentration of 80 µg/ml completely suppressed the HIV-induced cytopathic effect in MT-4 cell line which carried HTLV-1. Furthermore, antiviral effect was also observed when SA was only present at absorption period of HIV. Production of HIV was also suppressed in peripheral blood mononuclear cells (PBMC) infected with freshly isolated HIV. The cytotoxicity of SA was low (50% cytotoxic dose for MT-4 cells and PBMC was 20 µg/ml). When HTLV-1 and HTLV-2/HIV cells were co-cultured, multimerized giant cells appeared at the concentration of SA more than 200 µg/ml, the formation of giant cells was inhibited. SA at the concentration of 200 µg/ml inhibited 80% of reverse transcriptase activity of HIV, HIV was exposed to SA for 2h. At concentration of 200 µg/ml, SA reduced infectivity of HIV. These anti-HIV effect of SA was considered to be caused by the inhibition of HIV binding to the cells and reduction of infectivity of HIV.

M.C.P.81 ASSESSMENT OF THE THERAPEUTIC ACTIVITY OF PROSOPHOLACTONE-TRITHYR ADENINE AND ACETAMINOPHEN (AZT) IN A MURINE MODEL OF ACQUIRED IMMUNODEFICIENCY DISEASE

J. David Gagnier*, Erik De Clercq*, Alan Metzger*, J. Maria-Rot Hochreppel**, University of South Carolina, Columbia, SC, USA; **CIMA-GLIGI, Basel, Switzerland; **Katholieke Universiteit, Leuven, Belgium.

The murine model of acquired immunodeficiency disease (AIDS) was used to evaluate the therapeutic potential of two nucleoside analogues, proso-pholactone (proso) and acetylmethoxyadenine (AZT). The antiviral activity of proso was compared to AZT in mice receiving drug either immediately following infection or at later times in disease progression. Both AZT (oral, 30 mg/kg) and proso (parenteral, 25 mg/kg) were effective in preventing the development of disease when administered daily beginning on the day of infection. In contrast, neither drug alone was effective in modifying disease outcome when administered several weeks after viral infection. This was not, however, the case when alpha interferon was used in combination with proso. Disease outcome was modified when infected mice put on a continuous regimen of proso (25 mg/kg) and alpha interferon (5 x 10⁶ IU/kg). A number of humoral and cellular immune functions were severely depressed 60 days after LP-200 infection. Immunosuppressed mice were highly susceptible to acute (lethal) infection with HIV-1, while unappreciated immunocompetent littermates were not. Proso was as effective as acyclovir in the treatment of HSV-1 infections in immunosuppressed mice. The data suggest that the *in vivo* antiviral activity of proso is comparable to AZT. An important advantage of proso is its usefulness in the therapy of opportunistic herpesviral infections.

M.C.P.83 EXPERIMENTAL AZIDOThYMIDIN (AZT) PULSE THERAPY LEADS TO ADEQUATE AND PROLONGED LEVELS OF INTRACELLULAR AZT-TRIPHOSPHATE (AZT-TP)

Yoshitaka Kuzuhara, M. Nishi, Y. Jono, R. Sasagawa, M. and Lohby, R.
Department of Infectious Diseases, Zurich, University Hospital, Zurich, Switzerland

Objectives: Our earlier studies showed that single daily AZT pulse exposure effectively inhibit HIV-1 and HIV-2 replication in vitro. We have now evaluated intracellular AZT metabolites both in pulse and continuous therapy models.
Methods: Based on earlier dose finding studies using a newly developed *in vivo* model, duplicate cultures with peripheral blood mononuclear cells were either exposed to 10 µM AZT (45 µg/ml) (H-AZT) for 60 min. or to 1 µM AZT (5 µg/ml) (P-AZT) for one day. After 24 h in culture, cellular extracts were analyzed by HPLC. HIV-1 and infectivity was plasma levels after a single daily oral dose of 1 g AZT was performed using a computer model (throughout Wellcome, UK).

Results:

Treatment	Acetaminophen (pmol/10 ⁶ cells)	Diphosphate	Triphosphate
24h 1 µM AZT	33	0.4	0.9
1h 10 µM AZT	33	2.0	2.0

Mathematical simulation of a single oral dose of 1 g AZT revealed plasma levels of 10 µM or higher for 60 min.

Conclusions: Single day *in vivo* pulse therapy leads to adequate intracellular levels of AZT-TP thus explaining the observed anti-HIV effect of this regimen. The effect of a single daily oral dose of 1 g should be explained in clinical trial.

M.C.P.80 INHIBITION OF HUMAN IMMUNODEFICIENCY VIRUS (HIV-1) REPLICATION BY SYNTHETIC OLIGONUCLEOTIDES

Agnes S. Spector*, Sun, D.**, Sarin, P.S.**, Zemanick, P.C.*
* Worcester Foundation for Experimental Medicine, Worcester, MA, U.S.A.
** Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD, U.S.A.

A number of approaches are currently being investigated for treatment of human immunodeficiency virus (HIV) infected patients with acquired immunodeficiency syndrome (AIDS). We have used antisense oligonucleotides to selectively block virus replication by competitive hybridization (Zemanick et al., PNAS 79:320, 1982). We have investigated three classes of phosphate backbone modified oligodeoxynucleotides viz. methylphosphonate, phosphotriphosphate and various phosphoramidates for their antiviral activity. The inhibition of HIV-1 expression in presence of antisense oligonucleotides was carried out by infecting 90 or MDL-3 cells with HIV-1 (HIV-III), or HIV-III-3, 3. Studies were carried out by simultaneous addition of viral and antisense oligonucleotides to cells in culture. After four days, the cells and supernatants were examined for the level of HIV expression by counting specific (MDL-3 cells), viral antigen expression and cell viability. The sequences tested were complementary to splice acceptor and donor sites of HIV RNA. Inhibition of up to 100% HIV-1 replication was observed at 1 to 5 µM concentration of these oligonucleotides. Acute toxicity studies in mice and rats show a relatively low level of toxicity. These studies suggest that phosphate backbone analogs of oligonucleotides are potent inhibitors of HIV-1 replication and could be potentially useful in the treatment of AIDS.

M.C.P.82 INHIBITION OF HIV REPLICATION BY ALPHA INTERFERON

Gailb. Marilyn S., Brian, R., Threether, R., Pagano, J.S. Univ. of W.C., Chapel Hill, NC, USA

Objective: To investigate the mechanism of inhibition of HIV replication by interferon alpha 1b.
Methods: T cells were infected with HIV and treated with interferon alpha 1b or chronic producing cell lines, HTLV-1 and HTLV-2. HIV production was assayed by reverse transcriptase activity and p24 concentration. Cellular extracts were assayed by western blot and p24 ELISA; cells were examined by electron microscopy.

Results: In the C3 line, the EC₅₀ was 5.5 U/ml and EC₉₀ was 274 U/ml. We attempted to determine if high concentrations of intracellular particles were accumulating by assaying extracellular p24 and p24 levels, the intracellular p24 and viral protein levels, or by EM. In cells treated with IFN, the p24 and p24 levels decreased proportionally, whereas the intracellular p24 levels remained nearly constant. Western blots of cellular protein showed only a small 2X decrease in viral proteins; the amount of processing of precursor to p24 and p17 did not change in the presence of interferon. By EM, the cells treated with 512 U/ml showed almost no virus budding into extracellular spaces; however, no intracellular particles could be seen.

Conclusion: Thus, inhibition of this human retrovirus by alpha interferon does not appear to involve decreased processing of viral proteins or intracellular core formation.

M.C.P.84 COMPARISON OF AUTHENTIC AND ENZYMICALLY ACTIVE HIV AND HIV2 PROTEASES IN SACCHAROMYCES CEREVISIAE

Changsheng Serrino*, Babu, L.*, Barr, P.**, and O'Neil, C.*
*University of California, Davis, California, USA
**Chiron Corporation, Emeryville, California, USA

Genetic analysis of the HIV genome has revealed a 99 amino acid protease encoded at the 5' end of the pol gene which is essential for the growth of *gag* and *gag-pol* polyoma virus. The protease encoded by HIV1 and HIV2 genomes are 41.5% identical in their amino acid sequences. Functional and structural studies of these viral proteases require quantity levels of the authentic enzyme which can be achieved by heterologous expression of the cloned gene. An expression system employing the ADHI2(LA)PHI promoter was used to over-express both retroviral proteases intracellularly and extracellularly. In order to determine the localization of the enzymes, two different DNA fragments were fused to DNA encoding the 5' cytosine alpha factor signal/leader sequence. These viral fragments encode either the mature 99 amino acid protease or a precursor containing additional residues at the N and C termini of the protease in order to monitor self-processing. For intracellular localization, retroviral sequences encoding the protease were fused to the C-terminus of human superoxide dismutase. Expression of mature HIV1 and HIV2 proteases was demonstrated for all systems by immunoprecipitation in virus supernatants or cellular extracts. Self-processing activity was confirmed by amino acid sequence analysis of the mature enzyme. The HIV1 protease has been purified and structural studies have been initiated. Extracellular localization of the protease has permitted purification to homo-purity using a size exclusion procedure. From 20 liters of media 1 mg of protein can be purified. This protease is active on both native and synthetic peptide substrates. Both the HIV1 and the HIV2 protease correctly process HIV1 *gag* polyprotein precursor. Results indicate that yeast cells provide an efficient expression system for the overproduction of active forms of HIV1 and HIV2 proteases.

M.C.P.85 IMMUNOLOGIC EFFECT AFTER SINGLE DOSE ATROGEN (ANALIGEN) IN HEALTHY VOLUNTEERS

Remick, Carol; Liewman, F.; Ye'o, P.; Margolis, J.; Paraganan, M. Decty, S. Johns Hopkins University, Schools of Medicine and Hygiene and Public Health, Baltimore, Maryland, U.S.A.

Objective. To evaluate the degree and time course of immunologic stimulation after a single 200 mg intravenous (i.v.) dose of atrogen, a attenuated DNA, in healthy volunteers.

Methods. This was a randomized, double-blind, inpatient study in four healthy volunteers. Subjects served as their own controls, randomized to one of two treatment sequences, atrogen or placebo followed 7 days later by placebo or atrogen. We measured a- and y-interferon, 2'-5' oligoadenylate synthetase (3AS), isoperitin, T cell subsets (CD4, CD8, CD4/CD8, Leu 11, Leu 15), natural killer cell (NK) activity and lymphocyte proliferation (1F) after exposure to soluble antigen (SM, tetanus toxoid, pokeweed mitogen).

Results. No symptomatic, clinical or laboratory changes were noted in either drug or placebo periods. Neither a- or y-interferon were measurable during the 5 days following atrogen infusion. Biochemical markers of interferon action, specifically, 3AS and T cell subsets, were not significantly different after atrogen dosing compared to placebo. Neither the NK nor 1F assays showed any differences in response between atrogen or placebo treatments.

Conclusions. Arogen induces no immunologic enhancement in the parameters measured after a single 200 mg i.v. dose in healthy volunteers.

M.C.P.86 STUDIES ON ANTI-HIV ACTIVITY AND METABOLISM OF 2',3'-DIHYDROCAVORTINE (d6C)

Remick, Lionel; Basse, M. E.; and Mian, M. A.**
Mount Sinai Medical Center, Miami Beach, Florida, USA, **Sylvester Comprehensive Cancer, University of Miami, Miami, Florida, USA.

Objective. To study the anti-HIV activity and metabolism of d6C.

Methods. The anti-HIV activity of d6C was determined by a syncytium-inhibition assay using MT-2 cells and by the inhibition of reverse transcriptase activity in H9 HIV-infected cells. In drug uptake studies, cells were exposed to 10⁻⁶M d6C for predetermined periods. Cells were isolated by centrifugation through an oil layer and the intracellular radioactivity was determined. In metabolite studies, drug treated cells were extracted with aqueous methanol and the extracts were analyzed by anion exchange and C18 reverse phase HPLC procedures.

Results and Conclusions. Data indicate that d6C is equivalent to ddC or ddI in its anti-HIV activity. Dexamethasone and dexamethasone diphosphate (d6D) inhibited HIV activity of d6C, whereas 8-aminocaproic acid failed to enhance. In drug exposed cells, the intracellular radioactivity increased over time and reached a plateau at 30 minutes. Addition of an excess of d6C or d6D reduced the uptake of d6C by 25-40%. Metabolic studies indicate that d6C enters the cell and is metabolized to guanine which is further metabolized to GMP, GTP, and dGTP. Under the experimental conditions employed, we were unable to detect the formation of 12-oxo-d6C. These observations raise the question regarding the importance of this metabolite's role in the anti-HIV activity of d6C. (Supported by IVAL Corp. and NIH U01-A123696).

M.C.P.87 THE ANTIVIRAL EFFECT OF BERTRAN SULFATE (BES) IS HIV STRAIN DEPENDENT

Remick, Lionel P. and Basse, M. E.*
*Mount Sinai Medical Center, Miami Beach, Florida, USA.

Objective. To study the anti-HIV activity of BES using different isolates.

Methods. The anti-HIV activity of BES (10⁻⁶ M, 5000) were investigated using a syncytium-inhibition (MT-2 cell) assay. The peripheral blood HIV strains studied were: HIV-1 (IIIB (lab strain), TN (cell-type), WP 30 (clone) and HIV-2 (ROD (clone)). Syncytium-forming units, cell viability, and HIV (cellular p24 Ag) were utilized as measures of HIV expression. The log₁₀ concentration of HIV was standardized by limiting dilution and sensitivity to AZT. Combinational effects of BES and ddRNs (AZT, ddC, ddI) were analyzed and a fractional inhibitory index calculated.

Results. The higher the MW of BES, the more potent the anti-HIV effect. The ED50 was greater than 1µg/ml for all BES. The ED50 of BES was HIV strain dependent [ED50 (µg/ml): IIIB (5-21), TN (50-300), WP 30 (18-22), ROD (17-45)]. The anti-HIV effects of BES (8K and ddRNs) were synergistic. However, the combination of BES (5000) and ddRNs were synergistic (therapeutic range of BES) or antagonistic (sub-therapeutic range of BES) when using HIV-1 TN.

Conclusions. The anti-HIV activity of BES is strain and MW dependent. The combination of BES and ddRNs may yield synergistic/antagonistic effects. (Supported by IVAL Corp. and NIH U01-A123696).

M.C.P.88 IN VITRO ACTIVITY OF ZIDOVUDINE (AZT) AND COMBINATION WITH OTHER ANTIVIRAL DRUGS AGAINST HIV-1

Remick, Lionel P. and Basse, M. E.*
*Mount Sinai Medical Center, Miami Beach, Florida, USA.

Objective. To determine if zidovudine inhibits HIV replication in vitro

independently of other antiretroviral drugs. The effect of zidovudine (10⁻⁶ M) on HIV-1 replication was determined in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) using a syncytium-inhibition assay. The effect of zidovudine on HIV-1 replication was also determined in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) using a syncytium-inhibition assay.

Results. Zidovudine (10⁻⁶ M) inhibited HIV-1 replication in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) in a dose-dependent manner. The effect of zidovudine on HIV-1 replication was also determined in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) using a syncytium-inhibition assay.

Conclusions. Zidovudine (10⁻⁶ M) inhibited HIV-1 replication in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) in a dose-dependent manner. The effect of zidovudine on HIV-1 replication was also determined in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) using a syncytium-inhibition assay.

Table 1: Fractional Inhibitory Index (FII) for HIV-1

Drug	10 ⁻⁶ M	10 ⁻⁷ M	10 ⁻⁸ M	10 ⁻⁹ M	10 ⁻¹⁰ M
Zidovudine	0.50	0.50	0.50	0.50	0.50
ddC	0.50	0.50	0.50	0.50	0.50
ddI	0.50	0.50	0.50	0.50	0.50
ddR	0.50	0.50	0.50	0.50	0.50
BES	0.50	0.50	0.50	0.50	0.50

Table 2: Fractional Inhibitory Index (FII) for HIV-1

Drug	10 ⁻⁶ M	10 ⁻⁷ M	10 ⁻⁸ M	10 ⁻⁹ M	10 ⁻¹⁰ M
Zidovudine	0.50	0.50	0.50	0.50	0.50
ddC	0.50	0.50	0.50	0.50	0.50
ddI	0.50	0.50	0.50	0.50	0.50
ddR	0.50	0.50	0.50	0.50	0.50
BES	0.50	0.50	0.50	0.50	0.50

Conclusions. Zidovudine (10⁻⁶ M) inhibited HIV-1 replication in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) in a dose-dependent manner. The effect of zidovudine on HIV-1 replication was also determined in the presence of ddRNs (ddC, ddI, ddR) and BES (10⁻⁶ M, 5000) using a syncytium-inhibition assay.

M.C.P.89 SUPPRESSION AND CHARACTERIZATION OF CHIMERIC PROTEINS LINKED TO HUMAN IMMUNOGLOBULIN HEAVY CHAIN CONSTANT REGION

Minkami, Tamio; Smith, C.D.; Sawyer, S.A. and Noss, R.

Laboratory of Viral Treatment of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD 20892, USA

Objective. To express and characterize the properties of chimeric proteins composed of human CD4 and human immunoglobulin G (IgG) heavy chain constant regions for the potential therapeutic use of these proteins as new targeted anti-HIV agents.

Methods. The chimeric proteins were produced using a vaccinia virus-based expression system and tested for the binding properties to various ligands and antibodies against each domain.

Results. Three types of chimeric proteins with different lengths (1-109, 1-178, and 1-372) of the CD4 extracellular region linked to human IgG1 heavy chain constant regions were designed and expressed in CHO-1 and RPMI8226, a human myeloma cell line secreting a Ig light (lambda) chain. The chimeric proteins expressed in both cell lines bound to the HIV-1 gp120, CD44 (anti-CD4), an anti-human IgG(Fc) polyclonal antibody, and Protein A-agarose. The chimeric proteins which were expressed in RPMI8226 formed complexes with human Ig light chains synthesized by the host cell line. **Conclusion.** The CD4-IgG chimeric proteins had the expected binding properties of the domains used for their construction. The chimeric proteins when co-expressed with human Ig light chains formed complexes which might have structures analogous to that of natural immunoglobulin molecules.

M.C.P.90 ANALYSIS OF 3'-AMINO-2'DEoxyCAVORTOSINE INHIBIT HIV-1 REPLICATION

Lee, Raimond; H. Vanden Berghe and G. Badi. *Department of Medicine, Washington University, Biological Sciences Department, St. Louis, Mo., USA

Objective. Several different nucleoside analogs have been demonstrated to inhibit retroviral DNA-dependent RNA polymerase activity in preference to cellular DNA-dependent DNA polymerase. This study analyzed the anti-HIV-1 activity and host cell toxicity of 3'-amino derivatives of 2'-deoxyadenosine.

Results: Reverse transcriptase (RTase), PAINS 2'-phosphothriphate, and 3'-amino-2'-deoxyadenosine triphosphate all inhibited HIV-1 replication in acutely infected cells at concentrations at least 10-fold lower than those which inhibited cell growth. No antiviral effects were seen with 96-dithiopyridine, adenosine, or propovirin. In chronically infected cells, no antiviral activity of PAINS could be detected. The effect of PAINS was demonstrated at an early step in HIV-1 replication, most likely reverse transcription.

Conclusions: 3'-Amino nucleoside analogs are a novel class of inhibitors of HIV-1 replication which require further analysis in cell culture and animal studies.

M.C.P.91 SULFATED CHITOSAN INHIBITS HIV. *Maria McClure**, Cecilia Whitford*, Richardes Chongroo-Poppe*, Donald M. Nelson*, Donald Derwent*, and Robin A. Weiss*. ¹Institute of Cancer Research, Harlow, Essex, U.K. ²Royal Free Hospital, Belsize Park, London, U.K. ³Harlow Hospital, Du Cane Road, London W11 0BQ, UNITED KINGDOM

Objectives: To test sulfated polysaccharides for evidence of antiviral activity.

Methods: The effect of drugs on HIV infection was assessed by syngeneic cocultivation, RT and p24 antigen synthesis on lymphocytic and monocytic cells and on CD4-transfected HeLa cells.

Results: The compounds will be defined and data presented to show that:

- The degree of sulfation is important for antiviral function.
- The compounds, one of which has been newly synthesized, inhibit by 10,000 fold on the CR166 infectivity assay a wide range of HIV-1 isolates.
- HIV-2 was inhibited by one compound, but not as strongly.
- There is low cell toxicity and no adverse effect on protein synthesis or T-cell function.
- The drugs themselves appear to have a cytotoxic effect on PBL.

M.C.P.93 SYNTHESIS OF NEW SUGAR-FLUORINATED GUANOSINE ANALOGUES AS POTENTIAL ANTI-HIV AGENTS

Puech, F.; Gosselin, G.; De Clercq, E.; Jabeck, J.-J.
* UA 488 du CNRS, USTL, 34050 Montpellier Cédex 1, France
** Katholieke Universiteit, Leuven, Belgium

Presented by Guy, Roger, Université de Nice, France

Objective: Purine nucleosides fluorinated in the sugar moiety have been not very investigated owing to the difficulty in their synthesis. Here we report the synthesis of hitherto unknown fluorinated analogues of guanosine and their evaluation as potential anti-HIV agents.

Methods: The synthesis of 9-(3-deoxy- and 2,3-dideoxy-3'-fluoro-2'-cytidyluronyl)guanine (1) and (2) was accomplished by a multi-step approach involving prior preparation of a suitably protected fluoroguanosine, 3'-deoxy-3'-fluoroguanosine (3) was prepared by reacting the corresponding nucleoside of xylol configuration with (diethylamino)azluril trifluoride. The mixture of 9-(3-deoxy-2'-fluoro-9- α -arabino)uronyl)guanine (4) and 9-(2-deoxy-2'-fluoro-9- β -xylo)uronyl)guanine (5) was obtained by ring opening of the lyxo epoxide of guanosine.

Results: The compounds 1-5 were evaluated in HIV infected MT4 cells. Only the mixture of 4 and 5 was found to inhibit significantly viral replication.

M.C.P.95 ANTIRETROVIRAL ACTIVITY OF AN AQUEOUS EXTRACT OF HYDRANTHUS AFRICANA

Amadi B. Pabon*, Blaise M. Nkomo, A. and Hoggan, M.D.*
*NIAD, ** NCI, Bethesda, MD, USA

Objective: To study the anti-retroviral effect of an aqueous extract of the Indian Ayurvedic medicinal plant, *Hydranthus africana*.

Methods: An ethoacetic extract of dried powdered *Hydranthus africana* (HA) was prepared by vortexing followed by sterile filtration. HA extract was diluted 1:200 in 1R80 by addition to tissue culture medium. The effects of the HA on HIV-1 infection were studied by use of a syngeneic fusion assay in SupT1 cells, plaque formation in M14 cells and kinetics of virus production and cytotoxicity in M14 cells and PBLs. The effects on murine leukemia viruses (MuLV) were studied for MoMuLV and HIV in NIH 3T3 cells. Virus yield was assayed by determination of reverse transcriptase production, and for HIV-1, production of focus-forming units (ffu).

Results: A 1:200 dilution of HA resulted in a greater than 80% reduction in HIV-1 induced syncytium formation in SupT1 cells and a similar inhibition of plaque formation in M14 cells. In suspension cultures, HA treatment resulted in a 2-3 day delay in the appearance of HIV induced cytopathic effect and cell death in M14 cells. No comparable delay of cytotoxicity was observed in PBLs. In studies of MuLV infection, HA resulted in an 85-90% decrease in virus yield as monitored by RT production and similar decreases in the production of HIV-1. Studies of the mechanism of antiviral effect in the M14 system showed that HA was not directly cytotoxic and did not inhibit virus adsorption. Protection by removal of HA did not inhibit MuLV yield suggesting that HA was not acting as an interferon inducer.

Conclusions: An aqueous extract of *Hydranthus africana* appeared to inhibit the replication of HIV-1 and MuLVs in several different assay systems. The degree of anti-HIV effect varied in different cell types further mechanistic studies and biochemical characterization of active compounds will be required before its potential usefulness can be ascertained.

M.C.P.92 CSF FROM PATIENTS WITH EARLY HIV INFECTION PRODUCES INTRACELLULAR CELL KILLING IN VITRO: PREVENTION BY PEPTIDE T Nary, J.M., Bremmen, D.R., Salazar, A., Martin, A., Ruiz, M.R. and Tardieu, A. ¹INSERM, U. 105, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

Objective: To test for the presence of gp120 the neuronal killing activity in CSF from seropositive patients and the ability of peptide T to prevent CSF-induced neurotoxicity.

Methods: Twenty-eight cerebrospinal fluid samples from neurological controls and HIV-infected individuals were tested (to the investigator) in murine hippocampal cultures. HIV+ individuals had been referred for neuropsychological evaluation and 83% were in Walter Reed Stages 1-5. All individuals received a comprehensive neuropsychological and neurological evaluation at the time of the spinal tap and 6 months later. CSF samples were diluted 10,000-fold and incubated for five days in the presence and absence of peptide T. Previous studies have shown that the envelope protein of the HIV, gp-120, is potently neurotoxic in this developing neuronal culture. VIP neurotoxicity, peptide T and monoclonal antibodies against mouse CD4, prevented gp120-induced neuronal cell death (Bremmen et al. *Nature* 338:529-52, 1988).

Results: CSF from 9 out of 18 HIV-infected individuals showed significant (>20% of control) in vitro neuronal killing activity which was blocked by peptide T. Only one multiple sclerosis case out of 10 neurological controls had significant neuronal killing. **Conclusion:** The ability of CSF to potently kill neurons in culture is associated with HIV+ individuals. Peptide T prevents CSF-induced toxicity in vitro. These data are consistent with our previous suggestion (Bremmen et al. *Drug Development Research* 13:361-369, 1986) of the causal role of gp120 in neuropsychiatric/neurological deficits of HIV.

M.C.P.94 POPULATION PHARMACOKINETIC BEHAVIOR OF ZIDOVUDINE (AZT) IN PATIENTS WITH AIDS
Elmer, J., DeGroot, M., Epstein, H., Staszko, and The Participating Centers for AIDS Research, University of Maryland and the New Cooperative Studies, Baltimore, MD, and the University of Colorado, Denver, CO, USA

Objective: There is little information on the clearance of AZT. The which is available has been generated in populations of patients with AIDS. First experience with other compounds has led to the prediction of a drug to be cleared primarily by the disease state of the population in which it is administered. As we were performing a large, multicenter, randomized, double blind evaluation of AZT in patients with AIDS with zidovudine (AZT) cells, we decided to evaluate the pharmacokinetics of AZT in this population. Blood was obtained for AZT assay on a scheduled and random basis from all study patients, remaining the blind. Serum AZT concentration was determined by HPLC. Seventy-seven patients had more than one serum specimen with available AZT, with a total of 277 specimens suitable for analysis. In order to derive the information in the most methodically correct fashion, point estimates of population pharmacokinetic parameters were sought using the program NONMEM (non-linear mixed effects modeling). A one compartment open model with first order absorption and first order elimination from the central compartment was employed. Mean Cl_{CR} (ml/min) of 70, volume of distribution (V) and absorption Rate Constant (Ka) were the estimated parameters. A proportional error model was employed for all observed parameters. Mean Cl_{CR} was 70 ml/min, the elimination rate constant was 0.105 (1/hour) (95% CI 0.083, 0.136) and the volume of distribution was 145 (liters) (95% CI 100, 200). The mean Cl_{CR} was very large, with a broad 95% confidence interval, leading to large interpatient variability. Estimates of individual variation (CV) were not robust, but did not differ on the estimation of the system parameters. The population approach resulted in a fit to the data which was excellent. The larger volume of distribution noted is probably a function of studying healthy patients with larger body masses. It is important, because it is normally difficult to obtain good pharmacokinetic information on drug disposition in the clinical setting. AZT Phase I trials typically enrolled only 3-6 patients. The population modeling approach means that the more broadly employed as newer agents for therapy of HIV and HIV-related disease are evaluated.

M.C.P.96 ACTIVATION OF THE ANTI-HIV AGENT 3',3'-DIETHOXY-2',3'-DIISOBUTYRIDINE (D4T) BY HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) IN CULTURE.

Hsu-Tao Ho, N. Yung and M.J.M. Hitchcock
Bristol-Myers Pharmaceutical Research and Development Division, Wallingford, Connecticut, U.S.A.

Objective: To compare metabolism of D4T with AZT in resting and phytohemagglutinin (PHA)-activated human PBMC.

Methods: PBMC were prepared by sedimentation of fresh whole blood in a dextran gradient and the cell suspension tubes with separation (5 mg/ml) was for 12 h, and the PHA was then washed out. After incubation with 2 μ M radiolabeled D4T or AZT, cells were washed and extracted with 60 % methanol, and the extracts were fractionated by anion exchange HPLC.

Results: In resting PBMC incubated with 2 μ M compound for either 24 or 48 h, cell-associated D4T and AZT were both detected at close to the intracellular concentration, but no phosphorylated forms of either compound were observed (detection limits of 1 and 20 nM for D4T and AZT, respectively). In activated PBMC at 24 h, 55 % of the phosphorylated D4T was present as the triphosphate. Its intracellular concentration was estimated at 100 nM, which is above the K_i for HIV reverse transcriptase. By contrast, the only phosphorylated form of AZT detected was the monophosphate (about 27,000 nM) and the di- and triphosphates were not detected. The results indicate that the rate of phosphorylation of D4T is much faster than that of AZT.

Conclusion: These results demonstrate a significant difference between the metabolism of D4T and AZT in activated PBMC. This may translate to a different, and possibly better, toxicity profile in vivo.

THREE DRUG SYNERGISTIC INHIBITION OF HIV-1 REPLICATION BY RECOMBINANT ZIDOVUDINE (AZD), ZIDOVUDINE (AZT), AND RECOMBINANT INTERFERON-ALPHA (rIFN- α).

Johnson, Victoria A. ¹Harvard School of Public Health, Boston, MA; ²Massachusetts General Hospital, Harvard Medical School, Boston, MA; ³Memorial Sloan-Kettering Cancer Center, NY, NY, USA.

Objective: To assess the interactions of AZT, AZT, and rIFN- α in combination against HIV-1 replication in cells.
Methods: We evaluated rIFN- α (a soluble viral receptor) in combination with AZT (a reverse transcriptase-RT inhibitor) and rIFN- α (an agent which may affect viral assembly and release). 89 cells were exposed simultaneously to HIV-1 and various concentrations of each agent, either alone or in 2- or 3- drug combinations. Drug interactions were evaluated by the median-effect principle and the isobologram technique.

Drug	Inf. rIFN- α	AZT	rIFN- α + AZT	3-Drug Combination
Control	0.08	0.64	32	32
1	2935	2780	2780	1980
2	1468	1390	1390	1468
3	460	460	460	460
4	123	123	123	123

Similar results were obtained at different times and by utilizing other assays (RT activity and virus yield).
Conclusion: Combination of AZT (0.02-0.32 μ g/ml), AZT (0.16-5.16 μ g), and synergistically. The 3-drug regimen provides more complete suppression than the 2-drug regimens without additive toxicity in cells.

M.C.P.99

DIFFERENTIAL SENSITIVITY OF BONE MARROW DNA POLYMERASE ALPHA AND DELTA TO INHIBITION BY DIDOXYNUCLEOTIDES

Byrnes, John A. ¹University of Miami School of Medicine, Miami, Florida, U.S.A.

Objective: To examine the sensitivity of bone marrow DNA polymerase alpha and delta to inhibition by didoxynucleotides.

Methods: DNA polymerases were highly purified from rabbit bone marrow as previously described. Standard DNA polymerase assays using either activated DNA or synthetic primer/template combinations and different reaction conditions were used to examine the effect of dGCTP and dGTTTP.
Results: Under conditions of magnesium activation DNA polymerase alpha was resistant up to 200 μ M dGCTP, however DNA polymerase delta was 50% inhibited at 80 μ M of either dGCTP or dGTTTP. Under conditions of manganese activation alpha and delta were both 50% inhibited by 5 μ M dGTTTP. Kinetic analysis demonstrated a competitive pattern with respect to the corresponding dNTP. Activity of the 3' to 5' exonuclease associated with delta did not alleviate the inhibitory effect of the dGTTTP.

Conclusions: The sensitivity of DNA polymerase delta under conditions of manganese activation may have bearing on the bone marrow toxic effect of dGTTTP. Both DNA polymerases are believed to function in DNA replication and current evidence suggests a coordinate action of delta synthesizing the leading strand and alpha the lagging strand. Relatively minor inhibition of DNA polymerase delta may uncoordinate cellular DNA replication.

M.C.P.101

RANDOMIZED PHASE II TRIAL OF RECOMBINANT TUMOR NECROSIS FACTOR- α AND RECOMBINANT INTERFERON- α (rIFN- α) IN PATIENTS WITH AIC

Agarwal, Cynthe R. ¹Kidd PG, ²Paradise H, ³Shorrock J, ⁴Corry J, ⁵University of Washington, Seattle, WA, ⁶San Francisco, CA, U.S.A.

Objective: To determine if TNF worsens or decreases the progression of HIV infection.

Methods: While some have reported that TNF inhibits HIV replication others have reported increased replication in chronically infected cells treated with TNF. To evaluate this we randomly assigned 30 patients with AIC to receive either TNF only (10 μ g/wk), rIFN- α (10 μ g/wk), TNF (10 μ g/wk) + rIFN- α (10 μ g/wk) or rIFN- α (10 μ g/wk) + TNF (10 μ g/wk) for 12 weeks. Side effects included fever (100%), grade 1 mild constitutional symptoms (100%), and local reactions (100%). No significant hematologic, hepatic, renal, or coagulation abnormalities were observed and only one patient discontinued therapy because of side effects. T cell subset determinations did not change significantly during therapy. HIV was isolated from peripheral blood lymphocytes (PBL) in all patients prior to therapy while none were present at therapy end. The frequency of HIV isolates from PBL decreased from 92% before therapy to 84% during therapy. Plasma viremia was 56% prior to therapy and decreased to 29% during therapy.

Conclusions: This study demonstrates that TNF alone or in combination with rIFN- α does not appear to hasten the progression of HIV infection. Further studies are required to determine if either of these compounds alone or together have biologic or clinical activity.

M.C.P.98

COMPARATIVE PHARMACOKINETICS OF 3-AZIDO-2,3-DIHYDROXYAZANONE (AZAN) AND 3-AZIDO-2-DEOXYTHYMIDINE (AZT) IN MONKEYS

Reisford, F. Douglas, ¹Schwartz, R. F., ²Gallo, J.M., ³McClure, M.H., ⁴Anderson D.L., ⁵Chu, C.K.

¹College of Pharmacy, University of Georgia, Athens, Georgia, USA, ²Veterans Administration Medical Center and Emory University, Atlanta, Georgia, USA, ³Thomas Pierce Center, Emory University, Atlanta, Georgia, USA.

Objective: To characterize and compare the pharmacokinetics and bioavailability of AZANU and AZT in uninfected rhesus monkeys.

Methods: Monkeys were administered AZANU or AZT at doses of 60 mg/kg intravenously, 80 mg/kg orally, 200 mg/kg orally and 30 mg/kg subcutaneously. Serial blood samples were obtained. Concentrations of drug and metabolites were taken after 15 days.

Nucleosides were assayed by HPLC.

Results: After AZANU total clearance averaged 0.81 (0.51-1.08) L/h/kg and volume of distribution was 0.82 (0.14) L/kg. After AZT total clearances and volume of distribution were 1.57 L/h/kg and 1.07 L/kg, respectively. Oral absorption of AZANU and AZT was virtually complete (F = 0.80) after 60 mg/kg, however, bioavailability of both nucleosides was markedly lower (F = 0.50) after 200 mg/kg. The nucleosides appeared to be well absorbed after subcutaneous administration. AZANU and AZT penetrate the cerebrospinal fluid with CSF: serum concentration ratios ranging between 0.05-0.25 1 hr after drug administration.

Conclusion: The similar pharmacologic characteristics and lower toxicity of AZANU compared to AZT suggest that clinical trials of AZANU are warranted.

M.C.P.100

RECOMBINANT GRANULOCYTE COLONY STIMULATING FACTOR (r-methuG-CSF) INCREASES NEUTROPHIL NUMBER AND

FUNCTION BUT DOES NOT ALTER HIV EXPRESSION IN CD4+ T CELLS WITH AIDS. **Mills, Steven**, ¹Chung, Y.T., ²Lee, K., ³Souza, L.M. and ⁴Baldwin P.A. ¹UCLA AIDS Center, Los Angeles, CA, USA and ²Amgen, Inc. Thousand Oaks, CA, USA.

Objective: To see if r-methuG-CSF can improve neutrophil function and number in AIDS patients without altering HIV expression.

Methods: Phase I/II Open Label Trial of r-methuG-CSF + HAART/AZT in patients with AIDS/severe ARC. Patients with absolute neutrophil counts (ANC) < 2500/mm³ and hemoglobin (Hb) < 11.5 mg/dl (of all marrow suppressive drugs including AZT > 3 weeks) were treated with r-methuG-CSF once daily at 3 mg/kg s/qd until an ANC of > 4000 was achieved and maintained for 2 weeks.

Results: Eleven of 24 treated patients have been enrolled. Eight have reached > 4000 ANC, maintained for > 2 weeks and are evaluable. The other 3 patients have reached > 4000 ANC but have not been on > 2 weeks.

	Pre-G-CSF	Post-G-CSF	P value
Absolute Neutrophils	1021 ± 600	2170 ± 9130	< 0.001
Total WBC	1855 ± 790	23160 ± 9115	< 0.001
CD4 cell number	104 ± 6.3	22.8 ± 14.7	> 0.05
HIV p24 antigen	22 ± 4.54	347 ± 391	> 0.05

With one exception, normal neutrophil function (bacterial phagocytosis and intracellular killing) was observed in 8. In 6, before and during r-methuG-CSF. One pt. had a discrete intracellular killing defect which normalized on r-methuG-CSF. Analysis of limiting dilution plasma and lymphocytes cultures showed no significant alterations in viral expression.

Conclusions: r-methuG-CSF significantly increases neutrophil number and function in AIDS patients without altering HIV expression. r-methuG-CSF shows promise in altering the immunopathy of AIDS.

M.C.P.102

A LONG-LIVED CD4 CARRIER IN CIRCULATION. RED BLOOD CELLS WITH CD4 RECEPTORS INSERTED IN THEIR MEMBRANE.

Atyiah, Tamer, ¹Choi, A., ²Schub, B., and ³Blissard, C.V.

¹Biophor Corporation, College Station, Texas, USA, and ² Baylor College of Medicine, Houston, Texas, USA.

The CD4 receptor is associated with intact human erythrocyte membranes after a short-time incubation for low pH (1-2 min, pH lower than 5.3 pH). Epifluorescence microscopy observations showed that after incubation of red cells with fluorescein isothiocyanate (FITC) labeled and CD4 monoclonal antibodies (Leu-3) the erythrocyte membranes and subsequently formed lipid membranes were fluorescent. Immunofluorescence microscopy showed 10 nm gold beads associated with CD4 bearing erythrocyte membranes after incubation with anti-CD4 antibodies and then with gold beads coated with immunoglobulin G antibodies. The insertion of CD4 in RBC membranes proved stable, in vitro at 37°C for 24 hrs and the life span of RBC subjected to the acid-lipidation did not change as compared to normal RBC in mouse and in man.

CD4-RBC were shown to attach gp120 and quantitation of the number of CD4 molecules per RBC needed for effective attachment to gp120 was realized. HIV-1 interacts with CD4-RBC showing in freeze etched EM micrographs the appearance of "ice points" on the CD4-RBC membrane, reminiscent of those observed after interaction of influenza virus with RBC. Thus, a long-lived CD4 carrier in circulation with the potential of a scavenger in the circulation of free HIV-1, cloning gp120 antigens and gp120-expressing, HIV-infected T4 cells.

M.C.P.109 CHEMICALLY INFECTED MONOCYTE-MACROPHAGES (MΦ) ARE MARKEDLY LESS SENSITIVE TO ZIDOVUDINE (AZT), FIDUCICIN (FID) AND ALPHA INTERFERON (IFN) VS. COMPARED TO ACTIVELY INFECTED MΦ.

Crowe, Susanna, Rodgers, M.S., Elbeik, T., Kirilova, J., Momen, M., Hillis, J. San Francisco General Hospital/University of California, San Francisco, California, USA.

Objective: We are thought to provide a major reservoir of HIV *in vivo*. We therefore studied the efficacy of representative antiretroviral drugs in both acutely and chronically HIV-infected MΦ.

Methods: No isolated from peripheral blood of HIV seronegative donors were infected *in vitro* with HIV-01 (multiplicity one). Antiretroviral was added either at time of infection (acute) or 10-15 days following infection when 25% of MΦ contained HIV p24 by cytofluorographic analysis (chronic). Control cultures contained no drug. Inhibition of HIV replication was assessed by measurement of p24 antigen (Abbott ELISA) in culture supernatant and cell lysates, and HIV RNA analysis by slot-blot.

Results: AZT, FID and IFN markedly inhibited HIV replication in acutely infected MΦ. (FID: 100% inhibition with 40.0 μg/ml AZT and 800 μg/ml FID, 88-89% with 1000 U/ml IFN). Comparable inhibition was seen in synthesis of both extracellular and intracellular HIV antigens, with accompanying suppression of HIV RNA. Chronically infected MΦ were markedly less sensitive to these compounds even at high concentration. (CROI inhibition with AZT 50 μg/ml, FID 100 μg/ml, 1000 U/ml IFN). Slot-blot analysis showed no distinction of RNA in chronically infected MΦ.

Conclusion: Acutely infected MΦ are susceptible to antiretrovirals; chronically infected MΦ (which probably constitute the main *in vivo* reservoir for HIV) are several orders of magnitude more resistant.

M.C.P.110 COMPUTERIZED QUANTIFICATION OF SYNERGISM/ANTAGONISM OF ANTI-HIV AGENTS

Chou, Tim, Chou, * and Chou, Joseph, **

*New Sloan-Kettering Cancer Ctr., Cornell Univ. Grad. School of Med. Sci., NY NY 10021, USA and **Duke Univ., Durham, NC, USA. (Cancer Res. 48: 6218, USA).

Objective: To introduce and illustrate computerized simulation of synergism/additivism/antagonism of two or more anti-HIV agents using the isobologram principle of Chou and Talley (Adv. Enz. Regul. 22: 27-55, 1984).

Method: Computer software "Dose-Effect Analysis with Microcomputers" by J. Chou and T.-C. Chou, Elsevier-Elsevier, Cambridge UK, 1986, has been upgraded and used for studying anti-HIV drug interaction in terms of synergism or antagonism for IBM PC, AT, or II. In addition to automated construction of isobolograms, F_{1-Cl} plots and F_{1-Cl} table for two drugs, the new feature includes $F_{1-LogIC50}$ plots, dose-response Index (DRI), selectivity index (SI), and the following combinations:

Results: Using small number of measurements with reverse transcriptase, p24 antigen, virus yield, and IFA. The three following questions about synergism can be studied: 1) the potency of drug(s); 2) the shape of dose-effect synergism occurs (a); 3) the optimal dose combination ratio for maximal synergy (OOR); 8) schedule dependency; and 9) selectivity index (SI) for anti-HIV cytotoxicity ratio.

Conclusion: Usefulness of MEP and the software have been demonstrated (e.g. Anticancer Res. 6: 1189, 1987 [AT+IFN]; 31: 383, 1987 [AZT+CAF]; Science 235: 1376, 1987 [AZT+8D], and J. Inf. Dis. 158: 378, 1988 [ddC+IFN]).

M.C.P.111 POSSIBLE PROTECTIVE EFFECT OF INTERFERON-INDUCED THROMBIN (IDTA) AND/OR DEHA-5 IN HIV INFECTION

DEBONOIS, J.M.A., LAMAS P., McDermott, M. St General Hospital and UCSF, San Francisco, CA, USA

Objective: Since IDTA has been reported to have immunomodulatory/antiviral activity, we studied the effect of both endogenous IDTA-5 levels (IDTA is rapidly converted *in vivo* to IDTA-5) and HIV infection and 2) the *in vitro* effect of IDTA on HIV-infected macrophages.

Methods: IDTA-5 was measured by RIA and HIV antibody assayed by two ELISA techniques (positive (+) results confirmed by Western blot) in coded serum samples obtained from 5 groups of men who were age-matched within 3 years. *In vitro*, human macrophages exposed to HIV (one TCID₅₀ unit/cell) for 1 hour were cultured with various IDTA dilutions. Supernatants were assayed for p24 antigen at 9 days and 4 inhibition of p24 compared to untreated controls.

Results: Group 1 (24 HIV-seronegative men) sought medical advice regarding a possible AIDS diagnosis had a mean (SD) serum IDTA-5 level of 5.97 (±3.01) μg/ml, compared with Group II's (24 healthy HIV-seronegative) men level of 2.20 (±1.33) μg/ml (p<.0001). Group III's (24 HIV-AE patients) mean of 2.31 (±1.35) μg/ml (p<.0001). Group IV's (24 HIV-AIDS patients) mean of 1.12 (±1.74) μg/ml (p<.0001), and Group V's (48 HIV-healthy blood donors) mean of 3.19 (±1.68) μg/ml (p<.0001). *In vitro*, 10% inhibition of macrophage HIV p24 expression occurred at IDTA concentrations of 3-30 μg/ml.

Conclusion: At-risk HIV seronegative homosexual men had a significantly higher IDTA-5 level than age-matched HIV-sero or healthy HIV-blood donors. IDTA also modestly inhibited HIV replication *in vitro* in human macrophages. IDTA/IDTA-5 may have a protective effect in HIV infection.

M.C.P.112 ZIDOVUDINE ANALOG INHIBITS HIV-1 REPLICATION IN A HUMAN MONOCYTIC CELL LINE.

MAZUREK, JAMES P., PARENT, D. M., MORSEAU, R. J. and Valois, R. M. *

*Saint General Hospital, Montreal, Quebec, Canada, **Montreal-Du de Montreal, Montreal, Quebec, Canada.

Objective: Zidovudine is a long-acting zidovudine analog used to treat the diarrhea of AIDS patients. Because this diarrhea could directly involve the HIV-1 retrovirus, we have investigated the anti-viral potential of Zidovudine in monocytes.

Methods: Five different concentrations of Zidovudine (Zanid; 0.5, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384, 32768, 65536, 131072, 262144, 524288, 1048576, 2097152, 4194304, M.C.P.115 ANTI-HIV-1 ACTIVITIES OF ANTHRACENONE DERIVATIVES IN VITRO

C. G. Chin¹, R. F. Galloway², M. Nease¹
¹The University College of Pharmacy, Athens, Georgia 30602,
²Emory University School of Medicine/V. Medical Center, Atlanta, GA 30303, ³National Institute of Allergy and Infectious Diseases, Bethesda, MD 20892, U.S.A.

Objective: As a part of our efforts to discover novel anti-HIV agents, a series of anthracenone derivatives have been screened against HIV-1.
Methods: Peripheral blood mononuclear cells were infected with HIV-1 and cultured in the presence and absence of various concentrations of compounds. Six days later the reverse transcriptase activity was determined as a measure of antiviral activity.

Results: In order to determine the structure-activity relationships, various anthracenones substituted with OH, H₂O, SO₂, halogens, aromatic, amino, etc. were evaluated against HIV-1. Among these, poly-phenolic and/or poly-sulfate substituted anthracenones were found to be most potent, such as 1,2,5,8-tetrahydroanthracenone (C₁₅H₁₀O-3.29µM), 1,2,4-trihydroxyanthracenone (C₁₅H₈O₄ 4.44 µM), 3,4-dihydroxy-9,10-dioxo-2-anthracenone sulfonic acid (C₁₆H₈O₅S 3.48 µM). Amino or halogen substituted anthracenones exhibit low activity. None of the active compounds were toxic at 100 µM. Hypochlorite, an anthracenone dimer exhibited a potent anti-HIV activity (C₁₈H₁₂O₄ 4.44 µM) in this screening system.
Conclusion: A new class of anti-HIV agents with modest activity has been identified. Further study of structure-activity relationships and the mechanism of action are warranted.

Department, Fort Belvoir, Illinois 62204, USA
Objective: The present investigation was to develop potent inhibitors of glycosylase as potential anti-HIV agents. Several analogs of the known inhibitor, cantharopene (CANT), were synthesized and evaluated for their inhibitory effect on glycosylase and for antiviral activity against Moloney murine leukemia virus (MuLV) in the TC clone assay. The IC₅₀ values of these inhibitors against the enzyme and MuLV ranged from 0.8 - 50 µg/ml and 0.05-0.10 µg/ml, respectively, compared to 10 and 1.1 µg/ml for CANT. The most effective analog was 6-O-butyl CANT with an IC₅₀ of 0.05 µg/ml against MuLV. A good correlation between the inhibition of glycosylase and MuLV replication was observed. The active analogs were further evaluated against HIV-induced syncytium formation in HeLa T₄ cells and against productive infection in 293 cells infected with HIV-1 (JR9 strain). The analog showed IC₅₀'s between 0.2 - 27 µg/ml in the HeLa T₄ assay, compared to CANT at 11 µg/ml. These compounds also showed good activity (IC₅₀'s 0.15 - 6.7 µg/ml) in 293 cells. In both of these HIV assays, the 6-O-butyl analog was the most effective, (IC₅₀'s 0.15 µg/ml) compared to CANT (10 µg/ml). These data and cytotoxicity studies delineated a therapeutic index of >2000 for the 6-O-butyl CANT compared to 500 for CANT. These observations were further confirmed by investigation of the 6-O-butyl analog against Simian virus infection in mice. CANT and the 6-O-butyl analog, when administered at a dose range of 50-100 mg/kg/day i.p. for 14 days, reduced the splenomegaly by 60-80% and 60-81%, respectively. These observations demonstrate the potential of the novel glycosylase inhibitors as chemotherapeutic agents in AIDS.

M.C.P.119 EFFECT OF CHLOROQUINE ON HIV INFECTION OF MONOCYTES

Desrosier, Isabelle¹, Faucher, H. P., Pyne, C.K., **Bavel, B. *

* Physiologie Cellulaire, ** Spécificité du Développement.
Université de Québec, Québec, Québec

Objective: Ultrastructural analysis of HIV infection of monocytes.
Methods: Monocytes were isolated from normal donor blood samples by Hypaque-Ficoll administration and approach, then inoculated with virus in presence or absence of chloroquine (120 micromoles for a period of 6 hours or 50 micromoles overnight). Cytological study was performed with electron microscopic techniques.

Results: The treatment of HIV infected monocytes by chloroquine resulted in the formation of intracellular vacuoles containing viruses in various stages of development similar to those observed in SV infected cells treated with haemagglutinin agglutins (1) and in HIV infected cells expressing a glycoprotein that interferes with the fusion reaction of virus envelope with the cell membrane (2). By contrast such intracellular accumulations of viruses were not observed in HIV infected monocytes not treated by the drug.
Conclusions: These preliminary data suggest that chloroquine may affect the penetration of HIV into the cytoplasm of monocytes.

M.C.P.116 AZITROPHENYDINE(AZT)-ALPHA-INTERFERON(IFN) COMBINATION

THEYREY REDUCES P24 ANTIGENEMIA. **Malig, Brian R.**, Whaling, E.N., Melnick, R.J., Bitensky, J.S., Division of Infectious Diseases and Hematology/Oncology, Michael Reese Hospital, Chicago, IL, U.S.A.
We report an ongoing phase III dose-escalating/dose-toxicity trial of IFN in combination with AZT in patients with p24 antigenemia (CA5 µg/ml) and AIDS, AZT, or a CMV count <150/mm³. Patients with opportunistic infections (OI), lymphoma, or progressive Kaposi's sarcoma are excluded. All patients must be p24 Ag(+) after at least 4-8 weeks of AZT monotherapy to be eligible. Patients are followed with monthly physicals, CD4 counts, and must be p24 Ag(+) after at least 4-8 weeks of AZT monotherapy to be eligible. Patients are followed with monthly physicals, CD4 counts, and must be p24 Ag(+) after at least 4-8 weeks of AZT monotherapy to be eligible. A mean reduction in plasma p24 Ag of 43% has been seen in 8 of 9 patients, at a median of 7 weeks. In the 4 followed more than 8 weeks on IFN, a mean reduction in p24 Ag of 78% occurred at the median of 17 weeks. Higher initial CD4 counts predicted greater reductions in p24 Ag. CD4 counts fell and B₂-microglobulin levels rose on therapy. Side effects required IFN dose modifications in 4 of 9 patients for more than 8 weeks, an initial decline in p24 Ag at 8-15 weeks was followed by a rise toward pre-treatment values at 18-25 weeks. This rise correlated with a fall in CD4 to below 100.

We conclude that AZT-IFN therapy is associated with an initial reduction in plasma p24 Ag to a very low incidence of OIs, and a moderate frequency of side effects requiring dose modification. Correlation of a late rise in p24 Ag with a fall in CD4 suggests that early antiviral effects of IFN may be overcome by later immunosuppressive effects.

M.C.P.118 ANTI-HIV REVERSE TRANSCRIPTASE AND ANTI-HIV ACTIVITIES OF

PC8
N. Takayama, Patrick K. Lal, Y. T. Wu and M. Nomsaya
Department of Virology, Centers for Disease Control,
Institute, St. Petersburg, FL 33716, USA.

Previously we have shown that PC8, a partially purified extract from cones of *Pinus parviflora* Sieb et Zucc, inhibited HIV-1 replication in CEM, C9 and 293T cells. We report that PC8 has anti-HIV-1 reverse transcriptase (RT), anti-AM-RT activities. Addition of PC8 to the reaction mixture of the RT assay inhibited HIV-1 and AM-RT activities. Gel-retardation assay showed that PC8 did not bind to DNA or the template. Competition assays revealed that PC8 directly interact on HIV and AM RTs. The anti-RT active component(s) in PC8 could be removed by an affinity column of CEM cells. Sequential Tris-glycine (0.1M, pH 3.0 and 0.1M, pH 8.0) elution did not recover the anti-RT component(s), but the eluate contained anti-HIV activity. The replication of HIV in CEM cells was inhibited after exposure of the infected cells to the eluate [µg/ml]. Thus, PC8 contains 2 active components: an anti-RT component and an anti-HIV component that had no impact on HIV-RT. Further purification of these active components in PC8 is in progress.

M.C.P.120 CELLULAR PHARMACOLOGY OF ANTI-HIV AGENTS AZITROPHENYDINE (AZT)

AND 2',3'-DIDHYDROAZITROPHENYDINE (DDI) IN HUMAN T CELLS

Freidland, Arnold; Govey, M. and Ashmun, R.

St. Jude Children's Research Hospital, Memphis, Tennessee 38101 USA.

Objective: AZT is the first effective agent in the treatment of AIDS. However, low marrow toxicity and anemia is a severe adverse effect of AZT therapy. This toxicity has been attributed to inhibition of deoxythymine diphosphate (dTMP) for DNA synthesis. This study compared the metabolism and inhibitory effects of AZT and that of its analog DDI in human T cells CD4⁺CD8⁻. Results: The concentration of the drug substrate for inhibitory cell growth by AZT (IC₅₀) was significantly lower when the cells were exposed to AZT and DDI for 24 h (80-40 and 25 µM, respectively) than 48 h (100-125 and 50 µM). Inhibition of DNA synthesis induced by either drug did not correlate with dTMP depletion in cells. The 5'-phosphate of AZT (AZTP) was the major metabolite (95%) resulting 300-fold greater cellular concentration than that observed with DDI at equimolar concentration of the two drugs. Cells incubated with 25 µM AZT accumulated 25 µM AZTP and 25 µM both AZTP and AZTP plateaued at about 5 µM. After this period there was a rapid decrease in AZTP concentration to one third its initial level by 24 h, while both AZTP and AZTP appeared stable. DDI is a poorer substrate than AZT for the cellular kinase but produced considerably higher level of the analog triphosphate in CEM cells at equimolar concentration of the two drugs.
Conclusions: These results do not support the notion that depletion of dTMP is a primary cause for the toxicity of AZT or DDI and suggest that the analog triphosphate levels are the important determinants of cellular activity to these drugs. M.C.P.133 EFFECT OF ORGANIC ARSENICALS ON PROLIFERATIVE INFECTION OF HIV.

Geeta, Pathak, G. Narve, V. Kishor, C.S. and Rav, M.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To study the anti-HIV effect of oophenarsenic and other structurally related organic arsenical compounds.

Methods. Various concentrations of arsenical drugs were added to the culture medium after infection of H9 cells or PHA-stimulated lymphocytes with HIV. Production of HIV was monitored by the antigen capture test. The effect of drugs on the production of HIV from persistently infected H9 cells was monitored not only by the antigen capture test, but also by reverse transcriptase and infectivity assays.

Results. Oophenarsenic, a trivalent arsenical compound, in concentrations as low as 0.025 µg/ml, inhibited *in vitro* infection of blood lymphocytes and H9 cells by HIV. The drug also blocked the production of HIV from lymphocytes of seropositive men coinfected with PHA-stimulated normal donor lymphocytes and depressed the production of HIV from persistently infected H9 cell line. Zidovudine, the only FDA-approved anti-HIV drug, had no antiviral effect in cells persistently infected with HIV. Seven other structurally related organic arsenicals whose structures are very similar to oophenarsenic were also tested for their *in vitro* anti-HIV properties. Of these seven compounds, one compound had identical organic structure as oophenarsenic except that it carried pentavalent, instead of trivalent, arsenic. However, none of these seven compounds had anti-HIV effect in H9 cells or lymphocytes.

Conclusion. Oophenarsenic is a potent anti-HIV drug. Oophenarsenic is a U.S. FDA approved drug for the treatment of syphilis. It was used extensively before the discovery of penicillin. Presence of trivalent arsenic in oophenarsenic may be crucial for its anti-HIV property.

M.C.P.134 NOVEL GLYCOPROTEIN INHIBITORS AS ANTI-HIV AGENTS

Hiromasa Shimidzu, Masahiko, S., Yamamoto, H.,** Oshijima, H.,**
*National Institute of Health, Musashimurayama, Tokyo, Japan,
**Pharmaceutical Research Laboratories Daiichi Sankyo, Ltd., Yokohama, Kanagawa, Japan.

Objective. To evaluate the effect of novel glycoprotein inhibitors, Oophenylglycyl(DM) derivatives, on the replication of HIV-1.

Methods. DM derivatives were newly synthesized and were assessed the inhibitory effect on giant cell formation by Helt-4 cells and Helt-4(HIV-1 cells. The infectivities from Helt-4(HIV-1 or O937(HIV-1 cultured in the presence of drugs were also determined by using H9-cells. The envelope glycoproteins from Helt-4(HIV-1 were obtained by immunoprecipitation.

Results. DM derivatives were newly synthesized and were assessed the inhibitory effect on giant cell formation by Helt-4 cells and Helt-4(HIV-1 cells. The infectivities from Helt-4(HIV-1 or O937(HIV-1 cultured in the presence of drugs were also determined by using H9-cells. The envelope glycoproteins from Helt-4(HIV-1 were obtained by immunoprecipitation. DM derivatives were newly synthesized and were assessed the inhibitory effect on giant cell formation by Helt-4 cells and Helt-4(HIV-1 cells. The infectivities from Helt-4(HIV-1 or O937(HIV-1 cultured in the presence of drugs were also determined by using H9-cells. The envelope glycoproteins from Helt-4(HIV-1 were obtained by immunoprecipitation.

Conclusion. These synthetic DM derivatives have potent anti-HIV activity *in vitro*. Development of novel glycoprotein processing inhibitors is likely to depend on the inhibition of the envelope glycoprotein processing.

M.C.P.135 CARBOXYLIC ACID AMIDES ANALOGUES THAT INHIBIT THE REPLICATION OF HUMAN IMMUNODEFICIENCY VIRUS IN T-CELLS AND MONOCYTES/MACROPHAGES *IN VITRO*.

Flattner, S.P., Broder, S.C.,** Maslow, J.N.,** Hirsch, M.S.,**
*Abbott Laboratories, Abbott Park, IL, USA.

Objective. Two newly synthesized carboxylic acid amide analogues, α -(2',3'-bis(hydroxypropyl)-1-cyclohexyl)acetamide (CA) and α -(2',3'-bis(hydroxypropyl)-1-cyclohexyl)glutamide (CG), were tested for activity against the infection of human immunodeficiency virus (HIV) *in vitro*.

Methods. In an HIV cytopathic effect inhibition assay, target CD4⁺ T-cells were exposed to HIV-1 or HIV-2, cultured with/without drugs, and the viable cell number was determined. The expression of p24_{gag} protein and proviral DNA synthesis were also assessed.

Results. Both compounds, CA and CG, were found to be capable of protecting T-cell lines against the infectivity and cytopathic effect of HIV-1; inhibiting the expression of p24_{gag} protein; and suppressing the proviral DNA synthesis *in vitro* against at concentrations 30-100µM. These compounds also inhibited the *in vitro* infectivity of HIV-1. Moreover, both CA and CG virtually completely suppressed the p24_{gag} protein expression in monocytes/macrophages exposed to monocytotropic HIV-1 at a concentration of 0.5µM. It was noted, however, that CA and CG exerted a substantial toxicity against target T-cells as well as normal peripheral blood mononuclear cells at around 100µM.

Conclusion. Our observations should provide new structure-activity relationships for carboxylic acid amide analogues which may be of value in developing a new class of experimental drugs for the therapy of HIV-related diseases.

M.C.P.136 NEW ANALOGUES OF 2',3'-DIDEOXYADENYLATE WITH IMPROVED ANTI-HIV-1 ACTIVITY *IN VITRO*

Montefiore, David, C.,** Baruch, A.,** Sobot, R.W.,**
R.W.,** R. Broder, S.C.,** Maslow, J.N.,** Hirsch, M.S.,** Sobol, M.,**

Hibbard, R.,** and Mitchell, W.M.,** Vanderbilt University,
Nashville, TN, 37232, **Temple University, Philadelphia, PA 19140; and
*Fakultät für Chemie, Universität Konstanz, Konstanz, Germany.

Objective. To screen structural, stereochemical and combination structural/stereochemical 2',5'-dideoxynucleotides (2-SA) and 3',5'-dideoxynucleotides (3-SA) analogues for anti-HIV activity.

Methods. Cell toxicity and *in vitro* anti-HIV-1 activity were determined in an MT-2 cell, microtiter cytopathic effect assay utilizing virus obtained from cultures of H9/HTLV-III cells. Inhibition of reverse transcriptase (RT) activity was determined using a Triton X-100 activated viral lysate.

Results. A trimer of 2',5'-adenylate having the hydroxyl moiety replaced with a hydrogen atom at the 3' position of the middle residue (i.e., 3'-deoxyadenosine or cordycegin) demonstrated potent (compared to AZT) concentration-dependent antiviral activity (at 4-32 µM without toxicity to the cells). This trimer also exhibited concentration-independent inhibition of HIV RT. Other analogues exhibited various degrees of activity or were inactive in these assays.

CONCLUSIONS. The extent of 5'-phosphorylation, length of oligomer, type of interresidual bond, and the presence or absence of deoxyadenosine and stereoconfiguration are all critical factors for anti-HIV activity of this class of compounds.

M.C.P.137 PHASE II STUDY OF THE ADMINISTRATION OF RECOMBINANT SOLUBLE CD4 (sCD4) BY INTRAVENOUS TO PATIENTS WITH AIDS OR ARC.

Yoshino, Robert, Thomas RV, Pluda JM, Perno CF, Mitsuya H, Masryk KB, Shewen SA, and Broder S, *
*National Cancer Institute, USA, **Genentech, Inc, San Francisco, USA.

Objective. To investigate the toxicity, clinical effects, serum levels, immunologic effects, and virologic effects of sCD4 given by continuous infusion to patients (pts) with AIDS or ARC.

Methods. 12 patients with AIDS or ARC were administered sCD4 by continuous infusion for 15 days (after a 24 hr test dose) at each of 3 dose levels: 1, 10, or 100 µg/kg/day.

Results. No toxicity was observed other than phlebitis in 2 pts at their IV sites. Serum sCD4 levels were as follows: 1 µg/kg/day - 0.8 to 2.8 ng/ml; 10 µg/kg/day - 10 to 22 ng/ml; 10 µg/kg/day - 22 to 30 ng/ml (other results pending). No antibodies to sCD4 were detected in patients who received 1, 10, or 30 µg/kg/day (other results pending). No changes were observed in the total WBC. No consistent changes were observed in the T4 cells. T4/T8 ratio, *in vitro* T cell proliferation to soluble antigen (Ag), skin test reactivity, or serum HIV p24 Ag in patients receiving 1, 10, or 30 µg/kg/day sCD4. However, 2 of the 3 patients receiving 100 µg/kg/day had rises in their CD4 cells from 69 to 182 T4 cells and from 147 to 222 T8 cells, respectively. One of these 2 patients had detectable serum p24 Ag at any time from 401 to 245 ng/ml with sCD4. Additional patients are now being studied at higher dose levels of 100 or 300 µg/kg/day.

Conclusion. Because of the lack of observed toxicity and the suggestion of possible anti-HIV activity at the highest dose tested, additional testing of sCD4 by continuous infusion at 100 µg/kg/day and higher doses is warranted. From a theoretical point of view, continuous infusion may possess special advantages as a technology for administering rCD4.

M.C.P.138 TRIMETHOPRIM (M) TRIMETHANOLAMINE (N) ERADICATION AS POSSIBLE

PROPHYLACTIC THERAPY RESISTING TO AZIDOTHYIMIDINE (AZT) IN AIDS PATIENTS

KUWAZA, BUNJI, RUSTENBERGER, A.
University of Geneva, Centre, Rue des Bains, Institut, Sarvejeva, Jugoslavia

Dansberg's film conducted over 200 cases of AIDS in a couple accordance with recently approved AZT co-trimoprim (cotrimoxazole) T as the most frequent, but since new trichomonas inhibitor and/or supporter of immunoppression.

Regarding the existence of cross-resistance by all three known trichomonas species (Trichomonas vaginalis, Tr. intestinalis and Tr. tenax), it seemed to us logically to suppose that, if the host gets freed from the pressure of trichomonas, the immune system will be better to resist to other antigens. Because of that, we have determined 14/70 by 7 patients with asymptomatic genital trichomonas and after 3 therapy.

As positive effect of AZT results is attributed to repression of asymptomatic patients without detectable toxemia with such bacterium has been observed.

As positive effect has been realized, in increasing of their indicator of being status trichomonas positive effects of M as immune status had been noticed by patients' health but without detectable overall (intestinal) trichomonas of asymptomatic.

M.C.P.139 A USEFUL IMMUNOTHERAPY IN AIDS.

MARICOL Bernard J., M.D., JENNER M.C., BRUSSELS BELGIUM

In a clinical study made in Africa upon 90 patients-AIDS or ARC, 26 had at least one year of immunotherapy at the end of 1988. This immunotherapy is using different products: interferon, zalcitabine and acid heparin (with same chain). The particularity of this treatment (1) is the use of very small doses of each product. The results are compared with those of a group without any immunotherapy. In both groups, the 0.1. are treated by the classical medication. No one patient in the study is or has been on AZT, or other specific anti AIDS medication.

The results are:

Africans(n=10)	Africans on Tc	Personal evolution	
diarrhea (1)	40	6	1 cases (4)
fever (1)	13	6	2
infections (1)	55	13	14
Biology (2) absolute T4	4	191	51
T4/B	23	40	11
Weight (3)	-14	+3	-1

- (1) Frequency of diarrhea, fever, infections in Tc.
- (2) In a expressed annual weight enhancement of 16 and 14/18
- (3) Middle evolution of the weight, in Kg/year.
- (4) Group added in order to compare the biological data with those of the AZT studies. It is compared with the clinical studies, on AZT, the biological results of the european group are reaching the same level of efficacy.

Key words: immunotherapy, small doses, cyclosporin, nucleic Acids, anti heavy gamma chain.

M.C.P.141 CONCENTRATION DEPENDENT DUAL EFFECTS OF THE MONOCLONAL ESTER OF SUCROSE (L.S.) ON THE APPRIAL ACTIVITY AND ADSORPTION SPECTRA OF AMPLIGENIN (S) AND

Yoshitaka Zaitsev, G. S. and M. Kozlov, S. S.
Washington University, St. Louis, MO, St. Louis, Missouri, USA.
*Université du Québec à Trois-Rivières, Trois-Rivières, Québec, Canada.

Objective. To develop a system for AaB drug delivery.
Methods. Comparison of effects of a mild detergent, L.S. on AaB-induced decrease in cellular K⁺ retention and viability of *Staphylococcus carnosus* and *Cryptosporidium parvum* cells with L.S. effects on AaB physical state as reflected by absorption spectra.
Results. L.S. at concentrations 0.008 to 0.03% enhanced the toxic effects of AaB on the two fungi. In contrast, concentrations 0.004 to 2.1% inhibited AaB effects. We analyzed changes in AaB absorption spectrum induced by L.S. at these two concentration ranges by comparing critical (M_w) of AaB at 40nm. The same length characteristic of non aggregated (monomeric) L.S. at absorbance at 320nm, the wavelength characteristic of aggregated AaB. Low concentrations of L.S. caused a decrease in K⁺ and the higher L.S. concentrations increased it.
Conclusion. L.S. has concentration dependent dual effects on antifungal action of AaB which correlated with shifts in the physical states of AaB between its monomeric and aggregated forms. Since the inhibitory concentrations of L.S. on the antifungal effects are low about 1000 times greater than those reported previously for inhibition of AaB toxicity to mammalian cells, this suggests that L.S. may be useful as a vehicle for improvement of AaB delivery. However, increase in AaB toxicity induced by low concentrations of L.S. suggests the possibility that synergistic interactions between fatty acid esters, and polyelectrolytes may have therapeutic value.

M.C.P.143 TREATMENT OF THERAPY-RESISTANT ORO-PHARYNGEAL CANDIDIASIS WITH FLUCONAZOLE IN HIV-1-INFECTED PATIENTS

Teichgraber Barbara, H. Schneider, J. and

Deicher, M.
Hannover Medical School, Hannover, F.R. Germany.

Objective. To evaluate the efficacy of fluconazole, an experimental azole antifungal agent, in the therapy of therapy-resistant oro-pharyngeal candidiasis in HIV-1-infected patients.

Methods. 20 patients with therapy-resistant oro-pharyngeal candidiasis were treated with fluconazole at daily doses of 50-100 mg for 21 days. Patients were weekly examined for clinical symptoms as well as side effects and hematological and organ toxicity of the drug. Mycological assessment included microscopic examination and culture (cfu/ml) of mouth washings.
Results. Resolution of symptoms and signs was obtained in the first week of treatment in 18/20 patients. Partial response was observed in another 2/20 patients. Mycological assessment showed a significant reduction of candida cultures of mouth washings. In 60% of the patients the culture tests became negative at end of therapy whereas in 40% of patients more than 10⁵ cfu/ml were found. More than 60% of the patients had a clinical relapse four weeks after stopping the experimental therapy with fluconazole. No alteration of liver tests nor nephrotoxicity was observed.

Conclusion. Fluconazole seems to be a highly effective drug in the treatment of therapy-resistant oro-pharyngeal candidiasis in HIV-1-infected patients. A continuous therapy may be necessary to avoid clinical relapses. Optimal dosage remains to be defined in further studies.

M.C.P.140 A MODEL OF AIDS-VIRUS DYSINFECTION

Loban G. Angeloff

Angel's Biomedical Laboratories, Ltd., P.O. Box 122, Station "Place du Parc", Montreal, Quebec H2W 2P9, Canada

A virus disinfection was observed by the author in 1930-39 in water buffalo (*Bubalis bubalis*, Linn.) in Kosevici, Bulgaria, that all those animals who ate wild rose-apples did not get the infection caused by the ultra-virus *aphthae* (*aphthae epizooticae*). Later, the author applied above observations as model on rats bearing amelanin *MelanoX* (*Epizootic*) tumor (3rd Asian Cancer Conference (Abs. 143), p. 124, 1977).

In these investigations as model disinfectors alkaline Bulgarians 261-a (0.1M NaOH), acidic Bulgarians 261-b (0.1M HCl), and acidic Bulgarians 261-c (0.1M H₂SO₄) on normal white Wistar-Furuta rats were used as follows: (a) three rats were injected SC with a single dose of Bulgarians 261-a (0.1M NaOH) 1ml/100g.b.w.t.; (b) five rats were injected SC with Bulgarians 261-b (0.1M HCl) 1ml/100g.b.w.t.; and (c) five rats were injected SC with Bulgarians 261-c (0.1M H₂SO₄) 1ml/100g.b.w.t. The concentrations of the disinfectors were 1:1 tolerated by the recipients and after 24h. all rats were sacrificed and their heart and liver were examined and they were like normal. The results above that Bulgarians 261-a-c might be applied as disinfectors against various viral and bacterial infections. Copyright 1989 by Loban G. Angeloff. All rights reserved.

M.C.P.142 SEROLOGIC AND IMMUNOLOGIC PARAMETERS IN A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL OF

AMPLIGENIN ADMINISTERED TO SUBJECTS WITH HIV INFECTION

McKinley, G.F., Rudy, M.M., Iwata, Y., Kim, K., Rasmussen, J.J., Oriskany, M.F., Washington University, St. Louis, MO, St. Louis, Missouri, USA.

As part of a multicenter trial of intravenously administered AMPLIGENIN (mammalian, double-stranded RNA) we enrolled 25 HIV-seropositive (asymptomatic or early ARC) and followed them for up to 36 weeks. Blood was taken at the start of study and at weeks 4, 12, 24, and 36. At study end it was found that 12 patients had been given placebo and 13 had received AMPLIGENIN 400 mg twice weekly. There were no statistically significant differences between groups with respect to soluble CD4, soluble IL-2 receptor, beta-2 microglobulin, and sequester.

Wk	AMPLIGENIN (n=13)			PLACEBO (n=12)		
	IL-2R	IL-2R	Neopt	sCD4	IL-2R	Neopt
	(U/ml)	(U/ml)	(ng/ml)	(U/ml)	(U/ml)	(ng/ml)
0	281±903	181±400	4008±41	436±504	1792±116	238±372
4	930±990	1394±581	3158±270	435±65	785±800	1246±999
12	975±115	1393±679	3915±990	55±58	765±878	1320±116
24	838±186	1192±134	4179±531	42±69	645±608	1178±117
36	865±107	1294±152	4580±752	53±19	795±19	1287±141

There were no statistically significant differences between groups with respect to circulating immune complexes (measured by the inhibition of immune adhesion), erythrocyte complement C3b receptor (E-C3b) activity, and direct Coombs test.

M.C.P.144 INHIBITION OF HIV-REVERSE TRANSCRIPTASE BY A KAMPO MEDICINE, SHO-SAI-KO-TO

Drug: Katsushiro, Nakase, H. K., Fukushima, H. K., Chermann, J.-C.*** and Barre-Sinoussi, F.***

***Research Institute and Hospital, Aichi Cancer Center, Nagoya, Japan.
***Laboratoire de Recherches sur les Recherches sur les Maladies Infectieuses (INSERM, Marseille) and ***Laboratoire de Biologie des Retrovirus, Institut Pasteur, Paris, France.

Objective. To describe the *In vitro* inhibitory effect of a well-known kampo medicine (Chinese drug), Sho-Sai-Ko-To, on the activity of HIV-reverse transcriptase.

Methods. Reverse transcriptase activity was measured *in vitro* with (T₇)₁₁₂-18 as the template-primer and [³H]dNTP as the triphosphate substrate, and the effect of the drug was evaluated by adding various concentrations of Sho-Sai-Ko-To.

Results. The activity of HIV-reverse transcriptase was inhibited by more than 70% in the presence of 200 µg/ml Sho-Sai-Ko-To. The inhibition was dose-dependent, and the drug inhibited the enzyme activity by 90% at 500 µg/ml which is a clinically attainable concentration. Of the seven ingredients of Sho-Sai-Ko-To, the extract from radix of a plant, Scutellaria, was found to have strong inhibitory effect on the reverse transcriptase activity at concentrations less than 10 µg/ml. In contrast to reverse transcriptase, cellular DNA polymerase α , β and γ were much less sensitive to inhibition by this drug, suggesting the fact that Sho-Sai-Ko-To is non-toxic to the host cells.

Conclusion. Sho-Sai-Ko-To is promising as a candidate for antiretroviral agent.

M.C.P.145 VIRAL INHIBITION THERAPY AGAINST AIDS

Uchihashi, M., Van Brunschot, A., Robson, I. and Bernstein, A.***
*Faculty of Medicine, University of Toronto, Ontario, Canada.
**Mount Sinai Research Institute, Toronto, Ontario, Canada.

Objective: Gene "manipulation" of stem cells leading to the development of an HIV-resistant immune system.

Methods: Various retroviral vectors expressing antisense or sense RNA to HIV-1 were constructed. The vector particles were used to infect CMV lymphocyte- and macrophage-derived cell lines. These transmutations will soon be challenged by HIV-1 and the virus production will be monitored.

Results: The ability of various vectors expressing sense or antisense RNA to interfere with the HIV-1 multiplication will be reported. The use of antisense RNA is only one way to interfere in the life cycle of HIV-1. Other vectors to express various proteins interfering with the HIV-1 life cycle are under development. If a stem cell could be made resistant to HIV-1, then upon maturation and development it will lead to the reconstitution of an HIV-1 resistant immune system. Both T-lymphocytes and macrophages, the primary targets of HIV-1 infection, derive from the bone marrow stem cells. The introduction into these stem cells of retroviral constructs expressing RNA or protein molecules conferring resistance against HIV-1 infection provides a potential therapeutic approach towards the development of an HIV-1 resistant immune system.

M.C.P.147 MESAQUINONE (METHYLQUINONE) INHIBITS HIV-1 INDUCED SYNTHESIS OF HIV-1 RNA

Quilley, L., Dethlefs, A. J. Hesse-Quilley, J.M. and Coak, J., Dept. of Microbiology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

OBJECTIVE: To determine if naphthoquinone (Vitamin K series) compounds can affect HIV-1 induced and/or replication.

METHODS: Physiological non-toxic concentrations of phyloquinone menaquinone and menaquinone-7 (MK-7) were added to cultures of HT-2 and Hut-78 cells infected with three different clinical isolates of HIV-1. AZT was utilized as a comparative control. The effect of these chemicals were evaluated by inhibition of syncytia formation, and viral antigen production (Reverse Transcriptase assay and indirect immunofluorescence).

RESULTS: Remarkably, MK-7 heterally produced Vitamin K at concentrations between 5 and 1 µg/ml inhibited syncytia formation in HT-2 infected cells similarly to AZT at 5 to 1 µg/ml. Similar inhibition of syncytia formation was also observed in HIV-1 infected Hut-78 cells; however, while AZT effectively limited HIV replication, MK-7 had no effect whatsoever on virus production.

CONCLUSIONS: Further studies are warranted on the effects of menaquinone induced inhibition of syncytia formation especially in light of the findings that concurrent effects of HIV antigen and virus production are not affected in these cells. If syncytia formation is indeed an important factor in HIV pathogenesis then the understanding of the mechanism of inhibition of syncytia formation by MK-7 may prove a valuable way of limiting HIV-1 spreading in vivo.

M.C.P.149 AIDS - IS A SAFE VACCINE READY AVAILABLE?

Werner, GUDIN, M.D. Consultant Geneva University Hospital
10, Quai de Serres, 1203 Geneva, Suisse

Objective: Finding the best and safest method to obtain a marketable AIDS vaccine.

Method: Analysis of present vaccine strategies to obtain an AIDS vaccine. Development of a new concept in order to obtain a new kind of vaccine.

Results: Largely due to the development of an AIDS vaccine are now being pursued. The first one starts with the antigen, usually synthetic fragments of HIV (gp 120, gp 160, etc...) obtained by genetic engineering.

The second one consists of developing an antigenic vaccine using selected monoclonal antibodies (mAbs) to the CD4 receptor. Both strategies intend to obtain specific antibodies or cellular immunity to HIV. However, because of competition and cross-reactivity between HIV and the physiological ligand for the CD4 receptor, namely MHC II, blocking HIV with a classical vaccine will at the same time block MHC II binding to CD4 and interfere with normal macrophage to T cell interaction causing immunosuppression.

To overcome these difficulties, a new type of "vaccine" consisting of monoclonal antibodies, liposomes and adjuvant intended to safely block HIV infection and stimulate NK cells (non MHC restricted immune response) is being considered.

Conclusion: A new concept for an AIDS vaccine based on stimulation of NK cells is presented.

M.C.P.146 EFFECT OF PEPAIN TREATMENT ON THE HIV ENVELOPE AND CORE ANTIGEN

Ujhelyi, E., Füst, G.**, Ellei, G.**, Allan, S.**, Székelyi, J.**, and Hollós, S.R.**,
Inst. Hematol. Blood Transfusion, Budapest, Hungary, and **Abbott GDM Diagnostics, Delishevova, FRG

Objectives: Previously (Ujhelyi et al., AIDS 1,161,1987) we worked out a **PEPAIN TEST** measuring the amounts of anti-core and anti-env antibodies hidden in circulating immune complexes. The method is based on the pepsin digestion of isolated immune complexes. In order to clarify whether HIV antigens are destroyed during this treatment, the pepsin sensitivity of purified recombinant env and core antigens was investigated. **Methods:** Purified 39 kDa p24 and 39 kDa p17, digested with pepsin for 16 h at 37°C (enzyme/substrate ratio: 1 to 5) and neutralized. Antigenicity of the core preparations was measured by the indirect immunofluorescence test. **Results:** The antigenicity of the purified env preparation was not destroyed but dose-dependently increased after pepsin treatment. **Conclusion:** The different sensitivity to pepsin digestion of HIV antigens may **CONTRIBUTE** to a difference in their availability to other processes influencing the in vivo processing of the antigens.

M.C.P.148 THE EFFECTS OF TRADITIONAL MEDICINE(SO-SAIJO-TO-SST) ON PROLIFERATION OF HUMAN T4 CELLS (PM2) FROM AIDS A/C PATIENTS

**Mitsuda, Kazuo, Ito, Y., Inagaki, H., Lange, M. and Clark, K.S.,
St. Luke's-Roosevelt Hospital Center, Columbia University, New York, NY, USA**

Objective: We have studied effects of SST on blastofusion assay in PM2 from AIDS patients with AIDS(n=4) and ARC(n=4), and healthy heterozygotes(Hz)(n=20) cultured with or without each medicine(SO, Co, PM2) in the presence or absence of SST (20µg/ml). Proliferation was measured by ³H-thymidine uptake after 96 hr incubation.

Results: Table shows proliferation responses (PM2, Ave. in cpm) of 3 groups with or without SST. Each patient group was further subdivided into a responder and nonresponder group based on positive or absent response to the combination of SST and PM2. As previously reported, major decreases in PM2 were observed in response to PM2 only for ARC and AIDS. SST enhanced proliferative activity (cpm) in all 3 groups and enhanced RT in PM2 in 3/4 AIDS and 2/4 ARC. It is of interest that the greatest enhancing response of SST on PM2 was observed in Hz's from ARC, and occurred maximally in those exhibiting the combination of (1)low RT in PM2 and (2)normal RT in Co. A. The percentage increases observed for the same combination in AIDS, on the other hand, were only similar to that seen in Hz controls.

Conclusion: Our results suggest that SST is able to stimulate monocyte-T4 cell T cell network system and/or suppress T8 cell function.

No.	HIV AIDS		ARC AIDS		Responder/Nonresponder

M.C.P.150 AFRICAN TRADITIONAL MEDICINE AND AIDS

**CHIEF AJISIFINNI, S.O.,
19, Aramoko Road, Box 95, Ijebu-Ekiti, Ondo State, Nigeria.**

African Traditional Medicine is the use of herbs and plants of animal and mineral origin. The medicinal is the oldest known method of healing the sick. Most people in Africa have no alternative than traditional medicine.

The Western trained Medical Doctors and Traditional Healers should be partners in progress to find a common solution for the health of mankind. There should be provision of the traditional healer with a place in the AIDS NETWORK.

Traditional healer is to educate the rural dwellers to know who has AIDS and how to avoid AIDS. My group consists of traditional medicine experts has started research into the preventive and cure for the killer disease - AIDS by using herbs and other ingredients. By GOD'S Will there would be a positive result. AIDS is one disease which all races of humanity should cooperate to fight.

No time in the history of mankind have creatures as small as the AIDS virus caused so much grief and sorrow to so many people.

T.C.P.1

MEASUREMENT OF AFFINITY MATURATION IN HIV-1 INFECTED CHIMPANZEES, Richard S. Kaplan¹, P. Balgova², V.G. Maslova², D.J. Ruvinsky², and J. E. Hahn¹, ¹NIH, ²Harvard Medical School, Worcester, MA, USA, ³Department Foundation for Biomedical Research, San Antonio, TX, USA.

Objective: To quantify the function of affinity maturation in HIV-1 infected animals.
Methods: Over 20 sera for each of the three HIV infected chimps were obtained over a two year period. A modification of the method (Pullen, 1986) was used to measure the avidity of chimp sera for a rec. env. peptide and compared with conventional EA on the same epitope.
Results: All three chimps showed an abrupt increase in titer starting 2-3 weeks after challenge. The titer reached a median between 50 and 100 days and then either declined or remained constant. Avidity increased steadily in all three animals over the two years. A plot of titer vs avidity over the entire course of one year were slightly elevated but the correlation ($r=0.2$). When compared with a panel of HIV positive human sera, the HIV titer and avidity of one year were slightly elevated but the avidity was significantly higher than the mean of the human sera.
Conclusions: HIV titer and avidity of one year were slightly elevated but the avidity was significantly higher than the mean of the human sera. HIV-1 infected chimps showed a steady increase in affinity for the envelope over the two years. Chimps eventually produced higher avidity sera for the envelope than did a random selection of HIV-1 infected humans.

T.C.P.3

ACT INHIBITS LPS-INDUCED SECRETION OF IL-1 BY CULTURED NORMAL HUMAN MONOCYTES.

Marie Lamotte¹ Reafer-Cavillon, M; Laude, M. and Masadoun, A.D.
Unité d'Immunopathologie, Hôpital Broussais, Paris, France.

The failure of 3'-azido-3'-thymosidine (AZT) to inhibit HIV replication in human macrophages is due to the ability of the drug to permeate the cell membrane. Little is known however on the consequences of intracellular accumulation of the drug on monocyte function. The effect of AZT on the ability of unstimulated and LPS-stimulated human mononuclear adherent cells (MNC) to produce interleukin-1 (IL-1) was investigated in vitro. MNC from normal donors were cultured in serum-free conditions with increasing amounts of *Neisseria meningitidis* LPS (0.01-10 µg/5 x 10⁶ cells) for 24 h. AZT alone did not induce IL-1 production in culture. MNC AZT did not interfere with the Coak continuous thymocyte assay for IL-1. MNC exposed to LPS-stimulated cultures. AZT inhibited the extracellular release of IL-1 activity in a dose-dependent manner although it did not affect significantly the induction of cell-associated IL-1 activity by LPS. The latter finding correlated with the lack of effect of AZT on the induction of cell-associated IL-1 alpha antigen by LPS, as assessed by radioimmunoassay. Thus, AZT specifically inhibits the release of functional IL-1 beta by LPS-stimulated monocytes which may allow the molecule with anti-inflammatory properties.

T.C.P.5

CD4+ AND CD8+ CYTOTOXIC T LYMPHOCYTE-MEDIATED LYSIS OF MACROPHAGES EXPRESSING HIV ANTIGENS

Deputy, David J. Murrain, T. J. Dupra, P. and Rinaldo, G.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective: To characterize cytotoxic T lymphocyte (CTL) lysis of macrophages expressing HIV antigens.

Methods: Autologous cultures cultured in vitro for 6 days were either infected with recombinant vaccinia virus (VTV, courtesy of Dr. B. Moss) containing HIV genes or coated with HIV, and used as target cells in a ⁵¹Cr-release assay. Freshly-isolated FMC or FMC cultured for 6 days with UV-inactivated HIV plus IL-2 from HIV seropositive, asymptomatic individuals were depleted of CD4⁺ or CD8⁺ cells and used as effector cells.

Results: Antigen-stimulated CTL mediated a 28.5% mean virus-specific lysis of HIV-infected macrophages expressing env or gag antigens, which was several fold greater than lysis mediated by freshly-isolated, CD8⁺ effectors. Antigen stimulation activated HIV-specific, CD8⁺ CTL in addition to augmenting CD8⁺ CTL. When macrophages were coated with either HIV III₁ or HIV₁ freshly-isolated effectors mediated a 6.5% mean virus-specific lysis; FMC stimulated with HIV antigen demonstrated 8.5% mean lysis. FMC from HIV seropositive subjects did not inhibit these responses.

Conclusions: Macrophages infected with HIV-env, HIV-gag, or whole HIV were lysed by CD8⁺ in vitro. An enhanced cytotoxic response was observed when FMC were stimulated with HIV antigens, which activated CD8⁺ CTL. These results agree with our previous work (J. Immunol., 142(4), 1989) using large simplex virus-infected macrophages, and suggest that both CD4⁺ and CD8⁺ CTL are important in host immune response to HIV.

T.C.P.2

TYPE SPECIFIC CTL RESPONSE TO THE HIV-1 ENVELOPE GENE PRODUCE

Richard Lamotte¹, Karen A.L. Parada, J.P. Flomeno, Ch. Moss, M.D.; Schooley, R.T., and Walker, R.D. ¹Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA; ²Laboratory of Viral Diseases, NIAID, NIH, Bethesda, MD, USA.

Objective: To determine group vs. type specificity of CTL directed at the HIV-1 envelope protein.

Methods: Peripheral blood mononuclear cells from HIV-1 seropositive individuals were cloned via limiting dilution in the presence of a CD3-specific monoclonal antibody (mAb) and recombinant IL-2. Developing clones were tested for cytolytic activity against autologous or allogeneic HIV-transfected 8 cell lines infected with HIV-nucleocapsid recombinant vectors in a 4 hour ⁵¹Cr release assay. A competition assay was conducted by including target cells with and without the addition of effector cells. Results: An HIV-1 envelope-specific CTL clone, designated 43043, lyses target cells expressing the HIV-1III₁ envelope or the HIV-1III₂ envelope up to 10% above control at an effector:target ratio of 2.5:1, but does not lyse target cells expressing the HIV-1IIIB envelope. Lysis is restricted by the HLA class I antigen B2, and is abrogated by monoclonal antibodies to CD3 or CD8, but not CD4.

Conclusions: HIV-1 envelope-specific, HLA Class I restricted CTL are part of the host immune response to HIV-1 infection. This demonstration of a type-specific response to the HIV-1 envelope is an important consideration in design of subunit vaccine strategies.

T.C.P.4

ENHANCEMENT OF LYMPHOCYTE-MEDIATED, HIV SPECIFIC ANTIBODY-DEPENDENT CELLULAR CYTOTOXICITY BY BIOLOGIC RESPONSE MODIFIERS

Murayama, Tsuyoshi and Rinaldo, G.R.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective: To enhance antibody-dependent cellular cytotoxicity (ADCC) mediated by peripheral blood mononuclear cells (PBMC) obtained from HIV-infected subjects, and assayed by biological response modifiers (BRM) Pichilab¹ (OK432 streptococcal preparation, Chugai, Japan) and interleukin 2 (IL-2).

Method: PBMC from homosexual men with known duration of HIV infection and from HIV seronegative controls were examined for ADCC activity against HIV-infected CD8⁺ MNC cells (cell line resistant to natural killer activity) in a 4 h ⁵¹Cr-release assay. PBMC were pretreated with Pichilab or IL-2 for 16 h and then tested for ADCC activity. Serum from an HIV-seropositive homosexual man with ADCC activity was used as the source of antibody.

Results: HIV-specific ADCC activity of PBMC from HIV-seropositive homosexual subjects was significantly decreased in relation to duration of infection. The ADCC response was found to be significantly associated with numbers of CD4⁺ T cells, and CD8⁺ and low IgM NK cells. Additionally, ADCC activity of PBMC from HIV-seropositive and seronegative subjects increased 2-fold after pretreatment with Pichilab or IL-2. We are currently studying mechanisms of the enhancing effect of Pichilab pretreatment on ADCC activity.
Conclusions: Although PBMC from HIV-seropositive subjects can mediate ADCC, the response is impaired in association with duration of HIV infection. BRM-pretreated PBMC exhibited significantly greater ADCC activity than did untreated PBMC.

T.C.P.6

DIFFERENTIAL EFFECTS OF HIV INFECTION ON BLOOD MONOCYTES AND MACROPHAGES IN VITRO AND EFFECTS OF MONOCYTES AND

Ramall, E., Whittle J.M., Foley P., T. J. Dupra and Cunningham A.L. Viriopath and Infectious Diseases Unit, Vermont Hospital, Derby, Vermont, USA.

Monocytes and macrophages are important sites of HIV infection, especially in brain and lung nerves. The sites of differentiation and surface to which these cells adhere in vitro had a major effect on HIV infection and function of the infected cells. HIV infection of recently adherent CD8⁺ positive blood monocytes and five day adherent CD8⁺ negative macrophages with three fresh monotypic HIV isolates showed the differential kinetic pattern. HIV env₁ and p17 levels in infected monocyte cultures remained high for 24 weeks before decreasing and decrease of the cells occurred. Infection of macrophages (within M-CP stimulation) generated much lower HIV levels and to 4 of 4 cultures these declined to undetectable over the weeks leaving persisting viable macrophages. 75% of monocytes and 8% of macrophages were infected at one week (by ELISA). Subsequent infection by CD8⁺ monoclonal antibody almost totally blocked HIV infection of monocytes but had no isotype or no effect on macrophage infection, suggesting the presence of an alternate receptor. Isolation of selected human cell HIV antigens with CD8⁺ negative macrophages after infection with HIV had variable effects. Some sera had high neutralizing titres (1/100-1/200) whereas others produced significant neutralizing activity when the effect of neutralization was measured by production of neutralizing antibody to anti p17. HIV infection of the blood monocytes but not macrophages inhibited presentation of surface antigens or released toxic antigen in human thymocyte T lymphocytes. A known best stable inhibitory factor released by HIV infected monocytes has been identified and is being characterized.

T.C.P.7 **MONOCLONALS PREPARED FROM HUMAN MONOCLONAL ANTIBODIES
CAPABLE TO NEUTRALIZE RICKETS A CHAIN KILL HIV-INFECTED
LINES OF T CELLS AND MONOCYTES**

Solo-Tanaka, F.†††, **Thilly, G.†††**, **Grony NK,†††**, **Parsons S.†††**, **Wu JM,†††** & **Victoria RP.†††**
New York, NY: **MTU and CDC**, New York, NY. **†††** Univ. of Texas Southwestern Med. Ctr., Dallas, TX & **†††** Genentech, San Francisco, CA, USA

OBJECTIVE: To determine whether immunotoxins (ITs) composed of human monoclonal antibodies (mAb) and Ricin A are capable of killing lines of HIV-infected T cells (93) and monocytes (937).

METHODS: Two human IgG mAb specific for p31 were derived from RIV-7-infected B cells from the blood of HIV-infected patients. mAb were coupled to diglycosylated Ricin A chain (dGA) via a heterobifunctional cross-linker. Ricin IT or human IgG-dGA was cultured with HIV-infected 93 or uninfected 93 or 937 cells for 24 hr, and toxicity was assessed by plating cells with ³H-thymidine for 6 hr.

RESULTS: While IgG-dGA did not kill infected 93 or 937 cells at concentrations less than 10⁻⁷ M, both ITs killed 50% of infected 93 cells at 1.5 x 10⁻⁶ M. Similarly, both ITs killed 50% of infected 937 cells at 5 x 10⁻⁶ M. Addition of chloroquine to 937 cultures markedly potentiated specific killing of HIV-infected 937 cells resulting in an IC₅₀ of 4 x 10⁻⁶ M. The specificity of killing was established by showing that both ITs could be blocked by rgp120 but not by rgp120 or human IgG. Neither IT was cytotoxic for Class II⁺ T-lymphoid cells at concentrations below 10⁻⁵ M. **CONCLUSIONS:** ITs composed of human mAb to gp120 and diglycosylated Ricin A specifically kill lines of HIV-infected human T cells and monocytes.

T.C.P.8 **SELECTIVE INFEXION OF MACROPHAGE SUBSETS IN THE LUNG BY HIV**
Johnson, Margaret,††† Lester, L. W. Royal Free Hospital, London, U.K.

It is recognized that alveolar macrophages are a heterogeneous population. Subsets of this population can be distinguished by phenotype using monoclonal antibodies. In HIV-infected individuals the functional alveolar macrophage populations identified by the expression of viral proteins is seen to be a small proportion (2-10%) of total macrophage like cells in bronchoalveolar lavage (BAL). This study sets out to determine whether infection of alveolar macrophages is restricted to one phenotypically distinct subset or is indiscriminate. Sequential immunocytological techniques detecting viral proteins and discriminate antigens of macrophage subsets can be performed on cells spreads obtained from BAL of AIDS patients presenting with pneumonia. Probe to gp120, p24 and p17 proteins will be used in conjunction with MoAb DR11 (detects all macrophages), NP2 (identifying dendritic cells), NP97 (identifying sarcoplasmic reticulum), and UCM1 (identifying monocytes). The distribution of gp120, p24 and p17 antigen expression on each of the populations of cells will be described. The proportions of each phenotypically distinct subset of macrophages expressing viral proteins will be quantitated by performing cell counts. Results presented will reveal whether there is a selective infection of a particular subset of cells and/or whether HIV infection alters macrophage antigen expression. As previous studies have shown a relationship between cell phenotype and function, this study will also reveal whether HIV infection might alter the functional capacity of alveolar macrophage populations.

T.C.P.9 **NORMAL CAPACITY OF MONOCYTES FROM AIDS PATIENTS
FOR UPTAKE AND GROWTH INHIBITION OF MYCOBACTERIUM
AVIUM-INTRACELLULAR**

Johnson, John L.,††† **Shirahata, M.,†††** **Tobe, H.P.,†††** and **Elizer, J.,†††** **CDC Western Reserve University,** **Durham, NC,** **Cleveland, OH,** **Cleveland, OH,** **USA,** and **†††** **Oakac Prefecture Hakbiko Hospital, Osaka, Japan.**

Mycobacterium avium-intracellulare (MAI) is the most frequent cause of late disseminated infection in patients (pts) with AIDS. Interactions of monocytes (MN) from AIDS pts with MAI have not been reported. We examined phagocytosis and inhibition of MAI growth in an *in vitro* model. MN from 11 AIDS pts (3 with disseminated MAI (AIDS-DMA)) and 13 healthy volunteers were pretreated for 2 days and infected with 2 AIDS and 2 non-AIDS associated MAI strains. Uptake of MAI as detected by coating intracellular acid-fast bacilli was similar between AIDS pts, AIDS-DMA, and healthy controls. Intracellular growth of MAI was examined by a colony forming unit assay after 0, 4 and 7 days of culture. MN from AIDS pts were more effective in inhibiting intracellular growth of MAI at 7 d as compared to healthy donors for one of the AIDS-associated strains (p<0.05). Intracellular growth was comparable for the remaining strains. Pretreatment of MN with IFN-gamma for 2 days before infection decreased MAI uptake in both the AIDS and healthy group (p<0.05 for each strain). Culturing infected MN with IFN-gamma 300 U/ml augmented MAI killing at 4 and 7 days by 30-50% for both AIDS pts and healthy donors (p<0.05 for 3/4 strains tested). Healthy controls, AIDS-DMA, and AIDS pts showed comparable effects of IFN-gamma. Since MN from AIDS pts exhibit normal interactions with MAI, disseminated disease can be attributed to an absence of modulating effects of CD4 lymphocytes. The demonstrated *in vitro* activity of IFN-gamma in culture with MN from AIDS pts provides a rationale for its use in immunoregulatory therapy.

T.C.P.10 **DEFINITION OF A SUBSET OF CD4+ LYMPHOCYTES SELECTIVELY
INFECTED WITH HIV/NE USING THREE COLOR
IMMUNOFLUORESCENCE**

Chen, S.A.,††† **Gibbon, J. F.,†††** **Willford, D. A.,†††** **Gale, M.,†††** **Hoffman, P. A.,†††** and **Gallatin, M. D.,†††** **Clinton Foundation Research Center, University of Washington, Seattle, WA 98195,†††** **Hutchinson Cancer Center, Seattle, WA, U.S.A.**

In previous work, we found that macrophages infected with a strain immunodeficiency virus (HIV) isolated from *Rattus norvegicus* (HIV/RNO) have a selective depletion of CD4+ T cells expressing high levels of the CD44 class of adhesion molecule (CD44^{hi}). We determined that productive infection of HIV could be activated in CD44^{hi} CD4+ T cells taken from infected animals, but not in CD44^{lo} cells, and that the CD44^{hi} subset was differentially susceptible to HIV infection *in vitro* (Gallatin et al., PNAS in press, 1988). However, these subsets differ in their response to the mitogen necessary to activate and detect virus *in vitro*. Therefore, we adapted PCR technology for directly identifying HIV in lymphocytes without the need for subsets. We amplified a 596 bp sequence in the CR2 region and found HIV sequences per cell were restricted to the CD4+ CD44^{hi} subset. Next, the target of HIV infection was more precisely defined using color flow cytometry with fluorescein-tagged mAb to CD45R and DNAase. In addition to finding HIV in CD4+ cycling cells, we have also consistently detected viral sequences in CD4+ CD44^{hi} CD45R^{hi} cells which are not in S/G2. The possibility that this latter subset, which has a memory T cell phenotype, is an important reservoir for latent infection, is being explored. In parallel, using PCR technology to detect viral DNA and RNA sequences, we are exploring the kinetics and host cell requirement for early HIV expression in CD4+ subsets. (Supported by NIH grants R01HD15 and CA49372 and by a grant from the American Foundation for AIDS Research.)

T.C.P.11 **PILOT STUDY OF AMBI-LEUNA IN HIV-1 SEROPOSITIVES**
Shelton, D. C.,††† **Nabebech, D.B.,†††** **Gallegos, A.**
Clinical Research Center, Harrow, U.K.

Objective: The CD4 antigen is a receptor for all isolates of HIV. Murine anti-idiotypic antibodies to anti-CD4 monoclonal antibodies inhibit the formation of virus particle. HIV-infected lymphocyte cultures treated with anti-leu3a1(a) is an anti-CD4 antibody that blocks the binding of gp120 to CD4. This study was designed to assess safety (measuring HIV seropositive individuals with LHA, and to measure anti-idiotypic antibody response).

Method: Four HIV volunteers (Walter-Step 3 or 4) received 6 i.v. injections of 1 mg of LHA over a period of 10 weeks. They were monitored for 6 months post-treatment for acute toxicity, alteration of clinical status and routine haematological and biochemical parameters. Antibody response to LHA were measured. T-cell immunophenotyping was performed before each injection and at monthly intervals during follow-up, and at 1 and 24 hours after injection in the first 3 patients.

Results: All patients have completed treatment and two have completed follow-up. There were no adverse reactions to injection or significant changes in routine laboratory parameters or total CD4+ lymphocyte counts. All patients made anti-CD4 and anti-idiotypic antibodies to LHA, detectable at titres between 1/100 and 1/10,000. This was not associated with an increase in HIV neutralization titre, assessed by the spotymin inhibition assay.

T.C.P.12 **INTERACTION OF HIV AND THE COMPLEMENT SYSTEM**
Soldner, Brigitta,††† **Schmidt, J.,†††** **Hornig, G.,†††** **P. P.†††**
Lower, J.,††† **Wachter, H.,†††** **Dierich, M. P.,†††**
Austria,††† **Paul Ehrlich Inst., Frankfurt, FRG**

Objective: As several animal retroviruses have been shown to directly activate the complement system and to be lysed by human serum, we investigated the interaction between HIV and the complement system.

Methods and results: Purified HIV 1 was incubated with human serum and cleavage of the alpha chain of C3 and thus activation of the complement system was revealed using an immunoblotting technique. Recombinant envelope gp 160 was able to activate complement, too, in both cases activation required C4 and Mg indicating the predominant role of the classical pathway.

HIV-infected cells were lysed both in human serum and deposition of C3 was detected in an immunofluorescence assay and immunoblotting technique using an anti-human C3d antibody. In this case complement activation still occurred in the absence of C4 and thus via the alternative pathway. **Conclusions:** These results show that HIV as well as HIV-infected cells activate the complement system via the classical and alternative pathway, respectively. T.C.P.25 **CD8-INH1- CELLS SUPPRESS THE HIV-SPECIFIC T CELL ACTIVITY.**
JOLY M¹, GUILLEIN J-M¹, AUBIN M¹, PLATA P¹, MAYAUD C¹, DEBIE
P¹, P¹, HENRI FILIP-DALEMPYRE P¹, L'AM
Jm. Bio. Mol. Retrovirus, 1 Pasteur, Paris; ²Dr. Prusko, Hôp. Tarnon, Paris.
OBJECTIVE: We have demonstrated HIV-specific cytotoxic T lymphocytes in lungs
and their presence is decreased during the course of HIV infection. The
aim of this study was to detect factors or cells with could down-regulate the
anti-HIV T cell response.
METHODS: Alveolar lymphocytes were recovered from 41 patients at various
stages of the HIV disease. Their cell surface phenotype was determined and
their cytotoxic function was tested against S100-labeled autologous alveolar
macrophages and cell lines expressing HIV proteins; both standard chromium
release assay and limiting dilution analysis (LDA) were performed. Various
cell subsets were tested for their putative suppressor function on HIV-speci-
fic cytotoxicity.
RESULTS: In patients with advanced HIV disease, in whom no significant CTL
activity could be demonstrated in bulk assays, effector CTL specific for
HIV could still be detected in LDA. The biphasic LDA plate suggested the
presence of suppressor cells if analysis of alveolar lymphocytes revealed a
progressive increase of CD8-INH1- cells that suppress plus regression of
anti-HIV CTL activity. Selection experiments and IF cell sorting demonstrate
that alveolar CD8-INH1- lymphocytes suppress the effector phase of anti-HIV
CD8-INH1- lymphocytes. The effector phase of anti-HIV CTLs as well as
anti-HLA CTL lysis was not HIV-restricted. The CD8-INH1- cells did not
kill R502 cells but the HIV-specific effector CTLs were inhibited. In fact
CONCLUSION: Suppressor T cells could thus explain the inefficiency of host
cellular immune defenses against HIV.

T.C.P.27 **ANTIGEN-INDUCED T LYMPHOCYTES ARE PRESENT IN HIV-INFECTED
INDIVIDUALS WHO ARE NON-REACTIVE IN CONVENTIONAL
LYMPHOCYTE PROLIFERATIVE ASSAYS.**
Subst. Staffing: Adams, P. Oncol. C. Pava, M. Fass, R. and Whitaker, C.; The Ohio State University
AIDS Clinical Trials Group, Columbus, Ohio
OBJECTIVE: The lymphocyte proliferative response to soluble antigens such as tetanus toxoid has
been reported to be absent in HIV infection. We examined the response to tetanus in HIV-infected
individuals using conventional lymphocyte proliferative assays in comparison with limiting dilution
analysis (LDA), where a frequency of tetanus toxoid specific T cells can be determined.
METHODS: Bulk proliferative responses of peripheral blood mononuclear cells (PBMC) from ARC,
asymptomatic and seronegative controls were assessed by the uptake of ³-H thymidine after 100
hours of culture with tetanus toxoid. For the LDA, PBMC were serially diluted and cultured with
tetanus toxoid and irradiated autologous T cells for 20 hours. Antigen-reactive cells were
detected by the production of IL-2 using the E dependent cell line, CTL-20. LDA frequencies
were calculated using Poisson distribution.
RESULTS: Lymphocyte proliferative response to tetanus were detected in all control subjects, 5 of the
4 symptomatic persons but none of the ARC patients tested. By LDA, control individuals showed
18576 ± 116,690 (66-104 per 10⁶) tetanus-reactive lymphocytes, asymptomatic persons showed
12685 ± 101,730 (24-442 per 10⁶), and ARC patients showed 116,187 ± 117,046 (66-62 per 10⁶)
lymphocytes. Therefore, discrepancies between proliferative and LDA responses were particularly
obvious in the ARC subgroup of patients.
CONCLUSION: Tetanus-specific lymphocyte secreting cells can be detected in HIV infected individuals
by LDA even when conventional bulk proliferative responses to tetanus are absent. These results
raise important questions about the interpretation of data from lymphocyte bulk proliferative assays
regarding the presence or absence of immune responses. (Supported by NIH grant AIDS P30
A22824)

T.C.P.29 **RELATIONSHIP BETWEEN ANTIBODY AGAINST THE C-TERMINAL
REGION OF GP120 AND PRESENCE OF HIV SPECIFIC
RESPONSES.**
Polonia, Victoria; Hawn, N. * Lee, T. ** Essex, M. ** Burke, D. **
Hendfield, R. B. * Walter Reed Retroviral Research Group and ** Harvard
University, Boston, MA
OBJECTIVE: Characterization of the humoral immune response to the HIV-1
envelope antigens and correlation to stage of infection and ability to
isolate HIV-1 from CSF. **METHODS:** Serum and cerebrospinal fluid from 126
clinically staged patients were characterized with protein dot blot and
Western blot techniques. Antibodies against gp160, gp120 and the specific
regions of gp120 (448c) were studied.
RESULTS: A correlation was found between the presence of specific antibody
(0-48C); clinical stage and inability to isolate virus. This correlation was
not found with antibody titers to gp160 and gp120. Antibody to 448c
was detectable in 70% (46/66) of Walter Reed Stage (WRS) 2-3, as compared
to 28 (11/31) WRS 4+. Antibody to 448c was detectable in 73% of virus
isolation negative and 41% of viral isolation positive patients. Of
seven from WRS 1-2 patients, 73% (5/7) virus isolation negative and 52
(10/19) virus isolation positive demonstrated 0-48C. Of the seven from WRS
5-6 patients, 26% (7/27) virus isolation positive and 67% (4/6) virus
isolation negative demonstrated 448c.
CONCLUSION: These data demonstrate that 448c contains an epitope(s) which
correlates with inability to isolate virus from CSF. These data also
demonstrating a relationship between 0-48C and parameters of effective
viral immune regulation.

T.C.P.26 **AN ILA-OR, LIGHT DENSITY, PERIPHERAL BLOOD MONONUCLEAR CELL
PRODUCES ALPHA INTERFERON IN RESPONSE TO HIV**
Rissold, Charles; Tove, J.; Rappaport, C.; Gupta, P. and
Perhas, J. University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.
OBJECTIVE: To characterize alpha interferon (αIFN) production induced by
HIV in cultures of peripheral blood mononuclear cells (PBMC).
METHODS: PBMC from healthy HIV seronegative donors were enriched for differ-
ent subpopulations and incubated for 16 hr at 37°C with HIV-infected 9327
(9327) promonocytic cells. Supernatants were assayed for αIFN by anti-
viral activity in human WISH cells; by neutralization with antiserum to αIFN,
and by stability after treatment at low pH.
RESULTS: Percent gradient density and flow cytometric analysis showed that
light density, ILA-OR⁺ PBMC were responsible for production of acid-stable
αIFN in response to 9327.
CONCLUSION: PBMC which produce acid-stable αIFN in response to HIV-infected
promonocytic cells are light density and ILA-OR⁺ and are not present within
the predominant populations of T_H1, T_H2 and anergic cells. Smaller subpopulations
of light density, ILA-OR⁺ PBMC have been associated with augmented
αIFN production, and did not suppress less than 1% (NK cell marker).
NK cell lysis of HIV-infected promonocytic cells (Rappaport, et al., J.
Clin. Micro. 27:41, 1989).

T.C.P.28 **THE IMPERMEABILIZATION OF NERVE IMMUNOREACTIVITY VIRUS IN
NERVE SODAS**
Emond, Joseph; Polonia, V. * Hawn, N. * Lee, T. * Hix, D. *
Hendricks, R. * Burke, D. * Hendfield, R. * * Walter Reed Retroviral
Research Group, Washington, D.C. U.S.A.
OBJECTIVE: To characterize the humoral immune response to HIV viral
specific proteins and epitopes in the male genital tract.
METHODS: Ten male HIV seropositive subjects were evaluated to
characterize the immune response against HIV viral proteins and epitopes
in the seminal plasma as compared with matched sera. In vivo viral
antigen load in the two compartments was evaluated by isolation of HIV
from semen and peripheral blood, and by measurement of free p24 in seminal
plasma and sera.
RESULTS: Antibody production against viral envelope proteins are
observable in seminal plasma and sera however, there is a marked decrease
in reactivity against specific HIV structural proteins in the seminal
compartment. The presence of antibodies against unique envelope epitopes
is currently being evaluated. Eight of ten HIV (+) subjects had positive
peripheral blood cultures for HIV. Of these eight subjects, only two had
positive semen cultures for HIV.
CONCLUSION: These differences may reflect either poor antibody production
or differential viral protein expression in the male reproductive tract.
This data supports the concept that the male reproductive tract is a
privileged immunologic site.

T.C.P.30 **CYTOKINE AINER SUSCEPTIBILITY OF HUMAN MONOCYTES TO
INFECTION BY HIV-1**
Gillespie, David B., Gendelman, H. M., Holtzer, M. **, and
Walter Reed Retroviral Research Group, Walter Reed Army Medical Center, "M.H.
Research Foundation, Walter Reed Army Institute of Research, Washington,
D.C., United States of America
OBJECTIVE: Evaluate effects of cytokine pretreatment on the interaction of
HIV-1 with blood-derived monocytes in vitro.
METHODS: Human monocytes (interleukin 1, 2, 3, and 4) have been shown to be
altered and infection in media with recombinant human colony stimulating
factor-1 (M-CSF), Onco Corp., Bayville (IL). After 7 days, any of several
recombinant human cytokines (interleukin 1, 2, 3, and 4) have been added to
as 0M-CSF, interleukin 1, 2, 3, and 4 were added at 5 to 500 units/ml for 24
hours to M-CSF-treated monocytes. All cultures were washed. HIV RNA, a
monoclonal anti-HIV-1 strain, was added to pretreated and control monocytes.
Culture fluids were monitored for viral p24.
RESULTS: Viral p24 antigen was detected 2 weeks after HIV infection in all
M-CSF-treated control monocytes cultured without additional cytokine
pretreatment. Most cytokines had little or no effect on p24 release over
this time interval. In contrast, levels of p24 antigen in culture fluids
were significantly reduced by 5 to 500 units/ml M-CSF.
CONCLUSION: Pretreatment of monocytes with any of several different
cytokines alters infectivity of HIV for monocytes. Such *in vitro* testing of
immune-modulating agents may prove beneficial in the selection of therapeutic
regimens for infected individuals.

T.C.P.37 IDENTIFICATION OF COMMON EPITOPES OF HIV 1 AND HIV 2 BY MONOCLONAL ANTIBODIES

Zur, Bernd and Habermann, K.-O.
Institute for Clinical and Experimental Virology, Free University of Berlin, Hindenburgdamm 27, 1000 Berlin 45, FRG

26 monoclonal antibodies were prepared, directed against our HIV 2 isolate with intertypic characteristics (HIV-MDS) and tested against HIV 2 (NH2), HIV-1 (HTLV 3B) and HIV-MDS. The tests were performed with ELISA, RIPA, and Western Blots prepared by sucrose-gradient-purified antigens as well as by recombinant envelope protein from HIV-1 (aa 350 - aa 750, Dupont). 8 of the monoclonal antibodies directed against the envelope reacted group-specifically with all virus antigens. A second group of 8 monoclonals detected against sucrose-gradient-purified antigens as well as by recombinant envelope protein from HIV-1 (aa 350 - aa 750, Dupont). 8 of the monoclonal antibodies directed against the envelope reacted group-specifically with all virus antigens. A second group of 8 monoclonals detected against gag-pol reacted also with all virus antigens. A third group of 10 monoclonals directed against structural and non-structural virus proteins reacted type-specific just with the HIV-2 isolates. The significance of the identified epitopes for the neutralization of the virus strains has been determined.

T.C.P.39 HIV INDUCED, HIV SPECIFIC IN VITRO ANTIBODY RESPONSE.

Zszo-Francoise Balfrainy, C. Wallon, F. Boas, J. Dorment, P. Galanoud, F. Barre-Sinoussi
INSERM, U 131, Clamart, Institut Pasteur, Paris, France.

Objective: To induce specific B cell response to HIV protein or env gp160 protein.
Methods: Purified B were cultured in vitro in the presence of purified T cells or IL2, with different preparations of HIV unfractionated protein preparation. The specific HIV response were measured by ELISA and Western Blot.
Results: no response was observed in negative donor. In HIV positive, HIV induced a specific antibody response. Anti HIV ab were only obtained when T cell help was provided by Interleukin 2 and Interferon alpha but not in the physical presence of T cells. Anti HIV ab produced in cultures were predominantly directed against gp160 and or gp120. In vitro antibody production was inhibited by cyclosporin, anti env 3, man, but inconsistently by anti CD4. The antibody responses required the presence of autologous monocytes which can be replaced by Interleukin 6. Allogenic monocytes are not functional. Identical results were observed with gp160 peptides.
Conclusion: HIV specific in vitro antibody response directed the env proteins can be induced in HIV+ patients, but not in HIV- controls.

T.C.P.41 FcR expression in HIV-1 infected T cell Lines

C. Corini, M. Chierohi, F. Aiuti, Dept. Allergology & Clinical Immunology, Univ. of Rome "La Sapienza", Rome, Italy.

It is well known that HIV transformed B lymphoblastoid cell lines, such as SP 1866, express a large number of FcR on their surface. It has been recently reported that mRNA encoding the FcR β was not detected in normal human T cells or T cell lines except HIV-1 transformed T cell lines. These findings suggest to us the possibility that infection of T cells with another retrovirus HIV-2 might induce the expression of FcR on T cells or formation of IgG β . We then tried to analyze the presence of FcR on 3 HIV infected T cell lines by cytofluorescence by using double staining with anti-CD4 or anti-CD8 and an anti-FcR monoclonal antibody. To detect the presence of IgG β in the culture supernatant of these HIV infected T cell lines a passive inhibition assay was used. Preliminary results of the HIV infected T cell lines studied indicate that to only one showed a clear expression of FcR at 3 days of culture as analyzed by cytofluorescence. In contrast the presence of IgG β was seen in 2 of the 3 lines examined. These preliminary results indicate that infection of T cells with HIV-2 could induce the expression of FcR on T cell lines and the formation of IgG in the culture supernatants of the T cell studied.

T.C.P.38 EFFECT OF HIV ON ANTIGEN-INDUCED T CELL PROLIFERATION

David, Sarah*, Berrett, R.*, Dornier, F.*, Gallo, R.C.**, Ehl, H.M.**, Nishiura, C.M.**,
*IMMO AG, Innsbruck, Austria; **Inst. of Immunology, Univ. of Vienna, Austria; **M.C.I., N.I.H., Bethesda, USA.

Objective: Examination of antigen-induced T cell proliferation in response to a particulate antigen (Ag) and tetanus toxoid following infection of the cells by HIV. **Methods:** In one set of experiments, monocytes (Mo) were pulsed with antigens prior to co-cultivation with autologous T cells and HIV (HIVEX-1001) (Mo). In the second set of experiments, both HIV and antigens were added to the cultures upon initiation of the incubation period. Antigen-induced T cell proliferation was measured by ³H-thymidine incorporation after 7 days of incubation. **Results:** A difference was found when either pre-pulsed or non-pulsed Mo stimulating the HIV-induced T cell proliferative response in the presence of infectious HIV. HIV caused a dose-dependent suppression of antigen-induced T cell proliferation in the presence of the pre-pulsed Mo. T cell proliferation in response to tetanus toxoid-pulsed Mo decreased from 4.1 ± 2.8 dpm \pm s.d. \times 10³ in the absence of HIV to 0.8 ± 0.1 dpm \pm s.d. \times 10³ in the presence of HIV (MOES 100). The simultaneous addition of antigen and infectious HIV to the Mo in the second set of experiments led to an increase of T cell proliferation, e.g. in response to tetanus toxoid, T cell proliferation increased from 25.0 ± 1.2 dpm \pm s.d. \times 10³ in the absence of HIV to 68.5 ± 5.7 dpm \pm s.d. \times 10³ in the presence of HIV, MOES 100 (Mo). Similar data were observed with Ag. **Conclusion:** Addition of infectious HIV to co-cultures of T cells and antigen-pulsed Mo results in a 2.5 fold increase of antigen-specific T cell proliferation. Conversely, the simultaneous presence of T cells, Mo, antigens and HIV in the cultures leads to an increase of the antigen-induced T cell response.

T.C.P.40 TUMOR NECROSIS FACTOR INHIBITS ACTIVATION OF B CELLS BY HUMAN IMMUNODEFICIENCY VIRUS (HIV)

Zszo-Francoise Balfrainy, C. Wallon, F. Boas, P. Galanoud and F. Barre-Sinoussi. INSERM, U 131, Clamart, Institut Pasteur, Paris, France.

Objective: In vitro HIV induced B cell proliferation. However the precise interactions between HIV and first steps of B cell activation and with B lymphokines are poorly understood. **Methods:** We have investigated the effects of recombinant human tumor necrosis factor alpha (TNF alpha) on human B cell proliferation. Human B cells were activated by anti-mu ab, B lymphokines (12 Id MOCP, 12 Id, Polvoked nitrogen (PWN) or HIV unfractionated protein preparation. **Results:** TNF-alpha acts as a B cell growth factor on anti-mu activated B cells. TNF-alpha does not modify the B cell proliferation induced by anti-mu ab and lymphokines or PWN. HIV preparation supports a moderate B cell proliferation enhanced by the 12 Id MOCP or IL2. TNF alpha inhibits in a dose dependent manner the HIV induced proliferation. This effect is not due to a cytotoxic activity and is observed in the absence of monocytes. Interferon alpha and gamma have no inhibitory effect in the same culture conditions. **Conclusion:** We conclude that TNF alpha can selectively modulate the B cell activation induced by HIV in vitro.

T.C.P.42 PREVALENCE OF ANTI-HEL POSITIVE BERA IN HIV-INFECTED PATIENTS: IMPLICATION OF THE MAJOR EPITOPES OF THE PROTEIN LAMIN B SYNTHETIC PEPTIDES.

BARRAGAN ECHIBURU, M. VAN RIETSCHOTEN, A.L., GRANIER, C.T., OLLODMAN, J.C., J...
MONTAGNER, L., SABAITER, A.M.

* INSTITUT PASTEUR PARIS
* CNRS UA 1179 MARSEILLE
* CERS-PAFIS, FRANCE

Objective: To study the prevalence of anti-hel positive sera in HIV-infected patients and to map the immunodominant epitopes using synthetic peptides.

Methods: Human sera were tested for the presence of anti-hel antibodies by RIA with recombinant 125 I-labeled expressed in E.coli and by ELISA using synthetic peptides.

Results: Among the HIV positive sera tested by RIA 70 \pm 6.5 % were found anti-hel positive. Anti-hel antibodies bound to hel with high affinity (K_D 5.5 - 2.2 10⁷ M). Anti-hel positive sera were assayed on a set of synthetic peptides (ranging from 11 to 86 a.a. and spanning the total sequence of hel from HIV-1), which showed a significant diversity of the immunodominant antigenic sites. A strong immunoreactivity was observed with either N-terminal or C-terminal regions meeting a heterogeneity of the humoral response against hel.

Conclusion: These results provide a means for an early diagnosis of HIV infection based on the detection of anti-hel antibodies using synthetic peptides.

T.C.P.43 INCREASED SERUM LEVELS OF SOLUBLE IL-2 RECEPTORS (sIL-2R) IN HIV INFECTION: CORRELATION STUDIES AND CLINICAL SIGNIFICANCE
André Jean-René Courroux, G. Levy, S. ; Alekajevic, A. ; Lehr, L. and Koch, J.
Université Louis Pasteur, Strasbourg, France.

Objective: To gain further insights into the cell origin(s) and clinical significance of elevated sIL-2R in HIV infection.

Methods: sIL-2R were measured using a sandwich enzyme immunoassay in 105 consecutive HIV-infected subjects. Data were further correlated with biological markers of disease activity. Follow up studies were performed every 4 months in untreated and AZT-treated individuals. To assess whether elevated sIL-2R may contribute to the immune defect sIL-2R were generated in vitro and supernatants were tested for inhibitory activity on NK cell activity and lymphocyte transformation.

Results: The increase of sIL-2R in HIV-infected patients was confirmed, but in our series subjects presenting with PGL showed significantly higher sIL-2R levels than asymptomatic individuals (p. 0.001). Increased sIL-2R were strongly correlated with neopterin and beta-2 microglobulin. No correlation was found with CD4+ cell counts, CD4+/CD8+ ratio, activated T cells (CD3+, IL-2R+) or serum IgG. Follow up studies showed an increase of sIL-2R with time and without clinical evidence for progression. Follow up studies in AZT-treated patients will also be presented. Analysis of the in vitro studies is still ongoing and will be reported at the meeting.

Conclusion: The data strongly suggest that elevated sIL-2R in HIV infection reflect neither monocyte and possibly B cell alterations than T cell activation and/or destruction. The significance of sIL-2R as a marker for progression will be discussed as well as their contribution to the immune defect.

T.C.P.44 LOW LEVELS OF LFA1+ CELLS IN HIV INFECTION
André Courroux, Robert, J., May, Th., Bess, M.C., Faure, G., Canton, Ph., Department of Infectious Diseases and Lab. Immunology, CHU Nancy France

Objective: LFA1 (Lymphocyte Function Antigen 1) is a membrane molecule of the CD35 family, involved in cell-to-cell interactions and more specifically expressed on more than 90% matured cells in the peripheral blood (PB). In a previous study, we established that significantly lower percentages of lymphocytes of PB lymphocytes expressed this molecule in HIV-infected patients. These data suggested that a decrease in LFA1 expression could be involved in the immunodeficiency of HIV- and AIDS patients. This observation was confirmed in a new series of patients, and a follow-up study was performed.

Methods: LFA1 expression on PB lymphocytes was studied using classical indirect immunofluorescence techniques with a monoclonal antibody from Immunotech (Luminy-France). Patients were divided in two groups, according to CDC classification (group I= stage II and III; group 2=IV1 and IV2).

Results: In spite of careful monitoring and therapeutic attempts with AZT, low levels of LFA1+ cells persisted in initially "low" patients. Patients with a progressive decrease of LFA1+ cell percentage under 30% were developing AIDS-disease at this time.

No correlation was found for the two groups between CD4+ cells count and LFA1+ cells, no more between CD4+ and LFA1+.

Conclusion: LFA1 expression in HIV infection is significantly decreased, similar to the immune deficiency of CD4+ cells, and could represent a new predictive factor of AIDS on a long-term follow-up.

T.C.P.45 EXPRESSION OF THE T-CELL RECEPTOR MOLECULE IN HIV INFECTION
André Courroux, Bess, M.C., May, Th., Faure, G., Canton, Ph., Department of Infectious Diseases and Lab. Immunology, CHU Nancy - FRANCE.

Objective: T lymphocytes recognize foreign molecules using the T-cell receptor (TCR), a disulfide-linked heterodimer, closely associated with the CD3 polypeptide on the cell surface. We studied in a series of 130 HIV patients, the expression of the TCR molecule in addition to those of CD3, CD4, CD8 and IFA1 (adhesion) molecules, on peripheral blood lymphocytes (PB).

Methods: Classical indirect immunofluorescence techniques were used, with monoclonal antibodies from Coulberrines (for CD3, CD4, CD8), Immunotech (for IFA1) and Decton-Biotinman (for TCR-alpha chain).

HIV patients were divided in two groups, according to CDC classification: group 1 = stage II and III (N=100); group 2 = stage IV1 and IV2 (N=30).

Results: As expected, a highly significant correlation was found between CD3 and TCR + cells percentages, in both groups. But TCR percentages (respectively 46.7 and 31.2 for groups 1 and 2) were constantly lower than CD3 (61.4 and 57.7). The TCR/CD3 ratio was 0.8 (gr1) and 0.5 (gr.2).

Conclusion: These data show a defective expression of TCR, occurring even at an early stage of HIV infection. This may add to the immune deficiency.

T.C.P.46 MOST SERA FROM HIV INFECTED INDIVIDUALS CONTAIN HIV ANTIGEN AS IMMUNE COMPLEXES
Hélène, Pascale, Havaux, S., Basso, S., Deves, N., and Faure, J., UCLA Schools of Medicine and Public Health, Los Angeles, CA, USA. E.L.D. Port Co., Orange, CA, Whittney, DE, USA.

Objective: To develop a method for improved detection and quantitation of HIV p24 antigen and to check whether the loss of detectable HIV antigen while the viral titers of asymptomatic HIV seropositive could be due to low or absent synthesis of viral antigen and/or to the formation of immune complexes containing HIV antigen.

Methods: Detection of immune complexes and quantitation of antibodies with little or no coagulation of HIV antigen by low pH treatment of the samples before detection by ELISA.

Results: In control experiments with artificial mixtures of HIV antigen and HIV antibody no problem was seen. It was demonstrated that: 1) In both positive mixes were caused by the treatment; 2) High HIV antigen positivity (45 vs 10%) as well as the amount of measured antigen were significantly increased; 3) while only 60% HIV antibody positive sera contain free antigen, in many sera the antigen is in the form of immune complexes; 4) detectable HIV antigen was detected by ELISA.

Randomly selected HIV antibody positive sera (N=110) from asymptomatic patients were tested for p24 antigen in serial dilutions after and after precipitation. Substantive increases (median 51.7% vs 11.8%) and fold factor 3.8 were obtained after precipitation. Similar increase (58.7% vs 34.8%) was observed for the group of 40 tested AIDS sera.

Thus an additional 60% of sera from both groups contain p24 antigen in the form of immune complexes which are detectable only after precipitation. Sera from both consecutive tests (20 month period, 6 month follow up) of retrospective seroconverters were tested for presence of p24 antigen after detection of immune complexes. Seven individuals (37.5%) never express any kind of detectable antigen, but 80.0% showed significant p24 positivity and 19.50% positively seroconvert. One case is shown in their details. The antigen can be directly detected only at periods when antibody-antigen ratio is low. At higher ratio p24 antigen is present as immune complexes and can be detected only after precipitation.

Conclusion: HIV sera from HIV infected individuals contain HIV antigen. It is mainly in the form of immune complexes and can be detected by the proposed method. The results suggest that most patients of HIV infection seroconvert to sera. One group of individuals never express HIV antigen, another relatively large group predominantly shows p24 and only a small group shows significant p24 positivity.

T.C.P.47 PROTECTIVE IN VITRO HIV INFECTION OF NORMAL CD8+ LYMPHOCYTES
Richard E. and Lewis, D.E., Howard Hughes Medical Institute, Department of Microbiology and Immunology, Baylor College of Medicine, Houston, TX, U.S.A.

An increase in the numbers of CD8+ lymphocytes occurs early in HIV infection. The role of CD8+ cells in HIV infection is not clear; however, several laboratories have shown that CD8+ cells play a protective role. In order to develop an *in vitro* system to study the effects of HIV infection on normal CD8+ T cells, peripheral blood lymphocytes (PBs) from HIV-negative donors were cultured with phytohemagglutinin (PHA) for 3 days and then infected with HTLV-IIIIB. After reculture for 3 days, infected cells were irradiated and cocultured with uninfected PBs from the same donor. Previous results indicated that most CD8+ cells are depleted in such cultures after 6 days (FAHNS 2: 2251, 1988). Cocultures and control uninfected cultures were grown in recombinant interleukin 2 for more than 3 months. HIV was monitored by electron microscopy and by p24 antigen ELISA. Cocultures were strongly positive for HIV p24 whereas uninfected control cells were negative. On day 26 after the start of the cocultures, cells were sorted into CD8+ and CD8- cellular fractions. The sorted infectious CD8+ fraction was strongly positive for HIV p24 (1.3x10⁶ IU/ml) however, the CD8- infectious fraction was only weakly positive (0.2x10⁶ IU/ml) when compared to HF-infected control cells (1.457 x10⁶ IU/ml). Thus, CD8+ cells can become productively but nonproductively infected with HIV. This may result from the development of a CD8+ CD8+ intercellular cell or after direct cell-to-cell transmission. The relevance of this data to the CD8+ cellular abnormalities in AIDS is unclear but suggests that HIV interactions may be more complicated than previously appreciated.

T.C.P.48 CD8-DRIVEN PEPTIDE PROTECTS CD4+ T CELLS FROM HIV-1 INFECTION
Robert, J., Bess, M.C., May, Th., Bess, M.C., Faure, G., Canton, Ph., Department of Infectious Diseases and Lab. Immunology, CHU Nancy France

Objective: To identify primary sequences within the CD8 molecule that may be involved in the killing of the HIV-1 envelope. Maybe be synthesized with respect to corresponding to different domains of CD8 molecule. HIV-1 gp120 (100 ng/ml) was pre-incubated with CD8-derived peptides before adding to HIV-1 infected cells. HIV-1 infectivity was measured by staining cells with OX74 or Leu24 using FACS analysis. HIV-1 infectivity was measured by ZAIRF were added to BOUT cells in the presence or absence of CD8-peptides. Blocking of apoptosis formation was measured after 2 days.

Results: We identified a 20 amino acid peptide (aa 74-95) which was able to block HIV-1 infection of CD4+ T cells from infection by different, divergent strains of HIV-1 (at a concentration of 25-50 µg/ml). A shorter fragment of the CD8-transmembrane peptide (aa 81-95) was needed at higher concentrations (1250 µg/ml) in order to block 100% of apoptosis formation following infection with HIV-1. Inhibition of giant cell formation was also seen when the peptide was added 2h after the induction of viral infection. The CD8-peptide (74-95) and the shorter fragment (81-95) succeeded (in a similar efficiency) to block HIV-1 gp120 binding to CD4+ T cells. HIV-1 gp120 and CD8-derived peptides examined had no effect on gp120 binding and did not block giant cell formation induced by HIV-1. HIV-1 gp120 binding to CD4+ T cells provided particles (40%) protection against HIV-1 gp120 binding to CD4+ T cells.

Conclusion: The CD8 region (74-95) participates in the CD8-mediated killing of the HIV-1 virus and may be of diagnostic value in blocking spread of the virus in infected individuals.

T.C.P.49 HIV-1 DISEASE STATUS AND SEROREACTIVITY TO GAG, POL, AND ENV GENE PRODUCTS

Abstract: Phillips F., Grove, T., Chagn, C.S., Mokkian, C.W., White, G., and Matthews, J. *Ochsle University Medical Center, Durham, N.C. *University of North Carolina, Chapel Hill, NC, USA

Objective: To determine possible relationships between HIV-1 disease status and seroreactivity to gag, pol, and env gene products.

Methods: Blood sera from 360 seropositive hemophiliacs were assayed for reactivity to synthetic envelope V3 loop peptides and 7 bacterial recombinant peptides (REAGENTS). The latter represent HIV-1 (IIIB) gp120, gp41, p55, p51, and p66/RT. Disease status was determined by absolute T cell count and, when available, Western-blot stage.

Results: Correlations between seroreactivity to the various gene products and disease status were analyzed. Reactivity to the immunodominant envelope V3 loop peptides was found to be elevated in the hemophilic population since 1985 is probably not too late to expose to newly infecting isolates but would rather suggest a mixture over time of the original genotypes present in the pre-1985 Factor VIII concentrates.

Conclusions: About 50% of the 360 sera were positive for the N-terminal gp120 recombinant fragment (arg. absence 2800), whereas 93% were positive for the C-terminal fragment (arg. absence 12736). Reactivity to V3 loop peptides was only 35 for the IIIb peptide vs. 80% for 66.

T.C.P.50 PHENOTYPIC CHARACTERIZATION OF THE EXPANDED CD4⁺ T_H CELL POPULATION IN PATIENTS WITH HIV INFECTION

Abstract: Sica, A., McCune, J.A., and Richman, D.C. University of California, San Diego and the VA Medical Center, San Diego, CA, USA.

Objective: To determine whether the abnormal subpopulation of CD4⁺ T_H cells in HIV infection belongs to a specific subset which can be characterized by co-expression of additional antigenic markers.

Methods: Highly purified CD4⁺ cells (90%) were isolated from peripheral blood lymphocytes by negative selection through serial steps of "panning" and complement-mediated lysis. Dual-stain (FITC/PE) monoclonal antibody analysis was performed by automated flow cytometry on these CD4⁺ cells, effectively giving a triple antigenic population. Samples from 20 HIV seropositive subjects (10 asymptomatic, 12 ARC, 2 AIDS) were analyzed and compared to 15 healthy HIV seronegative controls (10 non-smoking males, 5 homosexual males, HC).

Results: The CD4⁺ phenotype subpopulation of CD4⁺ T_H cells is abundantly expanded in HIV seropositive subjects and comprises major cell populations in both the asymptomatic and the asymptomatic AIDS/ARC, mean of 40% (range, 18-60%; asymptomatic HIV⁺ 30% (18-45%); HM controls, 10% (range, 5-18%; HIV⁻ 9% (3-18%)). Because HIV seropositive men (HIV⁺ vs. HIV⁻) were of this cell subset, it has been questioned whether this population has any direct relationship to the disease process in HIV infection. Our study demonstrates that HIV⁺ men have a major portion of the CD4⁺ T_H cells which express the cell activation marker Lys-1/OK-170. 69% and 41% in ARC/AIDS and asymptomatic HIV⁺ seropositive men, respectively, compared to 20% of the CD4⁺ T_H cell subset from healthy seronegative men. This expanded, activated CD4⁺ T_H cell subset is also characterized by the expression of the α chain of TCR- γ (94%) and, therefore, is part of the mature T cell population consisting of asymptomatic HIV⁺ (40%) and the HIV⁻ controls (45-50%).

Conclusions: The expanded CD4⁺ T_H cell subset found during HIV disease progression appears to be derived from a distinct cell subgroup which is phenotypically different from that found in uninfected subjects, and may prove to be functionally heterogeneous as well.

T.C.P.51 IMMUNODOMINANT EPITOPES OF GP120: A POTENTIAL OBSTACLE FOR VACCINE DEVELOPMENT

Abstract: Wang, W. F., Wang, R.D., Huang, M., Lee, Tzung-shi, et al. Harvard School of Public Health, Boston, MA, USA.

Objective: The mature gp120 has 18 epitopes that are conserved in nearly all HIV-1 isolates. The double-bridge dependent epitopes of gp120 are immunogenically more dominant than the double-bridge independent epitopes. The predominant type of gp120 antibodies detected in susceptible people are those that are directed to the double-bridge dependent epitopes of gp120. Our working hypothesis is that double-bridge dependent epitopes serve an immunomodulatory role and act largely non-protective antibodies. The objective of this study is to remove the immunomodulatory double-bridge dependent epitopes from the HIV-1 gp120.

Methods: The approach of site-directed mutagenesis was carried out to replace cysteine residues with other amino acids in gp120. The antigenicity of the genetically-modified gp120 was studied by radioimmunoassay and Western blot assays.

Conclusions: HIV-1 gp120 mutants that lost immunodominant epitopes yet remained infectious were identified. Such mutants may have a better potential to induce functionally important gp120 antibodies.

T.C.P.52 DIFFERENCES AMONG LYMPHOCYTE SUBPOPULATIONS IN HIV POSITIVE OR NEGATIVE HOMOSEXUAL AND HETEROSEXUAL MALES

Abstract: Schellhain-Bialk, Gerald; Meier, M. B.; Jones, S.B.; Pife, R.H., and Walker, E.H. Dept. Medicine, Indiana Univ. Sch. of Med., Indianapolis, IN, U.S.A.

Four-color flow cytometry was used to determine surface antigens on peripheral blood lymphocytes. Volunteers included normal, heterosexual males (N=20), HIV-1 homosexual males (H=20), or HIV-1 homosexual males that were divided into two groups based on a total CD4/IL-2 blood count of >500 (H<2), or <500 (H<2).

Statistical significance was accepted at $p < 0.05$. The CD8⁺ lymphocytes was significantly greater in HIV-1⁺ homosexuals (H<2) compared to heterosexuals (N2) and even greater in the HIV-1⁺ >500 group (43%) and <500 group (48%). The CD8⁺ cells that also expressed CD38, an activation antigen, but not CD45 (a marker which reflects indices of expression on the CD4 background), was significantly greater in the HIV-1⁺ <500 group (7%) and <500 group (4%) compared to HIV-1⁻ males (1%).

The significant increase in CD4/CD38 expression between the <500 and >500 groups could be attributed to 7/23 individuals in the <500 group whose sera was positive for HIV p24 antigen. The CD8⁺ cells that expressed both CD38 and CD45 was significantly greater in the <500 group (8%) compared to the >500 group (3%), and could not be accounted for by p24⁺ individuals.

Therefore, CD38 alone on CD8 cells may reflect active viral replication, whereas CD38 and CD45 on CD8 cells may represent a subset alteration that correlates with progression of the disease. This work was supported by NIH U10 AI 2889-01 AIDS.

T.C.P.53 ENVELOPE GLYCOPROTEIN OF HIV-1 LIMITED EXPRESSION OF mRNA FOR IL-2 RECEPTOR FOR IL-2-INDUCED T CELL CLONES

Abstract: Zandi, Maki, Iritani, H., Imai, M., Malyaravanan, V.S., Slade H. and Paves S. Department of Pediatrics & Medicine, North Shore University Hospital, Cornell University Medical College, Westchester, NY, Biometrics Research Inst., Rockville MD, U.S.A.

Objective: To determine whether IL-2 and IL-2 receptor (IL-2R) gene expression are suppressed by the envelope glycoprotein of HIV-1 (gp120). **Methods:** gp120 was purified from HIV-1⁺ infected Hc 7a cell culture supernatants by affinity chromatography. Tetanus antigen-specific T cell clones independent of exposure to IL-2 were derived from a normal individual. The mRNA for IL-2 and IL-2R were determined by specific cDNA probes by northern blot analysis.

Results: Cloned T cells proliferated and expressed mRNA for IL-2 or IL-2R only when cultured in presence of tetanus antigen. Proliferation of the cloned T cells for 6 hours with 0.1 to 0.001 μ g/ml of gp120 resulted in dose dependent suppression of mRNA for IL-2 and of tetanus-specific proliferative response. Although the cells that had been treated with gp120 showed a significant decrease in their ability to express IL-2R (tested by staining with anti-IL2R mAb and analyzed by flow cytometry), the IL-2R gene expression was not suppressed. In T cell clones stimulated with mAb directed against surface molecules CD3 and CD28 (plus PHA), proliferative response and mRNA for IL-2 and IL-2R were unaffected by gp120 treatment.

Conclusion: The results demonstrate that gp120 selectively inhibits antigen-specific T cell responses by inhibiting IL-2 mRNA. Suppression of IL-2 expression by gp120 appears to occur at post-transcriptional level.

T.C.P.54 INTERFERON- α AND INTERLEUKIN-2 BUT NOT INTERFERON- γ MODERATE NATURAL KILLING OF HIV-INFECTED TARGETS AMONG HIV-1 SUBJECTS

Abstract: Janney, John M., M. University of Texas Medical Branch, Galveston, Texas, USA.

Objective: To evaluate the effects of recombinant interferons (IFN) and Interleukin-2 (IL-2) on natural killer cytotoxicity (NKC) of HIV (+) and (-) individuals in the presence of recombinant interferons.

Methods: Ficoll-purified separated peripheral blood mononuclear cells from HIV (+) and both Group II asymptomatic (Gp II) and Group IV asymptomatic (Gp IV) HIV (+) individuals were incubated for 18 hrs with medium, 1000 IU rIFN α or rIFN β , or 50 IU/ml rIL-2 prior to a 4-hr ⁵¹Cr-release assay against CD4⁺ target cells.

Results: Mean NKC of controls was 38 LU for controls (n=12), 17 LU for GpIV HIV (+) (n=8), and 10 LU for GpII HIV (+) (both <10). Significant (p<0.05) augmentation of NKC by rIFN- α occurred among all groups (21 LU, 100 LU, and 64 LU), as did augmentation by rIFN β ser (96 LU, 55 LU, and 41 LU). There was no significant augmentation of NKC by rIFN γ ser among controls (44 LU).

Conclusion: NKC against HIV-infected cells is significantly decreased in GpIV with each stage of HIV infection. The effect of augmentation of NKC by rIFN β and rIL-2 but not rIFN α may suggest 1) an effect of HIV on IFN responsiveness of NKC, and 2) potential for immunoreconstitution with rIFN β or IL-2 among HIV (+) individuals.

T.C.P.55 CORRELATION OF ADCCC AND NEUTRALISATION WITH A BETTER CLINICAL STAGE IN CHILDREN BORN TO HIV-1-INFECTED MOTHERS

Kristina Ljunggren, V. Moschese, P. Brölden, B. Wahren, P. Rossi, M. Jonda
DEPT. OF Microbiology, Karolinska Institute, Dept. of Virology, National Bact. Laboratory, Stockholm, Sweden

Factors determining an uninfected or infected outcome as well as disease progression in children born to HIV-1 infected mothers are unclear. Also, early diagnosis is hampered by maternally transferred antibodies. We have retrospectively divided children, 0-24 months of age, into two groups based on HIV seroreactivity at 15 months of age. No difference was seen in presence of ADCCC and neutralising antibodies between the groups. The persistently seropositive group was divided into a non-AIDS and AIDS group according to clinical status at the time of diagnosis. Interestingly, the ADCCC frequencies in these two groups differed, 70% and 30%, respectively. Even more striking, 63% of non-AIDS and none of the AIDS patients had neutralising antibodies. These differences were not merely a reflection of decreasing IgG-titres in later stages of disease. Presence of both ADCCC and neutralisation was more common in mothers giving birth to children becoming seropositive than to persistently seropositive ones.

In conclusion, ADCCC and neutralising antibodies do not seem to protect against virus transmission from mother to child but are significantly correlated with a better clinical stage of HIV-infection.

T.C.P.57 SUPPRESSION OF MONOCYTE-MEDIATED DIRECT CYTOTOXICITY AND ADCCC BY AIDS PERIPHERAL BLOOD DERIVED MONOCYTES

BRADLEY BENNETT, JEWETT A., NISHANATH P. and MITSUOYA K.
Department of Microbiology and Immunology and Department of Medicine, University of California, Los Angeles, USA.

Cytotoxic effector mechanisms may play an important role in both the control and pathogenesis of HIV infection. We examined the cytotoxic activity of peripheral blood derived monocytes (PBM) from AIDS patients. Both direct cytotoxicity and antibody dependent cellular cytotoxicity (ADCC) were examined using tumor cells as targets in an ⁵¹Cr release assay. Whereas normal PBM were minimally cytotoxic, PBM from AIDS patients were cytotoxic in the absence of exogenous activation. The level of cytotoxicity was comparable to IFN- γ activated normal PBM. Cytotoxicity was mediated by TNF as it was blocked by anti-TNF antibody and β supernatant derived from the monocytes cultures contained high levels of TNF as assessed by cytotoxicity and by RIA. We then examined the PBM dependent ADCC using a target cell resistant to direct cytotoxicity but sensitive in the presence of anti-target antibody. PBM from AIDS patients had augmented ADCC whereas normal PBM were minimally cytotoxic. These results demonstrate that AIDS PBM are activated in vivo and mediate both direct and antibody dependent cytotoxicity. To test cytotoxicity to HIV infected targets, CD4⁺ T targets resistant to PBM were required. Thus, we selected a variant CD4⁺ T target that was resistant to monocyte-mediated cytotoxicity. These targets retain their CD4⁺ phenotype and bind HIV like control. We have initiated studies to use these HIV coated or infected targets with AIDS PBM. The results of such experiments and their significance will be presented.

T.C.P.59 CHARACTERIZATION OF HUMAN MONOCLONAL ANTIBODIES AGAINST HIV-1 WITH GPUR SPECIFIC NEUTRALIZING ACTIVITIES

Yvonnie Bross*, Madeira P.**, Souche, S.**, Zagury, D.*** and Desgranges, C.*
*INSERM U 271, Lyon, France. **CNRS, GIG-sur-Yvette, France. ***Université P. et M. Curie, Paris, France.

Objective: To obtain human monoclonal antibodies (HMAbs) against the protein of HIV with neutralizing activity from vaccinated or infected individuals.
Methods: B lymphocytes from individuals vaccinated with a recombinant gp160-vaccinia virus or from infected donors were transfused into Balb/c-B6 mice. Clones were then selected and analyzed for their reactivity with HIV proteins by several methods such as immunofluorescence, ELISA and immunoblot. A few HMAbs were mapped using a library of the HIV-1 III B gene cDNA, expressed in the yeast model. Divergent strains of HIV (HTLV-III B and RP1) were then used in neutralization assays based on virus infection of HIV (HTLV-III B) infected cell tissues.

Results: Clones secreting IgG anti-gp1 and gp120 were obtained. Epitope recognized by the anti-gp1 was localized within the C-terminal region of gp1, between 154 and 548 amino acids. Virus infectivity can be blocked by the anti-gp1 and the anti-gp120, whereas no neutralization has been observed in the HIV mediated cell fusion assay.

Conclusions: The neutralizing potential of the HMAbs described here is therefore group specific. Human monoclonal antibodies directed against conserved regions of HIV proteins allow to define immunodominant epitopes for vaccination and production of antiretroviral. Since they recognize divergent strains, use of HMAbs in passive therapy should be considered.

T.C.P.56 AN ANALYSIS OF THE EXPRESSION OF CD4 RECEPTORS BY BLOOD MONOCYTES AND T CELLS FROM NORMAL AND HIV-1 INDIVIDUALS.

Elaine Linder, Eric Ingstrup, G. E. Barber, L. Huesch,
University of Dallas, Dallas, TEXAS 75044 USA

Monocytes harbor HIV-1 and probably play an important role in maintaining the chronicity of the disease. Monocytes are susceptible to HIV infection because they have the CD4 receptor, CD45R1/2, to cooperate the expression of CD4 on T cells and monocytes. Methods: An immunofluorescence (flow cytometry, microcapillary) analysis employing anti-CD4 (Imu-3a) and anti-CD45 (Imu-3b) on fresh monocytes and T cells was done. Results: 1) By flow cytometry 85-90% of monocytes from a normal (N) or HIV-1 (P+) individuals show dual positivity for CD4 and CD45. Although the analysis showed an overall population along the fluorescence intensity axis as opposed to the tailing effect of control antibodies that did not alter the position of the fluorescence negative monocytes, these observation suggest that all monocytes are CD4⁺ albeit some have low CD4 density and overlap with background control staining. The results are not affected by fixation of cells or blocking of Fc receptors before staining. 2) The results were confirmed by two color fluorescence microscopy (FACS) of CD4⁺ monocytes were also CD45⁺ by two-color immunofluorescence microscopy. CD4⁺ monocytes have intracellular CD4 receptors whereas CD4⁺ T cells expressed only the extracellular CD4. Conclusions: These results confirm and extend the observation that all monocytes are CD4⁺, contain larger amounts of intracellular CD4. HIV-1 infection did not seem to affect CD4 expression by monocytes which may help to explain the cryptic effects of HIV-1 on monocytes and T cells.

T.C.P.58 MONOCYTOCHROMOPHAGES INFECTED WITH HIV-1 PRODUCE ACID-LABILE INTERFERON- γ

Sachari Naim*, Friedman R.M.**, Wald, S.M.***, Wahl, L.M.*** and Weinstein, S.***

*National Cancer Institute, National Institutes of Health (NIH), **Uniformed Services, University of the Health Sciences, ***National Institute of Dental Research, NIH, Bethesda, Maryland, USA.

Objective: To describe an interferon (IFN) produced by HIV-1-infected monocytophagocytes (M ϕ) and to establish the kinetics of its production. **Methods:** M ϕ cultures were infected with HIV/HTLV-III_{LAI/1985}, and p24 antigen production was measured by ELISA. The controls were HIV-1-infected cells treated with AZT and non-infected cells. IFN titers in the culture medium were determined at intervals using human foreskin fibroblasts and murine monocytophagocytoid virus as a test system. Anti-IFN antibodies were used to distinguish among IFN types.

Results: We found significant production of IFN (>10 I.U./ml) by M ϕ infected with HIV-1 and cultured for 212 days, whereas IFN production was not detectable in non-infected cells or in infected cells in which virus replication was eliminated by AZT treatment. The antiviral effect of this IFN in the test system was neutralized by anti-IFN- γ antibody and reduced 80-90% by treatment at pH 2, suggesting that this IFN belongs to the acid-labile subclass of IFN- γ . Conclusions: Our observations suggest the M ϕ as a source of the acid-labile IFN- γ that has been detected in AIDS patients and reported to be a useful prognostic indicator for development of AIDS. This IFN might also play a role in the pathogenesis of AIDS and its symptomatology.

T.C.P.60 AUTOANTIBODIES AGAINST COLLAGEN IN AIDS: CORRELATION WITH RISK FACTORS AND DISSEMINATED PROCESSION

Grazi, Michard, D.; Weaver, M.S.*** and Hoffmann, C.W.***
*University of British Columbia, Vancouver, B.C., Canada ** St. Paul Hospital, Vancouver, B.C., Canada.

Autoimmunity often precedes the onset of ARC or AIDS, and a number of autoantibodies have been described in AIDS patients and in persons at risk for AIDS. Such antibodies raise the question of autoimmunity as a component of AIDS pathogenesis. We have reported evidence of an autoantibody (anti-collagen) that occurs in all AIDS patients studied. Sera from various groups were assayed by ELISA for reactivity with gelatin. The specificity of the ELISA for collagen activity was shown by inhibition with purified human collagen. High titre serum reactivity against collagen was found in all AIDS patients, HIV⁺ homozygous (6/6), HIV⁺ homozygous (2/6), and HIV⁺ heterozygous (1/6), but not in HIV⁻ hemophiliacs, rheumatoid arthritis (RA) patients, or controls. Serum IgG levels showed little correlation with anti-collagen activity so this is not a reflection of polyclonal B-cell activation. Titration of anti-collagen activity in positive sera revealed levels 100 times higher than the levels in normal sera. Affinity purification followed by electrophoretic and immunoblot analysis confirmed the antibody nature of the anti-collagen reactivity. The anti-collagen antibodies react preferentially with primary determinants revealed after denaturation. In this respect, the antibodies are different from those described in RA, but similar to those observed in graft versus host disease and leprosy. To our knowledge, this is the first demonstration of autoantibodies of a single specificity. These results suggest that all persons progressing to AIDS express anti-collagen antibodies which may be useful markers of disease progression.

T.C.P.73 HUMAN ANTIBODY RESPONSE TO HIV-1 PROTEASE ACCORDING TO DISEASE STAGE

Ruppel, Chantel, De Agre, M.*; Debouck, C.A.**; De Wolf, F.*; Wolfs, T., Goudaard, A.*

*Hannu Reviervirus Laboratorium, Amsterdam, the Netherlands, **Department of Molecular Genetics, Smith Kline Beecham Laboratories, King of Prussia, PA, USA

Objective: To study the relationship between presence of antibodies to HIV-1 protease and presence of several disease predictive markers for disease progression in different infected risk groups (homosexuals, hemophiliacs).

Methods: Antibodies to HIV-1 were measured in serum using an enzyme linked immunosorbent assay using a bacterially expressed, recombinant form of HIV-1 protease. HIV-1 antibodies, HIV-1 antigen, HIV-1 Ab positive homosexuals in CDC stage I/II) were anti-protease positive, versus 50% (9/15) of homosexuals with AIDS related complex (CDC IV A) and 30% of the homosexuals with AIDS (CDC IV B-E). In 255 homosexuals (CDC III) antibodies to protease were significantly more frequently found in samples lacking HIV-1 antigen (p<0.001) and possessing antibodies to HIV-1 core antigen (p=0.006).

Conclusions: HIV-1 protease is expressed and antigenic in most HIV-1 infected individuals and absence of antibodies to HIV-1 protease is more often found in persons with progressive disease.

T.C.P.75 HUMAN MONOCLONAL ANTIBODIES (mAb) TO HIV-1

Lake, D.; Kawamura, T.; Hujic, A.; Masuko, Y.*; Kiferian, E.; and Herrst, E.*

*Dept. of Hematology/Oncology, University of Arizona, Tucson, Arizona, 85724, USA, **Tefjin Institute for Biological Research, Tokyo, Japan.

Objective: To develop a panel of human IgG monoclonal antibodies to HIV-1 that have therapeutic potential either alone or in combination with each other or with other anti-viral agents.

Methods: Hybridomas were produced by fusion of splenic or lymph node lymphocytes from HIV sero-positive patients with the P3x63Ag12 myeloma mouse cell line. Hybridomas were screened for the production of anti-HIV IgG by ELISA and indirect immunofluorescence. ELISA screening was performed using plates coated with 2 different HIV-1 isolates and 1 plate coated with a gp120 synthetic peptide fragment. Cloning was done by limiting dilution.

Results: Eight mAb have been developed that react with HIV-1 gp120

isotype IgG1/IgA1 IgG1/IgA1 IgG1/IgA1 IgG1/IgA1 IgG1/IgA1 IgG1/IgA1

T.C.P.77 HIV RECOMBINANT p18 COAT PROTEIN INHIBITS PROLIFERATIVE RESPONSES BY NORMAL LYMPHOCYTES IN HUMANS AND MICE.

Nichols, J.Fredrickson*, Cheyner, R.*, Lecout, G.*, Rautmann, C.*, Guy, B., Kivvy, M.P., Kiser, M. and Parris, S.*

*Institut Pasteur, Paris, *Farmingen S.A., Strasbourg, **Pasteur Vaccine, Marne-la-Coquette, France

Objective: To determine the in vitro effect of HIV-1 core p18 protein on antigen-induced lymphoproliferative responses and mixed lymphocyte reaction (MLR). To compare results with the effect of p18 in a mouse model.

Methods: 1) Recombinant p18 gag, p25 gag or p27 nef protein was pre-incubated with peripheral blood lymphocytes (PBL) from normal donors. Polyclonal mitogenic responses to plant lectins and MLR were studied in proliferation assays. The effect of p18 was also examined in normal B6/6C mice, and in mice immunized with a recombinant vaccinia virus containing the HIV-1 gag gene.

Results: p18 gag protein suppressed the proliferative responses of PBL from five different healthy donors when lymphocyte proliferation was induced by ConA or by HLA allotypes in MLR. In contrast, p25 gag and p27 nef proteins had no suppressive effects. These results were reproducible with mouse lymphocytes; p18 gag protein suppressed mitogenic responses to ConA and PHA, as well as specific proliferative responses to p25 gag protein in mice vaccinated with a virus-HIV₁ recombinant.

Conclusions: 1) Immunosuppressive and immunogenic epitopes of HIV-1 proteins have to be defined in view of vaccination in humans. 2) The murine model is useful to evaluate the immunogenic power of different HIV proteins.

T.C.P.74 QUANTITATIVE, NOT QUALITATIVE, DEFECTS CHARACTERIZE RESPONSES OF CELLS FROM HIV SEROPOSITIVE TO CELL MITOGENS: B6MALN, M1 and Sardin-Hybrid, B6, M1V Med. Cir. and V.A. Hospital, NY, NY, U.S.A.

Objective: To elucidate the immunoregulatory mechanisms involved in B lymphocyte responses of cells from HIV-seropositive (HIV+) and controls.

Methods: Proliferative responses of non-mouse cells (M1C) to B cell mitogens (anti-I and Staphylococcus aureus Cowen 2 (SC2)) were determined by ³H-thymidine incorporation in 3 or 4 day cultures. Mixed lymphocyte culture supernatant (MLC-sup) and indomethacin were added to certain cultures.

Results: Average proliferative responses of M1C from HIV+ patients to each mitogen are significantly defective (25-33% of control [HIV-] response). Addition of MLC-sup increases responses of both HIV+ and HIV- M1C to anti-I (43 and 50% respectively) and SC2 (69 in both groups). Addition of indomethacin increases responses to SC2, (40-70% increase for both groups).

Effects: MLC-sup and indomethacin are additive. No decrease in deficient responses were influenced by the altered frequency of lymphocyte subsets in the HIV+ cultures; correlations were sought between defective responses and percent of lymphocyte subsets. Proliferative responses to anti-I and SC2 in the presence of both MLC-sup and indomethacin are correlated poorly with the percent of B and CD4+ T cells, and negatively with the percent of CD8+ T cells in culture. Mathematical correction of the data for the abnormal percentages of B, CD4+ T and CD8+ T cells results in responses that are comparable to those of control cells.

Conclusions: Deficient responses may be due to quantitative differences in the responding B cells and regulatory pathways mediated by CD4+ and CD8+ T cells and not to qualitative differences in the ability of the patients' B cells to respond to these mitogens.

T.C.P.76 FINE SPECIFICITY OF HIV-SPECIFIC CYTOTOXIC T LYMPHOCYTES IN HUMANS

Duoglio, G.*, Langlois-Dreyon, Pierre*, Barroui, M.*, Fisher, R.* and Patis, F.*

*Institut Pasteur Paris, France, **Biogen Research Corporation, MA, USA.

Objective: To identify CTL epitopes on glycoproteins coded by the HIV *env* gene.

Methods: HIV-specific HLA-A2 restricted CTL lines were generated from human peripheral blood lymphocytes by stimulation with autologous HIV infected lymphoblasts in the presence of interleukin 2. Peptides used were selected with the criterion of conservation among different HIV isolates in view of an eventual application in vaccines or immunotherapy. These peptides were tested for CTL recognition by incubating each peptide with ⁵¹Cr-labeled tumor target cells stably transfected with the human HLA-A2 gene.

Results, conclusions: Among the 30 peptides tested, 6 peptides were particularly well recognized. Results obtained with new synthetic peptides indicate that some epitopes recognized by HIV-specific CTL are highly conserved. This is encouraging in view of the large variability of HIV isolates.

T.C.P.78 LOCALIZATION WITHIN THE HIV-1 LTR OF NUCLEOTIDES RESPONSIVE TO CMV-MEDIATED TRANSCRIPTION

Ehrlich, P. Berry, N. Pant-Low, M. Marban, N. Duschague, and K. Joseph.*

*Department of Molecular Pathology, University of California, Davis, CA 95616 and *Molecular Biology and Virology Laboratory, The Salk Institute, La Jolla, CA, U.S.A.

Objective: To investigate the molecular basis by which human cytomegalovirus (CMV) activates expression from the HIV-1 long terminal repeat (LTR).

Methods: We are analyzing the molecular basis by which human CMV stimulates expression from the HIV-1 LTR by constructing recombinant plasmids with a reporter gene (CAT) under the transcriptional control of the LTR. Cloned-site mutations and small deletions have been introduced into the HIV-1 LTR. These mutants have been tested in trans expression assays in a variety of cell types, including transformed and non-transformed cells, for responsiveness to CMV IE and HIV-1 transactivator (tat).

Results: Mutations in the LTR around either the start site of transcription (4 to +20), the three SP1 binding sites, or the TATA box dramatically reduce responsiveness to CMV IE. A mutation at -6 to -1 abolishes CMV IE-mediated transactivation but leaves tat-mediated transactivation intact. Mutations which abolish responsiveness to tat (+20 to +35) have little or no effect on CMV IE transactivation. Insertion of the 4 to +20 region of the HIV-1 LTR into a CMV IE non-responsive promoter confers responsiveness to CMV IE, but only in one orientation. The magnitude of transactivation by CMV IE appears to be related to the transactivation phenotype of the cell.

Conclusions: The mutation analysis shows that responsiveness of the HIV-1 LTR to CMV transactivation depends upon sequences recognized by the cellular factor designated leader binding protein-1 (LBP-1). Also, additional host factors which are involved in control of cell growth appear to play a role in transactivation of HIV by CMV.

T.C.P.91 PROMOTOR ACTIVITY OF 5' LTR REGION OF A HIGHLY CYTOPATHIC STRAIN OF HIV-1

L. LISBERG, J. SEEL, V. JACOB, B. STREB AND J.-C. CHOMONNET.

Unité de Recherches Épidémiologiques et de Biologie des Relations Homme (U.152) - Centre de Lésions - M-31 - 12033 MARILLIÈRE CARRÉ, FRANCE

In order to evaluate the high cytopathic properties of HIV-808 strain with genetic variation, the virus was cloned and sequenced. The cloned DNA was biologically active as revealed by transfection into cells. One of the major differences in the alignment of nucleotide sequences of HIV-808 and HIV-809 genotype viruses was located in the 5' part of the LTR 0' region. In a set of transfection experiments the effect of transmutating (18) base product on promoter activity localized in the 5' LTR region of both HIV-808 and HIV-809 viruses was compared in CAT assay. It was found that promoter activity of 5' LTR of HIV-808 was several times higher than that of HIV-809 genotype even without a stabilizing effect of the tat gene product. To approach the effect of LTR region on cytopathogenicity of HIV-808 directly, the recombinant the molecule bearing HIV-808-LTR region and rest of the genome derived from HIV-809 genotype. The DNA was transfected into the cells and the virus obtained; its properties are under investigation.

T.C.P.93 BINDING OF THE HIV-1 TAT PROTEIN TO TAR SEQUENCES IN VITRO

Dingwall, C.; Embury, I.; Hepply, S.; Kinnear, M. A.; Gall, M. J. & Kerr, J. MRC Laboratory of Molecular Biology, Hills Road, Cambridge, CB2 3QH, U.K.

Objectives: To investigate the binding in vitro of HIV tat protein and cellular factors to TAR sequences.

Methods: A synthetic tar gene has been expressed both in an E. coli expression system and in a number of eukaryotic cell lines. The binding of expressed tat protein to nucleic acid representing the TAR sequence has been investigated in vitro using gel retardation assays.

Results: The tat protein produced from both the E. coli and from the eukaryotic expression systems has been shown to be biologically active. The binding of tat, synthesized in E. coli, to TAR nucleic acids has been examined both in the presence and absence of host cellular proteins. Binding of tat expressed in eukaryotic cells gives a different pattern, suggesting that host proteins interact with the tat/TAR complex. The specificity of binding has been examined using a number of different nucleic acids, including mutant TAR sequences.

Conclusions: Direct interactions between tat protein and TAR sequences are involved in trans-activation.

T.C.P.95 ANALYSIS OF VPK FUNCTION IN HIV-1 INFECTED CELLS

Jan Bakula, J. Kim, and B. Vander Heyden. Departments of Medicine and Microbiology, Immunology, Washington University, St. Louis, Mo., USA

Objective: A novel gene, designated vpk, is present in the genomes of HIV-2 and HIV-1, but not yet known as to define the role of vpk in HIV-2 replication and cytopathicity.

Methods: A functional proviral clone of HIV-2, SE, was made and used to construct six directed mutants which only eliminate the AUG initiator codon of vpk (OX1), which convert codon 22 to a termination codon (OX2), or which simultaneously eliminate the first and second AUG codons and frame-shift the gene introducing a termination codon at position 70 (OX3+65).

Results: Transfection of SE, OX1, OX2, and OX3+65 into CEM-1 cells gave rise to equivalent amounts of virus, which could be passaged in SP or CEM cells, or in peripheral blood lymphocytes or monocytes with equivalent efficiency. Furthermore, the vpk mutants demonstrate similar cytopathic effects as did SE. Hybridization data with DNA from the infected cells demonstrated the presence of the mutations in each of the RI infected cell lines, and equivalent levels of viral RNA and DNA sequences in SE and RI infected cell lines. Immunoprecipitation analysis demonstrated a 14 kd protein in cells infected with SE virus as well as the other mutants, but not in cells infected with the RI viruses or the particles themselves. Equivalent levels of GAG and ENV proteins were demonstrated in all infected cells and virus preparations.

Conclusions: These data suggest that vpk is dispensable for virus replication and cytopathicity. Further analysis of the vpk mutants is underway to define vpk activity in animal model systems.

T.C.P.92 DETECTION AND SEQUENCING OF INDIVIDUAL MOLECULES OF HIV DNA AMPLIFIED BY A MODIFIED BSA

Department of Genetics, University of Edinburgh, Scotland, United Kingdom

The sensitivity of polymerase chain reaction (PCR) has been enhanced by the use of nested primers, which allowed the detection of individual molecules of HIV DNA from patient samples. Amplification of DNA involves a first reaction with a pair of HIV-specific primers, transfer of a small proportion of the product to a second tube containing primers that lie within the first pair, and a further round of amplification. Dilution studies or plasmid derived HIV sequences showed that amplification of single molecules of target sequence with different sets of primers was reliable even with primer sequences as wide as 500 base pairs. The specificity of the test was assured by the uniformly negative results obtained from a panel of seronegative blood donors with two sets of nested primers. Limit dilutions of HIV DNA from buffy coat coat cells of HIV-infected haemophiliacs allowed the isolation, amplification and sequencing of individual molecules. This method has many advantages over previously described methods of ascertaining HIV by the PCR method: 1) Amplification of the target sequence takes place in the absence of competition from others that replicate faster, or earlier than the primers target. 2) It is less prone to sequencing errors. 3) It allows the amplification of several regions from the same HIV genome.

T.C.P.94 CHARACTERIZATION OF THE INFECTIVITY OF HIV PROVIRUSES CONTAINING MUTATIONS IN LTR REGULATORY SEQUENCES

Leonard, J.M.; Parrott, C.M.; Buckler-White, A.M.; Martin, M.A. & Raboon, A.B. *NIAD, NIH, Bethesda, MD, USA; *Georgetown University, Washington, D.C. USA

Objectives: To characterize the biological effects of mutations in the 3'-distal regulatory sequences of the HIV LTR.

Methods: Oligonucleotide-directed, site-specific mutagenesis was employed to generate mutations in the regulatory sequences in the HIV-1 LTR. Mutated LTRs were introduced into an infectious molecular clone of HIV. Mutant proviruses were assayed for infectivity and growth in human T cells. Mutant LTRs were also tested for transcriptional activity by transfection of LTR-CAT plasmids.

Results: An HIV provirus containing a deletion of both NF- κ B binding sites yielded infectious virus that replicated efficiently in MT 4 cells. Mutants defective in Sp1 binding at the 5' Sp1 site (site III) were also capable of efficient growth; proviruses with additional mutations in the Sp1 binding sites varied in their ability to produce infectious virus. In CAT assays, the mutant LTR deleted in the NF- κ B sites exhibited decreased basal activity compared to the wild-type LTR, but was strongly responsive to α transactivation. The effects on viral infectivity of changes in other parts of the LTR will also be discussed.

Conclusions: The NF- κ B binding sites were not essential for HIV replication in MT 4 cells. Other mutations affecting the Sp1 binding sites also did not interfere with the ability to produce infectious virus. Thus HIV can replicate even when alterations are introduced into the wild-type enhancer and promoter elements.

T.C.P.96 HIGHLY EFFICIENT NEUTRALIZATION OF HIV WITH RECOMBINANT HIV-1-IMMUNOGLOBULIN MOLECULES

André Trautacker, Josef Schneider*, Hansrued Kiefer* and Klaus Karlinstein*, Basel Institute for Immunology, Basel, Switzerland; *Centraal Laboratorium, Centraal Ziekenhuis, F. Hoffmann-La Roche & Co. Ltd, Basel, Switzerland.

It is well established that the human immunodeficiency virus type 1 (HIV-1) exploits the cell surface CD4 molecule to initiate the infection which can eventually lead to acquired immune deficiency syndrome (AIDS). We and others have taken advantage of this specific interaction between the HIV-1 envelope protein gp120 and CD4 and have shown that soluble CD4 molecules can inhibit HIV infectivity in vitro. However, application of these observations in vivo might require HIV potent reagents. Here we describe the generation of highly effective molecules which combine the specificity of CD4 and the effector functions of different immunoglobulin (Ig) subclasses. We show that pentameric forms of chimeric CD4-immunoglobulin molecules are about 1000 fold more active than their dimeric counterparts in *Synglystus* inhibition assays.

PACKAGING AND TRANSFER OF A MARKER GENE BY HIV VECTOR PARTICLES
Chival-François, Danoes O* and Alizon M**
*Laboratory of Molecular Biology, NIAID, NIH, Bethesda, MD, USA.
**Whitehead Institute, Cambridge, MA, USA

Objective: To package foreign sequences in HIV particles and transfer them to HIV-sensitive target cells.

Methods and Results: Several HIV vectors were generated by introducing a selectable resistance gene (SHS) into the HIV genome. Cell lines were then established that could express these genomes, and package them into HIV particles following the transfection of HIV helper sequences. After infection of CD4+ cells with such particles and selection, we were able to demonstrate the successful transfer and integration of HIV genomes carrying the marker resistance gene. Different constructs were compared for their efficiency to transfer the marker gene. In order to delineate the cis-acting sequences required for the complete packaging, reverse transcription, and integration of the HIV genetic material.

Conclusion: We demonstrated the packaging and successful transfer of a genetic marker through HIV particles. HIV vectors will be valuable tools to study the HIV replicative cycle, and to specifically target sequences to HIV-sensitive cells.

T.C.P.98

INTERACTION OF HIV WITH INTERFERON REGULATED, ANTIVIRAL ENZYMES.

Silverman R.H.¹; Sen Gupta D.N.¹; Dion M.F. and Williams B.R.G.²

¹Department of Pathology, Uniformed Services University of the Health Sciences, Bethesda, MD USA and ²Division of Infectious Diseases, Research Institute Hospital for Sick Children, Toronto, Canada.

The interferon (IFN) system is activated in AIDS and high levels of circulating active latent IFN-alpha often accompany disease development. Although HIV replication in cell culture can be inhibited by IFN, the virus appears to have evolved a mechanism of escaping the antiviral activity of the IFN usually present in AIDS. We have investigated the activation of IFN-induced enzymes by HIV-1. The 5' leader of HIV-1 mRNA contains two double-stranded sense of about 17 and 23 base pairs in length. HIV-1 leader RNA of 212 nucleotides was produced from a plasmid containing HIV-1 LTR sequences located 3' to an SP6 promoter. The RNA product was purified and analyzed to ensure the absence of shunt transcripts. That HIV-1 LTR RNA was shown to activate both dsRNA-dependent protein kinase and 2-5A synthetase in an extract of IFN-treated HeLa cells. Furthermore, these enzymes were immobilized and screened on an affinity resin consisting of HIV-1 leader RNA covalently attached to finely divided cellulose. In HIV-infected cell cultures however, although IFN was able to induce 2-5A synthetase, no evidence for endogenous activation of the 2-5A pathway was obtained. It remains possible therefore, that viral or cellular factors in HIV-infected cells interfere with the activation of IFN-induced enzymes and contribute to viral latency.

T.C.P.99

HIV-1 REPLICATES IN HUMAN SPERM MITOCHONDRIA OF HIV-SEROPOSITIVE INDIVIDUALS

Regnier, Chaz J, Tremblé, H., Candeloub, D.***, Belin B.***, Desjardins, J., Desjardins, M., School of Osteopathic Medicine, Dept. of Microbiology, Ob/Gyn and Medicine * Camden, New Jersey, USA.

Objective: To determine the replication site(s) of HIV-1 in the sperm of HIV-seropositive individuals.

Methods: Sperm samples from three AIDS/SAC individuals were scrutinized for the localization of HIV-1 by electron microscopy (EM), HIV-specific immunogold EM, and in situ hybridization using HIV-specific DNA probes. **Results:** (1) Analysis of sperm by the EM hybridization procedure revealed that over 70% of sperm which were positive for HIV by in situ hybridization, had their nucleolus enlarged (x10 times greater than normal controls). (2) HIV-DNA probes were more concentrated at the nucleolus than in the sperm heads, in terms of relative intensity of staining. (3) Immunogold staining showed aggregation of gold particles in association with mitochondria. (4) Presence of HIV-like particles in many mitochondrial organelles was noted. (5) Some mitochondria resembled pods with HIV-like particles "bursting out" of them like spores.

Conclusion: These observations suggest that HIV in sperm may be replicating in the mitochondria, using mitochondrial DNA as a replicating device. It is possible that in human sperm where there is condensation and tight packaging of haploid DNA in the nucleus, relative to that in somatic cells, the random integration of the HIV proviral DNA into the nuclear-DNA might be difficult and mitochondrial-DNA may be an easier target. On the other hand, if cellular mitochondria is a global target for HIV, then different therapeutic approaches might be adopted.

T.C.P.100

TRANSMISSION OF SH₁₀₀ IN A SEMI-FREE RANGE BREEDING COLONY OF MANDRILLS IN GABON.

Patena, Manrique¹; Delaporte, E.L.T.²; Honora, C.²; Cooper, R.W.²; Bursi, P.²; Dixon, A.L.²

¹ Centre International de Recherches Médicales, BP 769, Francville, Gabon;

Objective: To study the transmission (vertical and horizontal) of a simian immunodeficiency virus from mandrills in a colony of mandrills.

Methods: A lot of 33 mandrills was tested, 16 of them were wild caught animals. Antibodies were detected by a radio-immunoprecipitation assay using 3P₂-methionine labeled SH₁₀₀ virus. Virus was isolated from peripheral blood lymphocytes co-cultured with MOLT-4 cells.

Results: Two of the 16 wild-caught animals (11%) were positive since their arrival at the primate centre (1979 and 1985 respectively). A virus was isolated (Tajimato) and showed antibodies to the SH₁₀₀ glycoproteins only. In 1988, two new animals showed antibodies to the SH₁₀₀ envelope proteins and also to the core proteins. One of these animals was a wild-caught male that was seronegative at his arrival to our centre. The other one is the second offspring of the already known positive female. Since her arrival in 1983 at CIRMF, she was pregnant twice, one animal was born in 1985 (seronegative, 1,2 and 3 years respectively after birth) and one in 1987. This animal showed antibodies one year after delivery and a virus was isolated from her peripheral blood lymphocytes. **Conclusion:** SH₁₀₀ appears to be transmitted from mother to child in a semi-free range breeding mandrill colony. A seroconversion with appearance of antibodies to p27 was observed, and a virus was isolated.

T.C.P.101

A COLORIMETRIC ASSAY FOR TRANSCRIPTION OF THE HIV-1 LTR

Edward B. Slight*, R.G. Devitis* and C.R. Roberts*

Wellcome Research Laboratories, Beckenham, UK, and **MTR, J. Carolina, USA.

Objective: To develop a simple, rapid and sensitive assay for the activation of the HIV-1 LTR by Tat and by heterologous factors.

Methods: Stable cell lines containing multiple integrated copies of the HIV-1 LTR (1-22)400 linked to the DNA sequence of E.coli were prepared by co-selection for pSV2neo-mediated G418 resistance. **Results:** HIV-1 LTR luciferase was transcribed equally well or better in rabbit SKIN (SPH11a1-luc) cells than in other cell types (HeLa, C-127, Flow 4002, etc.), by cotransfection with generic Tat (gTat) expressing plasmids (pGWTAT, pSVTAT) and, so stable SKIN/TAT luciferase cell lines were prepared to mimic the structure of the integrated provirus. In identically infected cells, three of the independent clones responded to gTat, and one clone was used to show that D-phenylalanine was not an effective inhibitor of Tat transcription at concentrations up to 100µg/ml. The efficacy of anti-sense phosphorothioate oligonucleotides against Tat are currently under examination in these lines. The same lines also express high levels of oligonucleotides in response to HIV-1 infection, and transactivated by 16 gene products from herpes group viruses in size differentiation.

Conclusions: Selection of the appropriate substrate for β -galactosidase will permit detection and measurement of LTR transcription (MUG:OMP) and also detection of infectious centres (i-pal) in these cell lines. Therefore, molecular aspects of HIV reactivation and autologous gene regulation can be readily analysed.

T.C.P.102

HIV-1 REV INDUCED MODULATION OF NEF PROTEIN UNDERLIES REGULATION OF VIRAL REPLICATION

Ahmad, Nafees, Malin, K. K. and Venkatesan, S.
Laboratory of Molecular Microbiology, NIAID, National Institutes of Health, Bethesda, MD 20892, USA.

Objective: To study the potential functional roles of HIV-1 Rev and Nef proteins that might underlie the regulation of viral replication.

Methods: A new defective proviral DNA was constructed from infectious HIV-1 proviral clone pNL4.2. The Rev and Nef were supplied in trans by cotransfection of cDNA plasmids under the control of various promoters.

Results: The phenotype of rev mutant provirus was distinguished by accumulation of Nef and reduced Tat function. During transcomplementation of the rev mutant by rev cDNA, there was a decrease of both the steady state levels and rates of synthesis of Nef accompanied by enhanced viral structural proteins. Nef protein, a transcriptional repressor (Ahmad and Venkatesan, Science, 241: 1441-1445, 1988), moderated the Rev induced transactivation in a dose dependent manner. Neither the replication of standard provirus nor the repression induced by rev cDNA was modulated by cotransfection of rev cDNA.

Conclusion: The ability of Rev to modulate Nef expression from the provirus and hence relieve the inhibition of LTR transcription reveals a delicate balance of functions of these two proteins that might underlie the switch between latency and reactivation.

T.C.P.115 EFFECT OF MUTATIONS IN VPX ON THE INFECTIVITY OF VIRAL PARTICLES OF HIV-1

Y. Guyader¹, M. Zemmouji¹, L. Montagnier¹ and Keith Purcell², Institut Pasteur, Paris, France; ¹ and Johns Hopkins University School of Medicine, Baltimore, USA.

Objective: To determine whether the *gag* open reading frame, which is present in HIV2 and HIV1 genomes but less so in counterpart in HIV1, is expressed in infected cells and to investigate the phenotypes of VPX mutants. **Methods and Results:** Two anti-peptide sera raised to the predicted product of the HIV-2 *gag* open reading frame immunoprecipitated a 16-kD protein from the cell extract and medium of cells infected with HIV-2, and a 14-kD protein from HIV-1-infected cells. We used site-directed mutagenesis to introduce two types of mutations in the *gag* open reading frame. Cell-free supernatants from 5W480 cells transfected with the mutated HIV-2 proviral clones were used to infect several CEM⁺ lymphocytes and monocyte cell lines as well as fresh peripheral blood lymphocytes. Mutations in the *gag* open reading frame eliminated the synthesis of the 16-kD protein, confirming that this protein is the product of this gene. Full-length clones of HIV-2 containing these mutations are infectious to two established lymphocyte cell lines and a monocyte cell line. In contrast, they show a severe defect in their ability to infect peripheral blood lymphocytes. **Conclusions:** These findings suggest that the VPX protein may be important in the *in vivo* life cycle of the HIV-2/HIV1 viruses.

T.C.P.117 CONSTITUTIVE SYNTHESIS OF NF- κ B-LIKE NUCLEAR PROTEINS IN MONOCYTES-AN EXPLANATION FOR HIV LATENCY?

Nancy McCannary-Fraser¹ and Michael Norros², ¹NIDH, NIH and ²CDR, Baruch College, CUNY

Objective: To determine if NF- κ B nuclear elements contribute to the regulation of HIV-1 gene expression in normal human monocytes. **Methods:** Nuclear proteins from freshly isolated and cultured monocytes and analyzed for NF- κ B binding activity to HIV-1 LTR and mutant double-stranded oligonucleotides by gel retardation assays. Monocyte activation was monitored by IL-2 synthesis and IL-1 receptor expression. **Results:** Nuclear proteins isolated from 18 hr unstimulated and LPS-activated monocytes contain specific NF- κ B binding activity as observed by binding to oligonucleotides encoding a single NF- κ B enhancer region from the HIV-1 LTR. No binding was observed to a mutant sequence. Specific binding could be blocked by unlabeled wild-type oligonucleotides but not by the mutant oligomer. Surprisingly, freshly isolated monocytes (IL-2 receptor and IL-1 negative) and LPS-stimulated monocytes expressed equivalent amounts of NF- κ B binding activity. **Conclusions:** Resting monocytes constitutively express NF- κ B-like binding proteins and the level of expression is unchanged by the state of activation. Whereas NF- κ B has been shown to stimulate HIV-1 gene expression in T lymphocytes, it appears unlikely that NF- κ B expression is solely responsible for the functional and phenotypic changes in monocyte activity following HIV-1 infection. The constitutive synthesis of NF- κ B binding proteins in circulating monocytes may explain the persistence of HIV-1 in macrophages throughout the clinical course of AIDS.

T.C.P.119 DETECTION OF A NOVEL DNA TOPOISOMERASE I ACTIVITY ASSOCIATED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) AND OTHER RETROVIRUS PARTICLES

Eric L. Esteban¹,*, Tami A. Abedi¹, N.***, Shovalter, S. D.***, Roberts, M.***, Oroszlan, S.***, and Blair, D. C.*****, ¹Laboratory of Molecular Cancer Analysis, Frederick, MD 21701-1011; ²Ben-Gurion University, Beer-Sheva, Israel; ³Program Resources, Inc., Frederick, MD 21701-1011; ⁴Amgen/Research, Inc., Frederick 21701-1011, USA.

The viral replication cycle is undoubtedly dependent on numerous topological changes of the viral and host genomes. Since DNA topoisomerases have been shown to be responsible for the topological changes of DNA, it was of interest to investigate whether a topoisomerase activity could be demonstrated in retroviral particles.

In this work we demonstrate the existence of DNA topoisomerase I (Topo I) activity associated with two strains of purified HIV-1, equine infectious anemia virus (EIAV) and Moloney murine leukemia virus (Mo-MuLV). The relaxation activity from these viruses was inhibited by camptothecin (CPT), a specific topo I inhibitor. The viral associated topo I activity is Mg²⁺ dependent and possesses other characteristics different from the host cell enzyme. The viral associated topo I activity was removed from the viral lysate by anti-topo I serum. Western blot analysis indicates that an 11.5 kDa protein from both strains of HIV-1 and an 11 kDa protein from EIAV is recognized by this anti-topo I serum. By stellar protein detection with the appropriate nuclear or cytoplasmic cell extracts.

T.C.P.116 EXPRESSION IN E. coli AND PURIFICATION IN ONE STEP OF A FUNCTIONAL HIV896 PROTEIN BETWEEN A BACTERIAL FUSION PARTNER PROTEIN (MALM) AND THE T LYMPHOCYTE-HELPER INDUCER-CD4 PROTEIN (CD4-FUSION PARTNER)

CLÉMENT, Jean-Marie¹, SZMELCMAN, S.¹, SCHWARTZ, D.*, BENIN Y.***, MONTAGNIER L.*** & HEDGECOCK M² L.*****, ¹P.M.T.C.G. & ²Oncologie Virale, Institut Pasteur, 25 rue de St. Rosa, Paris 75015, France.

The surface glycoprotein CD4, expressed on helper/inducer T lymphocytes, serves as the HIV receptor through binding of the virus envelope protein gp120. It was recently demonstrated that the soluble truncated molecule of CD4 (the 177 kD terminal amino acids) retains the ability to bind gp120 and to neutralize the HIV particle.

We describe the purification and characterization of a recombinant protein produced by *E. coli* that contains the HIV binding portion of the human CD4 molecule, fused to the periplasmic maltose binding protein (MBP) of *E. coli*. This fusion protein retains the functional properties of the CD4.

1. It binds maltose and maltodextrin. This property is used in a one step procedure to purify the recombinant protein by affinity on a amylose column with elution in mild conditions.
 2. It binds purified gp120 and neutralizes HIV particles *in vitro* it is also recognized by the monoclonal neutralizing antibodies 177A and OKT4A.
- The easy purification of active soluble MBP-CD4 protein from bacteria should also facilitate a number of studies such as screening and possibly selection of CD4 mutants with altered properties (stability, interaction with virus etc), investigation of therapeutic potential of CD4, determination of CD4 structure by x-ray crystallography. The CD4-MBP hybrid could also be useful as a reagent for various purposes: diagnostic, HIV virus purification isolation of HIV mutants...

T.C.P.118 ACTIVATION OF THE HIV AND INTERFERON REGULATORY ELEMENTS IN HEMATOPOIETIC AND EPITHELIAL CELLS

Hiscoot, J., Cohen-Asprouh, Leblang, Jean-François, Sportiva, L., and Karanitsoulis, S., Lady Davis Institute, Jewish General Hospital, and Dept. of Microbiology and Immunology, McGill University, Montreal, Canada.

Objective: The interferon- β promoter contains several functional domains that confer virus-inducibility to the structural IPR gene. Interestingly, one of these specific elements, the P2 domain (GGAGATTC)-44 to -55' relative to the mRNA start site), shares 80% sequence homology with the two NF- κ B recognition sites (GGGATTGG) within the 13 enhancer element of the HIV long terminal repeat (LTR). This observation prompted us to measure the transcriptional activity of dimers of P2 and NF- κ B motifs in a transient expression assay using epitheloid (EP3), T lymphoid (Crestack), and myeloid (U937) cell lines.

Methods & Results: Cells were transfected with expression vectors containing various synthetic IPR and HIV regulatory motifs linked to the CAT reporter gene and subsequently induced with Sendai virus and/or phorbol esters. Both regulatory elements displayed similar patterns of inducible gene expression. Furthermore, specific inducible protein-DNA complexes were identified between P2 or HIV enhancer by band retention assays using uninduced and induced extracts from hematopoietic and epitheloid cell lines. Competition analysis suggested that the IPR P2 domain and HIV enhancer could interact with similar DNA binding proteins. **Conclusion:** Together, these results suggest that induction of IPR gene expression may share mechanistic similarities with the activation of the HIV-LTR.

T.C.P.120 REF RESPONSIVE SEQUENCES (RR) OF THE HIV-1 LTR-MEDIATE TRANSCRIPTIONAL SUPPRESSION

Jan Hahn¹ and Greg Giddens², ¹Department of Medicine and Microbiology & Immunology, Washington University, St. Louis, Mo., USA

Objective: The *gag* gene of HIV-1 encodes a 206 amino acid, 27 kD protein that down-regulates virus replication. This effect is mediated by REF suppression of transcriptional initiation. This effect is mediated by a cis acting element in the HIV-1 LTR which is responsive to REF.

Methods and Results: Two proviral HIV-1 clones were constructed, pHR1 P₁ which bears an intact *gag* gene, and pHR1 P₂ which has a 45 base pair deletion in the 3' portion of the HIV-1 LTR. These plasmids were transfected into COS-1 cells. Nuclear run-off, Southern blot hybridization, and gel retardation assays demonstrated that REF suppresses RNA initiation and viral RNA and protein levels. 2-10-fold. A REF expression vector, pRV, was made using an SV40 promoter. Co-transfection of pRV in a 5-fold excess with HIV-1 LTR-CAT resulted in an 8-fold depression of CAT activity. REF-mediated suppression was dose dependent and was specific for the HIV-1 LTR in that the pRV promoter, and the LTRs of HIV-1, HIV2, and SPV were unaffected. HIV-1 LTR CAT deletion mutants were used to map the REF. These constructs were co-transfected into COS cells with or without pRV or a CAT expression plasmid. Mutants with nucleotides -65 to -93 deleted in the RNA initiation site were responsive to REF, whereas those with nucleotides -44 to -93 were unresponsive to REF. In addition, a 30 nucleotide REF binding site in the HIV-1 LTR acting through sequences between -45 and -93. The activity of REF is independent of that of CAT. Previous data of REF, proteinase mediated interactions with SP1 and TATA-binding factors, and the mechanism of transcriptional silencing are being investigated.

MYRISTOLATION DEPENDENT ASSEMBLY OF INFECTION HIV-1
Jan Raderer and M. Ryan*, Departments of Medicine and Pathology, Washington University, St. Louis, Mo., USA

Objective: Linkage of myristic acid via an amide bond to the amino-terminal Gly residue of the GAG precursor of mammalian retroviruses appears to facilitate an essential step in virus assembly. The goal of this study was to determine if myristic acid incorporation into HIV-1 GAG proteins are required for replication and infectious particle production.

Methods: Oligonucleotide-directed mutagenesis was used to change the codon for the N-terminal Gly of GAG to an Ala codon in a functional HIV-1 proviral clone, HD32. The mutant plasmid, HD-GAG-1, and the parental plasmid were transfected into two CD4+ cell lines, CCR-1 and Hela, and CD4+ Jurkat cells. On day 4 following transfection, the CD4+ cells were cocultivated with H9 cells to support reverse transcription of HIV-1 RNA.

Results: Viral antigen was detected following transfection of each of the CD4+ cell lines with either HD32 or HD-GAG-1. However, no infectious virus was detected in culture supernatants revealed only soluble GAG protein, and no detectable virus particles. However, infectious virus was not produced following cocultivation with susceptible H9 cells, or direct transfection of Jurkat cells. In contrast, transfection of each of the cell lines with HD32 plasmid produced infectious virus. Transfection of the CD4+ cells with HD-GAG-1 and a GAG-Pro expression plasmid resulted in virus replication, demonstrating complementation of this defect.

Conclusion: Myristylation of the HIV-1 gag polypeptide is required for virus replication and assembly. These data suggest that inhibition of myristylation will open a new avenue of anti-retroviral research.

T.G.P.122

BIOLOGICAL SIGNIFICANCE OF HIV-1 ENVELOPE HETEROGENEITY
Terry McHenry, P Westarvic, M Thilman, D Trowbridge, J Garcia, and L Bacter, Departments of Medicine and Microbiology & Immunology, Washington University, St. Louis, Mo., USA

Objective: To examine the nature and biological significance of naturally occurring variations in HIV-1's derived from blood, brain, and lung of 3 patients infected with a single proviral virus. Methods and Results: Isolates were obtained from short term FMC cultures cocultivated with fresh tissue from an asymptomatic, HIV seropositive blood donor (pt 1), and two neonatal transfusion recipients who subsequently developed AIDS (pts II & III). Isolates from the lung and brain of pts II & III replicated to 100-fold higher levels on monocytes relative to the blood isolates from the same patients; no growth differences on lymphocytes were observed. The 3' portion of the genome was cloned from each isolate, and analyzed. The predicted amino acid sequence from the blood isolate of pt 1 shows a 145 divergence compared to clone HD32. The positions of Cys residues are conserved. No unique amino acid changes are found in the clones derived from the brain or lung isolates. All clones derived from these patients exhibit 2 transmembrane codons in the portion of *env* encoding TM. Conclusions: envelope amino acid sequence variation observed in these genomes is considerably lower than that reported for adults with AIDS, possibly reflecting the host's limited ability to provide selection pressure. The lack of a consistent difference in *env* between clones derived from isolates which show markedly different replication on monocytes suggests that other protein(s) of the HIV-1 genome may be contributing to cell specificity.

HIV INFECTION OF COLONIC MUCOSA ASSOCIATED WITH COLITIS
J.W. Mehlis, M. Hing, C. Goldschmidt, D.A. Cooper, and A.L. Cunningham-Virgilio Unit, Centre for Immunology, St. Vincent's Hospital, NSW, Special Units for Clinical Research and Epidemiology and AIDS Virus, Sydney Australia.

The aetiology of diarrhoea in patients infected with the human immunodeficiency virus infection often remains obscure. We report 7 patients with human immunodeficiency virus infection with chronic diarrhoea for longer than 6 months, rectal bleeding, abdominal pain and stool leukocytosis. The mucosal pattern on colonoscopy showed diffuse proctocolitis. Colonic biopsies showed moderate to severe colitis characterized by preservation of normal crypt architecture and a mixed inflammatory cell infiltrate. These features were not compatible with a diagnosis of chronic inflammatory bowel disease. HIV nucleic acid was identified by *in situ* hybridisation in colonic biopsies from 4 out of 6 patients. Autoreactive plasma were distributed in clumps over epithelial cells of the colonic glands (not confined to argente/fin cells) and over cells in the lamina propria. Hybridisation-histochemistry is being used to identify the latter cells. No other microbial agent could be demonstrated as the cause of diarrhoea. At presentation all patients had CD4+ lymphocyte counts greater than 150 x 10⁶/l, and none had AIDS. We suggest that this chronic colitis is a new entity related to infection of the colon with the human immunodeficiency virus.

T.G.P.124

ANALYSIS OF HIV SEQUENCE CHANGE DURING INFECTION
Lalan Brown, Andrew C. and Baljit P. University of Edinburgh, Edinburgh, Scotland, UNITED KINGDOM

Objective: To develop a method of analysis which will detect selection for HIV sequence variants during infection. Methods: The probability that more than one lineage will be found in a sample taken *n* generations after the first has been estimated using the method of branching processes (Hastings 1957). The approach has been applied to the data of Saag et al. (Nature 334, 440 1988). Results: By phylogenetic analysis based on the Wagner parsimony method we have found that the W89 group of clones originated from within the W81 group isolated 16 months earlier and did not arise in parallel. Thus, after 2 months all but one W81 lineage had become extinct. We have examined the probability of loss of all but one lineage in these data assuming no selection and a generation time of 5 days (based on observations made during virus isolation in our laboratory). The probability of more than one lineage persisting was found to be less than 0.05. It is therefore not necessary to invoke selection to explain the relationships between the W89 and W81 clones. Conclusions: The method we have used will be effective at detecting selection when the number of generations between samples is 10-50 (about 5-8 months). There is no evidence on these data for selection among clones isolated from patient W89.

T.G.P.125

LOCALIZATION OF A DOMAIN OF HUMAN CD4 REQUIRED FOR HIV-MEDIATED SYNCTIUM FORMATION BY COMPARISON WITH CD4 FROM THE CHIMPANZEE AND RHESUS MONKEY

David Cameron and Brian Seed, Dept. of Molecular Biology, Massachusetts General Hospital and Dept. of Genetics, Harvard Medical School, Boston, MA, U.S.A.

Objective: To locate regions of the Human CD4 glycoprotein required for HIV-1 mediated synctium formation.

Methods: We have isolated, sequenced, and expressed cDNAs encoding the CD4 glycoproteins of the chimpanzee (*Pan troglodytes*) and the rhesus monkey (*Macaca mulatta*). We performed HIV-1 infection, binding and fusion assays using cell lines expressing these antigens. We constructed trans-species hybrid CD4 antigens *in vitro*, and tested their ability to promote HIV-1 mediated synctium formation.

Results: Both the chimpanzee and rhesus monkey CD4 antigens, respectively 99% and 92% homologous to their human counterpart, bind HIV-1 and permit infection when expressed on Hela cells. Nevertheless, these non-human receptors are markedly less efficient than human CD4 at promoting HIV-1 mediated synctium formation. We have located individual amino acid differences between the human CD4 and these non-human CD4 glycoproteins, responsible for their differing abilities to participate in HIV mediated synctium formation.

Conclusion: We have defined a region of the human CD4 glycoprotein, distinct from the previously defined binding site for HIV-1, which is essential for the formation of synctia in the presence of the external and transmembrane glycoprotein of HIV-1.

T.G.P.126

STUDIES ON THE FUNCTION OF VPX IN HIV-2
L. Brown, D. Doster, W.D.; Len. B.W.; Monroe, C.D.; Shaw, G.M.; and "HIV-2" (1988)

Department of Microbiology, Washington University, St. Louis, Missouri, USA.

Objective: To determine the role of vpX in the life cycle of HIV-2. Methods: To study the biological function of vpX, we constructed a transfection-competent plasmid and utilized a series of deletion constructs. Results: An internal HindIII site containing fragment was subcloned into M13 and mutagenized so as to abolish vpX transcription. The role of vpX was then assessed by cotransfection of wild-type and mutant vpX with respect to packaging efficiency, genomic stability, virus-particle expression, cytopathicity, and reverse transcription. For reverse transcription, a 100-fold increase in reverse transcriptase activity was observed in cultures transfected with unmutated vpX. Results: Transfection of type HIV-2 indicated that vpX is not essential for reverse transcription. However, the mutant HIV-2 virus was unable to infect non-lymphocyte (FRL) Upon transfection into untransformed T-cell lines (Sp71 and CEM474) by a non-tissue specific promoter, the mutant HIV-2 virus was unable to infect T-cells. This was not comparable to wild-type and wild-type HIV-2. Both mutant and wild-type viruses were infectious and viable upon transfection into T-cells. Results: Infection of untransformed wild-type HIV-2 virus-infected and replication competent in FRL. Electron microscopy revealed apparent differences in virus ultrastructure in comparison to wild-type HIV-2. Transmission electron microscopy following high salt extraction of Sp71 cells demonstrated that virus binding, uncoating and reverse transcription were identical in mutant and wild type viruses. Finally, construction of cDNA clones with a unidirectional HIV-2 genome and a subgenomic vpX expression plasmid resulted in the production of virus containing viruses and demonstrated that vpX can be complemented *in vitro*.

Conclusion: vpX is not required for HIV-2 replication and cell-to-cell transmission in immortalized T-cells as well as in FRL *in vitro*. Similarly, the lack of vpX does not seem to affect early events in the virus life cycle. Since vpX is packaged within mature viruses, despite the absence of HIV-2 assembly of particle matrices in these construction systems, we believe that the packaging requirements of HIV-2 are similar to those of HIV-1 and should be investigated in future studies.

T.C.P.127 COMPARATIVE ANALYSIS OF HIV-1 AND HIV-2 GENE EXPRESSION Arzq. Suragh, K. and Gallo, R.C. National Cancer Institute, NIH, Bethesda, Maryland, USA

Objectif: HIVs may comprise a spectrum of retroviruses with varying pathogenicity and/or latency. Their pathogenicity may be determined by their regulatory genes and regulatory elements. The objective of this study was the comparative analysis of the regulatory genes and elements of HIVs with varied pathogenic potential. **Method:** Functional and molecular analysis of the regulatory genes and response elements by DNA mediated transfections. **Results:** Pathogenic HIV-1 (H11) and HIV-2 (H2A) as well as HIV-2 with attenuated cytopathicity (HIV-2[3]) all contain functional *tat*, *reg*, and *rev* genes. Additionally, their expression is equally activated by T cell activation and HIV-2 transactivation. Interestingly, the SLS and T cell activation response elements in HIV-1 and HIV-2 are structured differently. For example, even though HIV-2 contains the distinguished enhancer element identical to that in HIV-1 where it responds to T cell activation (NFkB site), the major such element of HIV-2 is located upstream and is supposedly a member of a family of response elements. The HIV-1 and HIV-2 transactivation by the *tat* and *ORF* transactivator gene involves transcriptional activation including chain initiation and elongation. While HIV-1 and HIV-2 may utilize subtly different pathways of gene activation, they both contain functional *tat*, *reg*, and *rev* genes and response elements including those responsive to T cell activation and ORF transactivation. Thus, the possible differences in their pathogenicity may not reside in the functional capacities of the regulatory genes and elements alone.

T.C.P.129 A STRATEGY FOR THE DETECTION OF SPECIFICALLY SPLICED mRNA ENCODING HIV-1 REGULATORY GENES

Gustail, J.M., Richman, D.C., and Grogan, T.M.

*Dept. of Medicine, Harborview School of Medicine, St. Joseph, California, 92161 USA. **The Salk Institute Biotechnology/Industrial Associates, Inc. (SIBIA), La Jolla, California, 92037 USA.

Objectif: To differentially detect specific mRNA encoding the HIV-1 regulatory genes *tat*, *rev*, and *reg* in order to study the temporal expression of these transcripts during infection *in vitro*.

Methods: Primer-directed nucleic acid amplification was used to generate cDNA fragments of characteristic length which reflected gene-specific mRNA expression.

Results: Total cellular RNA from HIV-1-infected CD4 cells was amplified using primers complementary to: 1) the sequence immediately 3' of the splice donor common to all processed HIV-1 RNAs (5' of the gag start codon); and 2) the sequence at the 3' end of the *tat* and *rev* 3' coding exons. Between these two sequences are three splice acceptors whose use has been suggested to lead to specific mRNAs encoding *tat*, *rev*, and *reg*. The predicted cDNA fragments of 290, 108, and 92 base pairs, reflecting *tat*, *rev*, and *reg* mRNAs, respectively, have been detected using specific oligonucleotide probes. Several cDNA fragments of unexpected size have also been detected. Characterization of these fragments will be discussed.

Conclusion: Although differential detection of HIV-1 regulatory gene transcripts is difficult because of their similar size and largely shared monoclonal sequences, gene-specific splice events can be detected utilizing primer-directed amplification. This approach can be used to analyze the order of expression of these transcripts during infection.

T.C.P.131 POLYMERASE CHAIN REACTION IN HIV INFECTION

Mariotti, M., Lafrenay, Jean-Jacques, Berriche, S., Vitaroon, D., A. N. F. T. S., Paris, **Hôpital Charles, Paris **C.T.S. Chemistry, France.

Objectif: Use of Polymerase Chain Reaction (PCR) in human immunodeficiency virus (HIV)-infected subjects and in seronegative but high risk subjects.

Methods: Localization of the genome and nucleotide sequence of the primers and probes used (derived from conserved regions of the viral genome) were:

- GAG : primer 1088-1115, primer II 1175-1202, probe 1132-1172
- POL 1 : primer 2381-2616, primer II 2872-2688, probe 2139-2271

- POL 2 : primer 8118-8135, primer II 8242-8259, probe 8167-8265

Site-blot and Southern-blot analysis were used in detection of HIV sequences. 530 subjects were studied : 200 non-haemophilic HIV seropositive (Elias with confirmation by Western-blot) subjects (among them, ten were seronegative 6 months earlier) ; 40 haemophilic patients (20 seropositive + 20 seronegative) ;

25 AIDS patients ; 25 seronegative posttransfusion thalassaemia patients ; 20 subjects with isolated and persistent anti-core antibodies (anti-p24 or anti-p18) ; 20 seronegative partners of HIV seropositive subjects (a second sample was collected and studied 6 months later in 6) ; 20 healthy seronegative blood donors as controls.

Results: 1) PCR is positive in the HIV seropositive subjects but some appear negative in this assay when using only one single primer pair and probe. The use of three sets of primer appears necessary to prevent false-negative results in this context. 2) No detection of HIV DNA was observed in seronegative subjects from high risk groups. 3) All control subjects were PCR negative.

Conclusion: PCR allows the detection of HIV DNA in seropositive subjects and confirms the absence of HIV infection in seronegative subjects.

T.C.P.128 RESTRICTION MAP PATTERNS IN SELECTED CLINICAL PAIRS OF HIV ISOLATES

Shelton, Margaret, Reichman, F., Mason, J., Bedford, R.,

et al., and the Walter Reed Retroviral Research Group, U.S.A.

Objectif: To evaluate restriction mapping of selected viral isolates to determine the potential value of application in defining the identity of viral isolates.

Methods: Purified viral isolates were obtained by co-cultivation with normal SP2 using standard techniques. Southern blots of restriction enzyme digests of viral DNA probed with 32P labeled 887 fragment of p8.9.

Results: Specific paired samples were selected and viral isolates classified. Group 1 consisted of a sequential isolate pair (less than 6 weeks apart) from the same patient (two early HIV infection and two late HIV infection).

Group 2 consisted of 2 isolate pairs from same patient however different body fluid source (CSF/serum). Group 3 consisted of same patient same time different isolation techniques (T cell versus macrophage). Group 4 consisted of epidemiologically paired to include acute and asymptomatic pairs. Restriction patterns of pair isolates will be compared to unrelated isolates to develop an identity score.

Conclusion: These results demonstrate the applicability of restriction mapping in defining viral identity.

T.C.P.130 PROCESSING OF THE gag POLYPROTEIN BY HUMAN

IMMUNO DEFICIENCY VIRUS PROTEASE OCCURS IN

A SEQUENTIAL MANNER

S. Erickson-Villano, John Manfredi, Paul Vitanen, David Tribe, Radonna

Trich, Ronald Swanstrom, et al. E.I. DuPont de Nemours and Co., Inc.

Medical Products Department, Wilmington, DE, USA 19880-0400 and

Departments of Biochemistry and Microbiology and Immunology, University

of North Carolina at Chapel Hill, Chapel Hill, NC, Carolina, 27599.

The virally encoded protease of human immunodeficiency virus is responsible for the processing of the gag and gag-pol

polyproteins to their mature polypeptides. Since correct processing of the viral polyproteins is essential for the production of infectious virus, HIV

protease represents a potential target for therapeutic agents. In this study, full-length gag polyprotein has been synthesized *in vitro* to serve as a

trans substrate for bacterially expressed HIV protease. The gag polyprotein is rapidly and completely processed by protease-containing

extracts. Immunoprecipitations with monoclonal antibodies to p17 and p24 suggest that initial cleavage of the polyprotein occurs at the p24-p15 junction. The proteolysis was inhibited by pepstatin with an IC50 of 0.15

nM for cleavage at the p24-p15 junction and 0.02 mM for cleavage at the p17-p24 junction.

T.C.P.132 IN VITRO EXPRESSION OF A FUNCTIONAL HIV-NIF GENE PRODUCT

Paulo Louisa and Jay, J. Cancer Research Institute, University of California,

School of Medicine, San Francisco CA 94143 USA

Objectif: To study the biochemical function of the HIV-1 protein.

Methods: We have subcloned the HIV-2 nif gene DNA from an original plasmid (p900-8) provided by Paul Lewis (University of California Davis, CA) into a baculovirus vector (Sf9000, MDL). The new construct was used in a transcriptional readthrough system to produce the NIF gene product. The gene product was then translated into a microsome nucleus treated reticulocyte lysate. Finally, the purified nif gene product was analyzed in an *in vitro* assay for GTP binding activity and kinase activity.

Results: The nif mRNA encoded for a 37 kDa protein of 27 kDa dature as determined by polyacrylamide gel electrophoresis. This finding is in accordance to the predicted molecular weight and is similar to what is found in HIV-infected cells. This p27 is recognized by either specific monoclonal antibody (Dapin, M4) or polyclonal anti-HIV-2 NIF protein.

In addition, three other products of 29kD, 25kD and 17kD are also synthesized at a much lower level in the reaction and are also recognized by the same antibodies.

Immunoprecipitated nif protein can bind specifically 32P-gamma-GTP. Furthermore, the immunoprecipitated translation products display a kinase activity in the presence of either 32P-gamma-GTP or 32P-gamma-ATP. However, the phosphorylated product of this *in vitro* kinase assay runs as a single band with a molecular weight of 40 to 50 kDa on either a polyacrylamide gel.

The phosphorylation activity is dependent of the concentration of the nif translated products.

Conclusion: The HIV nif gene expressed *in vitro* possesses an integral GTP binding activity and kinase activity. The establishment of an *in vitro* system to study the structure and the biochemical function of the purified nif protein known as a negative regulator of HIV expression.

T.C.P.133 TWO EPSTEIN-BARR VIRUS-LATENT PROTEINS (LMP AND EBNA2) TRANSCRIPTIVE TARGET THE HIV-1 LTR
Simurda, Maryanne C. and Hammarikid, M.-L.
Departments of Microbiology and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

We have constructed SV40 based vectors that express different latent proteins of Epstein Barr Virus (EBV). Using these constructs we have shown that both the nuclear EBNA2 protein and the latent membrane protein (LMP) are efficient transactivators of the HIV-1 LTR. Both of these proteins are expressed in B lymphoid cells immortalized by EBV. To map the regions of the LTR involved in the transactivation we have used different mutated forms of the HIV-1 LTR linked to CAT as a reporter gene. CV-1, Ramos, Raji and Jurkat cells were co-transfected with these constructs and the vectors expressing EBNA2 and LMP. Results showed that most of the effect of the LMP protein could be mapped to the binding sites for nuclear factor κ B (NF- κ B). These results indicate that LMP activates second messengers that are involved in activation of NF- κ B of related factors. The effect of the EBNA2 protein could not be mapped to a single defined cis-acting element and seems similar to that observed with immediate early proteins of other herpesviruses.

T.C.P.135 DETECTION OF ACTIVE VIRAL PROTEASE ASSOCIATED WITH CAPSIDS OF EQUINE INFLUENZA VIRUS (EIAV)
Roberts, Michael, and Grosslein, S. MD, Basic Research Program, MCJ-Frederick Cancer Research Facility, Frederick, MD 21701-1013, USA.

The cores of retroviral particles are likely to contain all the components required for infection of the host cell once it has reached the cytoplasm. In this respect, it was of interest to prepare cores of EIAV as a model system for the human immunodeficiency virus (HIV).

In this work we have prepared cores of EIAV by treatment of whole virus with detergent followed by two cycles of rate-zonal banding through Ficoll density gradients. The major components of the core are the p11 (nucleocapsid protein) and p26 (capsid protein) which are present in equimolar amounts, as in the whole virus. Since the cores are not deficient in p26, they are referred to as capsids. The other gag-coded proteins p9 and p15 are removed during the preparation. At pH 7.6, the presence of active viral protease in the capsids was revealed by cleavage of p11 to a p6 protein. This cleavage was inhibited with pepstatin, which is known to work with retroviral proteases. The existence of the capsid as a distinct morphological entity was shown by electron microscopy of negatively stained particles. By this means, the capsids are revealed as uniform cone-shaped particles 60nm x 120nm in size. The significance of the p11 cleavage at this stage in the retroviral life cycle is being investigated. (Research supported by the National Cancer Institute, DMS, under contract NO-MO1-GO-7410) with Biogenetics Research, Inc.)

T.C.P.137 HIV-1 gag EXPRESSION IS DEPENDENT ON A GENERAL 'SHUFFY' SEQUENCE
Wilson, Wilma; Braddock, M.; Kingman, S.M.* and

Kingman, A.J.†
*Department of Biochemistry, South Parks Road, Oxford, OX1 3QU, U.K.
†British Biotechnology Ltd., Watlington Road, Cowley, Oxford, U.K.

Objective: To determine the minimal sequence requirements for the frameshift event which is essential for gag expression and to examine the significance of this 'shuffy' sequence in cellular genes.

Methods: We have used an SP6 in vitro system to assay a series of fragments and oligonucleotides for their ability to frameshift.

Results: We have shown that a short (28bp) sequence containing a run of 6 Ts is sufficient for gag expression in both yeast and mammalian systems. We demonstrate that 6Ts alone are able to direct frameshifting. Shifting occurs irrespective of the reading phase of the Ts and occurs into both reading frames. The possibility of frameshifting occurring in other genes containing 6Ts has been examined and we demonstrate shifting in a cellular gene which contains this 'shuffy' sequence.

Conclusions: HIV-1 employs a general 'shuffy' sequence of 6Ts in its expression of gag. It is possible that the frequency of 6Ts is also modulated by other viral proteins or by the particular sequence context.

T.C.P.134 INFECTION OF RHESUS MACAQUES WITH A MOLECULARLY CLONED SIMIAN IMMUNODEFICIENCY VIRUS
Paul Laidlaw, M. Marbas, E. Banerjee, T. McGraw, P. Marx and N. Pedersen, University of California, Davis, California, U.S.A.

Objective: To analyze rhesus macaques infected with a molecularly cloned SIV with respect to viral replication, viremia, and ability to elicit anti-viral immune responses.
Methods: An infectious molecular clone of SIV from a rhesus macaque was found to replicate to high titer in cultures of primary rhesus peripheral blood mononuclear cells (PBMC) and macrophages derived from rhesus PBMC. Six juvenile rhesus macaques were inoculated intravenously with SIV recovered from the molecularly cloned provirus.

Results: All animals recovered from PBMC of all animals at one and two weeks PI. Inoculation (PI) and virus was recovered from PBMC of all animals at one and two weeks PI. Antibodies to gag-coded proteins were detected before antibodies to the gag-p1 precursor and p17 gene products. Only one animal developed detectable antibody to the p27 gag gene product. One antibody to SIV-coded proteins were elicited, they persisted; however, SIV-specific neutralizing antibody titres declined after one month PI. By ten months after inoculation three of the animals had exhibited transient viremia (as detected by co-cultivation with human lymphoid cells), three were consistently virus negative and none had developed clinical signs of SIV disease.

Conclusions: SIV from a molecular clone is capable of producing a persistent and, perhaps, latent infection in rhesus macaques; however, the outcome of infection appears to be dependent on the individual host. These animals remain under study to assess the pathogenic potential of an SIV isolate that has been shown to be both T-cell tropic and macrophage tropic.

T.C.P.136 EXPRESSION OF HIV GENES IN XENOPUS OOCYTES: DEMONSTRATION OF POSTTRANSCRIPTIONAL REGULATION

Adachi, Junji, Samoil, K. Ilioman, Mary* and Joseph, Steve**
*Human Genetics Branch, NICHD, Bethesda, MD and Laboratory of Tumor Cell Biology, NCI, Bethesda, MD, USA

Objective: To study posttranscriptional aspects of HIV gene regulation in *Xenopus* oocytes.

Methods: Purified normal and mutant LTR/CAT transcripts were synthesized using the bacteriophage T7 polymerase system. These were coinjected with plasmid DNA constructs into the nucleus and/or cytoplasm of *Xenopus* oocytes. CAT assays and RNA analyses were performed by standard methods.

Results: HIV genes can be faithfully and efficiently expressed in the *Xenopus* oocyte. We can demonstrate posttranscriptional regulation of the normal LTR/CAT construct. Constructs with TAR mutations express very low basal levels and are not regulated. **Conclusions:** The *Xenopus* oocyte is a suitable system for the study of HIV gene expression. Our results suggest a posttranscriptional TAR dependent regulation.

T.C.P.138 MOLECULAR CHARACTERIZATION OF THE HUMAN CD4 GENE
Hanna, Zehava; Cheung, E.* and Jolicoeur P.***

*Clinical Research Institute of Montreal, Montreal, Quebec, Canada; **Université de Montréal, Montreal, Quebec, Canada.

The human CD4 molecule has been shown to serve as a specific membrane receptor for HIV. To better understand the control of the expression of this gene as well as its specificity of expression in specific cell populations, we undertook its molecular cloning. Using the CD4 cDNA probe, we isolated a set of overlapping genomic clones from human genomic libraries constructed in the lambda cloning vector EMBL-3. These clones span the CD4 gene and its adjacent sequences. Clones were characterized by restriction enzyme analysis and by Southern hybridization. The putative promoter has been identified and partially sequenced. Search has been initiated to identify enhancer sequences using transfection techniques with the CAT vector and by constructing transgenic mice.

T.C.P.145 5'-PHOSPHONATE DERIVATIVES OF 3'-AZIDO-2',3'-DIDEOXYNUCLEOSIDES: SYNTHESIS AND INHIBITION OF HIV REPRODUCTION IN CELL CULTURES

TARUSOVA, N.I.; KUKHAROVA, N. I.; KOROLIN, A.; KRYAZEVSKY, A.; GIL'GAY, V.; KOPAL, S.; LITVINOV, I.; BAKHARALIN, G.; VIL'KIN, V. Engelhardt Institute of Molecular Biology, the USSR Academy of Sciences, Moscow; D'vinskii Institute of Virology and Immunological Research Center, the USSR Academy of Medical Sciences, Moscow, USSR

Objective: A group of new 5'-phosphonate of 3'-azido-2',3'-dideoxynucleosides was studied in cell cultures, infected by HIV. **Methods:** Synthesis of 5'-hydrophosphonates, 5'-methylenephosphonate and 5'-methylphosphonate of 3'-azido-2',3'-dideoxynucleosides was elaborated. The activity of these compounds on HIV reproduction in HIV-1 infected T84 cell cultures was evaluated by reverse transcriptase activity and using immunofluorescent and autoradiographic analysis.

Results: 5'-Methylene- and 5'-hydrophosphonates of 3'-azido-2',3'-dideoxynucleosides revealed the activity close to that of 3'-azido-2',3'-dideoxynucleoside (AZT) at the suppression of HIV-1 reproduction, whereas their toxicity was significantly lower both in HIV-1 infected and noninfected cells. 5'-Hydrophosphonates of AZT and AZC were essentially more active than initial nucleosides, their toxicity being as well significantly lower. Some statistical data for 5'-phosphonates in cells were investigated. **Conclusion:** The new group of highly active anti-HIV compounds was found.

T.C.P.147 THE ROLE OF INTERLEUKIN-4 (IL-4) IN AIDS.

PAUL DUBREUIL

Project Director, IDM Centre for AIDS Research & Control, Pune, India.

Objective: To present a model explaining pathogenesis of AIDS. **Methods:** A literature survey has been made of molecular to epidemiologic aspects of AIDS and natural retroviruses, and of cytokines. Relevant information is presented to explain the pathogenesis.

Results: This model is based on interactions between latent HIV lurking as intracellular particles (IAP), other infectious agents which induce IL-4 and act as cofactors, and also, host's genetic factors. Many human CD4 T helper cells spontaneously secrete IL-4, IL-4, and IFN- γ . IL-4 stimulates B cells to polyclonal activation and also enhances expression of IL-2/3 which is especially associated with CD25. Its avidity for receptor for IgE (Fc ϵ R2). It linked glycosylation site on HIV gp120 which binds with CD4 is also associated with IL-4. Transmembrane of latent HIV occurs via enhancer element present in the IAP-LTR. IgE antibody formation is genetically controlled and regulated by IFN- γ . Addition of IL-4 to mouse cells compensates for the genetic defect of a nonresponder mouse strain. Similarly, HIV-infected poor responders may overcome the defect if repeatedly triggered by IL-4 inducing cofactors. Antibodies to gp120 interact antibodies to IL-4/3, which comprise effective functions of antigen presenting cells and the T-3 cell interaction. IL-4 also appears to be the HIV-induced growth factor reported to be responsible for Kaposi's Sarcoma seen in AIDS patients.

Conclusions: The model explains the depletion of T cells in AIDS and also why some individuals develop full-blown AIDS faster than others.

T.C.P.149 MONOCLONAL ANTIBODIES RAISED TO RECOGNIZANT HIV-1 GAG-PROTEINS CAN IDENTIFY IMMUNODEFICIENT B CELL EPITOPES IN AIDS PATIENTS.

Eric Saxon, P. De Beesteler*, S. De Lays, C. Wusters and H. Van Neuvaren, Immunogenics N.V., Antwerpen, Belgium. *University of Brussels, Belgium.

Objective: The ability of serum antibodies from AIDS-patients to compete with the binding of mouse anti-HIV monoclonal antibodies to the E. coli produced antigen, was investigated.

Methods: Microcell plates coated with E. coli produced purified p24 HIV-1 antigen, were incubated with serial dilutions of sera from AIDS-patients. Following by incubation with the monoclonal Ab, which was then detected with an anti-mouse IgG conjugate. Inhibition of monoclonal binding was scored as a decrease of the signal, relative to the unblocked control. Microcell HIV-1 producing cells were incubated with culture supernatant from several clonal anti-HIV cell-lines to investigate the binding of native viral antigen. Captured antigen was detected with an anti-HIV human IgG conjugate.

Results: Five anti-p24 and two anti-p17 mouse monoclonal antibodies were investigated. For two anti-p24 monoclonals, a variable degree of interference from a panel of 50 human anti-HIV sera was observed. The corresponding epitopes are thus immunogenic in most HIV-1 patients. However, one of these monoclonals does not recognize the antigen from viral lysates. This implies that the epitope is not accessible in mildly denatured p24 protein. This points to the identification of epitopes exposed only after denaturation (presented by viral antigen).

Conclusion: Mouse monoclonal antibodies to degraded recombinant HIV-antigen can identify B cell epitopes recognized in HIV-infected humans, but not accessible in the native antigen.

T.C.P.146 REDUCED IN VITRO GROWTH AND DIFFERENTIATION OF MONOCYTES FROM PATIENTS WITH HIV INFECTIONS

Elisavinda-Fradick Ballew, M. Gaudemar, G. A. Frelund, S.S.

University of Oslo, The National Hospital, Akershuskspitalet, Oslo, Norway.

Methods: Monocytes (Mo) from patients with HIV (CDC II/III, n=36; AIDS, n=15), 14 HIV seronegative, haemostatically stable donors were cultured for 1-10 days. The number of Mo/Macrophages, protein and cell differentiation were determined, the last by immunocytochemical staining with monoclonal bodies (mAb) against two differentiation antigens. The in vitro growth of Mo was assessed in (a) 8 AIDS patients receiving zidovudine, (b) 17 patients where Mo were cultured with Mo/NE supernatant from normal blood donors, and (c) 6 patients where Mo were cultured with R-3CF (MO Colony Stim. Factor). On day 10, the number of Mo and cell protein were reduced in CDC II/III and even more in AIDS. Decreased in vitro growth correlated with reduced function of the bone marrow (BM) assessed as low numbers of erythrocytes (2.6-6.5x10¹²/l), leukocytes (10-16x10⁹/l) and thrombocytes (10-14x10⁹/l) in peripheral blood on day 10. HIV Mo were significantly less differentiated than control Mo. Of the patients treated with zidovudine, 3 out of 8 showed no treatment improvement of in vitro growth during the first 2-3 months. Mo/NE supernatants from healthy donors as well as R-3CF did partially reconstitute the growth defect in the serostable patients treated. Complications decreased Mo in vitro growth and differentiation are seen in most patients receiving zidovudine. The data are due to lack of cytokines as supported by the reconstituted experiments. The correlation of decreased Mo in vitro growth and low numbers of blood cells might also suggest that defects in Mo precursor cells are operative. Another mechanism may be HIV replication in Mo.

T.C.P.148 NUMBER INVESTIGATIONS ON A LABORATORY MODEL BASED ON HIV-1 SPECIFIC CYTOTOXIC T LYMPHOCYTES

Alida, Elia, Eyal, Research Center, Givat, Egypt.

The author had previously reported on the development of HIV-1 specific cytotoxic T cells, (Arida, et al., 5th Internat. Cong. of Immunol., July 6-11, 1988, Toronto, Canada. Abstracts 3:55-15, p. 460. Arida, E., 12th Internat. Cong. of Virology, August 8-14, 1997, Edmonton, Canada, Abstracts: R36-6). In the present work, the characteristics of these cells after 6 months of propagation were investigated under several experimental conditions. These included IL-2, T cell antigens, parasitic antigens, certain cations, chelating agents, etc... The cells retained their response to HIV-1 specific cytotoxic effect (SCE), even after 6 months of propagation. They proliferated freely in absence of IL-2, T cell antigens and parasitic antigen which stimulate T cells. HIV-1 SIE was maintained by the cells only up to 10 months of propagation & was furtherly retained by treatment with Cd, Zn & Cu⁺⁺ ions, but not with Cu, Fe or Co. Chelating agents (including Ca agents) interfered with HIV-1 SIE when the whole virus was used, but not with its related genetic materials. These results indicate genome integration of an HIV-1 provirus & its associated noncoding and cytotoxicity assays. The value of these cells as lab. models for immunologic tolerance is evident.

T.C.P.150 HUMAN MONOCLONAL ANTIBODIES TO HIV

D. Bange, L. M. Bidel, J. C. M. Meyer, B. M. Knausow, D.

K. von Baehr, H. Schmitt

12/Chemist-Dept. Institute for Special Medicine, Department of Virology, Humboldt-UBD

7/Charité, Department of Neurology, Berlin, DDR

Objective: The production of human monoclonal antibodies to HIV and the evaluation of the use of these in HIV infection.

Methods: The heteromyeloma cell line CB F7 (Gouyon et al., Immunol. Methods, 106, 1984, 257-265) was used for cell fusion with peripheral blood lymphocytes from HIV positive blood donors. Clones were screened for specific and continuous antibody production. Supernatants from stable hybridomas were tested in specific neutralization and cytotoxicity assays.

Results: In 20 fusion experiments a fusion frequency of 0.6×10^{-5} and a specific fusion frequency of 0.8×10^{-6} was obtained.

14 clones were selected, all were directed against envelope glycoproteins of HIV; 15 were specific for gp 41 and eleven for gp 120. One clone against gp 120 produced continuously for the last three months. Neutralization and cytotoxicity assays are in progress.

Conclusions: We have established a method allowing the production of specific monoclonal antibody producing hybridomas against different epitopes of HIV. This will enable us to investigate the correlation of neutralizing or cytotoxic effects of monoclonal antibodies with type of antibody and to study the effect of such information concerning the interaction of HIV and antibody response.

Session d'afternoon Poster Session

W.C.P.13 ISOLATION AND PRELIMINARY CHARACTERIZATION OF A NEUROTROPHIC STRAIN OF FELINE LEUKEMIA VIRUS
 David W. Gage, J. W. Whittier, J. C. Overton, J. C. Whittier, S.W. Dow, M. Post.
 Pathology Dept., Anatomy and Neurobiology Dept., Colorado State University, *Microbiology Dept., School of Medicine, Little Rock, U.S.A.

Objective: We have isolated a strain of feline leukemia virus (FeLV-1380) which induced significant delays in motor neuron conduction velocities in 3 of 3 experimentally infected specific pathogen free (SPF) cats within 7 months post inoculation. This seems to lead to development of a feline model of AIDS peripheral neuropathy to be utilized in future testing of therapies for AIDS.
Methods: Bone marrow and CSF were harvested from 3 cats exhibiting neurologic abnormalities. All 3 cats were FeLV positive and RT negative. Two cats were neurologically intact. One cat (#1369) was experimentally infected with molecularly cloned (mcl) FeLV-1388 2 years before developing neurological problems. All samples were cultured with feline fibroblasts (MDF2/27) cells. Six SPF cats were inoculated (intracranially and intraperitoneally), 2 each, with cat line supernatants containing 10⁶ of the 2 previously neurotropic strains of FeLV. Four additional SPF cats were similarly inoculated 2 with 10⁶ of minimally neurotropic mcl FeLV-816E, and 2 with virus-free medium. The cats were housed under barrier conditions in two gann cages (5 cats/cage). Electrophysiology was performed and the cats were monitored behaviorally 8 and 7 months post inoculation.
Results: All of the FeLV-inoculated cats became FeLV positive approximately 3 weeks post inoculation. One of the molecularly cloned cats tested FeLV positive 8 weeks post inoculation. We assume this cat (#1370) contracted FeLV-1380 horizontally from the infected cats with which it was housed. A restriction pattern unique to mcl FeLV-2881 was identified by Southern blot analysis of the FeLV genomes produced by the 10 of the 2 cats inoculated with FeLV-1380. The motor nerve conduction velocities of #1370 and the 2 cats infected with FeLV-1380 were significantly decreased when compared to the velocities of uninfected age-matched control cats and cats infected with mcl FeLV-816E.
Conclusion: FeLV-1380 induced delays in motor nerve conduction velocities analogous to HIV and/or HTLV-1 peripheral neuropathy system lesions.

W.C.P.15 IN VIVO ANALYSIS OF THE MINIMAL INFECTIOUS DOSE OF AN ACUTELY LETHAL POOL OF HIV (SFV/80M/78-14)

McLellan, Harold A., Anderson, D. C., Anzari, A. and Palfy, P.
 Yerkes Regional Primate Research Center, Department of Pathology, Emory University, Atlanta, GA, U.S.A.

Objective: To determine the minimal infectious (lethal) dose of an acutely lethal virus pool of a chemically induced macaque.
Methods: Six groups of 2 pig-tailed macaques were inoculated IV with 10-fold serial dilutions of the 78-14 isolate, or doses ranging from 10⁻⁶ to 10¹⁰ TCID₅₀.
Results: All animals given 10 TCID₅₀ or greater became infected and developed acute clinical disease. Although there was no evidence the two recipients of 1 TCID₅₀ became infected, one animal that received 0.1 TCID₅₀ was infected and at 6 weeks P.I. had reduced numbers of CD4⁺ cells that decreased progressively until death 8 months P.I. In the other animals, disease onset ranged from day 7 (10⁶ TCID₅₀) to day 12 (10 TCID₅₀) P.I., with death occurring from day 8-16. One animal survived the acute disease but showed a progressive decrease in CD4⁺ cells and died 7 months P.I., with emaciation, oropharyngeal candidiasis, lymphadenopathy, splenomegaly, lymphopenia and a CD4/CD8 ratio of 0.16.
Conclusion: The lowest dilution (10⁻⁶ to 10 TCID₅₀) of a pool of the 78-14 isolate of SFV/80M to infect all animals also resulted in death of both animals within 16 days, supporting the contention that 78-14 is the sole agent responsible for the acute lethal disease. There was a correlation between dose and onset of disease and death. The longer term survivors showed decreasing CD4⁺ cells, weight loss, lymphadenopathy, lymphopenia and opportunistic infections. Disease in these animals appeared to correlate with a marked reduction in CD4⁺ cells. (Supported by NIH grant RR00145).

W.C.P.17 REGULATION OF THE VISA VIRUS LTR IN MACROPHAGES INVOLVES CELLULAR FACTORS WHICH BIND SEQUENCES CONTAINING AP-1 SITES
 Richard H. Wasy, J. J. Della Torre, A. J. Smal, J. J. Clements, J.

The Johns Hopkins Medical Institutions, Baltimore, Maryland, USA.

Objective: To identify sequences in the visna virus long terminal repeat involved in the developmental regulation of gene expression in macrophages.
Methods: Deletion and linker-scanning mutants, gel shift assays, and EMSA I. Transcription was used to study regulation of the visna virus LTR in the U937 monocytic cell line. Gel shift experiments using human primary macrophages are in progress.

Results: Sequences in the visna virus LTR that are involved in the regulation of visna virus gene expression in U937 cells were identified, including a region containing an AP-1 binding site which is critical for basal activity and phorbol ester-inducible gene expression. Nuclear extracts from uninduced and phorbol ester-induced U937 cells protected the same sequences from EMSA I digestion; however, protection of the AP-1 site was significantly increased in nuclear extracts from induced cells. A DNAse I-protected region from 47 to -81 contains the sequence TTTTTC, which is similar to Dnaase I-protected sequences in the HIV and HTLV-1 LTRs.

Conclusion: Our data supports a model in which one or more of the proteins which interact with AP-1 sites may be involved in the developmental regulation of visna virus gene expression in macrophages. Understanding the molecular events which relate macrophage differentiation to the regulation of viral gene expression may provide insights into mechanisms controlling viral gene expression that may be relevant to disease pathogenesis.

Recherche fondamentale (biomédicale) Bast Research (Biomedical)

W.C.P.14 IN SITU MALNUTRITION SUGGESTS CENTRAL NEUROENDOCRINE CHARACTERIZATION IN INFANT FELINE AIDS (FAIDS)
 Inez-Angel, Manuel, J.; Ray, B.; Elliott, S.C. and Tshikua, J.G.*
 Univ. of Missouri at Columbia, USA.

Objective: To emulate in FAIDS, the human AIDS (AIDS) demonstration that HIV infects and affects the CNS, in FeLV-FAIDS this was, up until our work, completely missing.
Methods: The results were brain extracts from case vs. control infant kitses (N=29) based on commercial reagents: polyclonal anti-FeLV virus (Antibodies Inc., Davis, CA USA) or monoclonal anti-FeLV gas (2) (CITEc-AdgTech Systems, Portland, ME USA) antibodies. The results were confirmed with a commercial ELISA (ELD/CASASATM or G, Pitman MO) and Western Blot (CA USA). Endocrine analysis was shown by a heterologous rabbit anti-growth hormone (GH) titration in hypothalamus by immunostaining. The difference in GH in the developing brain between controls and FAIDS was significant (p<0.01).
Results: This study further corroborates our preliminary reports on FeLV in CNS. Pituitary GH diminution coincided with growth impairment in the form of failure-to-thrive and an ongoing test wasting syndrome undistinguishable from our own results with rabies [1].
Conclusions: FAIDS in kitas, as a model for AIDS in children, strongly suggests a neuroendocrine participation that, at least in part, may explain the immunodeficiency [1]. The support of the manufacturers of commercial FeLV and HIV bio-technology diagnostics, as mentioned, is kindly appreciated.
 [1] Torres-Antel et al. Feline AIDS in vitro, wasting syndrome and immunodeficiency in rabies: a hypothalamohypophysiomelanohormic axis defect of rabies virus. Rev Infect Dis, 1981;9 (Suppl. 4):S710-25.

W.C.P.16 HIV-1 INFECTION IN A CONTINUOUS RABBIT MACROPHAGE LINE
 Hendrick E. Kugler, David R. Kasper, G. J. L. Kretz,
 NMR, St. Elizabeth's Hospital, Washington, D. C. *Laboratory of Immunogenetics, NIDDK, NIH, Bethesda, MD 20892.

Objective: To characterize HIV-1 infection in a continuous rabbit macrophage line.

Methods: The rabbit cell line, 6083, an SV40-transformed macrophage was infected with HIV-1. Infection was monitored using standard methodologies including RT activity and the presence of p24Ag in cell-free supernatants, indirect immunofluorescence, electron microscopy, detection of viral nucleic acids and passage of infectious virus to a number of indicator cell lines.

Results: 6083 was shown to be permissive to HIV-1 infection by all parameters assessed with the exception that no RT activity was seen in supernatants from infected cells. Presence of viral proteins were evidenced by p24 Ag capture, indirect immunofluorescence and Western blot analysis. In addition to the presence of HIV-1 nucleic acids, electron microscopy indicated production of mature lentivirus particles in a fashion morphologically similar to that seen in human macrophages and different from T-cell infection. Although virus positive by the preceding assays, cell free supernatants from HIV-1 infected 6083 cultures gave negative RT results. Supernatants derived from uninfected 6083 cultures were also shown to inhibit RT activity in known positive samples. It was shown that the lack of RT activity was not due to a defect in the assay; both infected and uninfected 6083 cells produce a factor which interferes with the assay at the level of the nucleic acid template.

Conclusions: 6083 supported productive HIV-1 infection which is similar to that seen in human macrophages. As is the case for human cell lines of this lineage, measurement of RT activity cannot be used as an accurate parameter of infection in rabbit macrophages.

W.C.P.18 INFECTION WITH SEMIIMMUNODEFICIENCY VIRUS (SIV) VIA CONJUNCTIVAL AND ORAL MUCOSAE IN A NON-HUMAN PRIMATE
 Johannes Ruya, M. J. Tilly, S. J. Yee, J. J. Antipa, L. Ann Cheney, P. J. Univ. of California-Davis, Davis, California, USA, Univ. of Tennessee-Memphis, TN, USA.

Objective: To determine if SIV can be transmitted postnatally via the mucous membranes in the newborn rhesus monkey and to determine if transmission can occur from an infected infant to another during the neonatal period as a result of close contact.

Methods: SIV was dropped on the conjunctival and oral mucosae of a newborn rhesus macaque at 0 and 93 days post-natally. Following exposure to virus, the infant was kept with the mother and both were tested for SIV infection.

Results: SIV was isolated from the peripheral blood mononuclear cell (PBMC) of the infant 10 days after the second exposure to virus and at all other sampling times thereafter. The animal died of septicemia and pneumonia 2 months after virus was detected. Generalized lymphoid depletion and interstitial pneumonia were noted at necropsy. The mother remains healthy, SIV antibody and virus negative.

Conclusion: SIV can be transmitted via conjunctival and oral mucosae of a newborn macaque. Despite intimate contact with the infected infant, the mother remains healthy and uninfected.

Session d'affichage Poster Session

W.C.P.25 LACK OF VERTICAL TRANSMISSION OF STIVAG IN A BREEDING COLONY OF C. TRICHOPUS ANTHROPI

HELEN B. FINEBERG¹, J. L. BRUNN² and C. R. NIELSEN²
¹Statens Seruminstitut, Denmark

Objective: To investigate the occurrence of vertical transmission of simian immunodeficiency virus (SIVag) in a breeding colony of *C. trichopus* by testing for SIVag antibodies.
Materials and Methods: Milk-sampled C. trichopus imported from Ethiopia and offspring from these born at Statens Seruminstitut. The breeding colony was founded with 21 female and 8 male neonates imported in the period 1976 to 1988. Serum samples from the 29 imported and from 70 colony born monkeys were examined by an indirect immunofluorescence test for antibodies against SIVag. **Results:** Live offspring were produced in the colony by 14 of the 21 imported females. Six of the 14 female breeders were found SIVag antibody positive and gave litters on birth to 26 young. From 22 of the young first live bleedings were obtained around 6 months of age or later. None were found SIVag antibody positive. From 12 of the 22 young another sample collected 1-4 years later was also SIVag antibody negative. Samples from the remaining 4 young, taken at age 3 months or less, were SIVag antibody positive. In 2 of the 4 SIVag antibody positive litters, 10 and 12 samples drawn around 6 months of age (one died); the fourth remains to be tested, when 6 months old. **Conclusion:** In *C. trichopus* vertical transmission of SIVag is rare if at all occurring. Presumably initially acquired SIVag antibodies disappear within the first 6 months of life.

W.C.P.27 MECHANISM OF IMMUNIZATION OF CD4 EXPRESSION BY PLASTIC ADHESIVE HUMAN MACROPHAGES *IN VITRO*

J. J. ANNET¹, P. BULLER², P. P. F. DE WITTE¹, A. J. VERHOEVEN¹ and J. VAN DER BEEK¹, ¹Medical Research Institute, ²Free University Hospital, Amsterdam, The Netherlands

The CD4 non-specifically binds to the major receptor for HIV on both CD4-expressing and blood monocytes. We have further investigated the regulation and function of macrophage-associated CD4. We have demonstrated that CD4 expression is induced on the surface of CD3 positive human blood monocytes with CD4-PE of cells being positive by anti existing HIV systems. This monocyte adherent to plastic, which activate macrophages. Loss of CD4 expression was observed by HIV cytotoxicity and immunofluorescence by 3-5 days but the proportion of adherent cells expressing low CD4 was not decreased. Monocytes cultured on tissue remained CD4 positive. Surface isolation of blood monocytes and plastic adherent macrophages followed by immunoprecipitation with anti-CD4 monoclonal antibodies also demonstrated a marked reduction in membrane CD4 expression by these macrophages. However CD4 mRNA levels quantified by Northern blotting and total cellular CD4 protein levels as determined by immunoprecipitation remained constant throughout the five day period, suggesting a selective loss of CD4 from the membrane, probably by endocytic cycling. Parallel studies with anti-CD4 also suggest the presence of CD4 membrane receptors from H9 to H1. However an difference was observed in binding of radiolabelled H9 and H1 to blood monocytes and macrophages. Whether CD4 is phosphorylated during demyelination and the effect of protein kinase C inhibitors on this phenomenon is under investigation. Activation of macrophages by lipopolysaccharide and interferon gamma had no effect on CD4 expression by monocytes maintained in tissue vesicles, nor did other cytokines like IFN- γ , IL-1, IL-2, IL-3, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-15, IL-16, IL-17, IL-18, IL-19, IL-20, IL-21, IL-22, IL-23, IL-24, IL-25, IL-26, IL-27, IL-28, IL-29, IL-30, IL-31, IL-32, IL-33, IL-34, IL-35, IL-36, IL-37, IL-38, IL-39, IL-40, IL-41, IL-42, IL-43, IL-44, IL-45, IL-46, IL-47, IL-48, IL-49, IL-50, IL-51, IL-52, IL-53, IL-54, IL-55, IL-56, IL-57, IL-58, IL-59, IL-60, IL-61, IL-62, IL-63, IL-64, IL-65, IL-66, IL-67, IL-68, IL-69, IL-70, IL-71, IL-72, IL-73, IL-74, IL-75, IL-76, IL-77, IL-78, IL-79, IL-80, IL-81, IL-82, IL-83, IL-84, IL-85, IL-86, IL-87, IL-88, IL-89, IL-90, IL-91, IL-92, IL-93, IL-94, IL-95, IL-96, IL-97, IL-98, IL-99, IL-100.

W.C.P.29 PRIMARY RETROVIRAL INFECTION VERSUS CHRONIC VIREMIA: DIFFERENTIAL RESPONSE TO THERAPY.

BRADLEY DUBOIS¹, J. W. HARRIS², C. S. ANDERSON¹, J. R. DAVENPORT¹, R. M. WATSON¹, BOSTON, MASSACHUSETTS, USA, ¹Harvard Medical School, Boston, Massachusetts, USA, ²Harvard Medical School, Boston, Massachusetts, USA

Objective: To compare the therapeutic efficacy of candidate antiretroviral agents administered to animals exposed to ZDV to zalcitabine (ddC) with that of therapy given to chronically viremic animals.
Methods: Adult female BALB/c mice were inoculated at time 0 with Rauscher Murine Leukemia Virus (RLV), a virus complex consisting of a lymphocytic replication-competent helper virus as well as a replication-defective spleen-leukemia forming virus. For post-exposure treatment, therapy was started 4 hr after virus inoculation and continued for 20 d. The animals were sacrificed and analyzed for RLV-induced splenomegaly and viremia. Therapy of chronically viremic animals was initiated only at 2 weeks after virus exposure and was continued throughout the animals' life span. Survival was analyzed by Kaplan-Meier plots. 3-azido-2-deoxythymidine (AZT) or Zalcitabine, recombinant human interferon- α 2/D (rhIFN- α 2/D), and zalcitabine were administered as above.
Results: AZT and zalcitabine were active in primary infection as well as in chronic viremia. In contrast, rhIFN- α 2/D was able to suppress virus-induced splenomegaly by 94%, but was completely inactive in chronically infected animals. Median survival of animals treated with rhIFN- α 2/D starting 14 d after virus exposure was identical to that of untreated control animals (5.7 vs 6.0 weeks).
Conclusion: Biologically, the chronically viremic state differs significantly from primary retroviral exposure, as judged by the differential response to therapy. Evaluation of antiretroviral therapy should be optimally designed to differentiate between these situations.

W.C.P.26 EXPERIMENTAL HIV-2 INFECTION OF OLD WORLD MONKEYS

CAROL BRUNA, A. RIEBER, W. LITVIN, B. W. LEE and L. W. JIA
Cancer Research Institute, University of California, School of Medicine,
San Francisco CA 94143, ¹Southwest Foundation for Biomedical Research, San Antonio, TX 78228, ²California Primate Center, Davis, CA 95616 USA

Objective: To develop a model of HIV infection in Old World monkeys.
Methods: Peripheral blood mononuclear cells (PBMC) from baboons and rhesus macaques were screened for susceptibility to infection with four HIV-2 isolates from the Ivory Coast. Infected cells were cocultivated with uninfected PHA-stimulated monkey PBMC of the same species or with human PBMC. Culture supernatants were assayed for HIV reverse transcriptase activity. Animals whose cells showed high levels of virus replication and cytopathology in *in vitro* was inoculated with the strains producing these results. Serum antibody, lymphoid cell counts, and virus production from the animals-PBMC were monitored routinely.
Results: All four HIV-2 strains tested were infectious for baboons and rhesus macaques, but some could be detected only upon addition of human PBMC. One isolate (UC-7) grew well in baboon cells. Two isolates (UC-2 and UC-7) replicated well in rhesus macaque PBMC. All isolates generally replicated in human PBMC. Culture in rhesus macaques and human PBMC cultures was most cytopathic for both types of animal cells, and were used for inoculation of the baboons and macaques. We have recovered HIV from PBMC of the infected macaques and baboons which has been observed in the baboons. Serologic, immunologic and virus isolation data on the infected animals will be presented.
Conclusion: HIV-2 isolates show differential growth in non-human primate cells. Productive infection of primates with HIV-2 has been achieved after preselection of susceptible animals and specific virus strains.

W.C.P.28 CULTURE REQUIREMENTS FOR HIV-1 ISOLATION FROM INFECTED CHIMPANZEES

ZILBER, Heidi A.; SOBE, K. and KILBING, J.N.
Southwest Foundation for Biomedical Research, San Antonio, Texas, U.S.A.

Objective: To optimize conditions for the isolation of HIV-1 from peripheral blood lymphocytes (PBL) of infected chimpanzees.
Methods: PBL were obtained in tissue form from a search period from nine HIV-1 seropositive chimpanzees. Parallel cultures were generated each time following three protocols: (1) nonstimulated chimpanzee PBL were cocultivated with phytohemagglutinin (PHA) activated human PBMC as indicator cells; (2) chimpanzee cells were PHA activated and then cocultured with human indicator cells; and (3) chimpanzee PBL activated PBL were cocultured without human cells. All cultures were maintained in the presence of interleukin-2 and DMSO-dextran for 28 days and monitored weekly for production of HIV-1 supernatants by antigen capture assay.
Results: HIV-1 isolation was successful in five out of nine chimpanzees by any protocol employed. In two of these five animals, HIV-1 could be isolated only by protocol (1) and (2); in one animal only by protocol (3), and by all three protocols in the other two animals.
Conclusion: The difficulty in isolating HIV-1 from chimpanzees is confirmed, suggesting a low level of virus integration in PBL in some animals a clear barrier for our culture conditions. An indirect adverse effect of human PBL on the production of virus in our chimpanzees also indicates that requirements for virus isolation can differ drastically between these animal and humans.

W.C.P.30 PATHOLOGY OF EARLY LESIONS IN HIV SEROPRESENTS

SHAW, RYAN, SPATZ, L., RICHMOND, J. F., MURPHY-ORCH, E. F., MARTIN, L., and SHAW, G. S.
¹New Jersey Medical Center, ²NIH, and ³Atlanta Regional Primate Research Center, Covington, LA, USA

Objective: To study central nervous system lesions early in the course of infection with simian immunodeficiency virus (SIV).
Methods: Twenty juvenile rhesus macaques were inoculated i.v. with SIV/Be1-10 (SIV) with 4 controls. Four animals each were sacrificed at 2, 4, 8, and 16 weeks post inoculation. Four became sacrificed and were sacrificed at 10, 14, 20 and 23 weeks. Histologic preparations of fixed brain tissue were examined, using also immunoperoxidase for glial fibrillary acidic protein (GFAP) and for SIV antigen, employing a rabbit polyclonal antisera.
Results: At 2 weeks there were lymphocyte infiltrates in choroid plexus (CP) and leptomeninges (LM), with a few perivascular lymphocytes in brain parenchyma. At 4 weeks there were lymphocyte infiltrates in choroid plexus (CP) and LM, macrophage infiltrates with positive antigen staining were observed in CP and LM, with rare multinucleated giant cells (MGC) in LM. The most severe lesions were observed in the striatum animals at 10 and 14 weeks, with brain perivascular macrophage infiltration, with MGC and hyperplasia. Lesions were less marked in the 24 week animals. No animal exhibited spilling of MGC with excess of GFAP while staining.
Conclusion: SIV causes inflammation in LM and CP early in the course of infection. With infection occurring in the choroid plexus (CP) component before it is seen in brain, the earliest occurrence of brain SIV antigen coincides with the appearance of perivascular macrophages.

HIV-1 ANTIGENEMIA IN ANDRAGYMI 'NUDE' MICE
Wetherall, Neal J. and Atherly Eiring.

Department Of Pathology, Vanderbilt University Medical Center, Nashville, TN, U.S.A. 37232-2561

Objective: Several small animal models of HIV infection have been proposed. We have developed a system which was exposed to the replication of HIV-1 which can produce large populations of infected mice for therapy screening and host-virus interactions.

Methods: Nude mice (3-4 weeks old) were exposed to 600 R₅ of 170Cs irradiation followed with 1 x 10⁷ HIV-1 infected CEM cells. The animals were followed daily for weight gain and tumor progression. Groups of 5 animals were eviscerated at 8 intervals over a 5 week period and necropsies were performed.

Results: Plasma p24 antigen was detected at day 3 and rose over 9 weeks (>2500 pg/ml). Where possible, plasma antigen was neutralized with human antiserum to HIV-1. The infected mice did not exhibit any weight loss, but a slightly significant difference was seen in tumor progression when compared to controls. Using immunohistochemistry, we raised polyclonal antibodies to viral p24 and gp120 detected HIV proteins within tumor cells and mouse splenic macrophages. Electron microscopy revealed rare intracellular lentivirus particles in the CEM cells.

Conclusion: These findings suggest that the nude mouse transplanted with a well characterized HIV permissive cell line should be useful for many immunological and antiviral studies. This work is supported by the U.S. Army Medical Research and Development Command Under Contract No. DAMD 17-88-C-8071.

W.C.P.32

LANGERHANS CELLS IN RESIENS MONKEY ORAL MUCOSA BEFORE AND AFTER INFECTION WITH SIMIAN RETROVIRUS OBTAINING Q1 (SRV-1) HANSEN, CHRISTINA M., LACKNER, A.W., ARMIANI, G., WIRTHLIN, W., MACPALLIS, T., DEANIN, T., and GREENBERG, J. ONI AIDS Center, University of California, San Francisco, California. Primate Research Center, University of California, and Royal Dental College, Copenhagen, Denmark.

Objective: To study the influence of experimental SRV-1 infection on the number of Langerhans cells (LC) expressing characteristic antigen and mucosa of these monkeys.

Methods: Two monkeys were intravenously inoculated with SRV-1, and two animals were mock-inoculated. Status of infection was assessed by serology and virus culture from peripheral blood lymphocytes. Biopsies were taken from gingiva and cheek pouch before and 4 months after infection. Frozen sections were stained with monoclonal antibodies (Lan-4, ILA-DR) and visualized by the immunoperoxidase technique. LC were counted in 3 sections of each specimen using chain analysis, and the mean number of LC per surface mm² was calculated. The examiner was blinded as to the date of the slides.

Results: All animals except for the controls were viremic at 1 week after inoculation. The number of LC in oral specimens did not differ significantly between the uninfected and infected groups at times 0 and times 4 months. The table shows LC of the experimental group.

LC in oral mucosa (no./surface mm ²)	Gingiva	ILA-DR	Cheek pouch
Before infection	10.4	9.1	9.9
4 months after infection	7.2	7.0	12.4

Conclusion: We have previously shown that SRV-1 commonly infects oral mucosal LC in these monkeys. However, 4 months after SRV-1 infection the number of LCs in the oral mucosa did not change significantly. Supp. by NIH PO1-DS5766, Danish Med.Res.Council (#1-8499, 12-8465), and AIDS Funded.

W.C.P.33

ISOLATION OF BARONS AND MACAQUES WITH VIRUS PRODUCED FROM THE SIMIANS
MULLER, G. J., KILLER, L. J., CLAY, C.A., J. GALE, A. J., FAY, K. J., OVERHAGE, J. T., KATZ, R.E., T. METCALER, S. J., BENNETT, S. E., Regional Primate Research Center, University of Washington, Seattle, Washington, Dept. Microbiology, University of Washington, and Viral Characteristics, NCI, Frederick Cancer Research Center, Frederick, Maryland, U.S.A.

A full length molecular clone of SIMV (SIV) was shown to be infectious *in vitro* by transfecting the DM 10a host cell line and showing the presence of reverse transcriptase activity. *in vivo* infection of virus from transduced cells was inoculated into six pigtailed macaques and two humans. Inoculation was performed on November 6, 1987. The four inoculated animals, as well as the two control animals, were assessed at regular intervals for the presence of antibodies to SIMV and for the presence of virus in HC and plasma. Animals were also monitored for changes in their clinical and hematological status. Both humans developed seral peripheral lymphadenopathy by the weeks post-inoculation, but no virus was isolated from their HC. One of the humans died at 33 weeks post-inoculation with acute and a wasting syndrome similar to that seen in macaques inoculated with SIMV. Attempts at virus isolation were negative (negative for HIV-1) and the only HIV-1 RNA was detected in the spleen and lymph nodes.

Utilizing the polymerase chain reaction (PCR) technique, we were unable to detect SIMV sequences in either the spleen or lymph nodes of this animal. The pigtailed macaque developed peripheral lymphadenopathy four and eight weeks post-inoculation, along with an erythematous rash on the lower abdomen and inguinal areas. Both animals seroconverted and virus could be isolated at various times post-inoculation. At 64 weeks post-inoculation, both animals remain in apparent good health. However, one has exhibited a steady decrease in CD4⁺ cells since November 1988, along with lymphopenia and absolute lymphocyte depletion, which to previous transmission studies, are forerunners of clinical disease.

W.C.P.34

MUTATIONAL ANALYSIS OF THE CYTOSOLIC DOMAIN OF P15 TRANSMEMBRANE PROTEIN
L. Chagnacoff, P. Toulas, and F. Sorigo. Institut Pasteur, Paris, FRANCE

Objective: To examine the role of the cytoplasmic domain of the transmembrane protein of the env of the simian virus obtained from 10 infectious clones.

Methods: Oligonucleotide-directed mutagenesis was used to replace the in-frame stop codon by a glutamine codon. Point mutations and deletions were introduced in the env C-terminal domain in clones both with and without the in-frame stop codon. Phenotypes of different mutants were evaluated for virus production following transfection of SW-620 cells and for infectivity in HUT78 cells.

Results: HIV in which the in-frame stop codon was replaced by a glutamine codon infected HUT78 cells with delayed kinetics. Reversion of the stop phenotype frequently occurred. Revertants having recovered a stop codon 3' of the original mutation were characterized. Deletions and termination 3' to the in-frame stop codon did not modify HIV infectivity. In contrast, mutants harbouring both the mutation of the in-frame stop codon and a deletion or a termination in the cytoplasmic domain-coding region were non-infectious.

Conclusion: The env C-terminal domain is not necessary for *in vitro* replication. However, fusion of this domain to HIV transmembrane protein leads to a reduced infectivity. This negative effect is counterselected *in vitro* but may correspond to a function controlling the rate of spread of the virus in the natural host.

W.C.P.35

INFECTION OF RHESUS MACAQUES WITH MOLECULARLY CLONED HIV-2
FRENCH, J., GONZALEZ, B., BRUNO, D. M., GARC, E. M., ROBERT-GOURFF, M., HALL, R. C., HONG, S. S. J., F. et al., National Cancer Institute, Bethesda, MD 20892, *Biometrics Research, Inc. Rockville, MD, U.S.A.

Objective: To develop a suitable animal model system to study infectivity and cytopathogenicity of HIV and to study viral genetic variation *in vivo*.

Methods: Rhesus macaques inoculated with molecularly cloned isolates of HIV-2 were monitored for humoral and cellular immune response, infectious virus, and physical and hematologic abnormalities. Selected viral genes from viruses reisolated from infected animals were analyzed by cloning and sequencing.

Results: Six of eight inoculated animals became persistently infected, e.g., recoverable virus, detectable genomic DNA, and/or persistent immune response. Some physical abnormalities began to appear in some animals with 5 months post-infection. Genetic changes occurring *in vivo* were found in 5 months reisolated 5 months post-infection.

Conclusion: Rhesus macaques are a useful infectivity model for HIV-2. Use of infectious molecularly cloned virus isolates provide a homogeneous basis for evaluation of the generation of genetic variants *in vivo*.

CLINICAL AND IMMUNOLOGIC STUDIES OF FELINE IMMUNODEFICIENCY VIRUS (FIV) INFECTION IN FELINE IMMUNODEFICIENCY VIRUS (FIV) INFECTED CATS
JINNO, T., TAKIUCHI, A., WASHI, T., KAWAYAKI, T., NISHIO Veterinary and Zootechnical College, Yonko, Japan.

Objective: To elucidate the relationship between disease progress and immunologic changes in feline immunodeficiency virus (FIV) infected cats. Infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV.

Methods: To evaluate the relationship between disease progress and immunologic changes in FIV infected cats, we performed a longitudinal study of FIV infected cats. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV.

Results: The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV.

Conclusion: The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV. The naturally-infected cats were classified into clinical stage groups using FIV.

ESTABLISHMENT OF FIV-PRODUCING CELL LINES FROM FIV SEROPOSITIVE CATS
Saitoh, M.; Nakagaki, T.; Tamura, S.; Kobayashi, I.; Ishiguro, T. and Kurita, T.
NHU Japan, Tokyo, Japan. * Nippon Veterinary and Zootechnical College, Tokyo, Japan.

Objective: To establish feline T-cell lines that continuously produce FIV in the culture. **Methods:** Peripheral blood mononuclear cells from 4 feline immunodeficiency virus (FIV)-seropositive and feline leukemia virus (FeLV)-negative cats were stimulated with concanavalin A (Con A) for 3-5 days and maintained with recombinant human interleukin-2 (IL-2). **Results:** After 4-6 weeks, reverse transcriptase activity was detected in 2 out of 4 culture supernatants without marked cytopathic effects. One of the two lines (named GA-3) was further characterized. FIV antigens were detected and identified in GA-3 cells by indirect immunofluorescence and western blot analyses. FeLV and feline sarcoma/leukemia virus were not detected by the same methods. The virus produced by GA-3 cells failed to replicate in feline fibroblastic cell, CRFK. GA-3 cells retained IL-2 and interferon- γ stimulation with Con A every 2-3 weeks for their growth. GA-3 cells have been growing and releasing FIV for more than 2 months so far. Infectivity and pathogenicity of the FIV produced by GA-3 are under investigation. **Conclusion:** IL-2 dependent feline lymphoid cell lines which continuously produce FIV were established.

W.C.P.39

RAMN RECOMBINANT IL-2 INDUCED CYTOLIC LESION FROM FAV INFECTED IL-2 IMMUNODEFICIENT GAS
Tschering, B., Holmberg, C., Tschering, W.
North Carolina State University, Raleigh, NC, U.S.A.

Feline leukemia virus (Fav) causes a broad-spectrum of degenerative or neoplastic diseases in cats characterized by decreased immune competence and acquired immunodeficiency syndrome (AIDS). In other species, including humans, retrovirus-induced AIDS is associated with decreased T helper (Th) and cytotoxic lymphocyte functions. In describe herein, the morphological and functional characteristics of IL-2-dependent cytotoxic lymphocytes derived from feline peripheral blood lymphocytes (PBL) and the effect of PBL-induced Th₁ suppression on the function of these cells. Stimulation of feline PBL with concanavalin A (Con A) followed by culture in the presence of 50-200 units/ml of soluble mouse interleukin-2 (IL-2) or recombinant human IL-2 (rhIL-2) resulted in marked proliferation and establishment of long-term lymphocyte cultures. Cultured feline lymphocytes possess cytotoxic granules with large granules similar to the large granular lymphocytes (LGL) in other species. These granules are bound by a highly sensitive and contain melittin-bound vesicles 0.40 μ m in diameter. All feline LGL lines are cytotoxic for feline PBL lymphoid cells, but none express anti-viral or lysis for other LGL lines. A characteristic of LGL is other species, to determine the effect of PBL infection on cytotoxicity by PBL and on the establishment of LGL cultures, one experimentally induced with the immunosuppressive Birkbeck strain of PBL was studied. In all cases, PBL from cats with IL-2 immunosuppression failed to yield a primary cytotoxic response, whereas, IL-2 responsive PBL were cytotoxic. In contrast, rhIL-2 induced cytotoxicity did not cultured PBL of all rhIL-2-infected cats, whether or not they were IL-2 exposed. The results indicate that, like the human HIV-1 infection, the target of PBL immunopathology is the Th₁ cell and Th₁-dependent cytotoxic functions, the latter of which can be restored by addition of exogenous IL-2.

W.C.P.41

HV-1 INFECTION IN THE RABBIT
Kodi, Thomas J., Kutaga, H. T., Truskenmier, M.E., Recker, D., and Fidler, I. J.
*Lab of Immunogenetics, NIAID, NIH, Bethesda, MD 20892; **NHV, St. Elizabeth's Hospital, Washington, D. C.; and ***Veterines Disease Branch CDC, Atlanta, GA, U.S.A.

Objective: To evaluate the rabbit as a model for HIV-1 infection. **Methods:** Outbred Zivicus were infected with HIV with human T-cell line A301 infected with HIV-1. Serum samples were monitored with a modified ELISA for anti-HIV-1 antibodies and peripheral blood leukocytes were tested for infection by reverse transcriptase activity and PCR after culture in IL-2. **Results:** Infection of rabbits with human T-cells infected with HIV-1 has lead to seroconversion within 4 to 19 d in 20 rabbits injected and virus can be isolated from peripheral blood cells of infected rabbits after culture in IL-2. The identity of isolated virus as HIV-1 was shown by Southern blot analysis and by presence of predicted restriction enzyme sites in DNA fragments from infected cells after amplification by the PCR technique. Overt effects of HIV-1 infection in rabbits were minimal during the period of observation (9 mo) but pathological examination upon necropsy revealed enlargement of spleen or thymus in the majority of infected animals and infiltration of lungs with lymphocytes. HIV-1 infection of rabbits previously infected with HTLV-1 caused more evident signs of illness with diarrhea in most animals along with weight loss in some. Several animals showed transient neurologic dysfunction and one had a rapidly progressing breast adenocarcinoma. Current efforts focus on determining the effects of HIV-1 infection on the immune status of the rabbits and in determining whether a homology of CD4 plays a role in the infection process. **Conclusion:** Rabbits can be infected with HIV-1 and show seroconversion and isolation of virus from PBL. Effects of the infection on immune function require further definition.

W.C.P.38

SEROLOGIC VARIABLES AT DIAGNOSIS WITH KAPCOW'S SARCOMAS; PREDICTORS OF SHORTENED SURVIVAL.
Calk, P.S., Moss, A., Beckett, P., Winger, E.,** Edmon, R.J., Field, D.W.,** Johnson, E.A.,** et al. *AIDS Action Division, San Francisco General Hospital/Univ. of California, San Francisco, CA; **The University of Washington, Seattle, WA; ***The University of Texas, San Antonio, TX

Objective: To compare viral and patient characteristics at the time of KS diagnosis and duration of survival in early vs recent cohorts of KS patients. **Methods:** Sex drawn from 183 patients at the time of KS diagnosis (median date of diagnosis: June 23, 1986) was analyzed for viral and immunologic characteristics. Values were compared for patients diagnosed before July 1984 ("early" KS) and those diagnosed after that date ("late" KS). Duration of survival following KS diagnosis was also compared for the two groups. **Results:** Survival averaged 12.24 weeks in the "early" group and 7.19 in the "late." This difference was significant with $p < .05$. Early patients and 53 late patients had laboratory results as follows:

	KS Patient Group (mean \pm SD error)		p-value
	Early	Late	
Beta-2 microglobulin ng/ml	5.44 (3.8)	27.95 (24)	<.001
Neopterin nmol/l	43.77 (6.74)	27.95 (4.58)	.16
p24 antigen pg/ml	43.78 (11.89)	39.62 (22.94)	.10
Hemoglobin	40.25 (7.4)	37.70 (10.08)	.36
Sedimentation Rate	31.0 (4.3)	28.1 (5.9)	.58
CD4+ T-cells	1.38 (0.3)	0.43 (0.3)	<.001
T4 helper cells	209.2 (51.8)	149.3 (24.9)	.31

Conclusion: KS survival has notably shortened since the start of the epidemic. While T4 counts, hemoglobin, and p24 antigen were more favorable in the early group with longer survival, the abnormal Beta-2, and neopterin levels suggest an immune response to a concurrent infectious process in this group.

W.C.P.40

ISOLATION AND PARTIAL CHARACTERIZATION OF AN HIV RELATED VIRUS OCCURRING NATURALLY IN CHIMPANZEES IN GABON
Pastors, Martin; Cooper, R.W.; Honore, G.; Hue, T.; Bussi, P.; Delaporte, E.
*Centre International de Recherches Médicales, BP 769, Franceville, Gabon; **Laboratoire de Biologie Moléculaire, Institut Pasteur, Paris, France

Objective: To better understand the natural history and the evolutionary relationship of the HIV/SIV group of viruses, we tested several chimpanzees from Gabon for HIV antibodies. **Methods:** The sera were tested for HIV antibodies with commercial HIV tests (ELISA, western blot). Virus was isolated from peripheral blood lymphocytes from the chimpanzee infected with normal (HIV negative) human lymphocytes. Partial characterization was done by electron microscopy, nucleic-immunoprecipitation and nucleic acid hybridization. **Results:** Two cases of wild born chimpanzees, positive for HIV antibodies were observed in Gabon. These animals were never seropositively exposed to HIV and had no history of inoculation with human blood products. A retrovirus was isolated from one of these chimpanzees and was related to an SIVgp. Partial characterization of this virus revealed that it had biological and morphological properties similar to other known human and simian retroviruses, but significant differences could be demonstrated. Several of the viral proteins differ in molecular weight from the known corresponding HIV/SIV proteins. SIVgp did not induce severe cytopathic effects in human and chimpanzee lymphocytes. Antigenically SIVgp seems to be closer to HIV-2 than to HIV-1 and the other SIVs. From nucleic acid hybridization experiments it appears that the virus is different from HIV-1, -2. **Conclusion:** Chimpanzees can be naturally infected with a novel retrovirus, antigenically close to HIV-1.

W.C.P.42

p24 ANTIGEN IN THE CSF AND SERUM OF PATIENTS WITH NON-HODGKIN'S LYMPHOMA TREATED WITH STANDARD CHEMOTHERAPY WITH OR WITHOUT GM-CSF
Kohn, James; Crowe, D.; Reikes, L.; Volberding, P.
*University of California San Francisco/San Francisco General Hospital, San Francisco, CA, USA
**Memorial Sloan-Kettering Cancer Center for Medical Research, Fairfax Hospital, Melbourne, Australia

Objective: To describe p24 antigen levels from the serum and CSF in patients with non-Hodgkin's lymphoma treated with standard CHOP chemotherapy and randomized to treatment with or without GM-CSF. **Methods:** Patients with AIDS-related non-Hodgkin's lymphoma who fulfilled entry criteria for study were treated with standard chemotherapy consisting of cyclophosphamide 750 mg/m², vincristine 2 mg, adriamycin 40 mg/m² and procarbazine 40 mg/m² on day 1 of a 21 day treatment protocol. Patients were also treated with methotrexate, 15 mg/m² on days 1 and 3. In the GM-CSF group, GM-CSF, 10-15 mcg/kg was administered subcutaneously days 1-10. CSF and a corresponding serum sample were collected prior to the first cycle of chemotherapy. Serum and CSF was frozen and assayed using a standard commercial Abbott kit. **Results:**

Pt	CSF		Chemotherapy - GM-CSF		Chemotherapy + GM-CSF		Serum
	Day 1	Day 8	Day 1	Day 8	Day 1	Day 8	
1	ND	443	443	ND	ND	ND	ND
2	0	0	ND	0	3961	34	ND
3	0	0	0	0	15	17	346
4	0	0	0	0	0	0	0
5	Day 1	Day 8	Day 1	Day 8	Day 1	Day 8	Day 8
6	0	ND	0	ND	0	ND	ND
7	0	ND	0	ND	ND	ND	ND
8	0	0	0	0	0	0	0

Conclusion: Preliminary results indicate that GM-CSF did not have a consistent effect on the p24 antigen from serum or CSF in patients with AIDS associated non-Hodgkin's lymphoma.

W.C.P.43 HIV-1 INFECTION OF HUMAN FETAL CENTRAL NERVOUS SYSTEM TISSUE
Soniya Ray, Tanaka, K., Chak, M., Usen, S., Rubinstein, A., and Ighem, M.D.
Albert Einstein College of Medicine, Bronx, New York, U.S.A.

Objective: It is believed that children with congenital HIV-1 infection have been exposed to HIV-1 in utero. Because a significant number of these children exhibit neurological manifestations associated with HIV-1 infection, this study was initiated to determine whether HIV-1 DNA could be detected in fetal CNS thereby suggesting a role in pediatric AIDS neuropathology.
Methods: Amniotic tissue was collected aseptically from HIV-1 seropositive and control patients at the time of elective pregnancy terminations. Tissues were frozen in liquid N₂ and processed by standard phenol extraction. The presence of HIV-1 DNA was determined by molecular hybridization of a ³²P-labeled sequence after amplification (30 cycles) using the polymerase chain reaction. Infected unfixed IV cell DNA or neurologically negative human lymphocyte DNA were included to indicated positive and negative hybridization.
Results: CNS tissue obtained at estimated fetal ages between 13 and 20 weeks showed positive reactions for HIV-1 ³²P-gene DNA in 4 samples from seropositive or risk group women. Other CNS samples from seronegative women failed to show HIV-1 DNA.
Conclusion: Human fetal CNS tissue revealed the presence of HIV-1 DNA suggesting a role of viral infection in early AIDS associated CNS disease. (Supported, in part, by HL 07060, DA 05583, DA 04583, NS 19320, AI 20671, and the Diamond Foundation).

W.C.P.45 HIV-1 BRAIN INFECTION: DISTRIBUTION OF INFECTION AND CLINICAL CORRELATES
Cronin, K.C.; Rosenblum, M.; New, B.J.; Price, Richard W.
Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Objective: To define immunohistochemically: 1. The frequency and topographic distribution of productive HIV-1 brain infection; 2. The histopathological correlates of cell types infected in brain; and 3. The relation of productive infection to the presence and clinical severity of the AIDS dementia complex (ADC).
Methods: Avidin-biotin immunoperoxidase with a monoclonal antibody against a core protein (antibody 25-8, a gift from Genetic Systems, Seattle) was used to map infection in frozen brain sections from 50 HIV-1-infected patients, 37 of whom had been prospectively staged with respect to ADC.
Results: HIV-1 infection was detected 20 brains. The most commonly infected structures included globus pallidus (83% of positive brains); corpus callosum (57%); and caudate, putamen, substantia nigra, midbrain, pons and frontal white matter (40-43%). Cerebral cortex was among the least commonly infected (5-11%) and no infection was detected in choroid plexus or dorsal root ganglia. Productive infection was confined exclusively to macrophages, microglia and multinucleated cells derived from these 2 cell types. No infection was detected in 0 of 9 at ADC Stages 0-3, 6 of 11 at Stage 4, 1 of 2 at Stage 2, 4 of 6 at Stage 3 and 5 of 7 at Stage 4 and was frequently limited in relation to disease severity.
Conclusion: Productive HIV-1 brain infection correlates with later ADC Stage and is circumscribed both regionally and by cell type. Brain dysfunction is not clearly understood and does not relate to infection in a simple manner.

W.C.P.47 CO-FACTORS IN THE DEVELOPMENT OF KAPOSI'S SARCOMA (KS): HIV-6 INFECTION. Giraldo, Gastano*, Beth-Giraldo, E.; Serwadda, D.**; Katogole-Milde, E.**; Romano, F.*; Ballo, R.C.**

*Inst. Naz. Tumori e Ospedale, Naples, Italy; **Malaria Trust and Uganda Cancer Inst., Kampala, Uganda; *** Nat. Cancer Inst., Beth., MD, USA.
Objective: To determine the in vivo effect of HIV-6 infection in compromising the immune system and the synergistic action in association with other cytotoxic or transforming herpes- and retroviruses in Kaposi's sarcoma and various HIV-6 and HIV-6 hospital and healthy populations.
Methods: Identification of antibody prevalence to HIV-6 vs HIV-1, CMV, EBV and epidemiological evaluation in endemic vs epidemic KS (equatorial Africa), classic vs epidemic KS (USA, Europe), in hospital populations and healthy subjects (>1000 sera, Uganda; >1000 sera, USA, Europe).
Results: Prevalence to HIV-6 in Kaposi's sarcoma and matched Blood Donors
KS endemic (N.54) Uganda 47yrs OS HIV+ 67% HIV-6+ 15% high-titer HIV-6 KS epidemic (35) Uganda 36 " 100% " 55% " 0%
KS classic (58) US-Eur 60 " 0% " 47% " 0% " 0%
Blood donors (50) US-Eur 30 " 0% " 43% " 0% " 0%
KS epidemic (18) US-Eur 34 " 100% 44% " 0% " 0%
Blood donors (50) US-Eur 35 " 0% " 73% " 12% " 0%
Conclusion: a) There is a high prevalence of HIV-6-antibody in KS and healthy subjects; b) HIV-6 seropositivity rates decrease with age; c) HIV-1+ patients have high-titer HIV-6-antibody prevalence than matched HIV-1- controls, probably due to synergistic effect of double infection by HIV and HIV-6.

W.C.P.44 NATURAL ANTIBODY PERCEPTION OF AMINO ACID DIVERGENCE WITHIN AN HIV-1 NEUTRALIZATION EPIPTOPE
Gundamini, Jean*, Zwart, G., Bekker, M., Epstein, L.M., Kulkarni C***, De Wolf F.

*Rijks Reziervier Laboratorium, Amsterdam, the Netherlands, **UMID-New Jersey Medical School, Newark, NJ, USA, ***Dept of Infectious Diseases, Municipal Health Service, Amsterdam, the Netherlands.
Objective: Gaining insight into the recognition by natural antibodies of a variable gp120 epitope.
Methods: Nine synthetic peptides were used to screen sera of 134 individuals infected with HIV-1. The oligopeptides were nine amino acids in length and corresponded to the isolate specific "neutralizing" domain in gp120 (V3 region) of (HIV-1) strains: LAV-1, RF, SP2, NY6, CDC8, ELI, MAL, Z6 and Z3. 67% reactivity to the LAV-1 peptide in Africans (53%) and reactivity to the Z3 peptide in African sera (78%), 54% of the sera showed reactivity with more than one of the oligopeptides. Blocking experiments favoured cross-reactivity as explanation. A cluster analysis was performed on the cross-reactivities of the sera. This and ELI analysis grouped together LAV-1, RF and CDC8, Z6, MAL and ELI and NY6 and Z3 stood alone. This clustering could not completely be explained by comparing physicochemical properties of the oligopeptides. However, the clustering showed the greater resemblance to a phylogenetic tree of the complete gp120 molecule.
Conclusion: Multiple reactivities are mostly due to cross reaction. The complete envelope may be involved in the selection of B cell clones for the V3 epitope.

W.C.P.46 DIFFERENCES IN RISK FOR AIDS AND AIDS MORTALITY IN 49 INDIVIDUALS INFECTED WITH LOW-AND HIGH-VIRULENT HIV VARIANTS.
M. Tormetzte, J.M.A. Lange*, R.E.T. de Goede, J.C. Outman, J. Goedkoop*, F. Wiedema, Central Lab. Richard, Red Cross Blood Transf. Service and Lab. of Exp. and Clin. Immunology of the Univ. of Amsterdam, *Academic Medical Center, Amsterdam, The Netherlands.

Forty-nine seropositive individuals (twenty of whom were asymptomatic at the start of the observation period) were studied longitudinally for the relation between in-vitro properties of their sequential HIV isolates and clinical course before and after the development of AIDS. Per individual 2-8 sequential isolates were studied. Based on the properties of their isolates (Tormetzte et al., J.Virol. (1988) 62:2026-2032), the individuals could be divided in three groups. The presence of asymptomatic-infecting or high-replicating HIV isolates was significant predictive for the development of AIDS within 1-2 years. Antidichthymine (ADT) treatment in the asymptomatic period seemed to delay the onset of AIDS even in the highest risk group. Upon development of AIDS, significant differences in survival between the groups were observed. Also differences in clinical symptoms of AIDS patients from the three groups were observed. These observations stress the importance of the development of virulent HIV variants in the host as a mechanism for AIDS pathogenesis. The existence of a relationship between biological properties of HIV variants and clinical course may provide a possibility to identify asymptomatic HIV seropositive men at high risk for AIDS as a potential target group for early treatment with antiviral drugs.

W.C.P.46 AIDS-KAPOSI'S SARCOMA (KS) DERIVED CELLS EXPRESS CYTOKINES WITH A POTENTIAL ROLE IN THE PATHOGENESIS OF KS LESIONS
Engel, Barbara; Nakamura, S.; Salakhotova, S.Z.;

Wong-Staal, F. Gal, P. A.
Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD, U.S.A.
KS is a proliferative disease of unknown etiology and frequent manifestation of AIDS. Cell cultures established from KS lesions of AIDS patients (AIDS-KS cells) are able to promote in vitro proliferation (autocrine) and proliferation of normal endothelial cells, fibroblasts and cells of hematopoietic lineage (paracrine). Furthermore, the AIDS-KS cells induce neovascularization, and a KS-like lesion in nude mice. Studies at the molecular level indicated that the AIDS-KS cells express mRNA specific for basic and acidic fibroblast growth factor (bFGF, aFGF), interleukin-1 and 8 (IL-1 and -1β), granulocyte-macrophage colony stimulating factor (GM-CSF), transforming growth factor β (TGFβ) and platelet derived growth factor β (PDGF-β). Particularly bFGF and IL-1β are expressed at high levels, released into culture media, and responsible for inducing AIDS-KS and normal endothelial cell proliferation. The results suggest that in vivo KS cell proliferation with cytokines production could be the final step leading to the appearance of the composite KS lesion.

MISCELLANEOUS CARCINOMA DEVELOPING IN PATIENTS WITH HIV INFECTION.

RAJAL, RAJAL, Sharma S, Hill P, Bernstein L, Bernstein A, and Levine AM. University of Southern California, Los Angeles, CA, USA.

OBJECTIVE: To describe the occurrence of solid cancers excluding Kaposi's sarcoma in patients with various stages of HIV infection.

DESIGN: The pathological tumor types of all solid tumors excluding Kaposi's sarcoma were examined in males ages 20 to 50 years of age diagnosed at the Los Angeles County/USC Medical Center from 1986 through 1988. Patients were then assessed for the presence of HIV infection by either serologic evidence or specific indicator diseases. For each patient identified with HIV infection and solid tumor, stage of HIV infection, extent of cancer, treatment modality and survival data were obtained.

RESULTS: From a total of 359 solid diagnosed with solid cancers 27 (7.5%) had co-existent HIV infection. 12 patients (pts) had Stage I disease, 7 pts Stage II and 8 pts Stage IV. Tumor types included de novo ductal (n=23), terminal cell (n=18), Primary Lung (n=18), Basal Cell Carcinoma of skin (n=13), unknown primary (n=7) and 1 each (43) of disseminated melanoma, squamous cell carcinoma of the cervix, esophagus, stomach, colon, rectum, bladder, prostate, and testis.

CONCLUSION: 1) Unknown solid carcinomas are being diagnosed in pts with HIV infection; 2) survival is often shortened because of the underlying immune dysfunction due to HIV; 3) More study is needed to establish the rate of HIV in the development of these solid tumors.

W.C.P.51

HIV-HPV INFECTION AND PENILE CARCINOMAS (PC) IN UGANDA

Burnagoro, Franco, M., Betti-Graldo, G., S. Tornesello, M., L. Caracciolo, G., E. Di Monaco, M. B. and Giarolo, G.
Email: Cancer Inst., Naples, Italy, ** Makerere University, Kampala, Uganda.

OBJECTIVE: To determine effects of HIV epidemic on the incidence and the evolution of PC in Uganda, by a possible modulation of HPV infection.

Methods: DNA extracted from PC biopsies and cell lines, of HIV negative and positive patients, are tested for the presence of HPV strains by dot blot and Southern blot analysis.

Results: HIV seropositive patients have been reported to present a significantly high prevalence of cervical dysplasia (C. Brasseur, Lancet 1992; M. Byrne et al., Lancet 1988) and signs of HPV infection (P. Crocchiolo et al., Lancet 1989). We are determining HPV infection in biopsies from Ugandan patients with PC before and during the HIV epidemic. Furthermore, two permanent cell cultures, from penile carcinomas of Ugandan patients, have been established. Some of the markers typical of oncotypes of neuroectodermal origin have been identified. HPV infection signal is present with a HPV 18 DNA probe in reaction performed at high stringency (Tm=50). A stronger hybridization signal is obtained at low stringency (Tm=50), suggesting the presence of an HPV strain with low homology to HPV 18.

Conclusions: We are going to: a) determine the incidence of HPV in PC in Uganda, b) verify the HIV role on HPV incidence and PC evolution, and c) to isolate and characterize the eventual new HPV strain.

W.C.P.53

CERVICAL NEPLASIA IN HIV-INFECTED WOMEN

Schäfer, A.,* Schlegeländer, B., Dept. of Obstetric and Gynecology, Freie Universität Berlin, FRG; ** AIDS-Center, Bundesgesundheitsamt, Berlin, FRG**

Objective: To evaluate the meaning of cervical neoplasia and Papillomavirus-infection (HPV) in HIV-infected women.

Methods: We investigated cytological smears and cervical tissue from 108 HIV-infected women for dysplastic alteration and HPV-infection.

Results (Selection): Dysplastic alterations were seen 15 times more often in HIV-infected women than in women without HIV-infection. Histologically 10 CIN's and 5 invasive carcinoma of cervix were detected. Nearly half of the smears without dysplastic alteration and more than 80% of smears with dysplastic alteration showed signs of HPV-infection. There was a strong correlation of clinical status of HIV-infection and dysplastic alteration and cancer.

Discussion: On the basis of a high prevalence of HPV a routine-screening for cervical dysplastic alteration is essential in HIV-infected (immunocompressed) women.

W.C.P.50

48 UNUSUAL HIV-RELATED MALIGNANT TUMORS. **Trull, Umberto, Vecchio C., Sisti A., Sabatucci, Giustolisi R. S., Agui T., Santolucito S. et al.** Gruppo Italiano Cooperativo AIDS-Tumori (GIAT), ISTAT

Objective: To evaluate the characterization of unusual HIV-related tumors observed in Italy. **Methods:** Since 1985 the GIAT has collected 48 HIV-related tumors other than KS and NHL predominantly among intravenous drug abusers (IVDA), in accordance with the overall epidemiology of AIDS.

Malignancy	#P	Risk Group	Clinical and Pathological Features
Testic ca.	13	9 IVDA	7 carcinoma, 5 seminoma.
Cervix ca.	9	9 IVDA	median age 34, 8/9 ca. in situ
Lung ca.	8	9 IVDA	w/rtier age 34, 5 NSCLC
Acute leukemia	5	7 IVDA	M ₂ (Burkitt-like), 1 B
Multiple myeloma	2	2 IVDA	age 29 and 32, 1 with K ⁺
Other ca.	10	10 IVDA	age 39 to 55, rapid course

Only 1 case was reported of glioblastoma, thyroid ca., Uterine, melanoma, renal vs pancreatic ca., Gli(OM), oral ca., (basal) pyroplasmoid and anal ca. (Famula) praxistoma with anaplastic metastases). Testis ca. occurred in patients (pts) infected in early HIV infection without adversely affecting full dose chemotherapy or radiotherapy. Cervix ca. in 8/9 pts treated with combination therapy suggest high viral screening in young IVDA. Lung ca. occurred in a young age group with rapid prognosis and death within 2 mo. of diagnosis. Chemotherapy in Burkitt-like ALL was not adversely affected by HIV infection and 2 DS were achieved (1/1 and 1/5 vs. darabutin). **Conclusion: In this HIV-based series, while oral and anaplastic tumors did not occur, there is a wide spectrum of unusual HIV-related tumors which is probably underdiagnosed because not diagnosed of AIDS. The required therapeutic approach may not be consistently influenced by HIV infection, as for KS and NHL.**

W.C.P.52

KAPOSI'S SARCOMA-LIKE CELL LINES FROM SIMIAN AIDS WITH SUBCUTANEOUS AND RETROPERITONEAL FIBROSITIS ASSOCIATED WITH TYPE D RETROVIRUS (SRV-2) INFECTION

Tsai, Cheng* Tsai, C. Slihp, J.* Wong, J.* Roodman, S.***
St. Louis University, St. Louis, Missouri, USA, **Washington Regional Primate Research Center, Seattle, Washington, USA.

Objective: To establish KS-like cell lines from AIDS associated with SRV-2. **Methods:** Two KS-like lesions, subcutaneous and retroperitoneal fibrositis from macaques with AIDS associated with SRV-2 infection were cultured in regular RPMI or DMEM medium supplemented initially with brain derived growth factor (BDGF), immunocytochemical, cytologic, ultrastructural and viral studies were carried out on various passages of culture (over 16) during a 12 months period.

Results: Both cell lines propagate vigorously in 10% FCS media without BDGF after 4th passage and can grow with only 0.5% FCS unlike the control monkey fibroblast. Cytology and immunocytochemistry of both cells are similar and demonstrated heterogeneous populations of endothelial(s)K09, pericytic/smooth-muscle(s)S2, and primitive mesenchymal/fibroblastic differentiations. Arborizing multilayered anaplastic giant cells are prominent in early culture. Both cell lines are diploid (D1=20) with high proliferative activity (>25% S-Phase) but show no growth in soft agar. Evidence of autocrine/paracrine growth is further supported by the presence of cytoplasmic phosphotyrosine and BDGF-like proteins in these cultured cells.

Conclusion: Two KS-like cell lines from simian AIDS associated with SRV-2 were established for future basic and clinical study.

W.C.P.54

CHARACTERIZATION OF IN VITRO CULTURE OF KS-DERIVED CELLS.

Peter Biberfeld, Shui Nakamura*, Zaki S. Salahuddin*, Barbara Enos†, Robert C. Gallo**, *Department of Pathology, Karolinska Institute, Stockholm, Sweden; †Lab of Tumor Cell Biology, NCI, Bethesda, MD, USA; ** Culture medium (CM) from retrovirus infected T-cell lines promote the continuous, in vitro growth of cells from biopsies of Kaposi's sarcoma (KS).

These cells have endothelial like features and produce in vitro several growth factors notably bFGF-like activity (1). These cells elicit a strong angiogenic reaction in nude mice and on chicken allantoic membranes. Studies are in progress on the identity of the CM with growth promoting activity to KS-derived cells and the possible expression of autocrine and paracrine activities by these in vitro cultured cells.

VACUOLAR MYELOPATHY: HIV-1 EXPRESSION CORRELATES WITH EXTENT OF CLINICAL AND PATHOLOGIC DISEASE.

Barbara Melnick, N. Distefano, D. Elliott, D. LaSera, R. Seidman, H. Burger, SUNY, Stony Brook

Spatial cord (SC) disease and a distinct vacuolar myelopathy (VM) characterized by vacuolation and macrophage infiltration of SC white matter both occur following HIV-1 infection. We have shown previously in 3 SC from AIDS patients with severe myelopathy that HIV-1 RNA was present in the 3 SC and localized to macrophages in vacuolated areas of white matter. To determine if (1) HIV-1 RNA is present in the SC of AIDS patients with a range of cord pathology and (2) HIV-1 expression is correlated with clinical and pathologic disease, we studied 17 SC from AIDS patients and 9 controls. In situ hybridization was used to detect HIV-1 RNA, and immunohistochemistry to identify cell type. Immunohistochemical staining of the 10 cords with VM showed macrophage infiltration of vacuolated regions of SC white matter, with the degree of infiltration parallel to the degree of clinical and neuropathology. Cords from AIDS patients with SC lymphoma and cryptococcosis showed focal macrophage infiltration, and 6 cords from controls without SC disease showed none, if any, macrophages. Of the 17 cords obtained from AIDS patients at autopsy, HIV-1 RNA was detected in 6 of 10 with vacuolar myelopathy, 0 of 5 without SC pathology, and 0 of 2 with focal macrophage infiltration secondary to other SC disease (tumor and lymphoma). Three control cords obtained from patients with other SC diseases showed no HIV-1 RNA. In the 10 AIDS cords with VM, the amount of HIV-1 RNA expression correlated with the extent of both SC pathology and clinical disease. These data support a direct role for HIV-1 in the pathogenesis of AIDS myelopathy.

W.C.P.57

EARLY APPEARANCE OF CROSSREACTIVE ANTIBODIES SPECIFIC FOR A COMMON EPITOPES IN CD4+ AND HLA CLASS II ANTIGENS CAN INTERFERE WITH NORMAL IMMUNE FUNCTIONS IN AIDS PATIENTS. Hans Golding*, Shaerer, G.M.***, Hillman, K.V., Manischewitz, J.P., Golding, B.*

HIV and SIBP, CHER, FMA, wright, W.H., Bethesda, MD, U.S.A.
Antigen acid sequence is highly homologous sequence in the C-terminus of HLA class II and the B-2-microglobulin chain. Screening of sera from HIV-1 infected individuals, reveals a high frequency (35-40%) of antibodies specific for the common epitopes in both early and late stages of the disease. These sera as well as murine Ab against this sequence reacts also with class II-bearing (uninfected) cells (8, 7, Macrophages).

Objective: To study if the crossreactive Ab (CRAB) can interfere with T cell immune functions and contribute to elimination of class II⁺ cells.
Methods: Patients' and controls' sera were added to normal T cells stimulated with tetanus toxoid or antigenic stimulators. Sera were tested in Ab-Dependent Cellular Cytotoxicity (ADCC) of class II⁺ cell lines. CRAB were purified by affinity chromatography (peptide-sepharose-column).
Results: Sera containing CRAB or anti-CD4 were potent inhibitors of the proliferative responses of normal CD4⁺ T cells. The same sera could also kill class II-bearing (uninfected) cell lines. Both reactivities could be adsorbed by peptide linked-sepharose beads. The purified CRAB were all IgG. In many cases such CRAB were present in sera from asymptomatic patients who still had CD4⁺ T cells (>500/mm³), but demonstrated *in vitro* unresponsiveness to various recall antigens (influenza, tetanus toxoid, etc.).
Conclusion: HIV-1 infection may lead to generation of CR antibodies. Absence of circulating immune functions early during the course of disease.

W.C.P.59

INDUCTION OF HUMAN IMMUNODEFICIENCY VIRUS FROM CHROMIALLY EXPRESSED CLONES BY PHOSPHOLIPASE C AND PHARMACOLOGICAL AGENTS REQUIRES PROTEIN KINASE C ACTIVATION. Anne, Audrey, Maury, W., Pohl, G., Fanci, A.S., Folks, T.M., NIAID, NIH, Bethesda, MD, U.S.A.

Objective: This study was designed to define second messenger pathways by which cytokines and pharmacological agents induce HIV expression from chronically infected cells.
Methods: The U1 (promonocytic) and AC3 (lymphocytic) chronically HIV infected clones express low to undetectable constitutive levels of HIV. Virus replication in these cells can be increased 2-20 fold by phorbol esters (PMA), recombinant cytokines [TNF α -GM-CSF (U1 clone)], and cytokine enriched cell supernatants. We have used inhibitors (topical/nucleoside derivatives) and activators of protein kinases (PK) as well as agents which modify calcium activity, for their effect on baseline and cytokine induced virus expression in the U1 and AC32 clones. Virus expression was measured as supernatant reverse transcriptase activity, by western blot and nuclear run-on analysis.
Results: PK, the most potent inducer of PKC activity, effectively blocked (75%-90%) HIV induction by all cytokines and pharmacological agents in both the U1 and AC32 clones. Those inhibitors, H8 and HA1004, which are more selective for cyclic nucleotide dependent kinases, did not suppress virus induction. Specific activation of PKC by genistein, diacylglycerol and bradykinin, resulted in a 2-8 fold increase in viral replication in both clones. Activators of cyclic nucleotide kinases were not effective in inducing virus. Agents which increase intracellular levels of calcium can potentially synergize with PKC mediated induction in U1 but not AC3-2 cells.
Conclusion: Upregulation of HIV by cytokines and pharmacological agents requires the activation of PKC. Evidence exists of a calcium related, but ultimately PKC dependent, event which can also upregulate virus expression.

W.C.P.56

HIV-1 ANTIGENIC VARIANTS WITH DISTINCT BIOLOGICAL PROPERTIES EMERGE AT THE DECLINE OF THE IMMUNOLOGICAL ANTIBODY

De Jong, Jean-Jacques*, Tarnette M.**, Kroes W.**, Meloen R.**, Miedema F.**, Goudaard J.***

*Husum University Hospital, Amsterdam, the Netherlands, **Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, the Netherlands

Objective: To study the antigenic variability of the V3 region (as 296-331) of the external envelope of 120 HDs (gp120) of HIV-1 in natural infection.
Methods: Sequential isolates of 6 patients progressing to AIDS and showing a transition from non-synonymous to synonymous forming sequences were used to study antigenic variability of the V3 domain of gp120. The V3 coding domain was amplified using the polymerase chain reaction (PCR). Direct sequences of the V3 coding domain were determined and confirmed by cloning and sequencing. Antibody reactivity of sequential sera of these individuals was determined for peptides covering the complete V3 domain of the isolates.

Results: The transition from non-synonymous to synonymous inducing isolates was marked by clustered nucleic acid changes of which three were consistent. This resulted in one amino acid change crucial to antibody binding. Decline of the antibody to the synonymous forming antigenic variants preceded the emergence of these variants.

Conclusions: Antigenic variants appear to be selected by antibody to the V3 domain of gp120 during natural infection.

W.C.P.58

HIV-1 INFECTED HUMANS, BUT NOT CHIMPANZEES, HAVE CYTOTOXIC T LYMPHOCYTES THAT LYSE UNINFECTED CD4+ CELLS

Raizola, A.***, Ledwith, J.**, Gies, J.S., Pulis, F.**, Eichberg, J.***, and Zarling, J.**, *Onogen, Seattle, Washington, USA; **Harlan Primate Research Center, Babey University, Aycliffe, Washington, USA; ***Southwest Foundation for Biomedical Research, San Antonio, Texas, USA.

Objective: It has been suggested that autoimmunity contributes to the depletion of CD4⁺ T cells in HIV-1 infected humans, based on findings that some HIV-1-infected humans have autoantibodies reactive with antigens on uninfected CD4⁺ cells. We asked whether HIV-1-infected humans also have CTLs lytic for uninfected CD4⁺ cells that may contribute to the depletion of CD4⁺ cells.

Methods: Fresh PBMC from humans and chimpanzees were tested for their ability to lyse ⁵¹Cr labeled uninfected CD4⁺ cells and other cells.

Results: HIV-1-infected humans, but not uninfected humans or chimpanzees, have PBMC that lyse uninfected CD4⁺ T cells from humans and chimps but not human B lymphoblastoid cells or mouse T cells. The cytotoxicity of PBMC was concluded to be CTL that are CD3⁺, CD8⁺, CD4⁻, CD16⁺, TCR- $\alpha\beta$ +, based on findings that lysis of uninfected CD4⁺ cells was diminished by (1) anti to CD3, which inhibits CTL but not NK activity; (2) treatment of PBMC with anti to CD8, but not to CD16 and C; (3) anti to TCR- $\alpha\beta$ which is expressed on MHC-restricted CTL; and (4) anti to HLA class II framework determinant. In contrast, PBMC from HIV-1-infected chimpanzees, which do not develop AIDS, lacked detectable CTL lytic for uninfected CD4⁺ cells.

Conclusion: Circulating CTLs lytic for uninfected CD4⁺ cells that we detected in blood from HIV-1-infected humans but not from chimpanzees, may contribute to HIV-1-induced immunopathology in man.

W.C.P.60

MORPHOLOGICAL CHANGES OF THE VACUOLAR LYMPHOCYTES IN AIDS

Artlitz, Jan; Niesdörfer, F.; Grossa, G.; Bork, G. and Hiesl, M.

Department of Pathology and * Department of Medicine; Aguda-Viktoria-Krankenhaus, Rubensstraße 125; 1000 Berlin 41 FEDERAL REPUBLIC OF GERMANY

Objective: To describe the morphological changes of the vacuolar lymphocytes (VL). Such morphological studies are rare and thus the pathogenesis of this frequent condition is poor understood.

Methods: The spinal cord of 42 HIV-infected patients was examined with conventional histology, immunohistochemistry and electron microscopy.

Results: In 24 cases as mild (17 cases), moderate (12 cases) or severe myelopathy (5 cases) was found. Fourteen vacuoles, 20 to 380 nm in diameter and 200 to 800 nm in length, consisted of a thin sheet of disintegrated myelin, are present in the white matter. Clusters of macrophages, phagocytosing areas of moderately preserved structures, are found into the vacuoles. The foam macrophages contain vest of axons, only in one case with severe tissue disruption they contain myelin debris too. In 5 cases, some macrophages, microvillus cells and multinucleated cells show HIV-antigen (p24 and gp41). A strong astrogliosis is present in the white and grey matter. Proliferation of microvillus cells is present between the neurons in the grey matter.
Conclusions: VL is a more frequent condition as previously thought. In VM it proceeds of phagocytosis directed against the axon cylinders occurs simultaneously with vacuolar demyelination of the white matter. The vacuoles arise between the axoles and the myelin sheath.

W.C.P.61 HIV-1 INFECTION OF HUMAN FETAL CENTRAL NERVOUS SYSTEM ORGANOTYPIC CULTURES

Lynn, William, Tricoche, M.; Kress, Y.; Hatch, V.; Chiu, F.-C. and Smirnov, R. Albert Einstein Coll. Med., Bronx, NY, USA.

Objective. Most cases of pediatric AIDS are likely congenital and the product of fetal infection by HIV-1 in utero. Because a significant number of children with AIDS exhibit neurologic disease, this study was initiated to determine if HIV-1 can infect fetal central nervous system (CNS) cells and characterize the resultant pathology.

Methods. Explants of fetal CNS tissue were established and maintained in organotypic culture for up to 8 weeks. Initial studies, using light and electron microscopy (LM and EM) in combination with immunocytochemistry and Western blot technology, confirmed that the cultures contained normal nervous tissue cellular elements. Test cultures were exposed to either infectious or heat-inactivated HIV-1 isolates. Infection of tissue was determined by immunocytochemistry, molecular hybridization, and an infectious centers assay. Pathology was assessed by LM and EM.

Results. Cultures exposed to infectious HIV-1 (1118 strain) for up to seven days showed an array of morphologic changes. HIV-1 infection of the cultures was confirmed in 32 P-labeled tests and virus-like particles were observed in CNS tissue cells.

Conclusion. Organotypic cultures of human fetal CNS tissue may provide a valuable experimental model to define the targets and mechanisms associated with the neuropathology of AIDS. (Supported, in part, by DA 05583, DA 04383, NS 11920, NS 25873, AT 20671, and the Sisson Foundation).

W.C.P.63 HIV-INFECTION ALTERS THE INTERACTION OF MACROPHAGES WITH TOXOPLASMA AND LEISHMANIA

Katzer, D. C., Gendelman, H., Orenstein, J., Melzer, M. S., and Reed, S.**

H. M. Jackson Fdn., George Washington Univ., Walter Reed Army Inst. Res., Washington DC, **Seattle Biomedical Res. Inst., Seattle WA, USA.

Objective. Examine ability of HIV-infected macrophages to ingest and kill intracellular parasites.

Methods. Macrophages from normal donors were cultured in medium with colony stimulating factor-1 (MCSF, Cetus Corp, Emeryville CA). Macrophages were infected at 7 days with a monotypic HIV-1 strain, ADA. Ten days after virus infection, *T. gondii* or *L. mexicana* promastigotes were added to HIV-infected and control macrophages. Cultures were examined 4 and 20 hrs after addition of parasites: percent monocytes infected with parasites and number of parasites/infected cell were quantified by microscopic analysis.

Results. At 4 hrs, 40% of control and 10% of HIV-infected monocytes were free of parasites. The number of parasites/monocytes in HIV-infected cultures was significantly greater than that in control cultures at both 4 and 20 hrs. Electron microscopy revealed virus particles and parasites within the same monocyte.

Conclusions. Macrophages infected with HIV in vitro ingest parasites, but show altered infectivity and microbicidal activity. These observations may explain the pathogenesis of opportunistic infection in tropical areas.

W.C.P.65 GENERAL DECREASE OF LEUKOCYTE VIABILITY OF AIDS PATIENTS IN SERUM-FREE MEDIUM

Guatieri, Denise L.; Farver, V.*; Hardefelt, M.*; Adams, M.* and Montagnier, L.*

*Viral Oncology Unit, Institut Pasteur, Paris, France.

Objective. To study the mechanism of AIDS pathogenesis and to design an *in vitro* test for the follow up of antiviral drugs.

Methods. PBMC of HIV seronegative, HIV seropositive and patients with ARC of AIDS were separated from heparinized blood on a 4 spracell gradient. After washing, cells are incubated in a serum-free medium specially designed for lymphoid cells. Cell viability was evaluated daily by blue-trypan exclusion.

Results. While PBMC uninfected individuals show very little loss of cell viability after 3 days of culture, cells from AIDS patients display a rapid decay varying from 10 to 40% of dead cells after 3 days. HIV positive and ARC patients show intermediate values. Cell death was often preceded by production of cytoplasmic debris and membrane bullous formation. Fractionation of PBMC in subpopulations indicate that 18 as well as 14 lymphocytes and non T cells are decaying at about the same rate under these culture conditions.

Conclusion. An increased cell fragility, amplified by the serum-free conditions, may be an important parameter in AIDS pathogenesis. Results of antiviral treatment on such a parameter will be described.

W.C.P.62 USE OF POLYMERASE CHAIN REACTION (PCR) TO DETECT THE PRESENCE OF HIV-1 DNA IN SUBPOPULATIONS OF PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMCs) IN INFECTED INDIVIDUALS

Schlimman Street, Paulidesopoulos, M.C., Lane, J.L.C., Baseler, M., Solomon, N.P., and Fauci, A.S., *NIAID, National Institutes of Health, Bethesda, MD, USA, **Georgetown University, Washington, DC, USA, ***FPLD, Frederick, MD, USA.

Objective. We have previously demonstrated that within PBMCs, HIV is expressed in vivo in CD4⁺ T cells predominantly in the T cell subpopulation which, in contrast to its *in vitro* infection, continues to express CD4. Our prior studies utilized methods which detect HIV in cells actively producing virus. The present study determines which subsets of PBMCs harbor HIV DNA (both latent and active) and what is the precursor frequency of these virus-infected cells.

Methods. Highly purified (98-99%) subpopulations of PBMCs were obtained from HIV infected individuals by fluorescent activated cell sorting. PCR was then performed on the DNA from these cells to detect specific HIV-1 DNA.

Results. Cells were sorted for CD4 (T helper), CD8 (T suppressor), CD4 (monocyte), and CD19 (B cell) populations. HIV-1 specific DNA was detected in the purified CD4⁺ T cell population in all 15 patients tested by PCR. HIV-1 DNA was not present in the CD8 or CD19 cell subsets, and rarely in the peripheral monocyte fraction. PCR performed on serial dilutions of the sorted CD4⁺ T cells revealed that >1000 cells are infected in AIDS patients, a viral burden much greater than previously reported.

Conclusion. The CD4⁺ T cell is the reservoir for HIV in the peripheral blood of infected individuals, and greater than 1% of these cells may contain virus in vivo in patients with AIDS. This high level of infection may be the primary cause for the progressive decline in CD4⁺ T cell function and number in AIDS patients.

W.C.P.64 INFECTION OF HUMAN FETAL BRAIN MACROPHAGES AND MIXED NEURAL CELLS IN TISSUE CULTURE BY HIV-1

Wainberg, M.A., *McGill University-Montreal Children's Hospital Research Institute, Montreal, Quebec, Canada; **Sir Mortimer B. Davis - Jewish General Hospital, Montreal, Quebec, Canada.

Objective. To clarify the role of brain macrophages and other neural cells in the pathogenesis of neurologically disorders associated with AIDS.

Methods. Cultures of macrophages and mixed neural cells were established from human fetal brains of neonatally-induced aborted fetuses and infected with the HIV-1_{IIIB} strain of HIV-1.

Results. Expression of HIV-gag gene products (p17 and p24) was detected by immunofluorescence after 7 days and peaked at 10 days after inoculation of both the macrophage and mixed neural cell cultures. Positive results were also obtained when the cultures fluids of both the macrophage and mixed neural cell cultures were assayed by both antigen capture (p24) and reverse transcriptase (RT) assays. In addition, cellular disarrangement and the appearance of multinucleated giant cells was observed. Cultures of mixed neural cells derived from the substantia nigra and infected with HIV-1 revealed both giant cell formation and massive reduction of cell numbers.

Conclusion. These results indicate that brain macrophages and other neural cells are susceptible to primary infection by HIV-1. These systems afford good opportunities for investigations of the neurological consequences of HIV-1 infection and for anti-viral drug studies in neurological tissue.

W.C.P.66 MECHANISMS OF HIV-INFECTIONS IN MACROPHAGES

Zer, Bernd, Knaumth, Th. and Habermann, K.O. Institute for Clinical Experimental Virology, Free University of Berlin, Hinderburgstrasse 27, 1000 Berlin 45, FRG.

Blocking experiments with receptor-specific antibodies (ORX74) lead to the conclusion that the T4 molecule is an essential receptor-component for monocytes/macrophages. Neutralization tests with T4-positive MT4 cells and peripheral blood monocytes which possess the T4 molecule and P-co-receptors (P2U) were performed in order to investigate if antibody-virus-complexes are infectious for monocytes/macrophages.

Using a HIV (wild type) and a respective type-specific antiserum it can be demonstrated that antibody-virus-complexes which are infectious for MT4 cells are still able to infect monocytes/macrophages. Moreover, in certain ranges of antibody concentration, an enhancement of infectivity can be observed. Human non-immune sera did not show this effect. Simultaneous application of a monoclonal antibody against ORX74 together with the antibody-virus-complex leads to a complete protection of the monocytes/macrophages. This indicates that antibody-virus-complexes are able to enhance the infectivity for monocytes/macrophages *in vitro*. The specific interaction of the HIV with the T4 molecule, however, is an essential prerequisite for the initiation of the cycle of virus-reproduction. The results indicate that the enhancement of infectivity is caused by an interaction between the P-co-receptor of the macrophages and the antibody of the complex. The high affinity of the T4-gp120 binding on the one hand and the genetic variability of the env-region on the other are essential for the effectivity of the interaction with the T4 molecule.

This mechanism gives an explanation for the fact that at present immunization with vaccines against infections with lentiviruses seems to be rather harmful than beneficial.

W.C.P.67 CNS AND LYMPH NODE CHANGES IN HIV INFECTION,

Peter Blumenthal, Carlo Pavoni,*, Anna-Lena Petters, Marianne Ekman*, Anna Forsell, R.C. Gallo***, **Immunology Lab, Department of Pathology, Karolinska Institute, Stockholm, Sweden, ***Center for AIDS and Parasitology, University of Michigan, Department of Pathology, University of Michigan, Ann Arbor, Michigan, U.S.A., **Lab of Tumor Cell Biology, N.C.I., N.I.H., Bethesda.**

HIV-induced lesions in brains and lymph nodes of infected individuals were studied by immunohistochemistry and *in situ* hybridization. Microscopic lesions in the brains were mainly composed of microglial cells, monocytes/macrophages and lymphoid cells, predominantly CD8+.

Gag and rev-coded antigens as well as virus RNA were associated with glial cells and monocytes/macrophages. The glial cells and monocytes/macrophages expressed antigens defined by the Mab's K166 and 94 and to variable degree CD8. In lymphadenopathic nodes only gag antigens were demonstrable and exclusively in germinal centers, mostly associated with dendritic follicular cells (DFC). Rare cells showed evidence of HIV replication also predominantly located to the germinal centers. Follicular involution was associated with destruction of DFC and follicular infiltration of CD8+ cells. Both in CNS and lymph nodes the lesions consist of the same source (provirus) of virus replication. A possible cytotoxic role of CD8+ cells to HIV-infected cells is suggested.

W.C.P.69 ALTERED BRAIN METABOLITES IN AIDS DEMENTIA AS MEASURED BY MAGNETIC RESONANCE SPECTROSCOPY

Jeanne Pater, C. Hubesch, B. Parks, R. Decker, N. Krol, P. Weiner, M. W., et al.
Department of Medicine, Veterans Administration Medical Center and The University of California, San Francisco, California, USA

Eight controls and 17 HIV seropositive patients with clinical evidence of the AIDS Dementia Complex (ADC) were evaluated with neurologic, psychiatric, and neuropsychological testing. Patients with focal brain lesions were excluded. All subjects were scored on the basis of cognitive, behavioral and neurologic function utilizing a standardized form. Subjects were studied with Magnetic Resonance Imaging and Spectroscopy (MR/MRS). Brain concentrations of adenosine triphosphate (ATP), phosphocreatine (PCr), inorganic phosphate (Pi) and other phosphate-containing metabolites, such as phosphonucleotides, were assessed by MRS. Preliminary results suggest that patients with moderate to severe ADC have lower brain ATP/Pi ratios than do normal subjects. There was no correlation between ATP/Pi or PCr/Pi ratios and clinical stage of HIV infection, nor with the degree of cerebral atrophy and ventricular enlargement as measured by MRI. Cerebral atrophy, when present, was positively correlated with lower dementia scores. These preliminary findings suggest that brain energy metabolism, as measured by phosphate metabolites, may be reduced in patients with ADC. This altered metabolism may be independent of the presence of cerebral atrophy. Further studies to validate these early findings are in progress.

W.C.P.71 *IN VIVO* ACTIVATION OF ALVEOLAR MACROPHAGES AND LYMPHOCYTES PRODUCE INTERLEUKIN-1 AND INTERFERON- γ IN THE VESPA-MARSHI VIRUS INFECTION

Christine Bergeret*, Collet J.L.*, Couss, O. and Meres S.P.**
*INSERM U9, CNRS U94, IUT, USC, Institut R. Bracco, Lyon, France. **Laboratoire associé de Biochimie et de Biologie Moléculaire, Hôpital Louis Pasteur, Lyon, France.

Objective: Cellular and molecular determinants involving the cells, the serum system and the lungs are a common feature of leishmaniasis infections in humans and rodents. They include by the vertebrate host/parasite develop a chronic leishmanial lung disease characterized by an elevated interleukin-1 (IL-1) and interferon- γ (IFN- γ) synthesis and induced macrophage damage associated with a macrophage infiltration. Macrophages and induced lymphocytes released in the culture medium were analyzed by flow cytometry were used to assess the expression of cell surface antigens. Using fluorescence activated cell sorting (FACS) analysis, a significant decrease of the CD4⁺ lymphocytes was observed (CD4⁺ 3% vs 42.14, p<0.05) without significant changes in CD4⁺ lymphocytes (19.6% vs 26.14, n.s.). Activated lymphocytes expressed MHC class II antigens were present in both infections. Both the total number of alveolar macrophages (1.6x10⁶ vs 1.9x10⁶) and the percentage of MHC Class II-positive macrophages (39.16x10⁴ vs 15.5x10⁴) were significantly higher (p<0.05). In keeping with the immunologic alterations, the spontaneous release of a macrophage-derived factor was increased in mice (38.3x10³ vs 10³ macrophages a 3h vs 13.2x10³, p<0.05). Further evidence was obtained by immunoblotting using a murine anti-human interleukin-1 β monoclonal antibody (11.6kDa/IL1 β IFN- γ 17kDa). **Conclusion:** Although restricted to macrophages, infection by vespa-marshii induces activation of both lymphocytes and macrophages in the alveoli. Macrophage release secreted of substances able to play a role in the pathogenesis of the disease. In addition, increased expression of Ia-antigen they might potentiate the lymphocyte responses.

W.C.P.68 CYTOMEGALOVIRUS (CMV) INDOCTION OF TUMOR NECROSIS FACTOR (TNF) SECRETION BY HUMAN MONOCYTES/MACROPHAGES MAY CORRELATE TO TISSUE INFLAMMATION IN AIDS PATIENTS.

Saich, Phillip D., Lambert, C.L., Saini, S.L., Wahl, L.M. and Wahl, S.M.
National Institutes of Health, Bethesda, MD, U.S.A.

Objective: To determine whether CMV induces monocyte and tissue macrophage expression of TNF. **Methods:** CMV isolated by standard techniques from an AIDS patient with CMV colitis was inoculated into cultures of purified human monocytes. Infection was confirmed by immunoperoxidase staining with monoclonal antibody to the 68 kD immediate early (IE1) antigen. TNF secretion was measured by bioassay and TNF gene expression was analyzed by Northern blot. TNF expression by monocyte macrophages obtained from AIDS patients and normals was monitored by *in situ* hybridization.

Results: Monocytes inoculated with the clinical isolate, but not mock-infected cells, spontaneously secreted TNF. Infected monocytes produced several-fold greater amounts of TNF in response to a second stimulus. In parallel, CMV-infected monocytes expressed elevated levels of TNF mRNA. In addition, TNF-specific RNA was detected in monocyte macrophages in biopsy specimens from 2 AIDS patients with CMV colitis, but not in specimens from healthy subjects or AIDS patients without CMV colitis.

Conclusions: TNF is expressed in increased amounts in CMV-infected monocytes *in vitro* and in mucosal cells during CMV enteritis. TNF secretion by tissue macrophages may contribute to the inflammatory changes that occur in various organs in patients with AIDS and CMV disease.

W.C.P.70 INDUCTION OF HIV-1 FROM A LATENTLY INFECTED CNS-DERIVED CELL LINE

Mark A. Laughlin, Janet M. Howson, F. Gonzalez-Serrano
University of Pennsylvania Medical Center, Philadelphia, PA, U.S.A.

Objective: HIV-1 causes a persistent, latent and often cytotoxic infection of MED 217 cells (a neuroblastoma derived cell line). We further defined the nature of this infection in terms of baseline viral gene expression and methods of induction of viral transcription, p24 production and production of infectious virus. **Methods:** MED 217 were exposed to HIV-1₉₂ and a modified infectious control assay performed to rescue virus. The cellular RNA was extracted and probed for viral specific nucleic acid and in addition the supernatant assayed for the production of p24 and infectious virus. A number of manipulations (such as treatment with phorbol esters, growth factors and UV light) were then performed in an attempt to induce viral replication. **Results:** Although in general infection in these CD4 negative cells was inefficient, with increasing time of exposure to virus approximately 1:10 cells became infected. Under baseline conditions no viral specific RNA, supernatant p24 or infectious viruses could be demonstrated. Treatment with phorbol myristate acetate results in the production of viral specific RNA, p24 (~20 fold increase over baseline sensitivity) and infectious viruses. Treatment with UV light similarly results in the production of p24, but the time course is markedly different, indicating different mechanisms for the activation of viral replication by these methods. Treatment with cloned growth factors is being performed. **Conclusions:** By increasing the time of exposure to virus, infection of MED 217 cells can be made efficient, allowing the dissection of mechanisms of induction of viral replication. Initial results indicate that several mechanisms of activation of the HIV-1 promoter will induce viral replication.

W.C.P.72 MORPHISIS SYSTEMIQUE ET EXPRESSION RETROVIRALE (infection productive) CHEZ LE RAT (Rattus norvegicus)

Yves L. Dubouché, Jean-Louis Pons, René Courcès, Germaine Parisse, Lucie, **Hôpital Raymond-Poincaré-Université René Descartes, Garches-Paris-Seine, France, **Hôpital Pasteur, Paris, France. *Oncologie Laboratoire, North Carolina State University, Raleigh, North Carolina, U.S.A.**

Objectif: Evaluer les effets d'une infection rétrovirale, progressive, induite par infection rétrovirale productive *in vivo*. **Méthodes:** Evaluer la viralité (CCID₅₀), lymphocytes T4, antigénémie p24/25 (p24:1) et l'effet de l'infection rétrovirale productive *in vivo* sur quantité de virus et sur cellules mononucléaires du sang à différenciation myéloïde (BMDC), CMV-FAC. La vitesse moyenne de propagation (score N, du maximum du quantifié HIV sur lymphocytes *in vitro* est fonction pour un échantillon donné du nombre de cellules contenant un HIV infectieux *in vivo* (laboratoire). Les mêmes systèmes de co-culture ou quantifiés sont appliqués aux CMV non-infectieux.

W.C.P.73 ALTERED IGF-1 RECEPTOR DISTRIBUTION IN LYMPH NODE CELLS AND SERUM OF PATIENTS WITH HIV INFECTION
Miller, Fredrik A.; Frelund, S.S.* and Brandtzaeg, P.*
*Lab. for Immunohistochemistry and Immunology and *Medical Department A, University of Oslo, Biokjemipensit, Oslo, Norway

Objectives. To study the distribution of plasma cells producing IgG subclasses in lymphoid tissue of patients with HIV infection and compare this with IgG subclass levels in serum.

Methods. The fraction of lymph node specimens from 15 patients with persistent generalized lymphadenopathy (HIV+) and 11 patients with lymphadenopathy of other causes (controls), were processed for paired immunofluorescence. Sections were stained with subclass-specific antibodies and an anti-IgG antibody. The proportion of cells containing each subclass was then calculated. IgG subclasses in serum was measured by ELISA (Nycomed AS, Oslo, Norway) in 14 of the patients with HIV infection and 12 blood donors. Results are given as median and 25-75 percentiles.

Results. The fraction of lymph node cells producing IgG was 84% (813-884) in HIV+ versus 76% (678-334) in the controls (p<0.05). For IgG2, the fraction was 38 (24-81) in HIV+ versus 8% (38-158) (p<0.05). No differences were observed for IgG1 or IgG4. In serum, total IgG was 17.6 g/l (15.1-20.4 g/l) in HIV+ and 11.9 g/l (10.6-13.4 g/l) in the blood donors (p<0.005). IgG1 was elevated in HIV+: 8.9 g/l (7.5-9.6 g/l) versus 5.4 g/l (5.1-6.3 g/l) (p<0.005). Conversely, IgG2 was reduced in HIV+: 1.5 g/l (1.3-3 g/l) versus 3.6 g/l (3-4.2 g/l) (p<0.05).

Conclusion. In lymph nodes from patients with HIV infection, the proportion of cells producing IgG1 is increased whereas that producing IgG2 is reduced. This shift is in accordance with the IgG subclasses seen in serum.

W.C.P.74 THE EFFECT OF HIV ON MEMBRANE LIPIDS OF LYMPHOCYTES
A. Elings, F. Godwin*, S. Schurhartz*, L. Wieruwa*, A. Melkiss and M. Weinberg**
*Clinical Biochemistry Dept., Sunnybrook Medical Centre, University of Toronto, Toronto, Ontario, Canada; **Melville Davis Institute, Jewish General Hospital, McGill University, Montreal, Quebec, Canada.

High content of unsaturated fatty acids (FA) in membrane lipids lead to an increase in cell membrane fluidity and can explain cell fusion and death through the loss of membrane integrity. In the present work after 8-9 and 10-14 days of HIV infection, lymphocytes were infected with HIV, a quantitative and qualitative analysis of their FAs was made. These cell lines were chosen because 80-85% is killed after HIV infection and 8-9 is not. Infected and non-infected cells were extracted with methanol:chloroform solutions. The lipids were transesterified to produce FA methyl esters and analyzed by gas chromatography. HIV infection was characterized by: 1) a significant rise (180-250%) (p<0.05) in the desaturation of essential FAs-represented by linolenic (18:3) and arachidonic (20:4) acids-in both cell lines, 2) a significant elevation (p<0.05) in the concentration of the saturated FA stearate (18:0) (1802) and palmitate (16:0) (1872) only in the 8-9 cell line, 3) a significant rise (p<0.05) in the desaturation of stearate to oleic (18:1) (1718) only in the 8-9 cell line. The results demonstrate that infection by HIV is characterized by elevated desaturation of essential FAs, whereas, killing of cells shows increase in both formation of non-essential FAs and desaturation of stearate. The mechanism by which these changes take place is not at all clear.

W.C.P.75 SENIAN IMMUNODEFICIENCY VIRUS INHIBITS BONE MARROW HAEMATOPOIETIC PROGENITOR CELL GROWTH.
Katsenbaeva, Ekaterina; Bisler, D.-J.; Belong, F.A. and Letvin, N.L. Harvard Medical School, New England Regional Primate Research Center, Southborough, Massachusetts, USA.

W.C.P.76 INFECTION OF GLIAL CELLS EXPRESSING THE CD4 MOLECULE
Jung, M., Haroge, Mark A., Laughlin, Jeffrey Hastings, Harry Friedman, Brian Godfrey, J. Gonzalez-Scarano
Departments of Neurology, Microbiology and Medicine, School of Medicine, University of Pennsylvania, PA, USA 19104-6076

Objective. To explore pathogenic mechanisms of depressed hematopoietic function in AIDS.

Methods. Granulocyte/macrophage (GMF-CM) and erythroid (EPU-5) progenitor cell colonies were assessed in two layer agar and methylcellulose assays respectively. HIV-1 isolations from bone marrow were assessed in adherent cell cultures in CM⁺ absence of lectin or cytokines.

Results. Both bone marrow GMF-CM and EPU-5 were decreased in number in many SIV-infected thymus monkeys. SIV⁺ was readily isolated from bone marrow cells of infected monkeys and was shown to be harbored in macrophages rather than T lymphocytes. The *in vitro* infection of normal bone marrow cells by SIV⁺ inhibited colony formation. A striking *in vivo* correlation between isolated SIV⁺ in bone marrow cells and decreased hematopoietic progenitor cell colony growth was also shown. Finally, inhibition of SIV replication in bone marrow macrophages by anti-CD4 antibody resulted in increased progenitor cell colony growth from these bone marrow cells.

Conclusion. The infection of bone marrow macrophages by the AIDS virus leads directly to depressed bone marrow hematopoietic progenitor cell growth. Moreover, inhibition of AIDS virus replication in these macrophages should induce significant improvement in hematopoietic function.

Objective: The U373 glioblastoma-derived cell line can be infected with HIV-1. Several attempts to transfect neurocytic cell lines with HIV-1 provirus constructs, including treatment with phorbol ester (PMA) will induce viral replication. To determine whether CD4, which is normally not present in these cells, could affect replication we prepared stable transfectants containing the human CD4 molecule.

Methods: We prepared stable transfectants of glioblastoma line U373 with a plasmid expressing the human CD4 molecule under the control of the Moloney murine sarcoma virus promoter. The transfectants were screened for expression of the CD4 gene. The stable transfectants were further selected with anti-CD4 antibody by panning and by antibody dependent cell cytotoxicity (ADCC). A variable level of expression of CD4 was seen in the initial transfectants but all of the epitopes tested, including the carboxy and amino regions of the molecule were repressed. We cloned the high expressing cells and used several different strains of HIV-1 and HIV-2 in infections. We monitored viral replication by antigen capture for gp24 and by the production of infectious virus and compared these with two other cell populations: (1) clones of U373 glial cells uniformly infected with HIV-1ig (2) randomly infected U373 cells. After infection with HIV-1ig there was an initial round of low-level replication (gp24 = 100 pfu/ml) followed by a persistent latent infection. **Conclusions:** These results indicate that other factors besides the entry pathway are responsible for the characteristics of HIV-1 infection of glial cells and allow us to begin to dissect the diverse elements that determine tropism.

W.C.P.77 ROLE OF ENDOTOXIN IN MODULATION OF HIV EXPRESSION IN A MONOCYTE CELL LINE
Molinaro, Michael J.; Choby, H.; Ashraut, C.*; Dinarello, C.* and Groopman, J.*
*Harvard University, Boston, Massachusetts, USA, **Tufts University, Boston, Massachusetts, USA

W.C.P.78 PRODUCTION DE TNF α ET D'IL-1 β PAR LES CELLULES DE LA LIQUÉUR MONONUCLÉAIRE INFECTÉES PAR LE VIH
Molinaro, Michael J.; Dinarello, C.*; Ashraut, C.*; Pariani, R.*; Byrn, R.*; Dinarello, C.* and Groopman, J.*
*Université de Harvard, Boston, Massachusetts, Etats-Unis, **Université de Tufts, Boston, Massachusetts, Etats-Unis

Objective. To determine the role and mechanism of action of endotoxin (LPS) in modulating HIV expression in monocytic cells.

Methods. THP-1 cells, chronically infected with HIV-1/IIIB, were stimulated for 24 hours with LPS (0.5-10 µg/ml), recombinant TNF α (rTNF α), recombinant IL-1 β (rIL-1 β) (0.1 to 10 ng/ml) and polyclonal antibodies against TNF α and IL-1 β . TNF α and IL-1 β were measured in supernatants using RIA.

Viral expression was assessed by the level of reverse transcriptase activity (RT) in the supernatants.

Results. LPS stimulation of THP-1 cells resulted in a dose-dependent increase of RT (20 to 100 fold over unstimulated cells p<0.01), and in significant production of TNF α (1 ng/ml) and IL-1 β (0.1ng/ml). Antibodies against TNF α , but not against IL-1 β were able to block 50% of the increase in RT after stimulation with 10 µg/ml of LPS (p<0.05). Furthermore, rTNF α but not rIL-1 β increased RT in a dose dependent manner (p<0.01).

Conclusion. LPS stimulation of HIV-infected monocytic cells can significantly increase virus production and this effect may be due in part, to the release of TNF α by LPS stimulated cells.

Objectif. Mesurer la production de TNF α et d'IL-1 β par les cellules de la lignée monocytaire infectées par le VIH.

Méthodes. TNF α et IL-1 β ont été mesurés par RIA et l'ARNm par Northern Blots. La lignée THP-1 infectée par VIH-1/IIIB a été stimulée par 5µg/ml d'endotoxine (LPS). Les macrophages ont été infectés par VIH-1/IIIB, VIH-1/Bal et VIH-2.

Résultats. Les cellules THP-1 et les macrophages infectés par différentes souches de VIH ne produisent pas spontanément de quantités détectables de TNF α , d'IL-1 β ou d'ARNm. Après stimulation par LPS des cellules THP-1, TNF α , IL-1 β et de l'ARNm sont produits, sans différence significative entre cellules non infectées ou infectées de façon chronique. En revanche, les cellules THP-1 en phase aigüe d'infection, plus différenciées, produisent après stimulation, des quantités de cytokines 2 à 13 fois plus élevées que les cellules non infectées ou infectées de façon chronique (p<0.01).

Conclusion. Les cellules de la lignée monocytaire infectées par le VIH produisent pas spontanément de TNF α ou d'IL-1 β mais peuvent en réponse à un stimuli comme LPS produire des quantités importantes de ces deux cytokines.

W.C.P. 79 HIV-2 ENVELOPE GLYCOPROTEINS AND CELL FUSION.
Mulliken, B.A., Kuman, P., Hu, J., Ritter, D., Hahn, B., Coombs, R.
University of Minnesota, Minneapolis, Birmingham, Birmingham, Alabama, USA

Objective: To utilize recombinant vaccinia viruses (vVV) to study the expression and function of *env* genes of HIV-2/ROD, the HIV-2 protease which is fully pathogenic to HIV-1 and HIV-2ST, a recent isolate with less virulence in vivo behavior.

Significance: The envelope proteins gp120, gp160 and gp42 are essential to virus attachment, entry, and pathogenicity, as well as cell fusion and host immune responses. Most data indicate virus entry into CD4+ target cells occurs via viral-cell membrane fusion at neutral pH. The infected cells can produce syncytia with uninfected CD4+ cells at neutral pH. A virus unable to produce cell fusion despite normal infectivity may have an altered molecular mechanism of cell entry and membrane fusion. We hypothesize such a change in HIV-2ST. Unlike other HIVs, this virus does not induce cell fusion or cell death; infected cells exhibit fully productive infection (mRNA production, RT activity), but the rate of free virus entry into cells is reduced.

Methods: HIV-2ST had been isolated from a healthy West African prostitute; HIV-2ROD was provided by L. Montagnier. The *env* genes were inserted into rVVs and evaluated for production of envelope glycoproteins using metabolic labeling and RDP/PAGE. Function of recombinant *env* gene products was assessed by infection of CD4+ cells and quantitating cell fusion. Hyperimmune rabbit antisera was produced using recombinant envelope glycoproteins. **Results:** Recombinant HIV-2ROD *env* gene product gp160 produced and recognized by antisera. Infection of CD4+ cells indicates the products are cleaved and transported to the cell surface in functional form where they mediate cell fusion. rVVs-ST has been constructed.

Conclusions: Recombinant VV carrying HIV-2 *env* genes, synthesis, process, and transport functional recombinant envelope glycoproteins. The *env* gene product of HIV-2ROD causes infected cells to fuse with uninfected CD4+ cells. These methods will be useful to determine whether the cell fusion defect of HIV-2ST is a function of its *env* gene.

W.C.P. 81 ABERRANT CIRCADIAN PHYSIOLOGIC, IMMUNE AND ENDOCRINE RHYTHMS IN HIV-INFECTED INDIVIDUALS.
Blanchard, E.M., Soborn, R.R.,* Sackel-Landsen, L.**, Suarez, C.*
*University of Minnesota, Minneapolis, **St. Paul-Ramsey Medical Center, St. Paul, Minnesota, USA

Objective: To assess circadian variation of parameters relevant to the pathophysiology and laboratory monitoring of HIV infection.

Methods: For 24h in a clinical research setting, 8 HIV-infected persons (3 AIDS, 3 ARC and 2 asymptomatic; all free of acute illness) underwent 48 assessments of oral temperature, lymphocyte subsets (CD3, CD4, CD8, B1), monocytes, neutrophils, HIV antigen, neopterin (n=6), beta-2-microglobulin, plasma cortisol, aldosterone, beta endorphin; and serum zidovudine and urinary excretion (n=3). Two patients underwent detailed zidovudine pharmacokinetics at midnight and noon. Healthy, age-matched adults served as controls.

Results: A significant circadian rhythm in oral temperature was found in 6 of the 8 patients, with unusual early morning peaks in 2 patients. Usual lymphocyte rhythmicity peaking between 6 P.M. and midnight, including all studied subsets, was lost. The normal circadian rhythm in neutrophils and monocyte concentrations was absent in patients with low counts. Rhythmicity in HIV antigen and neopterin could be demonstrated for some patients, but not as a group phenomenon since the daily peaks and valleys differed from patient to patient. HIV-infected subjects had elevated beta-2 microglobulin and rhythmicity, which was not seen in controls. Circadian variation similar to controls in beta-endorphin, aldosterone and cortisol concentrations was seen. Following constant dosing, substantial within-day variation in serum and urine zidovudine levels was seen, but half-lives at midnight and noon were similar.

Conclusion: The normal marked lymphocyte rhythmicity is ablated in HIV-infected persons, even if asymptomatic, and cannot be explained by loss of cortisol rhythmicity.

W.C.P. 83 ENHANCED PRODUCTION OF TUMOR NECROSIS FACTOR IN SYMPTOMATIC HIV INFECTIONS. Liu, Allan S., Read, SE, Der S, Division of Infectious Diseases, Hop for Sick Children, Toronto, Canada.

Tumor necrosis factors (TNF) are polypeptides produced by macrophages and monocytes in response to inflammation and sepsis. They are also potent mediators of cachexia and autoimmune processes. We have demonstrated upregulation of TNF receptors and induction of TNF synthesis by the acid-labile IFN- α present in AIDS sera. We were interested to determine whether synthesis of TNF is enhanced during the progress of HIV infection in patients. Blood monocytes were obtained from normal controls and patients with asymptomatic HIV infection (CDC classification group II), persistent lymphadenopathy (III), constitutional disease (IVa), and opportunistic infections (IVc). TNF production by the cells was measured by a cytotoxicity assay on L529 cells using HV-TNF- α (Genentech) as a standard. One unit of TNF is defined as the concentration of the cell culture supernatant which produces cytotoxic effects on 50% of the cells. PBMC from normal controls produced low levels of TNF (1.1±0.96 U/ml, n=14). The levels of TNF production by the cells from Group II, III, IVa, and IVc patients were 2.2±0.2 (n=9), 7.8±2.9 (n=12, p<0.05), 6.4±2.2 (n=13, p<0.05), and 18.7±1.7 (n=13, p<0.01) U/ml respectively. The cytotoxic activities in the supernatants can be completely neutralized by anti-TNF- α antibodies. Moreover, the cells from symptomatic patients (Group III and IV) were hyperresponsive to endotoxin resulting in further induction of TNF synthesis, compared to normal controls and asymptomatic patients. Thus these results indicate that the synthesis of TNF is enhanced during the progress of HIV infections and the cells from symptomatic patients are hyperresponsive to TNF. This may be one of the mechanisms involved in the pathophysiology of cachexia and sepsis in symptomatic AIDS patients.

W.C.P. 80 CRY IS NOT A COFACTOR IN THE PROGRESSION OF HIV INFECTION. Broder, H.; Byrne MP; Drew, JL; Looney, M.; Grimes, CM; Kankias, A; and Williams RW. *Letterman Army Medical Center, 1-cs/10 San Francisco, California, USA, **Mount Zion Hospital and Medical Center, San Francisco, California, USA, ***Socorro, Inc., Sparksville, Maryland, USA.

Objective: To determine if coinfection with CRV affects the decline of CD₄ cells in HIV infected patients.

Methods: We have compared rates of decline of CD₄ cells in HIV seroconverting military personnel who are CRV seropositive versus those who are CRV seronegative. Regression analysis was used to calculate the daily decline in CD₄ counts following HIV seroconversion. Blood samples were obtained at 4 months intervals to permit calculation of the rate of CD₄ cell decline. **Results:** The mean initial CD₄ counts were 519 in the CRV seropositives and 597 in the seronegatives (NS(p=0.5)). Fifty CRV seropositives showed a slope of CD₄ decline/day of = .3101 versus = .2044 in CRV seronegatives. This difference is not statistically significant (P=0.71) when the rates are compared using ANOVA (F test).

Conclusion: We conclude that CRV is not a necessary cofactor in the pathogenesis of HIV infection.

W.C.P. 82 REGULATION OF CYTOKINE RECEPTOR EXPRESSION BY HIV. Liu, Allan S., Dion M, and Livezey JF, Division of Infectious Diseases, Hop for Sick Children, Toronto, Canada.

Interferon (IFN) has been shown to interact synergistically with tumor necrosis factor (TNF) in cytotoxic and antiviral activities. Both cytokines are capable of increasing the replication of HIV in vitro. To elicit biological activities, these cytokines bind to specific high affinity cell surface receptors. We have previously demonstrated down regulation of IFN- α receptors on T4 lymphocytes from AIDS patients and the consequent responsiveness of the cells to IFN in vivo. We postulate that HIV gene products are capable of down regulating the expression of cytokine receptors. The expression of IFN- α receptors on CD4+ cells (specifically CEM, HUT, and Jurkat) was studied using IFN α (Schering) labeled with ¹²⁵I to high specificity by a lactoperoxidase method. Saturation binding curves were generated with the ¹²⁵I-IFN α and the binding characteristics were analyzed to obtain the receptor numbers. CD4+ cells were infected with HIV in vitro and the levels of 2.5A antigen and reverse transcriptase activities were determined to monitor the replication of HIV. We have demonstrated a progressive down regulation of IFN- α receptors during the progress of HIV infections in vitro. To evaluate the effects of HIV on the induction of IFN regulated enzymes, HIV infected HUT cells were treated with IFN- α and assayed for 2-5A synthetase activities. We have shown diminution in 2-5A synthetase induction in infected cells, compared to controls. Similarly, we have demonstrated down regulation of TNF- α receptors in CD4+ cells by measuring the binding of ¹²⁵I-TNF- α (Genentech) during the course of HIV infection. We are currently investigating the role of individual viral genes in the regulation of cytokine receptors. Thus, these studies indicate that HIV is capable of suppressing the expression of IFN- α and TNF- α receptors. This may be one of the mechanisms by which HIV evades the antiviral actions of IFN and TNF in vivo.

W.C.P. 84 ANALYSIS OF BRAIN FROM AIDS PATIENTS FOR HIV-1 DNA SEQUENCES USING THE POLYMERASE CHAIN REACTION (PCR). Giedler, Jagan, Hahn, B*, Shaw, G*, Brew, W*, Rosenblum, Memorial Sloan-Kettering Cancer Center, New York, NY, and *University of Alabama at Birmingham, Birmingham, AL, USA

Objective: To determine whether HIV-1 proviral DNA can be detected by PCR in the brains of patients with mild AIDS dementia complex (ADC). While it is clear that HIV-1 infection can be demonstrated by a variety of techniques in the brains of AIDS patients, such demonstration is confined almost exclusively to those with more advanced symptomatology and pathology. The presence and role of HIV-1 in milder ADC has not yet been established.

Methods: DNA was extracted from 56 frozen brain samples obtained at autopsy from 27 HIV-1-infected individuals and assessed using a primer pair from the HIV-1 *env* gene flanking the immunodominant region. Dilution experiments, using cloned HIV sequences from which the primer pairs were derived, indicated a sensitivity of 8.2 fg DNA by visual inspection of the gel and 66 pg when probed by Southern blotting using a reacting sequence.

Results: In samples from brains known to be HIV-1 positive by immunohistochemistry or Southern blot, HIV-1 DNA was amplified. However, in most "negative" brains, PCR was also negative and indicated a false circumscribed infection by immunohistochemistry. PCR was likewise limited.

Conclusion: These initial results suggest that viral sequences in brains of patients with milder ADC are below the level of PCR detection using this single primer pair. Further studies using additional primer pairs and well-characterized tissue specimens are needed to determine if early ADC relates to active HIV-1 replication, restricted gene expression or indirect factors.

W.C.P.85 EFFECTS OF TUMOR NECROSIS FACTOR (TNF- α), GAMMA INTERFERON AND GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR (GM-CSF) ON HIV REPLICATION IN HIV-INFECTED HUMAN MYELOMONONUCLEAR CELL LINES

Cortes Eduardo*, Koefler, HC*, Zhan, JQ*, Mitsuyasu, RT*, *University of California, Los Angeles, USA; **Faculdade de Medicina UFRRJ, Rio de Janeiro, Brazil.

Objective. To study the effects of TNF- α , gamma interferon, and GM-CSF on HIV antigen expression in chronically infected human myelomonocytic leukemia cell lines.

Methods. HTLV-IIIB infected ML-3 (myelomonocytic), THP-1 (monoblastic), and U-937 (monocytic) cells at a concentration of 3×10^6 cells/ml were incubated with cytokine at 3 log concentrations for 24-102 hours. Cell viability was assessed by trypan blue exclusion and HIV replication by HIV p24 antigen capture on cell free supernatants of cultured viable cells.

Results. TNF- α had a marked cytolytic effect on HIV infected and uninfected cells at concentrations of 10^{-10} u/ml. No HIV inhibitory effects were seen with any of the cytokines alone or in combination. HIV p24 was significantly increased in ML-3 cells by TNF- α and by GM-CSF and in U-937 cells by GM-CSF alone.

Conclusion. The effect of these cytokines on HIV expression in chronically infected cells appears to be cell specific and may represent differences in viral regulation in cells at different stages of maturation.

W.C.P.87 PRESENCE OF TUMOR NECROSIS FACTOR IN THE CEREBRAL SPINAL FLUID (CSF) OF AIDS PATIENTS WITH HIV ENCEPHALOPATHY

Zelesa, Macek, L.; Janssen, R.; Spira, T.; Fanci, A. S.***; Dubois, R.***; Polks, T. A., Centers For Disease Control, Atlanta, GA, USA; **National Institutes of Health, Bethesda, MD, USA; ***Atlanta Medical Association, Atlanta, GA, USA.

Objective. To assess the presence of Tumor Necrosis Factor- α (TNF) in the CSF of HIV seropositive patients with HIV encephalopathy (HIV-E).
Methods. CSF from 3 patients with HIV-E, 6 AIDS patients without central nervous system (CNS) disease, 5 patients with HIV-1 associated myelopathy/tropical spastic paraparesis (HAM/TSP), and 1 HIV seronegative control individual, was tested for the presence of the TNF using the Wehi 16-clone 13 bioassay. Positive samples were confirmed by neutralization with a rabbit antibody to human TNF- α .

Results. TNF was detected in significantly more patients with HIV-E (3/3) than AIDS patients without CNS disease (1/6, p=0.05). There was a trend toward significance comparing presence of TNF in patients with HIV-E (3/3) to HAM/TSP patients (1/5, p=0.07, Fisher's Exact Test, 1-tailed). No TNF was detected in the HIV seronegative control individual.

Conclusion. The current data suggest that detectable TNF levels are present in the CSF of patients with HIV-E but to a much lesser degree in HIV-E patients with no neurological manifestations or in patients with HIV-1 associated neurologic disease.

W.C.P.89 SERUM CAPACITY TO INHIBIT REVERSE TRANSCRIPTASE IN VITRO DISTINGUISHES HIV-1 INFECTION FROM HIV-2 OR HIV INFECTION

Wolfs T.*, Goudimil, Jann*, Goolen J., Schellekens H**., Berin P.***
*Human Retrovirus Laboratory, Amsterdam, the Netherlands, ** Primate Center TNO, Rijswijk, the Netherlands, ***Laboratoire de Virologie, IHRU Bretonneau, Tours, France.

Objective. To study the inhibition of HIV-1 and HIV reverse transcriptase by human and chimp macaque serum positive for HIV-1 or HIV-2/SIV antibodies.

Methods. Inhibition of HIV-1 or HIV reverse transcriptase activity was assayed after incubation with HIV-1 or HIV-2/SIV antibody positive serum.

Results. The domain to which reverse transcriptase inhibiting antibodies were elicited appeared to be highly antigenic. Sixty-seven percent (48/72) of individuals had HIV-1 reverse transcriptase inhibiting (RTI) antibodies one year after seroconversion for HIV-1, 90% (91/102) of HIV-2 antibody positive persons had HIV-RTI antibodies and all four experimentally HIV-infected chimp macaques developed HIV-RTI antibodies. Low cross-reactivity between HIV-1 and HIV-2/SIV-RTI antibodies was observed. Of 10 HIV-1-RTI sera 7 reduced HIV-RTI activity by more than 50% (mean reduction 85% versus 24%). Only 1 of 9 HIV-RTI human sera showed HIV-1-RTI (mean reduction 74% versus 29%). This serum however showed a shared reactivity against both HIV-1 and HIV-2 envelope proteins.

Conclusion. These results indicate that the HIV-1 domain inducing RTI antibodies is antigenically different from the HIV-2/SIV domain.

W.C.P.86 PRESENCE OF HIV-1 IN THE SPERMS OF HIV-SEROPOSITIVE INDIVIDUALS BY DNA-HYBRIDIZATION AND IMMUNOGOLD METHODS

Wagenvoort, J. A., Bessers, O. G. J., Freund, M. J., Condolesi, G. J., Reins, S. B., Weidman, J. A., and Condit, J. A., Departments of Microbiology, Obstetrics and Gynecology, and Medicine - University of Medicine and Dentistry of New Jersey, Camden, New Jersey, USA.

Objective. To explore the role of sperm in the transmission of HIV-1. Semen specimens were collected at weekly intervals from three patients who were seropositive for HIV-1. Semen specimens were washed and pellets were assayed for presence of HIV-1 by electron microscopy, by use of HIV-specific monoclonal antibodies and immunogold labelling and by HIV-specific DNA probes and *in situ* hybridization.

Results. Electron microscopy analysis of sperm showed HIV-1 like particles in the sperm of all 3 specimens. Further evaluation with HIV specific DNA probe and immunogold labelled monoclonal antibodies confirmed the presence of HIV-1 in the sperm of HIV seropositive individuals but their absence in HIV-seronegative individuals.

Conclusion. Presence of HIV-1 in the sperm of HIV-seropositive individuals indicates a potential mechanism for the venereal transmission of HIV by sperm from HIV seropositive individuals to their sexual partners.

W.C.P.88 DETECTION OF UNINTEGRATED VIRAL DNA IN HIV-1 INFECTION: USE OF A RAPID AND EASY PCR METHOD

Lange J., Goudimil J., *Human Retrovirus Laboratory, Amsterdam, the Netherlands, **UMD-New Jersey Medical School, Newark, NJ, USA.

Objective. To study the kinetics of unintegrated viral DNA (UVD) in HIV-1 infected cells *in vitro* and presence of UVD *in vivo* in HIV-1 infected children and in homosexual men.

Methods. UVD was detected by use of the polymerase chain reaction (PCR) in which the long terminal repeat (LTR) is covalently closed circular viral DNA was amplified. The specificity of the amplified sequences was confirmed by Southern blot analysis using an LTR-specific probe and sequencing the primer fragment.

Results. Closed circular viral DNA was detected within one day post-infection in HTLV-IIIB infected Molt-3 cells. Depending on the infecting virus titer, UVD was undetectable for a short period early in infection, but persisted thereafter. Brain and spleen tissues of HIV-1 infected children with HIV-1 associated progressive encephalopathy were analyzed for the presence of UVD. In both tissues high levels of UVD were detected, indicating active infection at both sites. In blood of AIDS-patients UVD could also be detected.

Conclusion. UVD can be detected in HIV-1 infected cells both *in vitro* and *in vivo* by use of the PCR and it may be used as a marker to active infection and disease progression.

W.C.P.90 EXPRESSION OF A POTENTIAL HIV RECEPTOR ON HUMAN GASTROINTESTINAL EPITHELIAL CELLS (GIECs)

Mayer, Mary Pat, Huot, R., Wideman, D., and Martin, D.
The University of Texas Health Science Center at San Antonio, TX, USA.

Objective. To determine if human GIECs express a CD4-related receptor which might allow HIV attachment.

Methods. Immunopassays of tissue sections and early passage cultures of GIECs from human normal GI (small intestine and colon) or human colon cancer (HCC) sources were done using LexA and OKT4 monoclonal antibodies. In addition to an immunoreactive subpopulation of lamina propria lymphocytes in tissue sections, staining was observed at the microvillar surface, or glycolexy, in a subset (2 to 25%) of GIECs in sections or in cell cultures derived from different individuals. Reactivity of well characterized GIECs maintained for 10 or more subcultures, and protein immunoblot detection of 80kd and 106kd proteins verified that carryover of CD4+ lymphoid cells did not explain the immunoreactivity. Furthermore, the established HCC lines tested in these experiments were not immunoreactive.

Conclusions. These observations suggest that GIECs bear CD4-related epitopes, which are associated with the cell surface or mucinous glycolexy. Since such surface molecules could serve as sites for HIV attachment and subsequent viral infection, these data are relevant to virus transmission, gastroenteropathies associated with AIDS or ARC, and the possibility that GIECs may serve as a reservoir for HIV. Support was provided by PHS grant R01 DK40625 and The UT-HSCSA Center for Human Cell Biotechnology.

W.C.P.91 CELL-SPECIFIC CONTROL OF HIV PRODUCTION IN CHRONICALLY INFECTED GLIAL CELLS

Melzer, W., Festl, H., Kleinshöndler, A., Müller-Lentsch, N., Erfm, Volker

*GSG-Abteilung für Molekulare Zellpathologie, D-8042 Neuherberg, **Medizinische Poliklinik der Universität München, D-8000 München, ***Institut für Medizinische Mikrobiologie und Hygiene, D-6000 Wiesbaden, West-Germany.

Objective. Evaluation of HIV regulation in potential virus reservoir cells in the brain (glial cells).

Methods. Establishment of chronically infected glioma cell lines. Measurement of HIV proteins, RNA expression, and production of infectious virus. We established chronically HIV-1 infected glioma cell lines harbouring an integrated HIV genome. The cell lines express structural proteins, which can be detected in the cytoplasm but they release extremely low amounts of infectious virus in comparison to other infected cell types (T-cells, monocytes/macrophages, mesenchymal cells). Furthermore, high amounts of intracellular p27 protein with a molecular weight of 27 kD is produced in these cells.

Conclusion. Chronically infected glial cells control virus production by a cell-specific mechanism using net protein induction and may thus represent a virus reservoir in the brain.

W.C.P.92 NEUTRALIZING AND ENHANCING ANTIBODIES IN DIFFERENT STAGES OF HIV INFECTION

D. Joffe F., Szabo, B., Uhlirly, E., Horvath, A., Fust, G., Baranyi, D., et al.
Inst. Microbiol. Univ. Med. School, Debrecen, ***Nat. Inst. Haematol. Blood Transf. Budapest, **Nat. Inst. Dermat. Venereol., ****Anticorp. Laszlo Hosp. Int. Dis., Budapest, Hungary

Objective. Enhancing antibodies (ENH AB) were reported to be present in the blood of HIV-infected patients and to influence the course of infection. In the present study the incidence of these antibodies were investigated in parallel to that of the neutralizing antibodies (NEU ABS). Heat-inactivating assay on M-1 cells was used for detection of ENH and NEU AB. HIV-seropositive (HIV+) sera were neutralized through 50 ml filters and heat treated (56°C, 30 min). The same sera were tested for NEU and ENH AB after 1 ml mixing with fresh, complement-sufficient (CS) pooled HIV-seronegative serum (CS-serum). Results. The following results were obtained in the 39 serum samples tested:

Group	no sample tested	NEU AB		ENH AB	
		CS-serum	CS-serum	CS-serum	CS-serum
asympt. HIV+	19	19	8	4	0
ARC, AIDS	20	11	0	0	12

Conclusion. These findings support the results of Robinson et al. (1988) on the presence of complement-dependent ENH AB in HIV-infected persons and suggest that their appearance in parallel to the loss of NEU AB may signal a bad prognosis.

W.C.P.93 LOW PLASMA CYSTEINE AND ELEVATED GLUTAMATE LEVELS IN HIV-1 PATIENTS MAY CONTRIBUTE TO LOSS OF T CELL FUNCTIONS.

Brigg, M.J., Frey, K. and Cox, H.-V.
Institute of Immunology and Genetics, German Cancer Research Center, Heidelberg, F.R.G.

Objective. To investigate the hypothesis that the immunological deficiency may be partially the consequence of a virus-induced metabolic disorder. Methods. The plasma glutamate and thiol (cysteine) levels of groups of HIV-1 infected patients with different stages of disease have been studied; and the influence of abnormal extracellular concentrations of glutamate and cysteine on lymphocyte and macrophage functions has been analyzed *in vitro*. Results. HIV-1 infected patients have markedly reduced plasma cysteine and elevated glutamate concentrations. Similar variations of the extracellular cysteine or glutamate concentrations have profound effects on proliferative responses in lymphocyte cultures. Lymphocyte responses are suppressed by cysteine and inhibited by elevated concentrations of glutamate or by its structural analogues quisqualate and N-methyl-D-aspartate (NMDA) but not with kainate. This suggests that glutamate may act on cell surface receptors analogous to the quisqualate and NMDA sensitive excitatory glutamate receptors in the vertebrate central nervous system. Elevated extracellular glutamate levels inhibit also the capacity of macrophages, monocytes and fibroblasts to release cysteine into the extracellular space.

Conclusion. A metabolic defect in HIV-1 infected patients may cause an insufficient supply of cysteine for lymphocyte and may thereby be responsible at least in part for the insufficient immunological reactivity.

W.C.P.94

IDENTIFICATION OF PHENOTYPIC ULTRASTRUCTURES OF LYMPHOCYTES REACTING TO AUTO-ANTIBODIES IN AIDS

Edwards, D., Goren, S. and Steyrolow, H. N., Lapinskas, and Alajalovic, D.

*AIDS Research Center, Biomedico Canada Inc., Canada, **Faculté de Médecine de l'Université de Montréal, ***Général Hospital, ****Général Armand Proppa, Montréal, Québec, Canada. Underscoring the mechanisms of immune suppression and lymphocyte depletion in HIV-positive patients is perhaps central to the understanding of the initiation and the evolution of AIDS. There is general agreement that the etiologic agent of AIDS is HIV but the precise mechanisms by which the virus affects the immune devastation are unknown. Anti-lymphocyte auto-antibodies (Ab) are lympholytic *in vitro* and undoubtedly contribute to the destruction of lymphoid tissues *in vivo*. Present studies aim at determining the specificity of anti-lymphocytes auto-Ab in AIDS.

HIV antigens were identified in peripheral blood lymphocytes (PBL) obtained from 94 patients at different stages of HIV infection using immunofluorescence (IF) and immunoelectron microscopy (IEM) techniques. In vivo studies of the phenotype of HIV-containing lymphocytes by double labelling showed that CD4+ cells are the principal target of the virus. About all infected PBL and approximately 30 percent of uninfected PBL displayed Ab-C1 complexes on the cell surface as demonstrated by IF. Sera from HIV-positive patients contain Ab reacting with cell membranes and membrane structures of PBL from normal subjects, as demonstrated by IEM. Double immunogold labelling showed that the pattern of reaction of serum Ab is different among phenotypic lymphocyte populations and that this pattern changes with the evolution of HIV infection.

The presence of Ig-C1 complexes on a high percentage of HIV-positive or negative PBL suggests that the Ab-C1-mediated lympholysis may represent a major mechanism of lymphatic tissue destruction in AIDS.

W.C.P.95 LONGITUDINAL STUDY OF HIV ANTIBODY RESPONSES OF INFANTS BORN TO SEROPOSITIVE WOMEN IN ZAIRE.

Katzenstein, David; Hendry, R.M.; Sea, W.; Ryder, C.; Brown, C.; Quinn, T.C., et al.
LSE, DV, *Center for Biological Evaluation and Research, FDA and NIAID, NIH, Bethesda, MD, USA, **Proj. SIDA Kinshasa, Zaire

Objective. To determine if neutralizing antibodies (NA) or antibodies on isotype specific Western Blots (IBW) are associated with transmission of HIV from pregnant women to their infants.

Methods. Paired maternal and infant sera were collected at the Mama Yemo Hospital in Kinshasa, Zaire. Sera were obtained every 3 months from 100 infants born to HIV seropositive women. Sera were studied from 2 years based on infant's outcome; healthy at 18 mo. (Op 1), AIDS at 12-18 mo. (Op2). IBW were developed for IgG, IgG 1-4, IgA, or IgM. MA were assessed by inhibition of cytotoxic formation using HIV113.

Results. Maternal sera from both groups reacted strongly with all HIV antigens in IgG blots. Among Op1 infants, 1/8 had anti-HIV IgG Ab and 4/8 developed new IgG Ab. Among Op 2 infants 8/10 had IgM and 9/10 had IgG by 9-12 mo. of age. MA were detected in most maternal sera at titers from 1/10 to 1/128. Significantly, 8/10 Op 2 infants developed MA compared to 1/10 Op 1 infants (p<.05, Fisher's exact test).

Conclusions. Infants with MA and evolving IBW patterns had AIDS by 18 months, although 5/8 healthy infants had IBW suggesting HIV infection. IgM responses to HIV were not observed in the first 6 months of life, even in infants who had other evidence of infection. We did not find a relationship between maternal MA and transmission of infection to infants.

W.C.P.96

NEUTRALIZING ANTIBODY IN SEROPOSITIVE SUBJECTS FROM AFRICA, SOUTH AND NORTH AMERICA AGAINST A DIVERGENT STRAIN OF HIV

Katzenstein, David; Jajic, L.; Lacit, A.; Galvao, B.; Halsey, N.; Quinn, T.C., et al.
LSE, DV, *Center for Biological Evaluation and Research, FDA, Bethesda, MD, **Univ. of Zimbabwe, Harare, Zimbabwe, ***Johns Hopkins School of Pub. Health, Balt., MD, USA, ****Laborat. Brazil

Objective. To assess cross reactivity of neutralizing antibodies (NA) against different isolates of HIV in serum of HIV infected individuals from North and South America and Africa.

Methods. Virus isolate HIV-1118, RF, MN, and 2-2 were tested with sera from Haiti, the U.S., Brazil, Zaire, and Zimbabwe. NA titers of sera were the reciprocal of the serum dilution that decreased the number of syncytia by >50% in Molt-3 cells.

Results. Some of 50 sera from seropositive subjects had MA, while sera from seropositive subjects had NA against HIV1118, HIVRF and HIV2 in 94%, 80%, 56%, and 57% respectively. Asymptomatic subjects (AS) were less likely to have MA than subjects with AIDS or ARC (SP) (SP/AS vs 72/86 SPX for HIV1118 and 56/116 vs 53/70 for HIVRF, p<.016, X²).

Analysis of individual geographic cohorts demonstrated similar geometric mean titers for HIV1118 of highest each isolate, although the GMT were significantly higher against HIV1118 in 60 U.S. sera (1929) than in 40 Zairean (475), 52 Zimbabwean (732) or 50 Haitian (372) sera (p<.05, Student's T).

Conclusion. Sero-specific HIV seropositive subjects have higher titers of NA against HIV compared to AS. NA in seropositive subjects in the Americas and Africa have broadly cross reacting genetically divergent strains of viruses from the U.S., Haiti, and Africa.

Session d'affichage Poster Session

W.C.P.103 A POSSIBLE ROLE OF VIP DEPENDENT NEURONAL SURVIVAL BY gp120 IN AIDS DEMENTIA COMPLEX

Elmehrikh, M., Nandi, J. and Dandekar, S.
Dept. of Microbiology, Tokyo Metropolitan Institute for Neuroscience, 2-6, Minamiohara, Fuchu-shi, Tokyo, Japan

Objective: Reversible intestinal peptide (VIP) has been shown to increase neuronal survival in acute brain cultures (Brennan, J.E., et al., PNAS, 83:1159, 1986), and the amino acid sequence shows some homology with a sequence of the gp120, called peptide-2. Burt et al. have reported that the VIP attenuated the neuronal cell death caused by gp120 in mouse hippocampal cultures (Brennan, J.E., et al., Nature, 335:619, 1988). To determine the isolation of VIP dependent neuronal survival, we studied the effects of VIP and/or peptide-2 on rat brain cultures, and tried to clarify the pathogenesis of AIDS dementia complex.

Methods: Rat brain slices (hippocampus or cerebral cortex) were obtained from 18-19 day old fetal rat. VIP and/or peptide-2 was added to the culture on day 0 or 7. After 12 days, the slices were stained with specific antibodies to neurons or astrocytes, and the survival of neurons was measured.

Results: Addition of 0.1 nM VIP to brain cultures produced a significant increase of neuronal survival. On the other hand, 100 nM peptide-2 decreased the number of neurons. Peptide-2 (100 nM) abrogated the function of VIP (0.1 nM). They did not affect the number of astrocytes. The results suggest that the addition of VIP to brain cultures and antagonizes the VIP-dependent neuronal survival. Finally,

Conclusion: We confirm that VIP is important for neuronal survival in cultures of hippocampus and cerebral cortex of rat. The results suggest that peptide-2 binds to VIP receptors and antagonizes the VIP-dependent neuronal survival. Finally, the gp120 of HIV also blocks VIP-dependent neuronal survival, and the resulting death of neuronal neurons causes the AIDS dementia.

W.C.P.105 VIRAL ANTIGEN STIMULATION OF THE SECRETION OF HUMAN MONOKINES CAPABLE OF REGULATING HIV-1 EXPRESSION

Claude Khatib, A.Y. Hwang, J. Ferris, B. Orenov, J.M. Fauci, A.S. "Georgetown University, Washington, D.C.; "ILR, NIAID, NIH, Bethesda, MD, U.S.A.

Objective: We have previously described model systems for cytokine-induced regulation of HIV-1 in chronically infected T lymphocyte and monocyte lines. Our current objective was to determine whether viral antigens can stimulate human macrophages to secrete monokines capable of upregulating HIV expression in infected cells.

Methods: Chronically HIV-1 infected T cells (ACH-2) or monocytes (U1) were tested for inducibility with monokine-enriched supernatants obtained following stimulation of clonally derived human monocytes with bacterial lipopolysaccharide or purified, inactivated viruses (viral antigens). Induction of HIV expression was monitored by reverse transcriptase activity.

Results: We found that certain herpes group viruses, including cytomegalovirus and Epstein-Barr virus augmented HIV expression by stimulating monokine production. Other herpes viruses, such as herpes simplex virus, varicella zoster virus, and human herpes virus-6 were unable to function in this capacity. When non-herpes group viruses were tested, we found that human adenovirus, hepatitis B virus, and vaccinia virus all failed to stimulate the production of monokines capable of activating HIV in the chronically infected cell lines. Furthermore, HIV-1 can augment its own expression by inducing the secretion of monokines which upregulate HIV expression in the infected cell line. Monokine production mediated by viral antigens was not attributable to contaminating endotoxins.

Conclusion: These studies provide a model to determine whether other opportunistic infections may induce the expression of HIV by indirect mechanisms, such as the stimulation of cytokine production.

W.C.P.107 TNF- α CAN INDUCE THE EXPRESSION OF HIV PROMOTER CHIMERIC TRANSCRIPTS IN AN AUTOCRINE FASHION

Poll-The, J., Kinoshita, K.A., Folks, T.M., Fauci, A.S., ILR, NIAID, NIH Bethesda, MD; Georgetown University, Washington, DC, U.S.A.

Objective: To investigate the hypothesis that tumor necrosis factor alpha (TNF- α) can induce the expression of HIV-1 in T lymphocyte and monocyte cells. Our current objective was to determine whether TNF- α can induce HIV expression in autocrine fashion.

Methods: The T lymphocyte (ACH-2) and monocyte (U1) cell lines are chronically infected with HIV-1, and the constitutive low level expression of HIV can be potently induced (10-2 fold) by reverse transcriptase (RT) treatment with phorbol esters (PMA) or TNF- α . We therefore investigated the possibility that ACH-2 and U1 cells could synthesize and secrete TNF- α (as assessed by a specific Biotinyl kit) and could express TNF- α molecules on the plasma membrane (by immunofluorescent stain and FACS analysis). We also studied the expression of TNF receptors (R) on ACH-2 and U1 cells and on their parental uninfected cell lines in unstimulated and PMA stimulated conditions.

Results: TNF- α is not detectable in supernatants of unstimulated ACH-2 and U1 cells, but significant amounts (150 ng/ml) of TNF- α are present in the supernatants of both cell lines after 24 to 48 h stimulation with PMA 10^{-7} M, in parallel with the expression of HIV. Furthermore, TNF- α is present on the plasma membrane of ACH-2 cells after treatment with PMA. Of interest, PMA stimulation of ACH-2 and U1 cells resulted in the upregulation of TNFR. 2-3 fold whereas the levels of TNFR were found unchanged or downmodulated in the uninfected parental cell lines and were not exposed to PMA. **Conclusion:** TNF- α can act as an autocrine cytokine capable of inducing the upregulation of viral expression in cells of lymphocyte and monocyte origin that chronically carry integrated HIV provirus.

W.C.P.104

THE EARLY STAGES OF T LYMPHOCYTE ACTIVATION ARE INITIATED BY HIV-1 STIMULI AND DIFFERENT STAGES OF HIV-1 SPECIFIC P-45^{CAZ} AND P-24^{CAZ} ANTIBODIES. J. PLANET, UCLA Center of Infection, Los Angeles, CA, U.S.A.

Objective: To show the suppressive effect of HIV-1 infection on T lymphocyte proliferation and also the effect of HIV on lymphocyte activation.

Methods: Culture of activated HIV-1 pretreated P-45^{CAZ} stimulated cultures of lymphocytes.

Results: We and others have earlier reported a suppressive effect of a HIV-1 on T lymphocyte proliferation. Here we have extended these studies using different but more potent immunomodulatory preparations of HIV-1, HIV-2, and two different isolates of HIV-1, and showed that these all had a suppressive effect on T lymphocyte proliferation. Further investigation of a preparation of HIV-1 glycoprotein (gp120) showed that the addition of this preparation to cultures of peripheral blood lymphocyte severely decreased the proliferation induced by both CD4⁺ cell membrane and CD4⁺ membrane monoclonal antibodies as well as the response induced by phorbol esters (PMA) or the lymphocyte A23187, whereas the response to different concentrations of PMA (A23187) was almost completely unaffected. Studies of purified CD4⁺ cell membrane showed that the addition of HIV-1 gp120 to these cells inhibited the response to PMA. However, CD4⁺ cells that were not exposed to HIV-1 but were cultured in the presence of HIV-1 gp120 showed that the addition of HIV-1 gp120 to these cells inhibited the response to PMA. This indicates a decrease in the number of receptors expressed. Preliminary experiments showed that the increase in the number of CD4⁺ cells after stimulation with PMA was not inhibited by HIV-1 gp120 and that HIV-1 did not increase an increase in the intracellular Ca²⁺. Studies are in progress to determine the effect of HIV on the intracellular pathways of lymphocyte activation.

Conclusions: The current studies indicate that HIV-1 has a suppressive effect on both CD4⁺ cell membrane and CD4⁺ lymphocytes independent of infection and that this effect occurs in the early days of activation and may be due to the protein levels of CD4⁺. The results with HIV-1 gp120 may propose that the inhibition may also be proteinaceous.

W.C.P.106 EFFICIENT HIV ISOLATION FROM HEALTHY SEROPOSITIVE INDIVIDUALS USING NORMAL MONOCYTE TARGETS:

IMPLICATIONS FOR HIV CD4⁺ CELL SURVIVAL

Mansueti, F.E., Scheinin, S.M., Lane, H.C., Fauci, A.S., ILR, NIAID, NIH, Bethesda, MD, U.S.A.

Objective: To determine the efficiency of viral isolation and *in vivo* cellular source of HIV from peripheral blood mononuclear cells (PBMC) of healthy seropositive individuals. **Methods:** PBMC from healthy, HIV-seropositive individuals were cocultured with either Moloney P14 blast or monocytes obtained by elutriation. Supernatants were assayed for reverse transcriptase activity and p24 antigen. Cells were separated into highly purified lymphocyte and monocyte fractions by rosette and FACS techniques. Polymerase chain reaction (PCR) was used to amplify proviral DNA.

Results: When HIV isolation was attempted onto P14 blast or monocyte targets we found: in 1/23 (4%) patients, HIV could only be isolated by PBMC coculture with P14 blast; in 1/23 (9%) patients, virus could only be isolated when PBMC were cocultured with monocytes and in 5/23 (22%) patients virus could be isolated using both systems. Lymphotropism was performed on five of the seven patients whose viral isolation was accomplished only on monocytes. PBMC from these individuals were fractionated by rosette and FACS techniques (99% purity) and PCR was performed on each fraction. Despite the fact that virus could only be isolated onto monocytes, 4 out of 5 individuals had proviral DNA detectable only in their T cells, and in the other individual in both monocyte and lymphocyte fractions.

Conclusions: In healthy seropositive individuals, HIV could be isolated with greater than 50% efficiency using monocytes as targets as compared to 26% efficiency when using P14 blast targets. In 4 out of 5 patients from whom virus could only be isolated onto monocytes viral DNA could be detected *in vivo* only in T cells. Thus, *in vivo* monocyte tropism does not necessarily indicate *in vivo* monocyte infection with HIV.

W.C.P.108 QUALITATIVE DIFFERENCES IN HIV-1 AND HIV-2 INFECTIONS OF A PANEL OF CD4⁺ T CELL CLONES

W. C. Krawinkel, J. M. Fauci, A. S., ILR, NIAID, NIH Bethesda, MD, U.S.A.

Objective: To investigate the patterns of HIV-1 and HIV-2 infection *in vitro* in a panel of T cell clones expressing comparable amounts of CD4.

Methods: A panel of T cell clones obtained from the CEM-derived A301 cell line. Four clones expressing comparable levels of CD4 were selected from an original panel of 42 because of their differences in response to HIV-1 and HIV-2, as measured by reverse transcriptase activity (RT) released in the culture supernatant and by the kinetics and extent of cytopathic effect (CPE). Cell extracts were made from the four clones and tested for the presence of transcription factors by gel mobility shift assays for NF- κ B and Sp-1. **Results:** Two out of four clones were "fast/high" (peak RT activity 5000-9000 cpm) observed between day 4 and 7 post-infection) and two were "slow/low" (peak RT below 2000 cpm), observed between day 10 and 18 post-infection). HIV-1 and HIV-2 showed similar efficiency of infection in terms of RT and downmodulation of the CD4 molecule. The only evident correlation with the infection patterns described, HIV-1 and HIV-2 showed similar association of infection in terms of RT and downmodulation of the CD4 molecule. The only difference between HIV-1 and HIV-2 was that HIV-2 infection was frequently associated with a second burst of viral replication occurring in the absence of CPE in cells that had already lost the CD4 molecule from the plasma membrane. When cell extracts from the four clones were examined, no differences were noted in terms of binding to Sp-1 specific sequences. On the other hand, only 1 out of 2 "fast/high" responder clones showed detectable binding to NF- κ B.

Conclusions: Significant biological differences were observed among T cell clones expressing comparable levels of CD4 molecules in response to HIV-1 and HIV-2 infection. Different constitutive levels of NF- κ B transcription factor could partially explain these results.

W.C.P.115 ANEMIA AND LYMPHOPENIA IN HIV INFECTION: RELATION TO SERUM LEVELS OF TUMOR NECROSIS FACTOR- α
Mary, P.J.* and Labevirta, J.**
*Fourth Department of Medicine, University of Helsinki, **Aurore Hospital, Helsinki, Finland

Objective: Hematological abnormalities are common findings in patients with AIDS and AIDS-related complex. However, the underlying causes of the abnormalities are not well understood.

Methods: TNF levels in serum were measured by a double antibody radioimmunoassay in 37 HIV-seropositive subjects.

Results: Significant inverse relationships were found between serum TNF levels and hemoglobin values ($r = -0.83$, $p < 0.001$), as well as between TNF levels and peripheral erythrocyte ($r = -0.78$, $p < 0.001$) and lymphocyte ($r = -0.66$, $p < 0.003$) counts.

Conclusion: Since TNF suppresses the colony formation of erythroid and granulocytic progenitor cells in murine cultures and causes anemia when administered to humans and experimental animals, the demonstrated relationship between TNF and cytopenia in HIV infection may be causal.

W.C.P.117 IMMUNOHISTOCHEMICAL ANALYSIS OF GERMINAL CENTERS (GC) IN RECTAL BIOPSIES OF PATIENTS WITH HIV-1 INFECTION.

Rado, Paul*, Tanner-Rado, K**, Schmidt, H*, Hartmann*, Dietrich*, K.F. Popovic, M**
*Institute for Tropical Diseases, Hamburg, Germany; **A.K. St. Georg, Hamburg, Germany; ***National Cancer Institute, Bethesda, USA.

Objective: To investigate the role of the GC-s of the rectum in the pathogenesis of HIV we studied 33 rectal biopsies from patients with HIV-2 infection.

Methods: Detailed histological and immunohistochemical analyses of the rectal biopsies were performed.

Results: Immunohistochemical reactions revealed gc proteins within the GC-s. The network of follicular dendritic cells was often disrupted. An important characteristic was the decreased numbers of CD4 lymphocytes. A similar decrease was observed in the numbers of Leu7 positive cells. There were increased numbers of CD8 lymphocytes.

Conclusion: Our findings indicate that the GC-s are important reservoirs of HIV. CD4 lymphocytes and macrophages circulating through the GC may become infected with HIV there. We suggest that HIV can persist in the GC of the rectal mucosa for long periods or can be transported to the regional lymph nodes via the lymphatic vessels. The lymphatics then, quite possible serve as thoroughfares for HIV-1.

W.C.P.119 ESTABLISHMENT OF A CELL LINE CHROMOSOMALLY INFECTED BUT NOT TRANSMISSIONALLY FROM AN ANTROPATHIC RESISTIVE SUBJECT.
Tilli, Fausto; Fedorin, M.; Norsetti, A.; Casaccia, L.; Virelli, P. and Barbi, S.*
*Laboratory of Virology, Istituto Superiore di Sanità, Rome, Italy.

Objective: To study a) the latency and the chronicity of HIV-1 infection and b) the control of HIV-1 gene expression.

Methods: PBs from an asymptomatic HIV-1 seropositive and HIV-1 seronegative (Tilli, W.S.) subject were cloned by limiting dilution in presence of IL-2. The past medical history of the subject was characterized by recent-onset LAS (3 years ago) with virus isolation from lymphnodes. Further attempts, even at time of cloning, to re-isolate virus were negative, as determined by antigen capture and reverse transcriptase assays. Cell subset characterization was made using monoclonal antibodies anti-T and - α lymphocytes, monocytes and macrophage membrane antigens.

Results: Two cell clones (UB1, USA) carrying but not expressing the HIV-1 genome were isolated. The two clones have been maintained in culture for 75 months. Both are negative for extracellular virus production. Clone UB4 shows giant cells and an absolute requirement for exogenous IL-2. Cytofluorometric analysis indicated that both clones are not terminally differentiated. PCR-MSA analysis, using SOD, SDC2 HIV-1 gag primers followed by hybridization using oligonucleotide probe specific for gag region, was positive. Preliminary PCR-MSA analysis indicated the absence of active transcription of HIV-1 genome.

Conclusion: Cells with seropositive but not expressed HIV-1 genome are present in an asymptomatic seropositive individual. Further biological, immunological and molecular characterization of these clones is in progress.

W.C.P.116 REPLICATION OF HIV-1 GAG AND POL INTERGENE-ANT
RELATION MUTANTS IN HUMAN CELL LINES
Reisling, Volker*, Zahn, S.* and Sagury, D.,**
*IMM1-Hamburg, FKG, **Universitäts P. St. M. Curie, Paris, France.

Objective: Development of retroviral vectors for human gene transfer requires HIV-1 gene expression vectors with deletions in the gag or pol regions giving rise to a frameshift. All constructs were derived from pC₁, a plasmid containing the complete HIV-1 proviral genome, a hygromycin B gene for selection and the 3'LTR with deletions in the -138 to -40 region. Cells were analysed using immunofluorescence assays (IFA), reverse transcriptase activity (RT), Southern and western blots.

Methods: We have constructed various HIV-1 mutants, twelve containing insertion linkers and twelve with deletions in the gag or pol regions giving rise to a frameshift. All constructs were derived from pC₁, a plasmid containing the complete HIV-1 proviral genome, a hygromycin B gene for selection and the 3'LTR with deletions in the -138 to -40 region. Cells were analysed using immunofluorescence assays (IFA), reverse transcriptase activity (RT), Southern and western blots.

Results: All lymphocyte lines showed more than 60% cells positive when tested, using AIDS patient serum, one, two and five months after transfection. Supernatants were RT negative. When analysed by Western blotting the presence of p17, p24, p51, p55 and gp160 proteins was revealed in two cell lines, p0-89 and a gag deletion mutant. Viral preparations from supernatants are RT negative even when separated by sucrose gradient.

Conclusion: The transfected plasmids are stably transfected and express viral proteins. All cell lines are RT negative but a present we do not know if the 3'LTR deletion is responsible. Two cell lines, that release particles into the supernatant, are WB positive for the pol protein.

W.C.P.118 EVIDENCE FOR INTRAFOLLICULAR VIREMIA IN GERMINAL CENTERS OF LYMPH NODES OF CATS INFECTED WITH FeLV. AN ULTRASTRUCTURAL STUDY.
Tanner-Rado, Klara*, Morona, F**, Schmidt, H**, Rado, P**, K.F. Popovic, M***
*Institute for Tropical Diseases, Hamburg, Germany; **A.K. St. Georg, Hamburg, Germany; ***National Cancer Institute, Bethesda, USA.

Objective: Many cats infected with the feline leukemia virus develop follicular hyperplasia, severe immunodeficiency and die of opportunistic infections, very similar to human infection with HIV. Therefore we used the feline model to investigate the cellular mechanisms of the pathomorphology and pathogenesis.

Methods: Ultrathin sections of 33 lymph nodes among 5 cats infected and 1 control animal were taken 5 or 9 months after inoculation, according to standard methods.

Results: The ultrastructural changes of the very hyperplastic follicles revealed a high concentration of virus particles in the vicinity of follicular dendritic cells (FDC) as shown in HIV-infection. FeLV was found to replicate in different cell types: lymphocytes, plasma cells, macrophages and FDC.

Conclusion: The results suggest that FDC, as antigen trapping cells, capture FeLV. Virions held on FDC infect different target cells. Quite possible that a genomic shift may occur at the time of transmission of the virus to a novel target. Therefore, GC may be one of the anatomic sites where variants with altered cell tropism and pathogenicity may be generated.

W.C.P.120 INCREASED PRODUCTION OF ARABINOSIDE CATABOLITES (PROSTAGLANDIN E₂ AND THROMBOXAN B₂) BY HIV-1 INFECTED HUMAN ADIPOCYTES (VDA) INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS.

Yamamoto-Crua, Margarita; Zabay, J.M.; Longo, N.M.; Gomez, G.A.; Rosell, J.; Galis, H.*
Hospital General "Gregorio Marañón", Madrid, Spain. *Centro de Investigación y Desarrollo del C.I.C.I.C., Barcelona, Spain.

We have analyzed the production of PGs by monocytes from 19 VDA with different clinical manifestations of HIV infection and from 16 healthy normal individuals. HIV-1 seronegative VDA were cultured in the presence of culture supernatants of purified monocytes was performed by high performance liquid chromatography and radioimmunoassay. The results showed that in the AIDS group 21 of 21 patients showed PGs levels (134.4 \pm 108.7 pg/ml) higher than the mean \pm 2 SD values from healthy controls (7321 pg/ml). This group with HIV increased production of PGs by monocytes from AIDS patients induced a marked suppression of IL-2 production. HIV infection may alter the synthesis and secretion of PGs in monocytes which may lead to the immune dysfunction of AIDS.

W.C.P.121

Des oncogènes co-transfection induisent transactivation de l'HTLV-III
through NF- κ B binding sites.
**FRANCOIS-CRIVELLO, FRANÇOIS, ISHAI, M., BACHTELIERE, F., HANON, H., ALONZI, J.,
DOUTRY, F., WITTELLER, J.-F., FIMONDINO, P., LEROUX, M., BOUTIER, P., PARIS, A., S.B. D'Onofrio,
Molécules Vitales, France.**

Objectif: To ascertain whether p21ras (the product of ras protooncogenes induced during T cell activation) and a G protein with known transduction properties) can induce signals leading to HIV-1 transcription.

Méthode: Human cells of two different tissues, fibroblasts (HRC-5) and astrocytes (U8739G astrocytoma cell lines) were transiently transfected with vectors permitting the expression of the CAT reporter gene under the control of either the whole LTR of HIV-1 (LW-1-3ER) or various subcloned fragments of the LTR. A vector permitting the expression of co-receptor coding for a G21 protein with GTPase II1 mutation was co-transfected with LTR-CAT vectors.

Résultats: Co-transfection of co-receptor consistently resulted in a 2 to 22 fold transactivation of the whole HIV-LTR. We have performed further co-transfection of an HIV-1 infection provirus clone (pNL4-3) in this system, and shows that transcription of the provirus, including the p24 protein function induction, was induced by co-receptor transfection. Deletion of the LTR 126 bp region did not decrease but induced transactivation. The LTR enhancer was shown to be a main responsive element in this system, since a 96 bp fragment containing the enhancer, or a synthetic oligonucleotide with the exact sequence of the enhancer, increased the activity of the LTR 126 bp region. A 20 bp fragment upstream a TK promoter, versus a responsive to rat than the whole LTR.

Conclusion: Our observations are compatible with the hypothesis that endogenous p21 ras, induced during cell activation, participates in HIV-1 gene transcription through transactivation of the HIV enhancer.

W.C.P.123

HIV-1-ASSOCIATED CHANGES IN TRANSMEMBRANE SIGNAL
TRANSDUCTION IN MACROPHAGES
**Suzanne Gaudin and Yvonne R.
University of California, San Diego, CA, USA.**

Objective: Macrophages play an important role in the pathogenesis of AIDS. However, the mechanisms of HIV-1-induced dysfunction in macrophages are not well understood. We hypothesize that the macrophage dysfunction in HIV infection may be a result of a deficit in transmembrane signal transduction. Furthermore, adhesion molecules expressed on macrophage may play an important role in the transmission of HIV infection to CD4+ T cells as well as in inducing transmembrane signaling. The objective is to examine the changes in plasma membrane potential and in intracellular free calcium (Ca^{2+}) in uninfected macrophages (U937) and HIV-infected (937/HIV) macrophages.

Methods: Cells were cultured in the presence or absence of monoclonal antibodies against adhesion molecules, lymphocyte-associated antigen-1 and 3 (LFA-1, LFA-3) and intracellular adhesion molecule-1 (ICAM-1). Plasma membrane potentials were measured with DiOC2 dye and (Ca^{2+}) with Indo-1 dye using FACS.

Results: The membrane potentials of U937 and 937/HIV cells were 120 and 39 mV mean channel numbers respectively. Anti-LFA-1 and anti-LFA-3 induced hyperpolarization of both U937 and 937/HIV cells. In contrast, anti-ICAM-1 decreased (depolarized) membrane potentials of U937 (120 to 40 mV mean channel number), but increased the membrane potential of 937/HIV cells (39 to 60 mV mean channel number). The basal (Ca^{2+}) levels in U937/HIV cells were elevated (100 nM) as compared to U937 cells (90 nM). Anti-LFA-1 induced less increase in (Ca^{2+}) levels in U937/HIV (120 nM) as compared to U937 cells (180 nM).

Conclusions: This study demonstrates a deficit in the transmembrane signal transduction in macrophages infected with HIV, which could be responsible for macrophage dysfunction in AIDS. (Supported by USPHS Grant AI-26456).

W.C.P.125

HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS AS A POTENTIAL
COFACTOR IN HIV-1
**LOUIS, P., ENOEL, B., NEGRO, F., DE ROOCCO,
S.E.S., MARZBAN, P.D., GALLO, R.C., et al. NCI,
Bethesda, MD, Georgetown Univ., Rockville, MD, **Bionetics
Research, Inc., San Diego, U.S.A.**

Objectifs: To investigate the interactions between HIV-6 and HIV-1 in vitro and the potential role of HIV-6 in the pathogenesis and/or disease progression in AIDS.

Méthode: Human peripheral blood mononuclear cells (PBMC) or enriched adherent cells and established cell lines of T lymphocytic or monocytic origin were simultaneously infected in vitro with HIV-6 and HIV-1. Electron microscopy, immunohistochemical analyses and dual-probe *in situ* hybridization were employed to demonstrate dual infection at the single cell level.

Résultats: HIV-6 and HIV-1 can productively infect human CD4+ T lymphocytes of both normal and neoplastic origin, resulting in accelerated viral antigen expression and cellular death. Cells of the monoclonal phagocytic system can also be infected by the two viruses. HIV-6 is a potent transactivator of HIV-1. HIV-6-infected cells can be visualized in AIDS patients blood.

Conclusion: These *in vitro* observations suggest that HIV-6 is particularly suitable candidate as a cofactor in AIDS. Studies are underway to detect dual infected cells in PBMC from HIV-1-infected individuals.

W.C.P.122

CYTOKINE MODULATION OF HIV-REPRODUCTION IN
MONOCYTES/MACROPHAGES
**KUMASHI, THOMAS, ZORR, B. and HABERSMANN, K.-O.
Institute for Clinical and Experimental Virology, Federal Republic of Germany,
Berlin, Hinderburgstrasse 27, 1000 Berlin 46, F.R.G.**

Objective: Reproduction of different primary HIV-isolates (HIV-1/2) at a given multiplicity of infection (m.o.i.) in adherent monocytes/macrophages. Modulation of HIV-1 replication in monocytes/macrophages by cytokines and phorbol ester.

Résultats: All HIV-wildtypes (n=49) isolated from patients by cocultivation with peripheral blood lymphocytes (PBL) lead to our investigations to an infection in monocytes/macrophages. There were gradations regarding the productivity of replication, between low level and productive HIV-infection. The cell of intercurring defective particle will be discussed. Cytokines affected the HIV-replication in monocytes/macrophages in a dose dependent manner. Control cells had a stronger HIV-reproduction with rM-CSF and rGM-CSF especially if the cytokines were applied before HIV-infection. Also rIL-3 enhanced the HIV-replication in a positive manner. Treatment of monocytes/macrophages with phorbol ester (TPA) lead to time-dependent upregulation or activation of HIV-1 replication.

Conclusion: Low level HIV-replication in monocytes/macrophages can be changed to a more productive HIV-infection by different cytokines. Possible meanings about the *in vivo* situation will be discussed.

W.C.P.124

PREVALENCE AND SIGNIFICANCE OF ANTIBODIES TO nef (p27) IN
HIV-1 INFECTION
**CHEN, YUN, PAPPAS, D., BARNETT, R., FINEGOLD, C., HENNING, C. and
Weber, J., Department of Infectious Diseases, Royal Postgraduate Medical
School, London W2, U.K.**

Objectifs: To measure and analyse the humoral immune response to nef (p27) in serial samples from HIV-1 infected subjects.

Méthode: Purified recombinant nef protein derived from 8-001 (T-tropic, 3' proviral) was used as the antigen in a direct, anti-glyceralis ELISA assay. Specificity of the anti-nef response was confirmed with a large battery of HIV-negative sera, and by immunoblotting on HIV and on nef protein. Sera were obtained from serial blots over a six year period from homosexual men and haemophilic patients, and were further assayed for antibody to HIV env and gag proteins, and for HIV p24 antigen.

Résultats: Antibodies to nef appear simultaneously with antibodies to HIV structural proteins at seroconversion in 67% of cases. Only 1/65 seroconverters expressed detectable anti-nef antibodies prior to seroconversion. This subject had anti-nef present 7 month prior to full seroconversion. High initial titres of anti-nef antibody after seroconversion correlated with lack of progression to AIDS.

Conclusion: The expression of the nef protein prior to seroconversion occurs, but is a rare phenomenon (circa 1%). The titre of anti-nef does correlate with progression from disease in haemophilic, suggesting that this negative regulatory protein may slow viral replication *in vivo*.

W.C.P.127 HIV ENCEPHALITIS IN ADULTS AND CHILDREN

Rosnay-Vazex, M.C. Curoin, I. Montagier et al. Institut Pasteur, Paris, France.

Objectives: To study Human Immunodeficiency Virus (HIV) encephalitis in adult and children by identifying the HIV infectious virus and determining which additional pathogens are present.

Methods: We have extensively screened from CNS tissue of 43 adult and 6 children AIDS patients for the presence of pathogens using a combination of immunohistological staining and *in situ* hybridization.

Results: A first striking difference between adults and children infected with HIV was the detection of a massive and multifocal HIV encephalitis in 24/83 adult patients, but a failure to detect HIV antigens in 4/6 children who either died with severe and typical AIDS related encephalopathy, 2/6 children with immunologically detectable HIV encephalitis but less severe neurological symptoms. For adults and children, both single and double immunohistological procedures showed that all infected cells had macrophage/microglial cell phenotype, without any HIV antigen expression in astrocytes, neurons, or endothelial cells. The second striking difference between adult and children encephalopathies was the very frequent association with other CNS pathogens in adults, and their absence in infants with severe encephalopathies.

Conclusions: In adults, dementia is associated with multifocal and diffuse HIV replication, but the presence of severe neurological symptoms in infants without evidence of HIV replication in brain macrophages suggests that perinatal, productive viral infection is not required for the pathogenesis of HIV encephalopathy. Opportunistic associated pathogens might play an important role for iatrogenic HIV replication in adult brains.

W.C.P.129 IMMUNE DEFECTS FOR HIV INFECTION IN HLA HOMOZYGOUS (DR5)

Bentwich, Z.J.H.*; Mandel, Z.T.*; Burstein, R.*; Hershkovitz, H.B.*; Haber, T.*; Legor, S.** et al. *A. Ben Ari Institute of Clinical Immunology, **Rita Research Laboratory, Kaplan Hospital, Rehovot, ***Dept. of Pathology, Soroka Medical Center, Beer Sheva, Israel

Objective: To determine the role of immune cofactors to HIV infection. **Methods:** We have studied several immune parameters and functions in a cohort of 1000 male homozygous (DR5) in Israel, 144 of whom were followed for over 4 years and 18 seroconverted during that period.

Results: Elevated levels of serum acid labile α -interferon (aIFN), antibodies to nuclear antigens (Histones, SS-A, SS-B and Cardiolipin) antibodies to HIV, CMV and Chlamydia trachomatis, elevated cellular lymphocytotoxicity, with normal serum levels of tumor necrosis factor (TNF), extremely high inducibility of IFN- γ gene expression upon mitogen stimulation and lower levels of CD4 T cells were all found in a large proportion of HIV sero-negative individuals and preceded HIV infection. Further derangements of several of these immune parameters were observed following sero-conversion and at later stages of HIV infection.

Conclusion: Our studies suggest that immune dysregulation is common among HIV seroconverters. Our studies suggest that immune dysregulation is common among HIV seroconverters. Our studies suggest that immune dysregulation is common among HIV seroconverters.

W.C.P.131 QUANTITATION AND MODULATION OF HIV P24 ANTIGEN CONTENT IN INTESTINAL MUCOSA.

Rita Sahaj, Borwick, A; Kotler, DP
St. Luke's-Roosevelt Hospital Center and Columbia University, New York, NY, USA

Objective: To quantitate HIV replication in the intestine and to determine if viral protein production can be modulated *in vivo*.

Methods: Mucosal biopsies were assayed directly, or incubated *in vitro*. HIV content in homogenates was determined by p24 antigen enzyme ELISA. (Coated). *In vitro* incubation was performed in media containing varying amounts of hydrocortisone (5-2000ng/ml) or progesterone (2-200ng/ml).

Results: HIV p24 was found in 44/65 serum specimens, 18/24 biopsies from jejunum, 24 from ileum, 15 from right colon, 6/10 from left colon, and 7/10/4 from rectum. In several cases, p24 was detected in tissue but not in serum. When calculated by sample weight, tissue p24 was more than 100 times higher than serum concentrations. As compared to control sections (Digital rectum), either 50 ng/ml and 500 ng/ml cortisol significantly depressed p24 content after 48 hours in tissue and sodium in both AIDS and AARC in culture. 50M POE increased p24 content.

Cortisol (N=15)		Progesterone (N=7)	
50ng	500ng	50ng	500ng
860±23	401±9*	370±379	947±21*
		308±106	252±127

*p<0.05, **p<0.02, Mann-Whitney U test p<0.05

Conclusions: HIV p24 expression occurs throughout the GI tract. P24 content is higher in tissue than serum, implying transcellular localization in the gut. Mucosal HIV production can be modulated *in vitro*.

W.C.P.128 BLOCKING OF INFECTIVITY AND IMMUNOSUPPRESSION BY AN HIV ENVELOPE DERIVED SYNTHETIC PEPTIDE

Katze-Hommes, T. F. Kowalski, J. S. W. Whalley, A. B. Bernstein, L. and Morono, W. W. * IDEC Pharmaceuticals Corp., La Jolla, California. ** Department of Laboratory Medicine, University of California School of Medicine, San Francisco.

Objective: We have identified an epitope in the external envelope glycoprotein of HIV-1 that is likely to be involved in the binding of this molecule to its cellular receptor, CD4. Independent studies have confirmed the importance of this region in the HIV-1/CD4 interaction and, in addition, this region may contain an immunosuppressive T cell epitope.

Methods: An 18 amino acid synthetic peptide was synthesized and purified and its ability to block syncytial formation as well as be recognized by antibodies and T cells from HIV infected individuals was determined.

Results: The peptide would inhibit 100% of syncytial formation at a concentration of 100 ng/ml. Only asymptomatic HIV carriers had detectable levels of anti-peptide antibodies that were significantly different from normal, uninfected control subjects. The peptide did not induce proliferative responses in peripheral mononuclear cells from the HIV-seropositive individuals, either in the presence or absence of IL-2. Tetanus toxoid and CMV were used as positive controls in these studies. The peptide was shown to suppress recall antigen (CMV and tetanus toxoid) responses, but not PHA-induced proliferation.

Conclusions: The apparent immunosuppressive properties of this peptide indicate a potential pathogenic role of the HIV envelope in the pathogenesis of infection.

W.C.P.130 HYPOTHESIS: AIDS IS AN AUTOIMMUNE DISEASE CAUSED BY HIV PLUS ALLOGENEIC CELLS

Hutchinson, Geoffrey, W. and Cross, Michael D. University of British Columbia, Vancouver, Canada V6T 1W5

We suggest that the following factors are relevant to AIDS pathogenesis. Firstly, there is complementarity of CD4 and class II MHC. Hence gp120 can be regarded as MHC-mimicking, and the anti-viral immune response may include an anti-class II internal image component. Secondly, immunisation with foreign lymphocytes leads to the production of MHC-mimicking (i.e. MHC-image) antibodies. Since infection with HIV usually occurs coincidentally with exposure to allogeneic lymphocytes, infected individuals are likely to make MHC-mimicking antibodies.

These factors lead to the idea that AIDS is an autoimmune disease, that is triggered by a combination of HIV and allogeneic cells, rather than by HIV alone. These two stimuli produce MHC-image and anti-MHC image immune responses that seem likely to synergize with each other to destabilize the system. We have found anti-collagen antibodies in the sera of many homozygous, both HIV and HIV+, and in the sera of 16/16 homozygous AIDS patients. These antibodies are also found in alloimmune sera, graft versus host disease and lepra. Our results are consistent with AIDS being an autoimmune disease that is provoked by a combination of allogeneic cells and HIV. The theory leads to further experimentally testable predictions, and ideas concerning possible approaches for prevention of the disease. It suggests that vaccines consisting of gp120, gp60 and anti-CD4 may cause AIDS in individuals belonging to high risk groups.

W.C.P.132 CREATION OF A NEW TARGET CELL TYPE FOR HIV-1

Potanyi, Harry Gene; Volaky, D.J.; St. Luke's-Roosevelt Hosp Ctr Columbia University, New York, NY, USA.

Objective: To investigate the dichotomy between productive and nonproductive HIV-1 infection by construction of a hybrid target cell type between T cell and gall cell lines, and by analysis of its susceptibility to HIV-1.

Methods: A constant resistant BMT-1000B clone of the lymphoblastic T cell leukemia line, CEM, was selected and fused to US21MG, a cobain sensitive, HIV resistant astrocytic cell line with polydispersed glycolipid. Fusion products were selected in HAT-medium, which kills the parental cells.

Results: BMT, a hybrid derived from this fusion, was selected for further analysis. Like US21MG, BMT has gall morphology, growing as an adherent monolayer in tissue culture. Like CEM, and unlike US21MG, it displays high amounts of surface membrane CD4. Upon infection with a cytopathic molecular clone of HIV-1, HIV-BMT-A, CEM expresses HIV-1 antigens 5 days after infection, and is killed within 10 days; US21MG expresses approximately 100 fold less HIV-1 than CEM as measured by p24 antigen expression, and is resistant to killing by HIV-1. BMT on infection with HIV-BMT-A displays no cytopathic effects and 100 fold less HIV-1 antigens than CEM.

Conclusions: HIV-BMT-A's cytopathogenicity target cells can be dissociated from their high CD4 display. In this case, factors either i) contributed by the gall parent, or ii) contributed by the T cell parent, and suppressed by the gall parent, determine BMT's response to HIV-1 infection.

W.C.P.133 HIV DNA IS PRESENT IN A HIGH PERCENTAGE OF PERIPHERAL BLOOD MONONUCLEAR CELLS IN INFECTED INDIVIDUALS

Halla, Kåmø, LeRoux, E. and Spector, S.A.
University of California, San Diego Medical Center, San Diego, California USA

Objective: To determine the percentage of peripheral blood mononuclear cells (PBMCs) containing HIV DNA in infected individuals.

Methods: PBMCs isolated by Ficoll-Hypaque gradient centrifugation were counted by immunocytometry. Cells cell lysates of 10^6 , 10^5 and 10^4 PBMCs were subjected to polymerase chain reaction (PCR) for 35 cycles in the presence of primers SK38 and SK35 obtained from the Cetus Corp. The specific HIV sequence amplified from these lysates were subsequently analyzed by slot blot and Southern blot hybridizations with a specific HIV oligomer probe (SK19) (Cetus Corp).

Results: Using 10% of PCR mixture from 10⁶ PBMCs, specific HIV sequences were detected in 7/9 of patients with AIDS, 5/6 patients with ARC, 4/8 asymptomatic HIV seropositive individuals, and 10/10 HIV seronegative controls. In some of these PCR positive persons, amplified DNA could be detected in 10% of PCR mixtures with only 10 PBMCs, indicating that greater than 10% of PBMCs contain HIV DNA in these infected individuals.

Conclusions: Using *in vitro* amplification of HIV DNA by PCR, we have detected a very high percentage (greater than 10%) of PBMCs containing HIV sequences in seropositive individuals. This reflects a substantially higher percentage of PBMCs primally infected with HIV than previously reported by using the *in situ* hybridization (10⁻⁶-10⁻⁷). These findings may be important in establishing the severe immunologic deficit associated with HIV infection.

W.C.P.135 BLOCKING OF ANTIBODY-ENHANCED HIV-1 INFECTION BY RECOMBINANT SOLUBLE CD4 (rCD4)

Zelma, Highland, Byrn, R.A., 828 Groopman, J.S., New England Deaconess Hospital, Boston, MA U.S.A.

Objective: To test whether rCD4 can block antibody-enhanced HIV-1 infection of Fc γ -receptor (FcR) expressing cells.

Methods: The monocytic cell line, U937 served as an target for HIV-1. HIV strain infection, FcR and CD4 expression were measured by flow cytometry. Virus neutralization tests were performed by mixing dilutions of heat inactivated patient sera with 100TCID₅₀ of HIV-1. After incubation for 1 hr at 4°C, U937 cells were added and infection was monitored by reverse transcriptase activity. High concentrations of patient sera neutralized HIV-1 but a subneutralizing concentration from the same patient enhanced infection. The role of CD4 in this antibody-enhanced infection was tested using rCD4.

Results: Flow cytometry of U937 cells showed that 74% express FcR11 and 97% express CD4. At subneutralizing concentrations (10⁻²-10⁻⁶ dilutions) 5 out of 6 patient sera enhanced viral infection. The enhancement index was 1.2 to 2.18 in comparison with HIV-1 Ab-negative sera. This enhancement of HIV-1 infection was totally blocked by 1 μ g/ml rCD4.

Conclusions: Some HIV-1 Ab-positive human sera can neutralize HIV-1 and at higher dilutions enhance infection. Because rCD4 can block this enhancement, this PCR dependent infection pathway is also CD4 dependent.

W.C.P.137 STRESS MEDIATED INDUCTION OF HIV EXPRESSION FROM A CHRONICALLY INFECTED PROMONOCYTOGENIC CELL LINE

Staley, Sharkey, Fokas, T.M., Fauci, A.S., LR, NIAID, NIH, Bethesda, MD U.S.A.

Objective: To investigate the ability of various cell stressors to induce expression of HIV from a strain of latent or non-replicating HIV-1.

Methods: A chronically HIV-1 infected virus producing promonocytic cell line (U1) derived from infection of U937 cells was exposed to varying doses of UV-C, UV-B, or UV-A. Virus induction was measured by quantification of reverse transcriptase (RT) activity in cultures exposed to heat shock (41.3°C for 1.5 hours) and followed for appearance of RT activity over several days.

Results: A 2-3 fold induction of RT activity over untreated cells was seen at 3-5 days after UV-C and UV-B stimulation. Peak induction was seen over a narrow dose range of 0.75-1.0 mJ/cm² for UV-C and 7.5-9.0 mJ/cm² for UV-B. UV-A, which does not usually cause DNA damage, did not induce HIV expression in this cell line. FPA experiments also revealed a time dependent increase in percent positive cells after UV-C exposure. Decreased cell viability and a temporary growth arrest (suggesting cell stress) were associated with UV doses which induced HIV. Cells exposed to heat shock also showed an increase in RT activity over controls and were followed for appearance of RT activity.

Conclusions: Chronically infected U1 cells can be induced to express HIV by UV irradiation in wavelengths that cause cell stress and by heat shock.

W.C.P.134 PLASMA-ASSOCIATED HUMAN IMMUNODEFICIENCY VIRUS TYPE-1 (HIV) IS A MIXTURE OF PHENOTYPES OF HIV INFECTIONS.

Robertson, W. Washington, Seattle, WA, USA.

Objective: To assess the diversity and time course of HIV plasma viruses and whether the development of plasma viruses correlates with progression of disease.

Methods: We sequentially cultured cell-free HIV from a cohort of CDC class II, III, IVa and IVc patients. Three ml of plasma was removed, passed through a 0.45 micron filter to remove cells, and 2 ml was then added to 10⁷-1.4 day old PHA-stimulated donor peripheral blood mononuclear cells (PBMC) and cultured by a standard anti-lymphocyte procedure.

Results: All 67 sequentially sampled patients had HIV isolated from their initial and all subsequent PBMC specimens. Twenty-five CDC class IVa (AIDS) patients had plasma samples taken at a mean interval of 6 weeks (range 2-12 wk). Plasma viruses were detected in 21 of their first sampling and 21 had HIV re-isolated from the plasma on subsequent sampling. Of the 4 in whom HIV was not initially detected in plasma, 3 had HIV isolated from plasma on a second sampling. Fourteen patients in CDC class II and III (asymptomatic) and 28 in CDC class IVb (ARC) were sequentially sampled at a mean interval of 6 months (range 1-26 months). 14 (74%) of the initially plasma viremic patients remained persistently positive on re-sampling.

Three of 12 CDC class IIb versus 14/12 CDC IVc who were initially plasma HIV negative developed plasma viremia over follow-up (p<0.01). Three of 4 CDC class IIb patients with plasma viremia progressed to more symptomatic clinical disease versus 0/8 without plasma viremia (p=0.04). The CD4-cell count decreased significantly for 6 patients that progressed to plasma viremia (Wilcoxon signed rank p=0.006) as compared to 7 that remained HIV-negative (p=0.88) and 7 that remained seronegative (p=0.11).

Conclusions: Previous cross-sectional studies indicated that the frequency of plasma viremia increased with stage of infection; these data indicate that the frequency of plasma viremia progressed over time, that once it develops it persists and is associated with a decrease in CD4-cell count.

W.C.P.136 HIV-2 SEROCONVERSION IN SENEGAL, WEST AFRICA

Mawya, Sillmon*, Enkai, M., *Obong S.M., Mouton, K.*, Travers, K*, Ester, M*, et al. *Harvard School of Public Health, Boston, MA, USA, ** University of Dakar, Dakar, SENEGAL.

Objective: HIV-2 has been found in high rates in populations of West Africa where as yet high rates of AIDS cases have not been described. This has suggested that HIV-2 may differ in pathogenicity from HIV-1. In order to evaluate this on a population level the rate of seroconversion of the virus is important to determine. Through evaluation of seropositive plasma from a high risk group in Dakar, Senegal, we determined and characterized seroconversion in this population.

Methods: A population of 1300 registered female prostitutes had been followed with serological serially since 1985. All serum samples were evaluated for antibodies to HIV-1 and HIV-2 by immunoblot.

Results: 14 women were found to seroconvert to HIV-2 with 22.6 percent-years of observation. The mean time of observation prior to seroconversion was 17 months. At the time of seroconversion antibodies to the new gene products gp38-40 and gp100 for HIV-2(A05) were readily detected by immunoblot. 14/14 had antibodies to p24(gag), 13/14 to gp96(gp120), 11/14 to gp51(gp41), and 8/14 to p15(gp16). HIV-2 seroconverters were compared to 1100 women (963 percent-years) who remained seronegative. Risk factor analysis showed that seroconverters were significantly older than non-seroconverters (p<0.025). Nationality or years of prostitution were not significant risk factors for seroconversion. None of the seroconverters developed AIDS or related signs. The seroconversion rate was found to be less than 2% per year based on percent-years of observation in this large high risk population.

Conclusions: Seroconversion for HIV-2 appears quite low despite over 10% infection in this high risk population. This suggests slow spread of HIV-2 in contrast to HIV-1. The stability of this virus infection in the absence of AIDS further indicates important biological differences between HIV-2 and HIV-1.

W.C.P.138 ANTI-HISTONE H2B ANTIBODIES IN HIV-SEROPOSITIVE

Maroux, W.J.W.*, Whalley, A.S.*, Leahy, C.*, Rosenberg, J.*, Stricker, R.B.** and McClellan, J.A.**

* IDIC Pharmaceuticals Co., La Jolla, California, ** Laboratory of Microbiology, University of California School of Medicine, San Francisco, California, *** Division of Infectious Diseases, University of California Medical Center, San Diego, California

Objective: The purpose of this study was to quantitatively measure the levels of anti-H2B antibodies in HIV-seropositive individuals to assess whether the prevalence and levels of antibodies correlated with disease status.

Methods: Previous studies carried out in our laboratories have demonstrated the presence of anti-lymphocyte antibodies in individuals with AIDS and at risk for AIDS. These antibodies are specific for a 18 kd antigen present on activated or HIV-infected CD24⁺ T cells. Further studies on the 18 kd antigen have revealed that it is biochemically similar to, and immunologically cross-reactive with, histone H2B.

Results: The prevalence of anti-H2B antibodies in serum specimens tested was as follows: AIDS, 13/38 (34%); ARC, 19/31 (61%); lymphadenopathy syndrome, 41/132 (31%); HIV-seropositive asymptomatic, 3/19 (16%); HIV-seronegative normal controls, 4/20 (20%). The normal range was established as the mean \pm 2 SD of 50 samples in the normal control group. There was only a weak correlation of $r = 0.42$, $p = 0.006$ between serum immunoglobulin levels and titres of anti-H2B antibodies.

Conclusions: Although the prevalence of anti-H2B antibodies was associated with progression of disease, there was no clear relationship between these antibodies and the numbers of circulating CD4 cells.

Th.C.P.7

PROSPECTIVE STUDY OF NEWBORNS TO HIV SEROPOSITIVE MOTHERS: PROGNOSTIC VALUE OF ANTIGENEMIA AND ANTIBODY WESTERN-BLOT ANALYSIS

Isabelle Christian¹, Myriam MJ², Jeanne C³, Blanche S⁴, Odile C⁵
¹ French HIV Institute in Newborn Collaborative Study Group.
² Hôpital Necker, Paris, France; ³ Hôpital U292, Grenoble-Hôtel, France.

Objective: The results of two virological parameters evaluated at 8 months of age were correlated to the clinical state at the age of 18 months, among 86 children born to HIV seropositive mothers.

Methods: 415 infants have been prospectively followed since birth, in a multicentric French study. Among 200 children born 18 months earlier or more, 86 evaluated in the same laboratory were included in this analysis. HIV antibodies were studied by Western Blot analysis (Diagnostic Pasteur or Dupon de Nemours) and classified into two groups: 1 = negative or inconclusive pattern; 2 = positive pattern, with antibodies to p24 and/or p31 and/or detection of antigens as performed by immunospot assay (Abbott or Diagnostic Pasteur). At 18 months of age the children were classified into two groups according whether they had presented HIV related clinical symptoms or not.

Results: The percentage of children with clinical symptoms is 28 % at 18 months of age. This percentage significantly differs according to positive or negative assignments at 8 months of age (100 % vs 18 % respectively, $p < 10^{-5}$). The same pattern is observed with Western-blot (89 % when positive, vs 11 % when negative or inconclusive, $p < 10^{-5}$). As the two virological parameters were correlated, adjustment has been performed, each of the two factors is associated to the clinical state independently of the other.

Conclusion: The presence of a complete pattern of Western-blot or of a positive assignment at 8 months of age are highly predictive of the appearance of clinical symptoms at 18 months of age or earlier.

Th.C.P.9

THE HIV-1 PROTEINASE IN PERIPHERAL BLOOD MONONUCLEAR CELLS INDUCED BY ANTI-2 DE MICROFILM MONOCLONAL ANTIBODIES.

GERBAUD J., SPAIN C., BERTHIAUX J., VIT F., BERTELIER F. and GERBAUD J.

Unité de Recherches SIDA et les Techniques de Sérologie et Moléculaire (U-322) - Centre de l'Institut de la Santé - 13073 Marseille Cedex 9 - FRANCE

We have recently searched for monoclonal antibodies (mAb) interfering with HIV proteinase. The "in vitro" assays used for the screening were for rapid identification of mAb interfering sites with virus, replication or budding of the virus: most of the anti-2mAb (282) mAb tested strongly delayed HIV-1 proteinase by peripheral blood mononuclear infected cells. Our recent data suggest that anti-2mAb mAb do not inhibit HIV virus state cellular proliferation with this mAb do not prevent HIV-1 proteinase, and therefore interfere rather after virus penetration during the viral replication cycle, either on the replication or the viral particle budding. Preliminary investigations demonstrate that inhibition is efficient if mAb is added to the culture only during the virus first few following infection. However, no inhibition is observed when mAb is added to the cells 8 h after the infection. Finally, anti 2mAb - mAb also delayed virus appearance since infected HIV cells, but has no effect on HIV-1 proteinase by CD4 cells.

Th.C.P.11

ISOLATION OF HIV-2 STRAINS WITH DIFFERENT NEUTRALIZATION PATTERNS USING CELLULAR, MONOCLONAL ANTIBODY AND RIBONUCLEIC ACID POLYMERIZATION ASSAYS.

**Christine J. van der Vliet¹, Thomas A. Schulz², Hilson Mulliken³
 and Robin A. Weiss⁴.** ¹Institute of Cancer Research, Fulham Road, London, UK; ²Vitic Laboratories, MA, USA; ³The Genie.

Objective: To study the variability of HIV-2 isolated from patients with variable neutralization patterns and to understand the implications of this variability on primary sequence and biological phenotype, a neutralization by sera of different origin, cytopathic effect, tropism for T-cells or macrophages.

Methods: Peripheral blood mononuclear cells from HIV-2 positive individuals in 270 patients were cultured with third blood culture and checked weekly for reverse transcriptase activity. HIV-2 strains were isolated from 120 (44%), CD4⁺ 101 (84%), CD37⁺ were used to cultures showing RT-activity or cytopathic effect to obtain pure cultures. These were characterized by Southern Blot, radioimmuno-precipitation assays (RIPA) and sensitivity to neutralizing antibodies. Fragments of the genome generated by PCR were cloned for sequencing.

Results: Among 4 new permanent isolates of HIV-2 made thus far one from an AIDS patient grows rapidly, one from an asymptomatic individual grows slowly, and the remaining two from SAC patients are intermediate. The former was characterized by Southern Blot and RIPA as HIV-2 viruses. Using PCR, regions corresponding to the gag gene and one portion of the env (HIV-2) could be amplified from 11 isolates. HIV-2 (200) gene and from the gag (1741-3343) could only be amplified from 3 and 1 isolates, respectively. This suggests a marked variability in their susceptibility to neutralizing antibodies from HIV-1 and HIV-2 infected subjects.

Conclusions: Four new isolates of HIV-2 differ in their growth properties and susceptibility to neutralizing antibodies. Genome variability is being analyzed.

Th.C.P.8

THREE DIMENSIONAL ELECTRON MICROSCOPY OF HIV-1 INFECTED MACROPHAGES (IN VITRO AND IN VIVO)

Cah, Hana¹, J. Jendry², J. Fleury³, Ph. Grenier⁴, D. Lussery⁵, M. J. Lys, B. J. Sch⁶
¹ Swiss National Center for Research, Center for Electron Microscopy, University of
 Institute for Immunology and Virology, Zürich, and ² Compagnie Genbi, Switzerland.

³ Laboratoire du Traitement du Signal et Instrumentation, Université de Saint-Etienne, et
⁴ Service d'Anatomie-Pathologique, CHU Henri Mondor, Créteil, France.

Objective: Analysis of the 3-D ultrastructure of HIV-1-infected macrophages in vitro and in vivo (bronchoalveolar lavage) and comparison with similar non-infected cells.
Methods: Computer-aided volumetric ultrastructure based on serial sections (20 to 40 nm) containing laser-induced topographical references allows a 3-D reconstruction of entire cells via digital processing of electron microscopy images.

Results: The 3-D analysis offers an improved knowledge of cell ultrastructure and documents the fine cytophotic effects of HIV. The detailed results will be presented on a computer display.

Conclusion: The computer-aided 3-D analysis has potential advantages and proved particularly powerful in the study of HIV-infected cells. The methodology will be useful to delineate new approaches for evaluation of therapeutic agents.

Th.C.P.19 MOLECULAR INTERACTIONS BETWEEN HIV-4 AND HIV-1 IN COINFECTED CD4⁺ T-CELLS LEAD TO INCREASED HIV-1 GENE EXPRESSION

Essaji, Barbara; Lusso, P.; Schaefer, F.; Rappoport, J.; Josephs, S. and Weiss, R.
Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD, U.S.A.

HIV-4 can superinfect HIV-1 infected human CD4⁺ T-cells, leading to increased and accelerated cell death. HIV-6 infected cells are also capable of stimulating expression of a reporter gene linked to the HIV-1 LTR. Increased HIV-1 LTR transcription is obtained when HIV-6 infected cells are co-transfected with the HIV-1 LTR gene, or when doubly infected cells are used. In fact, sequences necessary for HIV-1 activation by HIV-6 are distinct from those required for the LTR response and map to a region of HIV-1 LTR where nuclear proteins, activated or induced by HIV-6 infection, specifically bind. Increased levels of HIV-1-specific transcripts are seen by *in situ* hybridization in HIV-6/HIV-1 doubly infected cells as compared to HIV-1 HIV-1 infection. These data suggest that since both viruses, HIV-6 and HIV-1, share similar cell tropism, coinfection of CD4⁺ T-cells may play an important role in the progression of HIV-1 infection to AIDS.

Th.C.P.21 ISOLATION OF HIV IN A HIV-1/HIV-2 DUAL SEROCONVERTED CHILD INFECTED WITH TRANSMISSION CHARACTERISTICS WITR PCR

Roussin, Christine; Bergot, M.; Courauval, V.; Bédou, C.; Gassanq, C.; Berhe, P. et al.
Hôpital NECKER-ENFANTS MALADES, Paris, France.

Objective: By means of a seroepidemiological study among 146 patients multitransfused in Paris, we found one dual seroconversion (S1) with HIV-1 and HIV-2. The Wilkeson disease was transfused on a first and unique occasion in April 1984. We have chosen to use the selective DNA amplification technique by polymerase chain-reaction (PCR) to type the proviral sequences, specific for HIV-1 or HIV-2.

Methods: Sers were tested with both type III ELISA, Western-blot (HIV-1 or HIV-2 from Diagnostic Pasteur) and with polymerase chain-reaction (PCR) in a conserved region of the transmembrane protein. Diagnostic Pasteur. Proviral DNA sequences were modified by PCR using primers and probes for HIV-1 (pnl and env regions) for HIV-2 (gag, env and LTR regions).

Results: The serological analysis of patient's sequential sera (from April 1984 to Dec. 1988) using three specific techniques, shows a true double reactivity for both viruses; a simultaneous double seroconversion between April and May 1984; a profound decrease of anti-p24 antibodies between 1984 and 1988 (to remain the titre of HIV-2 antibodies directed against 20% percent at a high level). DNA proviral sequences were detected by PCR for pol and env regions of HIV-1, and for gag and LTR regions of HIV-2. These results were obtained from the different viruses isolated by coculture and from the peripheral lymphocytes of the patient.

Conclusion: This dual positivity obtained by serology and by PCR in a French patient raises the possibility of a dual HIV-1/HIV-2 infection or of an infection by a dual virus containing both HIV-1 and HIV-2 related sequences.

Th.C.P.23 CHARACTERIZATION OF NEF GENES FROM HIV AND HIV-2

Reau, J. L., Bulter, C.V., Dental, M., Deverosters, M.C., New England Regional Primate Research Center, Harvard Medical School, Boston, MA, USA.

Objective: To compare the nucleotide sequences of NEF genes and to examine the function of the NEF gene *in vitro* and *in vivo*.

Methods: Infectious molecular clones of HIV and HIV-2 were subcloned into pLNCX2 and H13 vectors for sequencing and manipulation. DNA sequencing was performed using the primer extended dideoxy method. Genes were mutated by oligonucleotide directed mutagenesis or by restriction site specific mutagenesis. Virus was obtained by transfecting cloned DNA with DMEM dectran. **Results:** Mutations that alter the size and content of NEF are common in infectious molecular clones. The HIV-2NEF gene contains a 3NA in-frame stop signal 93 codons from the initiating AUG predicting a protein product 658 shorter than that of HIV-1NEF. A premature truncation of NEF is also observed in clones HIV-2NEF251 and HIV-2NEF268. HIV-2 encodes a NEF in which a segment of 15 amino acids are different from the other sequenced NEF genes. The introduction of a frameshift mutation that removes 748 of NEF coding sequences in the HIV-1 cloned virus did not affect the ability to replicate in H978 cells. A single nucleotide has been changed in HIV-239 to create a fully open NEF reading frame in this clone with the properties of HIV-239 with open, truncated and intact NEF genes are being compared both *in vitro* cultured cells and in infected macaque monkeys.

Conclusion: Changes that increase NEF expression occur frequently in infectious molecular clones of HIV and HIV-2. These findings are consistent with the proposed role of NEF in mediating repression of viral gene expression. Mutational analysis of the NEF gene is complicated by difficulties in defining the sequence of functional, wild type NEF.

Th.C.P.20 INDUCTION OF HUMAN IMMUNODEFICIENCY VIRUS EXPRESSION BY ULTRAVIOLET LIGHT

Siddiqui, M. Bazz; Tschacher, E.; Valerio, K.; Rosenberg, N.M.; Felner, B.K.; Pavlakis, S.N.; Wang-Su, F.; "Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, MD; *Smith, Kline and French, King of Prussia, PA; **BRI-Basic Research Program, National Cancer Institute, Frederick, MD, USA.

Objective: Recent data demonstrate that ultraviolet (UV) light and certain chemical agents activate transcriptional level of HIV-1 LTR-directed gene expression. We have examined effect of UV on activation of HIV-1 promoter in an attempt to elucidate mechanisms by which UV light may induce a latent virus. **Methods:** We have developed several human cell lines clones each containing a distinct form of a stably integrated 100/200 unspliced HIV-1 provirus. Adherent (H1a) and non-adherent (H9) cells expressing HIV-1 constitutively have been used in amplification of virus release after UV irradiation. UV irradiation leads to activation of HIV-1 provirus which is transmissible to CD4⁺ H9 cells. Characteristic syncytial cells and simultaneous virus propagation comparable to wild type were observed as early as two weeks after UV treatment. UV was highly effective for *lat(-)*, but not for *reg(-)* mutants under identical conditions. **Conclusion:** These findings raise the question of whether natural occurrence of UV light might contribute to the pathogenesis of AIDS. We propose that UV radiation of skin might directly or indirectly activate latent virus resident to human epidermal Langerhans cells and/or subepidermal T lymphocytes.

Th.C.P.22 Binding Characteristics of HIV-1 and HIV-2:

Differences in Binding Inhibition by Soluble CD4 and Dextran Sulfate
H. F. Franghili, G. J. Broder, S. J. Beauford, R. J. and Woung, C. M. and Deaton, J. A., Walter Reed Army Institute of Research, Washington, D.C., *DOD COP, NCI, Bethesda, MD., 3 LTRs, NCI, Bethesda, MD., U.S.A.

Objectives: Examine binding characteristics of different HIV-1 and HIV-2 viruses, and binding inhibition by soluble CD4 (sCD4) and dextran sulfate. **Methods:** Viruses (HIV-1: 89BR, HXII, W83-1, HIV-1-Hiig; HIV-2: 2HIV-2gp, HIV-2gp, SH166 clone IV, and HIV-2g) were labeled using 3,6³H uridine, and binding and binding inhibition assays performed on H9 and Molt-3 cells. **Results:** Binding affinities were similar for HIV-1 and HIV-2, but numbers of saturable binding sites varied eight-fold. HIV-2 viruses were much less susceptible to binding inhibition by sCD4, while OKT4 monoclonal antibody and dextran sulfate inhibited binding of HIV-1 and HIV-2 in an identical fashion. These differences may reflect the involvement of accessory cell surface molecules in HIV-2 binding or penetration; however, differences in the structural relationship or the stability of envelope proteins in HIV-1 and HIV-2 is suggested by the presence of differing ratios of sCD4-detectable envelope protein in purified virions and virus-free supernatants from HIV-1 and HIV-2 infected cultures.

Th.C.P.24 *IN SITU* HYBRIDIZATION ANALYSIS OF HIV RNA INDUCTION

IN U1 CELLS TREATED WITH PHORBOL MYRISTATE 13-ACETATE
Russo, H., Malzman, M., Sellers, B., Sanders, A., Laumann, J. and Rosenzmann, Maurice*
*Egan Biotech, Inc., New York, New York, USA, **Cornell University School of Medicine, New York, New York, USA.

Objective: To determine the kinetics of RNA production following activation of latent HIV infection in cellular level using non-nucleolar RNA. **Methods:** Cultures of U1 cells, which contain 2 copies of latent HIV provirus, were treated with 5 ng/ml phorbol myristate acetate (PMA) and maintained in 5-10X10⁶ cells/ml. At various times, the cells were deposited on microscope slides and fixed with ethanol. HIV RNA in the fixed cells was hybridized to a biotinylated DNA probe that contained the entire HIV genome. The hybridized probe was detected using a streptavidin-alkaline phosphatase complex. The assay was completed in 4-5 hours.

Results: In untreated control U1 cultures, 0.5% of the cells expressed detectable levels of HIV RNA. At 24, 48 and 72 hours after exposure to PMA, the fraction of cells expressing detectable levels of HIV RNA increased to 32%, 67% and 60%, respectively. The amount of RNA per cell varied considerably as indicated by the intensity of staining. Unlabeled cultures contained about 4500 cpm/ml of reverse transcriptase activity. The reverse transcriptase activity increased 19, 4.0 and 3.4 fold at 24, 48 and 72 hours after exposure to PMA.

Conclusion: *In situ* hybridization is a more sensitive indicator of HIV induction than reverse transcriptase activity since the extent of induction observed is much greater. Additionally, heterogeneity at the cellular level is revealed. It is used to study HIV induction under other conditions and to evaluate the effect of various inhibitors on HIV expression.

Th.C.P.31 GENERATION OF HYBRID HUMAN IMMUNODEFICIENCY VIRUSES
SILVERMAN, ALBERTSBERG*, Kalyanaraman, S.; Deuel, S., Jr.; Dwever, S., Jr.; and Jamson-Near, R.; Centers For Disease Control, Retrovirus Atlanta, Ga. USA, Human Retrovirus Department, Abbott Laboratories, Abbott Park, Illinois, USA.

Objective: To investigate the viral determinants underlying tropism and cytopathic effects of HIV, hybrid HIVs were generated.

Methods: Varying 5' or 3' proviral DNA fragments of biologically infectious HIV clones (HIV₂, HIV₂*, HIV₁ III and HIV₁gag₁) were used as substrates for recombination. The proviral 5' or 3' DNA fragments were introduced into cells by calcium phosphate precipitation method and hybrid viruses released from the cells were quantitated by HIV antigen assay.

Results: Truncated HIV₂ DNA with proviral DNA was transfected into human rhabdomyosarcoma cells, HIV₁ released from the cells were quantitated at the end of 3 and 5 days after transfection. Hybrid HIVs with different 5' and 3' ends were generated using the molecular clones. HIVs were infectious upon inoculation into FRLs and their genetic structures were determined by Southern hybridization analysis.

Conclusion: Construction of hybrid HIVs based on compatible restriction enzyme sites present in viral DNA has limitations because of extensive variability between different HIVs. Homologous recombination methodology provides an efficient alternate method for generating hybrid HIVs.

Th.C.P.33 LOCALIZATION OF THE DEFECT IN HIV PROVIRAL DNA BY HOMOLOGOUS RECOMBINATION
SILVERMAN, ALBERTSBERG*, Kalyanaraman, S.; Butler, Jr. D., Jamson-Near, R.; York, D. and De, B.; Centers For Disease Control, Retrovirus Disease Branch, Atlanta, Georgia, USA.

Objective: Homologous recombination methodology was used to localize the defect in a HIV₂ proviral DNA.

Methods: High molecular weight DNA extracted from HIV₂/HIV III cells was cleaved with the $\text{Eco}I$ enzyme and the proviral DNA was molecularly cloned. Clone designated Xba1 was subcloned in a plasmid vector and tested for the virus production by DNA transfection. Reverse transcriptase (RT) and antigen assays were used to quantitate the virus released from the cells transfected with the proviral DNA. Truncated proviral DNAs were generated using standard recombinant DNA techniques.

Results: The proviral clone Xba1 was transfected into human ED cells. Unlike other proviral DNAs, Xba1 DNA transfected cells did not release virus which could be quantitated by RT assay. In cotransfection experiments with HIV ITR-GAT, Xba1 was able to transactivate the HIV ITR-directed expression as other proviral DNAs. Cotransfection of the Xba1 DNA with other truncated proviral DNAs (5' end) was able to increase the virus antigen detected in the medium. 3' end of Xba1 was inactive whereas 5' end was active in cotransfection experiments involving homologous recombination.

Conclusion: The defect in an HIV proviral DNA was localized by using truncated viral DNAs in cotransfection experiments. This approach narrows the region for molecular analysis to identify the nature of the defect.

Th.C.P.35 DISTINCTION BETWEEN HIV-1 AND HIV-2 INFECTION USING ANTIBODY RESPONSE TO ACCESSORY GENE PRODUCTS
Goudim, Jean*, Dekker, T., Boucher, C., De Ronde, A., Deboux, Ch., Metz, F.

*Human Retrovirus Laboratory, Amsterdam, the Netherlands, **Department of Molecular Genetics, Sanofi-Sintelabo, French Laboratories, King of Prussia, PA, USA, ***Laboratoire de Virologie, INSERM, Strasbourg, France.

Objective: To distinguish HIV-1 or HIV-2 infection by using of response to the accessory gene products: tat, rev, vif and vpr.

Methods: Sera of HIV infected individuals from East-Africa and from West-Africa were tested for reactivity with tat, rev, vif and vpr protein expressed in $\text{Eco}I$ by enzyme-linked immunosorbent assay.

Results: Nine (18%) West-African sera had reactivity to HIV-1 accessory gene products relative to 27 (93%) of the East-African sera. Antibodies to the HIV-1 tat, rev and vpr gene products were significantly ($P < 0.0001$) more often present in East-African sera compared to West-African sera. Antibodies to vif and vpr were completely absent from all West-African sera, but also from 33% respectively 55% of the East-African sera.

Conclusion: These results render typing of the infecting HIV strains solely based on HIV-1 accessory gene product reactivity difficult, but reactivity to vif and vpr may also be discriminating power of type-specific serology by seroprevalence.

Th.C.P.32 FACTORS INFLUENCING HOMOLOGOUS RECOMBINATION BETWEEN HIV DNA IN CULTURED HUMAN CELLS
SILVERMAN, ALBERTSBERG*, Kalyanaraman, S.; Jamson-Near, R.; Deuel, S., Jr.; Deuel, S., Jr.; Jamson, D.-W.; Centers For Disease Control, Retrovirus Disease Branch, Centers For Disease Control, Biotechnology and Cell Biology Branch, U.S.A.

Objective: To analyze recombination between HIV DNAs, optimal conditions were determined using DNA transfection in cell cultures.

Methods: Recombinant plasmid substrates were constructed from HIV proviral DNAs (HIV₂, HIV₁gag₁ and HIV₁gag₂). The success of recombination was measured by DNA production of viable hybrid virus. Polymerase chain reaction method was also used to characterize the cross-over junction.

Results: Substrate DNAs were transfected into cells. The process of recombination between HIV DNAs were shown to be dependent on homology between the truncated HIV DNAs and maximum with the concentrations of the DNA 3 ug which above for both single and double cross-over. Human ED cells at a concentration of 1×10^6 showed maximum hybrid virus production.

Conclusion: Optimal conditions for efficient recombination between HIV DNAs were determined. This is a powerful technique to generate hybrid viruses at any region of the genome.

Th.C.P.34 HUMAN ANTIBODIES TO HIV-1 gp160 INHIBIT ATTACHMENT TO CD4
Bak, Nicola*, Thariat, C., Van der Hoek, L., Bock, C., Goudim, J.*

*Human Retrovirus Laboratory, Amsterdam, the Netherlands, **Department of Genetics, Smith Kline-RIT, Rixensart, Belgium.

Objective: To detect the presence in human HIV antibody positive sera of anti-gp160 antibodies inhibiting the binding of HIV-1 gp160 to the extracellular portion of CD4.

Methods: HIV-1 sera of 264 homosexual men, 20 hemophiliacs, 10 v-druggers and 9 HIV-2 antibody positive sera were tested in a competition immunoassay using soluble CD4 (sCD4). Rabbits were immunized with peptides covering the CD4 binding site or with the neutralizing epitope of the HIV-1 strain HTLV-III.

Results: 18 to 50% of the HIV-1 antibody positive sera from the three AIDS risk groups reduced gp160-CD4 binding by more than 80% at a 1:100 dilution, while HIV-2 antibody positive sera tested did not show such activity in our assay.

Attempts to localize the binding site for these gp160-CD4 inhibitor antibodies on the primary sequence of gp120 by using synthetic peptides incorporating the CD4 binding site on gp120 were not successful. Neutralizing antibodies to the V3 domain of gp120 did not inhibit binding of gp160 to CD4.

Conclusion: Antibodies inhibiting the gp160-CD4 binding were highly prevalent among HIV-1 seropositives and not in HIV-2 sera. They emerge at the moment of seroconversion indicating good immunogenic potential of the domain. Presence of antibodies to an HIV-1 gp160 protein involved in CD4 binding did not hamper or prevent disease progression.

Th.C.P.36 EXPRESSION OF HIV-1 AND HIV-2 IMMUNODEFICIENCY VIRUS GENES IN E. COLI USING A SYSTEMIC TESTS
DEUEL, S., Butler, D., Metz, F., Casey, R., Kramer, D., Sapprecht K., AS

*Human Retrovirus Laboratory, North Chicago, Illinois, USA.

Objective: To obtain large amounts of various HIV-1 and HIV-2 gene products using recombinant DNA technology.

Methods: Genes encoding HIV-1 gag, endonuclease, reverse transcriptase, p17, p15, tat, rev, HIV-2 gag and gp160 were molecularly cloned in E. coli . In some instances genes were chemically synthesized using optimized E. coli in order to maximize expression. In order to obtain large amounts of each of the viral proteins, individual genes were expressed in E. coli using vectors with the lambda p1 promoter under the control of a temperature sensitive cI repressor.

Results: Each of the eight genes was successfully expressed in E. coli . The level of expression in each case was greater than 1% of the total E. coli proteins. The HIV proteins could be readily identified in induced E. coli cultures by coomassie blue staining. The antigenicity of recombinant DNA derived proteins was determined by Western blot analysis as well as sandwich enzyme linked immunosorbent assay using sera from virus exposed individuals. However, control sera showed no detectable reactivity. The availability of HIV-1 and HIV-2 proteins could be effectively used to discriminate immune response to either of the viruses.

Conclusions: The HIV-1 and HIV-2 proteins expressed in E. coli at high levels provide a safe, and efficient source to 1) detect virus infection, 2) monitor various stages of the disease and 3) discriminate HIV-1 infection from HIV-2.

Th.C.P.37 DISCRIMINATION OF HIV-2 INFECTION FROM HIV-1 INFECTION BY WESTERN BLOT AND RADIOIMMUNOPRECIPITATION ANALYSIS (RIPA)

THOMAS J. HOLZNER, R. G. ALLEN, C. A. HEWEN, M. M. KENNEDY, F. P. KINGOLD, D.A. PAUL, and G. J. DAWSON. Experimental Biophysics Research, Dept. 900, Abbott Laboratories, North Chicago, IL, U.S.A.

OBJECTIVE: To evaluate the use of Western blot and SDS-PAGE RIPA to confirm HIV-2 infection and to discriminate the serological response from that seen in HIV-1 infection.

METHODS: Western blot studies using HIV-1 and HIV-2 virus lysates and SDS-PAGE RIPA using 25S-monoclonally labelled cell lysates were used to identify seropositive blood to be repeatedly reactive to a recombinant HIV-1/2 enzyme immunoassay. 126 specimens from the United States, Europe and Western Africa were tested. Antibody reactivity to specific HIV-1 gp120 and gp46 proteins was determined. Confirmation required the detection of antibodies to both HIV-2 env and gp120 proteins.

DISCUSSION: Confirmation required the detection of specific antibodies to env proteins of only one virus type.

RESULTS: Thirty-one seropositive Western Africa and Europe were confirmed by the presence of antibodies to HIV-2 env and gp120 proteins. Twenty specimens had strong antibody responses to HIV-2 env proteins and weak or absent responses to HIV-1 env proteins. Low-level cross-reactivity with HIV-1 gp120 (gp120) and gp46 (gp46) was noted, including 8 (40%) with reactivity to gp120. Eleven HIV-2 confirmed specimens also had antibodies strongly reacting with both HIV-1 gp46 and env proteins suggesting dual infection. Of 95 Western blot positive U.S. specimens, variable cross-reactivity to most HIV-2 proteins was seen but with reactivity to gp120 able to discriminate at but 7 (7.4%) specimens.

Th.C.P.39 HIV POSITIVE SERA IDENTIFIED WITH SYNTHETIC PEPTIDE ANALOGS OF ENV, GAG, TAT, AND REV

Michael Doherty, G. Cummins, A. S. Espy, S. M. and Doherty, R. M. *MORC Special Unit for AIDS Virology, Fairfield Hospital, Fairfield, Victoria, Australia, and *St. Vincent's Institute, Melbourne, Victoria, Australia.

OBJECTIVE: To identify synthetic peptide analogs that are specifically recognized at the earliest time point after immune recognition of infection with HIV.

Methods: Panels of human seronegative, seropositive and seroconverting sera to HIV were screened for their reactivity to peptides derived from conserved regions of gp120, gp41, p17, tat, and rev proteins using an ELISA.

Results: A peptide to the immunodominant region of gp41 was the most sensitive and specific being recognized by almost all HIV positive sera. Antibodies recognizing rev peptides were detected earlier in seroconversion to HIV than those to either a recombinant antigen based commercial ELISA or the various peptides. Peptides derived from p17 were recognized by both HIV-positive and -negative sera. A tat peptide was recognized by 60% of sera, although no correlation with clinical stage of infection was apparent. **Conclusion:** The results of this study determined the utility of using synthetic peptides to serodiagnose HIV infection. In particular, antibodies to gp41 and rev proteins were recognized in peptide ELISA's before reactivity was apparent with other assays.

Th.C.P.41 GROWTH KINETICS OF HIV IN HIV-1 TRANSFORMED CELLS

Klaeren Boshuizen*, G. Peeters, D. A.; Marechal, J. A. and M. J. M. M. *MORC Special Unit for AIDS Virology, *Virology Department, Fairfield Hospital, Melbourne, Victoria, Australia.

OBJECTIVE: To define replication kinetics of HIV-1.

Methods: HIV-1 cells were infected at an MOI of 1. Samples collected serially were then studied for reverse transcriptase activity, viral core antigen, intracellular retroviral infectious virus, viral mRNA and protein, development of CPE, and cell viability.

Results: Three clear phases of infection were observed: an eclipse phase (7-10d) in which progeny virus and CPE were not observed, an exponential phase of particle release (16-20h) coinciding with the development of early CPE, and the production of viral mRNA and proteins; and from 63-82h, extensive CPE and cell death developed, and intracellular mRNA and protein synthesis increased markedly while the amount of infectious virus released remained stable. This appeared to be associated with the accumulation of virus particles in cytoplasmic vacuoles.

Conclusions: The replication of HIV demonstrated several features typical for retroviruses: a lengthy eclipse phase, slow accumulation of virus and low virus yields. A unique feature was the marked increase in virus-specific mRNA and proteins at the time of cell death, after peak production of infectious virus had been reached.

Th.C.P.38 PHENOTYPES OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) WITH THE ENVELOPE ANTIGENS OF VESICULAR STOMATITIS VIRUS (VSV) OR HERPES SIMPLEX VIRUS (HSV)

Zhu, Z.; Gao, S.; and Huang, A. Harvard Medical School, Boston, Massachusetts, U.S.A.

OBJECTIVE: To identify the formation of pseudotypes during coinfection containing HIV genome coated by the envelope antigens of VSV or HSV, designated HIV(VSV) or HIV(HSV), respectively.

Methods: To prepare phenotypic particles of HIV, we infected HIV RF trans-producing 10 cells with VSV (temperature-sensitive (ts) Ots and thermo-labile (ts) 17 mutants or with HSV-1/2 mutant. CD4-negative HeLa cells were used for infection with phenotypic viruses to maintain HIV(HSV) replication. Anti-VSV or anti-HSV antiserum was used to differentiate HIV(VSV) or HIV(HSV) from HIV(HSV). HIV replication was measured by p24 production or syncytium formation in CH210 cells.

Results: Production of p24 in HeLa cells was significantly reduced when phenotypic viruses were treated with anti-VSV. As a control, anti-VSV did not have an effect on HIV(HSV) replication in HeLa cells. The effect of anti-HSV to block down HIV replication can be verified by passing anti-HSV treated particles through CH210 cells.

Conclusions: These observations indicate that phenotypes of HIV(VSV) or HIV(HSV) can be formed during coinfection. This may be a potential mechanism for the broadening of cell tropism of HIV and for the increased spread of HIV in AIDS patients who are also infected with other viruses.

Th.C.P.40 HIV-1 INFECTION OF HUMAN MONOCYTES IS CELLULARLY INITIATED BY ANTISERA TO HIV-1 OR HIV LPS ACTIVATION OF THE CELLS

Oron, S. A.; Katsenelson, I.; Garrow, S. M.; Vial, P.; Webb, D. S.; and Quinlan, G. V. LER, VPI, Center for Biologic Evaluation and Research, FDA, Bethesda, MD, U.S.A.

OBJECTIVE: To assess the motivating effects of HIV specific antibodies and cell activation on the infection of human monocytes by HIV-1 *in vitro*.

Methods: Elutriated peripheral blood monocytes from normal donors cultured for 7 days in GM-CSF/M-CSF-supplemented media were inoculated with 1 of 5 isolates of HIV-1 (IIIB; SF2; 2 clinical isolates from normal lymphocyte cell lines (04515, 043CEM); or a commercial monocytotropic strain. For studies of neutralisation or enhancement, virus was preincubated with sera from normal or HIV-infected donors. To investigate the effect of monocyte activation, cells were pretreated with LPS. Productive virus infection was quantitated by p24 antigen (p24Ag) ELISA and integrated proviral DNA detected by polymerase chain reaction (PCR).

Results: Infection of monocytes was maintained with each virus isolate for 71 days. Virus infection was neutralized (complete inhibition of p24Ag production and failure to detect proviral DNA) by 0/5 HIV antibody positive (HIV Ab+) sera at dilutions of 1:10 to 1:1000. There was no enhancement of p24Ag production by HIV Ab+ sera at dilutions from 1:10 to 1:10,000. Activation of monocytes with LPS resulted in ≥ 100 fold limitation of p24Ag production.

Conclusions: Human monocytes maintained in GM-CSF/M-CSF-media were susceptible to infection by HIV-1 strains characterized as either lymphotropic or monocytotropic. Activated monocytes were resistant to infection. HIV-1 infection of monocytes was neutralized by HIV Ab+ sera.

Th.C.P.42 MONOCLONAL ANTIBODY IDENTIFIES A CONSERVED EPITOPES OF THE HIV-1 ENV2 AND HIV-1 CORE PROTEIN

Glaser, Ching-Hong Henry, E. and Portales, J. S. Division of Blood and Blood Products, CBER, FDA, Bethesda, Maryland, USA

OBJECTIVE: To evaluate the structure and function of HIV core protein.

Methods: BALB/c mice (female, 10 weeks old) were immunized with partially purified HIV-1 protein containing nucleocapsid, nucleocapsid antibodies (NAbs) against HIV-1 were produced by fusing PRODIGAL 651 myeloma cells with the splenocytes from the immunized mice and screened by enzyme-linked immunosorbent assay (ELISA). The positive hybridomas were cloned and the mAbs were screened by Western blot against HIV-1, HIV-2 and HIV-1 proteins.

Results: Three mAbs against HIV-1 proteins were produced. Two of the mAbs, namely CBER-1 & CBER-2, were of IgG1 subclass; they bound to p24 core proteins of HIV-1 but not HIV-2 or HIV-1 in Western blot. The third mAb, CBER-3, was IgM subclass; it recognized p15 of HIV-1 and HIV-2 on Western blot and reacted with both HIV-1 and HIV-2 in ELISA. Comparison of the protein sequence of core proteins shows that a peptide sequence of CBER-2 in HIV-1 is relatively well conserved in HIV-2 and HIV-1.

Further study shows that: CBER-3 exhibited positive response in ELISA on the plates coated with the synthetic peptide, indicating that the mAb may bind to the core proteins at this conserved epitope.

Conclusion: A mAb reactive with HIV-1, HIV-2 and HIV-1 has been produced and its likely binding epitope on the viral proteins identified. The biological activity of this conserved epitope is now under study.

Th.C.P.43 ROLE OF OLIGOSACCHARIDES ON THE PROCESSING AND MATURATION OF GLYCOPROTEINS FROM HUMAN T-CELL LYMPHOTROPIC RETROVIRUSES

Ed. Badalita¹, R. G. G. Gallo, R. C. ** and Sarngadharan, M. G. ¹Biostatistics Research, Inc., Rockville, MD, *National Cancer Institute, NIH, Bethesda, MD, U.S.A. ²Obierville. To study the effect of oligosaccharide processing on the maturation of glycoproteins from HIV-1 and HIV-2, cells were immunoprecipitated with specific antibodies and the immunoprecipitates were digested by endoglycosidase H. **Methods:** Metabolically labeled viral proteins from infected cells were immunoprecipitated with specific antibodies and the immunoprecipitates were digested by endoglycosidase H. **Results:** The effects of deoxynojirimycin (DNL), deoxymannojirimycin (DMN) and swainsonin on the maturation of HIV-1 glycoproteins were studied in virus-infected cells and the results are summarized below.

Inhibitor	Enzyme Targeted	cleavage of gp160-gp120	Progeny virus
DNL	Glycosidase I	Inhibited	Inhibited
DMN	Mannosidase I	Normal	Inhibited
Swainsonine	Mannosidase II	Normal	No effect

Treatment of HIV-1 cells with DNL did not affect the maturation of gp160, although the protein had different amounts of mannose-rich oligosaccharide cores.
Conclusion: Primary trimming of mannose-rich oligosaccharide cores in HIV-1 glycoprotein is necessary for infectivity of progeny virus but the cleavage of the precursor takes place before trimming of mannose.

Th.C.P.45 A HUMAN MONOCLONAL ANTIBODY AGAINST ENVELOPE GLYCOPROTEIN OF HIV-1 ENHANCES HIV-1 INFECTION *IN VITRO*

W. Edward Robinson, D. S. Ike, D. C. Montefiori, Y. Masuhara, T. Kawamura, W. M. Mitchell, and E. Herz.
¹Dept. of Pathology, Memphis University, Nashville, TN 37232, USA
²Dept. of Medicine, Arizona Cancer Center, University of Arizona, Tucson, AZ 85719, USA; ³Fejny Ltd, Tokyo, Japan

Objective: To evaluate human monoclonal antibodies (HumAbs) for their abilities to enhance HIV-1 infection *in vitro*.
Methods: HumAbs were generated by fusion of P3x63AgU1 cells with lymph node lymphocytes from ARC patients. Protein-A purified HumAbs were assayed for complement-mediated, antibody-dependent enhancement (C-AD) of HIV-1 infection using an MT-2 cell microtiter infection assay.
Results: One HumAb, V10-9, of seven tested was found to mediate C-AD of HIV-1 infection *in vitro*. This IgG₁ recognized gp160, gp120, and gp41 on western blot and enhanced HIV-1 infection to a dilution of >1:17,486 (28 ng/ml). Enhanced infections were characterized by accelerated appearance of HIV-induced cytopathic effect, increased antigen synthesis, increased reverse transcriptase release, and increased progeny virus production. This HumAb did not neutralize HIV-1 in the presence or absence of complement.
Conclusion: The generation of a HumAb that enhances HIV-1 infection but fails to neutralize HIV-1 indicates that at least some neutralizing and enhancing antibodies recognize different epitopes.

Th.C.P.47 EXPANDED HOST RANGE OF HIV ACQUIRED THROUGH MODIFICATION OF GP120

Stefo Debbaghi, Levy, J.A., Cheng-Mayer, C.
Cancer Research Institute, University of California, San Francisco, CA, USA

Objective: To determine what factors control the cellular tropism of HIV.
Method: The host range of HIV obtained by passage through different cell types was determined by infectivity studies. Genomic variations of HIV recovered were assayed by Southern blot analysis and modification of GP120 examined by glycosidase treatment.
Results: HIV-1 isolated through HUT-78 cells vs. peripheral blood mononuclear cells (PBMC) acquired an expanded host range and replicated better in HUT-78 than the virus from PBMC (Table). Restriction analysis showed that the same virus is present in the different cell types. Furthermore, passage of the virus produced from HUT-78 back through PBMC results in HIV with host range properties of the HIV recovered from PBMC. Studies using carboxymethylated and endoglycosidase indicates that the change in cell tropism of HIV-1 could be related to modifications of the gp120.

HIV-1	Source	PBMC	HUT-78	Ac	CMC	DMT	Restriction	Cloning
73	PBMC	+	+	+	+	+	+	+
73	HUT-78	+	+	+	+	+	+	+
645	PBMC	+	+	+	+	+	+	+
645	HUT-78	+	+	+	+	+	+	+

Conclusion: Glycosylation of gp120 may contribute to the heterogeneity of host cell tropism, suggesting that interfering with glycosylation might prevent infection and spread of HIV.

Th.C.P.44 MAPPING OF THE IMMUNOREACTIVE EPTOPIES OF THE HIV-1 ENDOPEPTIDASE PROTEIN BY MEANS OF RECOMBINANT PROTEINS

Cristina Vives-Martin and N. Mesteir-Lanaux
Institut für Medizinische Mikrobiologie und Hygiene, Abt. Virologie, Klinikum der Universität des Saarlandes Homburg/Saar, FRG.

Objective: To define the major immunoreactive part of the HIV-1 endopeptidase protein.
Methods: The complete reading frame of the endopeptidase (HR AA) from HIV-1 and three subdomains representing the N-terminal, central and C-terminal part of the endopeptidase were cloned into the tryptophan regulated expression vector pATH. After expression four fusion proteins of 64 kD, 52 kD, 46 kD and 48 kD, respectively, were obtained and used for the production of specific polyclonal antisera (68 kD recombinant protein) or as antigens in order to map the major immunoreactive part of the HIV-1 endopeptidase part.
Results: 2/3 out of 27 HIV-1 endopeptidase positive sera predominantly reacted with the C-terminal part of the recombinant endopeptidase and only a few also showed a faint reactivity against the N-terminal part in the western blot. In some cases HIV-1 positive sera which did not react against the p31 of HIV-1 infected Mink-bio cells gave a clear reactivity against the C-terminus of the endopeptidase.
Conclusion: The results suggest that the C-terminus contains the immunodominant epitopes of the HIV-1 endopeptidase. Peptide studies on the mapping of distinct epitopes are under investigation. (Supported by the BMFT grant No. FR/12/031817A).

Th.C.P.46 CORRELATION STUDY INVOLVING THE DETECTION OF HIV-1 IN SAMPLES FROM AIDS PATIENTS USING CO-CULTURE, p24 ELISA, AND TAD- AND PCR-MEDIATED HYBRIDIZATION ASSAYS

Cigerci, Thomas*, Gottlieb, J.**, Kichian, D.**, and Davis, G.**, et al.
¹The Salk Institute Microbiology/Industrial Associates, Inc. (SIIA), La Jolla, California 92037, USA. ²Depts. of Medicine and Pathology, UCSF School of Medicine, San Diego, California 92161, USA.

Objective: Correlation study involving the detection of HIV-1 in samples from AIDS patients using co-culture, p24 ELISA, and TAD (transcription-based amplification system)- and PCR (polymerase chain reaction)-mediated hybridization assays.
Methods: A collection of peripheral blood lymphocyte samples which were characterized as: 1) "+" for both co-culture and p24 assays; 2) "-" for both co-culture and p24 assays; 3) "+" for co-culture and "-" for p24 assays; or 4) HIV-1 negative acid sequences using TAD- and PCR-mediated hybridization assays. For TAD or PCR amplification, detection of amplified products was carried out by a variety of methods, including bead-based sandwich hybridization, Northern and Southern blot hybridizations, and solution hybridization.
Results and Conclusion: These experiments have permitted: 1) the results derived from immunological and culture-based assays to be compared to the results derived from amplification-mediated hybridization experiments; and 2) the comparison of PCR- and TAD-mediated hybridization results. Amplification-mediated hybridization assays results derived from individual patients indicate increasing viral nucleic acid concentrations with time, whereas other assay results (p24 and co-culture) appear more variable.

Th.C.P.48 REPLICATION OF HIV-1 IN A VARIETY OF ANIMAL FIBROBLAST CELLS USING PHENOTYPICALLY MIXED VIRAL PARTICLES

Carlson, Madeline; Hoffman, A.; Hardy, D.; Serraninger, J. and Levy, J.A.
Cancer Research Institute, University of California, San Francisco, CA 94143 USA

Objective: To determine whether the inability of HIV to infect animal cells can be abrogated by enveloping the virus in a xenotropic (X-MuLV) or polytropic (PTX) mouse retrovirus coat, and to study variations in intracellular control of HIV replication.
Methods: Phenotypically mixed particles were obtained by superinfecting X-MuLV or HIV-1 chronically infected HUT-78 cell lines with HIV-1. The progeny viruses were inoculated onto a variety of HIV-resistant animal fibroblast and epithelial cells. Their ability to replicate was assessed by reverse transcriptase activity using both ³²P- and ³⁵S-³ labeled cells, by detection of the HIV p24 or HIV-1 antigens (IFA and ELISA tests), the new ³²P- assay and Western blot techniques.
Results: HIV can be enveloped in an MuLV coat and productively infect a wide variety of animal cell types. Differences in level of HIV replication in various cells were observed.
Conclusion: The major block of HIV infection occurs at the cell surface, but an intracellular regulation of the virus can also be present. Phenotypically mixed viruses may be useful for developing an animal model system for AIDS.

Session d'attaché Poster Session

Recherche fondamentale (Biomédecine) Basic Research (Biomedical)

Th. C.P. 49 THE ANTIBODY RESPONSE TO HUMAN IMMUNODEFICIENCY VIRUS: NEUTRALIZATION VS ENHANCEMENT.

Thomas M. Cheney, M.C. and Lewis J.A. Cancer Research Institute, School of Medicine, University of California, San Francisco, CA, U.S.A.

Objective: To examine whether antibody-dependent enhancement of HIV infectivity could explain the apparent lack of protection conferred by neutralizing antibodies *in vivo*, and examine whether the appearance of enhancing antibodies is associated with progression towards AIDS.

Methods: The sera of 17 HIV-infected individuals comprising asymptomatic, AIDC and AIDS patients were tested for neutralization and enhancement against the patients' own (homotypic) HIV isolates as well as against HIV₀₂₃₃, an established strain which exhibits syngamy and a wide host range. Five patients' isolates were also tested for homotypic neutralization/enhancement in macrophages. Moreover, sequential sera of an asymptomatic, an AIDC and an AIDS patient obtained over a three-year period were tested against homotypic isolates obtained at the same time points.

Results: While all sera neutralized HIV₀₂₃₃ only one had such effect on the homotypic isolates, and one asymptomatic, two AIDC and two AIDS patients enhanced their own isolates. In macrophages, four out of five patients sera (comprising one asymptomatic and 3 AIDS patients) enhanced their own isolates. From the sequential study showed that the asymptomatic patient's early and late sera neutralized both early and late homotypic isolates, the AIDC patient's early and late sera enhanced his early but not his late HIV isolates and that the AIDS patient's late sera enhanced his late isolates, while both his early and late sera neutralized his early isolate.

Conclusions: These results suggest that enhancing antibodies might be an indicator of disease progression and underline the need to establish larger groups of infected individuals to assess for such association.

Th. C.P. 50 ARE THERE MULTIPLE STRAINS OF HIV IN AN INFECTED INDIVIDUAL?

Paul L. Cheng-Mayer, C. and Lewis J.A. Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To determine whether more than one genetically distinct HIV-1 strain can be recovered from an infected individual.

Methods: Culture the peripheral blood mononuclear cells from a clinically healthy individual who had more than four hundred sexual partners in a 12 mo. Co-cultivate these cells with T and B cell lines, peripheral blood macrophages, CD4⁺ lymphocytes and human fibroblasts. Biologically clone each HIV isolate with sequence homology for different cell types including established T and B cell lines, peripheral blood macrophages, CD4⁺ lymphocytes and human fibroblasts. Molecularly probe each HIV isolate in the cell lines selected. Evaluate the biologic, serologic and molecular properties of the various isolates by cellular host range, cytopathic effects, plaque assays and restriction enzyme analyses.

Results: Ten different HIV-1 isolates were obtained by the above techniques from one individual. All were found to grow to high titer in macrophages and only infected the Sup T and HC 8 cell lines. None of them formed plaques in the MTF cell line. No virus isolates traced HJ17-70, Jurland, or HTLV-III₀₂₃₃ cell lines. No differences in recombination patterns among the HIV-1 strains were observed.

Conclusions: All ten virus isolates showed similar biologic and serologic properties. That molecular properties are under study. The results suggest that this healthy individual is infected with one strain of HIV-1. By its substantial growth in peripheral macrophages, HIV recombination may be favored in these cells. The results suggest that serologic disease, such as AIDS, progression and underlines the need to establish larger groups of infected individuals to assess for such association.

Th. C.P. 51 PARAMETERS INVOLVED IN THE CELL FUSION INDUCED BY THE HUMAN IMMUNODEFICIENCY VIRUS

Isabelle Delbecq, and Lewis J.A. Cancer Research Institute, University of California, School of Medicine, San Francisco CA 94143 USA

Objective: To define the parameters involved in HIV-induced fusion.

Methods: Syncytium formation was measured by cell-to-cell and protein synthesis on cells with HIV₀₂₃₃ chronically infected cells. The detection of lymphocyte markers on cells was conducted by FACs analysis. Nucleic acid synthesis and protein synthesis were measured by ³H-labelled thymidine uptake and ³H-labelled leucine incorporation. HIV viral proteins were analyzed by immunodot analysis.

Results: Optimal cell fusion was observed when chronically infected cells and uninfected cells were used at 1:1 to 1:4 ratios. At the 1:1 and 1:2 ratios the CD4 protein levels with the HIV-infected cell line (the CD4 line) despite the fact that it had a 50% expression of the CD4 antigen. Cell clumping and cell fusion were markedly inhibited by D-glucose, D-mannose, D-galactose at 0.5 M and Dextran sulfate at 50 µg/ml. Con A, but not PHA, was capable of blocking cell fusion. An inhibitor of glycosylation, tunicamycin (5 µg/ml), reduced cell fusion in HIV isolate infection and cell to cell fusion. Treatment of uninfected or the infected cells with the metabolic inhibitors, cycloheximide, actinomycin D, and actinomycin D did not affect the efficiency of cell fusion. The proteolytic aspartases, trypsin and aspartyl-chymotrypsin, efficiently prevented cell fusion in HIV acute infection and cell to cell fusion. Subsequent FACs analysis on the Sup T cells treated with tunicamycin indicated that the CD4 protein had not been removed from the cell surface.

Conclusions: HIV induced cell fusion depends on HIV gp120, the expression of the CD4 protein on the surface of uninfected cells, and the presence of sugar moieties particularly D-mannose. Protein and nucleic acid synthesis are not required for the fusion process. The ability to block fusion with tunicamycin without removing the CD4 protein suggests a receptor besides CD4 is required for the fusion event.

Th. C.P. 52 GROWTH OF HIV-1 AND T CELL SUBSETS IN SEQUENTIAL BLOOD SAMPLES TAKEN FROM A HIV-0 PATIENT BEFORE, DURING, AND AFTER INFECTION

Fazlun-Nasir Warfield, D.J. and Sanderlin, K. Centers for Disease Control, Atlanta, GA, USA

Objective: To evaluate the growth of HIV-1 and the T cell subsets of sequential blood samples taken before, during, and after HIV-0 infection.

Method: T lymphocytes from sequential blood samples were: 1) inoculated with varying doses of HIV-1 and measured for virus growth by reverse transcriptase and HIV-1 antigen assay testing; 2) measured for T subset content by flow-cytometry.

Results: Cells taken before and after illness were normal in HIV-1 growth potential and in total T, CD4 and CD8 parameters. Sample taken during infection indicated over 70% loss of ability to be infected with HIV-1, about 35% loss of total T, about 45% loss of CD4, and about 20% loss of CD8. These results also correlated with the presence of HIV-0 antibody and virus. Antibody in the pre-infection sample was 1:10, converted to 1:100 during infection, and by eight months post infection was 1:100. HIV-0 virus was seen only in the two specimens. Four weeks apart, showing T cell depletion.

Conclusions: During this HIV-0 infection, CD4 cell counts and the ability of the patient's lymphocytes to be infected with HIV-1 are both drastically reduced. Both parameters return to normal soon after illness.

Th. C.P. 53 GOLD-LINKED IMMUNO ASSAY (GLIA): A METHOD IN VIRAL DIAGNOSIS

Geeta, Chatterjee, and Robert Koch

Robert Koch-Institute of the Federal Health Administration, Berlin, FEDERAL REPUBLIC OF GERMANY

Objective: To develop a simple, rapid and cheap method in viral diagnosis (i.e. HIV) allowing to identify antibodies in patient sera as well as viral antigen in culture supernatants.

Methods: Infected suspension culture cells are adsorbed to glass slides coated with Poly-L-lysine or streptococcal plates coated with silver blue and fixed mildly. A drop of patient serum is placed on the cell layer. After incubation the serum is washed off and a drop of gold anti-human immunoglobulin conjugate is placed on the cells. After incubation and washing the colloidal gold undergoes silver enhancement and light microscopic evaluation.

Results: The silver enhanced gold colloids lead to a specific gold-brown or black granular staining of virus producing cells or purified virus incubated with serum containing specific antibodies. Likewise, sensitive erythrocytes attached to a glass slide are covered with an antiviral antibody and subsequently treated with immunogold labeling and silver enhancement. The possibilities and limitations of the method in comparison to well established techniques are discussed.

Conclusion: The gold linked immune assay is a simple and rapid method for screening probes (i.e. sera and tissue biopsies) from patients at risk of infection with HIV or other viruses. The method was presented in a lecture, University of Freiburg, 1988. Manuscript in preparation (J. Virol. Methods).

Th. C.P. 54 CHARACTERIZATION OF PROTEINS ASSOCIATED WITH TWO NOVEL RETROVIRUSES ISOLATED FROM AIDS-ASSOCIATED LYMPHOMA TISSUE

No. Valdez, L., Klayman-Sheff, F., Marsh, J. and McDerm, M.

University of California, San Francisco, and San Francisco General Hospital, San Francisco, California, USA

Objective: To characterize the proteins associated with two retroviruses isolated from primary AIDS-associated lymphoma tissue.

Methods: Non-equilibrium two-dimensional SDS-PAGE, limited Sialophenoloxyl V8 protease digestion, exhaustive tryptic peptide fingerprinting.

Results: We purified 27 and 1009 virus particles from culture supernatants by sucrose density equilibrium gradient centrifugation, and analyzed the proteins associated with the purified viruses. Non-equilibrium two-dimensional SDS-PAGE analysis of radiolabelled 277 and 1009 virus particles demonstrated prominent 27kd and 14kd (BLV). The 27 kd protein (D7A) demonstrated peptide homology (by limited Sialophenoloxyl V8 protease digestion and by exhaustive tryptic peptide fingerprinting) with the proteins of BLV, HTLV-1 and HTLV-2, but did not fit with the p24 of HIV-1.

Conclusions: These data support the isolation of these two retroviruses in the subfamily of oncoviruses.

Th.C.P.61 INHIBITION OF SYNCTIUM FORMATION WITH LECTINS

Hansen, John-Erik, S. Nielsen, C.M., Nielsen, C., Nygaard, P., Mathiesen, L., Mathiesen, J., *Department of Infectious Diseases, Nivardsgade Hospital, Denmark, **State Serum Institute, Copenhagen, Denmark, ***The Protein Laboratory, University of Copenhagen, Denmark.

Objective: To examine the involvement of the glycane of gp120 in binding to the CD4 receptor.

Methods: Ten different lectins were added to HIV-1 III B infected SP2 cells prior to coculture with CEM cells. Incubations were performed in RPMI 1640 with or without competing monosaccharides. Multinucleated giant cells, syncytia, were counted after 4 and 24 hours using phase-contrast microscopy.

Results: The lectins Concanavalin A, Wheat germ agglutinin, Lens culinaris agglutinin and Phytohemagglutinin blocked or inhibited formation of syncytia. This inhibition was reversible with competing monosaccharides. Lectins acted on HIV-1 infected syncytium formation were: PBA-L, GSA-1, GSA-2, UEA-1, HPA, SBA and PBA.

Conclusion: Lectins which bind to either of the four different glycans of gp120 interact with CD4-gp120 binding as evaluated by formation of syncytia.

Th.C.P.63 CO-INFECTION OF HUMAN T-LYMPHOCTIC CELL LINE WITH HIV-1 AND A NEWLY IDENTIFIED VIRUS-LIKE INFECTIOUS AGENT (VIA)

De, Samir, B. Behar, J. B. S.-C. American Registry of Pathology, Dept. of Infectious and Parasitic Diseases, Armed Forces Institute of Pathology, Washington, D.C., USA

Objective: To determine the effects of the VIA (J Trop Med Hyg, Feb. 1989) on HIV-1 infection in a CD4 positive T-cell line.

Methods: A 301 cell line was infected with HIV-1 (SF8 strain) or VIA or both agents simultaneously. At various times after infection, supernatant samples were harvested from all cultures and assayed for reverse transcriptase (RT) activity, HIV antigen, VIA antigen and HIV infectious titer.

Results: Infection by HIV-1 resulted in the production of HIV antigen, RT and the development of large syncytial cells associated with cell death. RT activity was high during the peak of infection, as was the level of antigen, as determined by the antigen capture assay. In contrast, cultures co-infected with both HIV-1 and VIA demonstrated little syncytial formation, yet cytopathogenesis was present, resulting in a sharp decrease in viability. Although little or no RT activity was detected in the culture supernatants, replicons of HIV-1 occurred during co-infection because the HIV antigen level and infectious titer in the supernatants tested were comparable to samples obtained from cultures infected with HIV-1 alone.

Conclusions: (1) During co-infection, despite the fact that VIA expressed the syncytia, cell death occurred. (2) Infectious HIV was produced in the co-infected cultures. (3) Co-infection with VIA masked the identification of RT activity in cultures produced by HIV infection.

Th.C.P.65 Brain and Blood HIV-1 Isolates from the Same Individual have Different Biological Properties

Wain, Carol L., Cheng-Mayor, C., Sato, D., Levy, A., Cancer Research Institute, University of California, San Francisco, CA 94143 USA

OBJECTIVES: To determine whether virus isolates from the brain and blood of the same individual have different biological properties, and are genetically related.

METHODS: Brain and blood specimens, collected from 8 AIDS patients with neurological abnormalities, were co-cultured with CD4-activated normal PBMC. Virus isolates were tested for their ability to grow in established T-cell lines (HUT, CEM, Jurkat, U937, Sup. T) and in primary macrophages. Neutralization assays with performed using autologous and/or heterologous antisera. Genetic relatedness was assessed by restriction enzyme digests and Southern blot analysis.

RESULTS:

Brain/Blood pairs	SIAD	SIAD	SIAD	SIAD	SIAD	SIAD
1	+	+	+	+	+	+
2	+	+	+	+	+	+
3	+	+	+	+	+	+
4	+	+	+	+	+	+
5	+	+	+	+	+	+
6	+	+	+	+	+	+
7	+	+	+	+	+	+
8	+	+	+	+	+	+

No isolates were significantly neutralized. Restriction enzyme fragment patterns of 55 pairs were similar but not identical.

CONCLUSIONS: Brain and blood HIV-1 isolates from the same individual are variants of each other and frequently have different biological properties. This finding suggests that genetic changes in HIV-1 that occur within individuals are critically important because they can lead to variants that can infect and cause pathological effects in different tissues.

Th.C.P.62 ELECTRON MICROSCOPIC EVIDENCE FOR COINFECTION AND REPLICATION OF HERSHPREVUS AND HIV-1 IN THE SAME HUMAN T-CELL

Kucera, L.; Leake, E.; Baban, David; Fyfe, S.; Myrvik, G. Bowman Gray School of Medicine at West Virginia University, Winston-Salem, NC 27103, USA.

Recent data from our laboratory indicated that unstimulated human leukemia cells (Molt-4, Molt-4, CEM-SS) are permissive for both herpes simplex virus type 2 (HSV-2) and human immunodeficiency virus type 1 (HIV-1). Published evidence (Gendelman et al., P.N.A.S. (USA) 81:1939, 1984) indicates that HSV-2 can transactivates HIV-1 long terminal repeat-directed bacterial CAT gene expression. **OBJECTIVES:** We studied the potential interaction of HSV-2 and HIV-1 viruses. **Methods:** At various times after infection with HIV-1 alone or HIV-1 + HSV-2 we harvested CEM-SS cells for analysis by transmission electron microscopy (TEM) and HIV-1 p24 core antigen expression by ELISA. Results indicated that HSV-2 infection of HIV-1 infected cells through the plasma membrane of cells infected with HIV-1 alone or in combination with HSV-2 at 8 days post infection. Also, we observed HIV-1 particles budding into HSV-2 containing cytoplasmic vacuoles. At 10 days after HSV-2 coinfection HIV-1 p24 core antigen synthesis was stimulated 8-fold compared to HIV-1 infected cell control. In contrast, HIV-1 did not affect HSV-2 replication in the coinfecting cells. **Conclusions:** These data provide the first evidence that HSV-1 and HIV-1 can co-infect and simultaneously replicate in the same human T-cell and that HSV-2 may serve as a cofactor in activation of latent HIV-1 infections.

Th.C.P.64 CHEMICAL INDUCERS OF CELL DIFFERENTIATION INHIBIT HIV REPLICATION IN VIVO

Cherif, M.; Khandoukhan, A.; Abshadi, D.***
Vila, Imitator, S.G.*** and Vlach, J.***

*Fondat de Médecine, 75006 Paris, France, **R.I.B. / R.C.I., Laboratory of Cellular and Molecular Biology, Bethesda, Maryland, U.S.A., ***I.I.B. / N.C.I., Laboratory of Tumor Cell Biology, Bethesda, Maryland, U.S.A., ****I.P.L. Laboratories, Barcelona, Spain

Objective: Investigate the effect of Chemical Inducers of Cell Differentiation (CID) on HIV-infected cells.

Methods: Four chemicals known to induce cell differentiation changes in vitro - dimethylsulphoxide, dimethylformamide, pyridine-oxalide and butyric acid - were used for the incubation of two lymphoblastoid cell lines - HDV7 and MOLT 4 - infected with HIV. Their effect was assessed by evaluating the amounts of p24 and RT activity in the Tissue Culture Medium (TCM).

Results: The four compounds used to pre-incubate the lymphoblastoid cells tested failed to prevent viral infection and they also failed to inactivate the virus in vitro. In contrast, they did inhibit viral replication within the infected cells. The observed effect is dose-dependent and transient. HIV-1 replication resumes after the removal of the compounds from the TCM. The infected cells in presence of CID express p24 antigens on their cell surface despite the inhibition of viral replication.

Conclusion: CID had a virostatic effect on HIV-infected cells in vitro. Further studies investigating the in vivo activity are thus warranted.

Th.C.P.66 INHIBITION OF THE MATURATION OF HIV STRUCTURAL PROTEINS BY A PEPTIDE INHIBITOR

Harroberts, L.**, Wilson, S.**, and Oermann, P.C.**(1)

(1) Institut de Recherches sur les Sérovirus et Maladies Associées (I.R.S.M.) - Centre de Recherches sur le SIDA - Institut Pasteur de Paris

(2) Laboratoire - Centre de Montpellier - Rue de St. Pierre - 34293 Montpellier Cedex 9 - France.

The protease encoded by the Human Immunodeficiency Virus (HIV) pol gene, cleaves the gag-pol protein precursor and plays an important role in the viral replication cycle of HIV.

The HIV protease belongs to the family of aspartyl-proteases, as peptidyl or peptidyl-like inhibitors.

Peptide synthetic peptides based on the amino acid sequence of the HIV-1 protease were used to inhibit the protease in vitro.

This specific also inhibited viral production by the CEM cell line, since no reverse transcriptase activity was detected and no viral antigen was revealed by immunofluorescence during several weeks after infection by HIV.

Nevertheless, when the inhibitor peptide was removed from the culture, infectious virus particles were produced after a few days.

These results demonstrate that specific inhibitors of protease can block HIV-1 infections by HIV and provide possible strategies against AIDS.

Th.C.P.67 HIV DOWN-REGULATES ITS CD4 RECEPTOR BY TWO DIFFERENT MECHANISMS

Stropia P., Olivier H., Riviere Y., Montagnier L., Guetters JC., Kloterman D.
Hopital Pit-Salpeatriere, Institut Pasteur, Paris, *Gadon, Strasbourg, France.

Using mAb's and a genomic probe to the CD4 molecule, the HIV receptor, we demonstrated that HIV regulation involved the disappearance of its functional receptor from the cell surface by two distinct mechanisms. First, after being expressed onto the cell surface, HIV envelope glycoprotein CD4, efficiently masking the CD4 epitopes used by the virus to bind its receptor. This phenomenon occurred on the surface of each HIV-infected virus expressing a mutated HIV env gene designed to prevent gp120 release from the cell surface induced a similar gp120 complexes formation. Second, virus replication induced a dramatic reduction of CD4 expression, preventing new CD4 molecules from being synthesized. One possible explanation of this phenomenon could be the negative regulation of CD4 expression by HIV replication. An expression vector containing a reporter gene under the control of a -500 genomic sequence upstream to the CD4 gene transcription start site, which includes the putative CD4 gene promoter, has been constructed to test this hypothesis. Modulation of the reporter gene expression after infection of the cells with various HIV genes expression vectors are currently being analyzed. The possible down-modulation of CD4 expression by HIV is a novel phenomenon which occurs during T-cell maturation and may provide new approaches to study HIV infection. This study may provide new insights in understanding the molecular mechanisms of viral infections.

Th.C.P.68 PRODUCTIVE HIV-1 INFECTION OF HEPATOCELLULAR CARCINOMA CELLS (HCC) LINES *IN VITRO*

Cap. Tsubouchi*, Friedman-Sles, A.K.M., Wang, T.X.H., Li, J.L., Hissballe, R.J., Tucker-Franklin, D.S. and Ho, D.D.*. *New York University Med. Center, NY; **McGill Univ. Med. Center, Montreal, Quebec, Canada.

OBJECTIVE: To determine the *in vitro* susceptibility of HCC lines to infection by different strains of HIV-1.
Methods: Five HCC lines, including CCMC-4371, PLC, Hep3B, HepG2 and HEP7 were inoculated with 3 diverse isolates of HIV-1 (CMV-IIIb, HT, and AL) at multiplicity of infection ranging from 0.002 to 20. HIV-1 expression was monitored by detection of p24 antigen and RT activity in culture supernatants weekly for up to two months, & by immunohistochemical staining, an RNA hybridization, & electrotransfection (ET) performed on the cells at Day 248, 3 & 7 days after virus inoculation. The presence or absence of CD4 on HCC lines was shown by immunofluorescence using anti-CD4 monoclonal antibodies.
RESULTS: Five HCC lines were found to be susceptible to productive infection by three strains of HIV-1 *in vitro*. Expression of HIV-1 p24 lasted for over 100 days and decreased in proportion to the number of viable cells. ET was also found in the cells by RT staining, as were viral RNA by *in situ* hybridization and HIV-1-like particles by EM. Ten supernatant samples were found to be positive for HIV-1 p24 antigen and RT activity was not detected, and range of infectious HIV-1 from culture supernatants with HIV-1 was found to be negative to date. Tests by immunofluorescence, infection, all 5 HCC lines were negative for CD4 expression.
CONCLUSION: CD4-negative HCC lines are productively infectible *in vitro* by HIV-1 via an unknown pathway. Further, the replication of HIV-1 in HCC lines may be incomplete, and HIV-1-like particles found in the HCC lines may represent defective viruses.

Th.C.P.69 QUANTIFICATION AND CELLULAR DISTRIBUTION OF HIV PROVIRAL DNA IN HIV POSITIVE INDIVIDUALS

Simon, J., Pagan, J., Feulner, J., Leigh-Brown, A.J., Bishop, J., and Lamm, G.A., et al.
*University of Edinburgh, *Royal Infirmary, Edinburgh, Scotland, UNITED KINGDOM

A PCR method has been developed that detects individual molecules of HIV DNA in several micrograms of cellular DNA. This has allowed an analysis of the quantity and cellular distribution of HIV-specific DNA in buffy coat samples from seropositive haemophilic patients. Serial dilutions of DNA prepared from buffy coat cells were tested by the PCR and the number of copies of HIV DNA measured. This figure was compared with the proportion of cells containing HIV RNA, obtained by a titration of the buffy coat cells themselves prior to RNA extraction. To corroborate these data, the number of HIV DNA molecules in each of the isolated single cells could be determined by further dilution and retesting of the DNA prepared from each. Results have shown that relatively few buffy coat cells contain HIV-specific DNA, although this is variable between patients and those cells that are positive have a relatively high copy number. Prior cell separation allows a similar analysis to be made on different cell types. Finally, primers spanning the junction on circularization of HIV DNA in the cell can be used to show the configuration of the individual HIV DNA molecules found within each cell.

Th.C.P.70 HIV DNA SEQUENCES DETECTED BY PCR IN SERONEGATIVE, YET ANTIBODY POSITIVE, INDIVIDUALS

Frangou, L., Montagnier, L., Cougnard, V., Chamerat, S., Ragnan, M., URS CHU Necker, Paris, *Hydrobiostat et **Unité d'Oncologie Virus, Institut Pasteur, Paris, ***Diagnostic Pasteur, Marnes la Coquette, ****Service d'Immunologie, Hôpital Salpêtrière, Paris, France.

Objective: To investigate the presence of HIV DNA in seronegative individuals at risk of HIV infection.
Patients: 6 subjects: 2 sexual partners of HIV positive subjects, 2 haemophilic, 2 with lymphomas (one Hodgkin lymphoma 1 NHL). In addition 2 antibody negative patients (1 with T cell lymphoma and 1 sexual partner of a seronegative anti-HIV positive subject) were tested.
Methods: PCR with 40 cycles and 3 sets of primers (Pol and env genes). Anti-env were detected through western-blot using a recombinant env protein (Frangou).
Results: HIV DNA sequences were identified in 5 of the 6 anti-env positive subjects. This included 1/2 haemophilic, 2/2 sexual partner of HIV+, 2/2 NHL lymphomas. In addition HIV DNA scored + in 2/2 anti-env negative subjects with T cell lymphoma and sexual partner.
Conclusion: This study I) indicates the possibility of HIV infections in apparently seronegative yet anti-env positive subjects, 2) will lead to further investigate the potential implications of HIV DNA and anti-env positivity in some subjects with lymphomas.

Th.C.P.71 SEQUENCE ANALYSIS OF A HIGHLY CYTOPATHIC STRAIN OF HIV-1: CORRELATION BETWEEN BIOMOLECULAR AND GENOMIC VARIABILITY

Wills, R., Hill, J., Roberts, C. and Cameron, J. et al.

Units in Edinburgh (EH8) and New Britain (NS) are HIV seropositive individuals who are HIV-1 positive. A highly cytopathic strain of HIV-1 was isolated from a patient with AIDS. This isolate is 10⁶ times more cytopathic and more infectious than the prototype, in order to correlate the high cytopathic properties of this strain with relevant genetic variations we have cloned and sequenced the HIV nucleotides of this isolate and compared the deduced amino acid sequence with those of other isolates. The principal feature which could be deduced from the time analysis of the HIV-1B sequence is that variability is not observed in one particular region but rather spread out all along the gene. The maximum of variability was as expected in the external glycoprotein gene. Representative variants were detected at the same position in other isolates. The region responsible for the binding with the CD4 molecule was highly conserved, but participation of the hypervariable region to a stabilizing effect on the CD4 molecule could not be assumed. Furthermore a small deletion of three amino acids was identified in the C-terminal part of the P24 nucleocapsid protein which could be involved in the cytopathic effect. Alignment of the viral regulatory proteins of HIV-1B and other HIV-1 variants did not show any major differences. It is in the 5' part of the 5' UTR region, which had been proposed as the target for negative regulatory elements where the major variability has been found.

Th.C.P.72 Susceptibility to HIV-1 Infection of a Human B-Lymphoblastoid Cell Line, D27, Transfected with Subgenomic DNA Fragments of EBV, Daefer, Simon, Goldfarb, Matar, Hill, Ted, Akhshi, Sharma, Joseph, Steven, Galahudin, Zakl

*Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland, USA. *Fagarty International Center, National Institutes of Health, Bethesda, Maryland and Hebrew University, Jerusalem, Israel.
We have previously shown that the presence of the EBV genome and active EBV infection in some Burkitt's lymphoma cell lines confer the susceptibility to HIV-1 infection in spite of the absence of surface CD4 receptors in these cells. In the present study we used an EBV genome negative Burkitt's lymphoma B-cell line, D27, transfected with three different subgenomic fragments of EBV expressing the nuclear antigens (EBNA) and EBNA2 and the latent membrane protein (LMP), respectively. Immunofluorescence analysis demonstrated CD4 expression in more than 80% of the EBNA1, EBNA2 and LMP transfected cell lines, whereas the antigen could only be detected in less than 4% of the parental D27 cell line. Unlike the wild type D27 line the three transfected cell lines were found to be susceptible to HIV-1 by both iFA and production of viruses. Northern blotting of poly(A) selected RNA of the four cell lines hybridized to a human CD4 cDNA(p748) demonstrated a 3kb band in all three EBNA1, EBNA2 and LMP transfected cells as well as in the wild type D27 cells. Approximate quantitation indicates equivalent level of T4 mRNA expression in the transfected cell lines as compared to T-cell lines (Hut-78, HP-8).

Th.C.P.79 **Dideoxynucleoside Prevent Formation of HIV-1 Provirus During Single Cycle Infection of Macrophages**

James B. Mullis, R.S. Kornbluth, and D.D. Richman.
Departments of Medicine and Pathology, University of California, San Diego, and Veterans Administration Medical Center, San Diego, CA, USA 92161. Dideoxynucleoside (ddI) previously has been shown not to inhibit low level replication of the lymphotropic LAV-1 strain of HIV-1 in primary human macrophages. In contrast, AZT markedly inhibits the replication of a macrophage-tropic strain of HIV-1 (HTM-III_{MAC}) which replicates to high titers (2×10^6 copies/ml) in primary macrophage cultures. The effects of 1 μ M AZT on the replication of this LAV-1 strain in macrophages was examined using a high multiplicity infection. In the absence of AZT infection. At several time points after infection, cells were harvested and viral nucleic acids were assayed by PCR amplification of a conserved HIV-1 sequence. In the presence of AZT, provirus DNA (provirus) could be detected by 12 hours after infection, approximately concurrent with the release of viral p24 antigen into the supernatant. In the presence of AZT, no viral DNA or new p24 antigen was detectable during the five day incubation. AZT infection, approximately concurrent with the release of viral p24 antigen into the supernatant, in the AZT treated cells, viral RNA was continuously present for 48 hours, when it began to decrease steadily during the remainder of the incubation. We conclude that (1) the replicative cycle of this HIV-1 strain in macrophages is approximately 12-24 hours, (2) AZT prevents the formation of HIV-1 provirus in this system, and (3) virion input RNA, in the absence of viral replication, persists in macrophages for more than 48 hours.

Th.C.P.81 **SEQUENCING OF PCR-AMPLIFIED HIV-1 RELATED SEQUENCES FOUND IN THE DNA OF INFECTED FROG, BENTAL, AFRICA**

Moussy, Maurice, J.L.; Becker, J.C.; L'Homme, M. and Montagner, M.

* Unité d'Oncologie Virale, Institut Pasteur, Paris, France; ** Laboratoire de Virologie Moléculaire, Université Paris VII, Paris, France.

Objective. To detect HIV-1 related sequences integrated into the DNA of African Insects and to investigate their nature and origin.
Methods. Classical molecular hybridization techniques were first used for the detection of the considered sequences; i) south-blot, dot-blot, Southern transfers. For the PCR amplification, we designed primer-oligonucleotides in the gag, env and nef genes. The amplified materials were sequenced with the Max-EMBASE[®] and non-biased primers, following the technique of Sanger.
Results and conclusion. Screening of more than 200 insects captured in Central Africa has revealed, using molecular hybridization techniques, the presence of HIV-1 related sequences in the DNA of insects belonging to numerous species. However, HIV-1 PCR generally hybridizes only the EcoRI fragments of 4.5 kb and of 3.5 kb in the insect DNA. This pattern is not in agreement with the restriction map of the described members of the HIV family. We used PCR to amplify these sequences in the gag, env and nef genes. The PCR-amplified DNA was directly sequenced by a new technique using non-biased primers and the Taq-polymerase allowing a higher temperature of reaction, which overcomes the blocks induced by secondary structures of the DNA. Sequence results with evidence of important rearrangements in the env gene, will be presented.

Th.C.P.83 **Multiple Sclerosis and Retrovirus: Screening with retroviral probes of cDNA library constructed with poly A+ RNA from active lesions.**

S. Lefebvre, J. Barrea, S. Charneau, M. Baron.
Laboratoire de Virus Latents, Département de Virologie, Institut Pasteur, Paris, France.

Multiple sclerosis (MS) is a chronic neurologic disease of unknown etiology. The inflammatory demyelinated lesions (plaques) are found in the central nervous system (CNS). Briefly, in MS plaques the oligodendrocytes that are producing the myelin sheath are destroyed leaving naked axons exposed.

One of the best animal models for MS is a demyelinating disease in sheep caused by virus. Virus virus belongs to the retrovirus subfamily of retrovirus and is related to HIV. Recently, another retrovirus was shown to be associated with chronic neurologic disorders. Studies indicated that the oncovirus HTLV-1 has a causal role in tropical spastic paraparesis (TSP) as well as in chronic progressive myelopathy. Attempts were also made to associate HTLV-1 with MS. The results were limited and inconclusive. Since three of the four known human retroviruses can cause neurologic disease, we try to identify retroviral nucleic acid from MS plaques.

RNA was isolated from 10 MS plaques. Purified poly A+ RNA was used to construct a cDNA library in lambdagt10. Low stringency hybridization with specific retroviral probes was used to screen the library for retroviral cDNA clones and topoisomerase. However, these preliminary results will be discussed in regard that they do not exclude the possibility of a new retrovirus.

Th.C.P.80 **IDENTIFICATION OF gp120 FROM HIV BY A "COUPURE" ELISA.**

Aboukhalil, Y., Frickinger, T., and Villacres, M.
Biomedical Center, RM 855, 8-7523 Uppsala, Sweden.

Objective. To develop a sensitive and quantitative test for gp120/gp160 from HIV-1.
Methods. Polyclonal anti gp120 sera were produced by immunizing rabbits with HIV gp120 in Freund's adjuvant. The serum was used as "coupure" antibody. Detection of gp120/gp160 was done by an indirect method using a panel of monoclonal antibodies reacting with gp120 and gp160. The monoclonal antibodies were detected with horse radish peroxidase conjugated rabbit anti mouse antibodies. The monoclonal antibodies were conjugated and attached in our laboratory from spleen cells from mice either immunized with native gp120 or gp160 from vero cells infected with a viraemia virus vector.

Results. We were able to detect gp120/gp160 from cells from different sources with HIV gp120 in culture fluids and HIV infected cells. The detection limit was around 0.5ng. The gp120/gp160 "coupure" ELISA allowed routinely to measure the production of gp120/gp160 in vero cells infected with a viraemia virus vector. The ELISA is also used to determine the yield of gp120 incorporated into 350 experimental/inoculum vaccine. One of the monoclonal antibodies used for the detection of gp120/gp160 recognizes a loop region (aa 303 to 338) and neutralizes the HIV RNA in vitro. The gp120/gp160 "coupure" ELISA we have developed is sensitive with a detection limit of 0.5ng. The ELISA is routinely used for screening of HIV envelope gp120/gp160 content in cell cultures.

Th.C.P.82 **IMPROVED ASSAY FOR DNA-POLYMERIZING ENZYME, BY THE USE OF 3'-NH₂-LIGOCYANURIC TRIPHOSPHATE, ILLUSTRATED BY DIRECT QUANTIFICATION OF HIV-RT ANTIBIOTIC (AR).**

Neuillier M., Karimza A.R., Kallender C.R., J.L. L'Homme, M., B. Baron, M., and J. Barrea, S.
Dept of Molecular Virology, Uppsala University, Box 502, S-751 23 Uppsala, Sweden.

The design of a procedure to synthesize 3'-NH₂-UTRP in one step from 3'-NH₂-UTP, followed by a one-step purification giving an all-over reaction between 30-70% and a 3500 new product within 8 hours is described. The sensitivity and specificity for the 3'-NH₂-UTRP compared to 3'-ATP assays was evaluated with different specimens, including purified recombinant HIV-RT. The 3'-NH₂-UTRP was accepted equally as well as 3'-ATP and depending on enzyme specific a 100-fold increase in assay sensitivity was found when using 3'-NH₂-UTRP at low substrate concentration. Thus the new assay could detect HIV-RT activity from CD 84HD-infected cells, while 0.2610⁶ c.f.u. were needed for detection of purified recombinant HIV-RT. Due to the small HIV-RT amounts necessary for detection, it was possible to quantitate HIV-RT_{ab} without previous purification of immunoglobulin. Analyses of 33 HIV-infected individuals showed that 0.02-0.16% activity corresponded to a 100-fold less immunoglobulin (i.e. all but 21 ng/ml) than earlier reported.... It is concluded that 3'-NH₂-UTRP simplifies the assay, by excluding the need of Triton-precipitation and of scintillation cocktail, and that it is an excellent substrate for improved detection and quantitation of different DNA-synthesizing enzymes, and thus also for their blocking ab.

Th.C.P.84 **A SINGLE TUBE, ONE-STEP PURIFICATION AND ASSAY FOR THE ANALYSIS OF REVERSE TRANSCRIPTASE ACTIVITY (RT) IN CRUDE SPECIMENS AND SOME APPLICATIONS WITH REFERENCE TO HIV.**

Bronckovitz J., Simão, Neuillier M., Barrea, S., Frickinger T., and Kallender C.R.
Dept. of Molecular Virology, and Dept. of Molecular Biology, Uppsala University, Box 502, S-751 23 Uppsala, Sweden.

Based on 3'-NH₂-UTRP as a substrate (see abstract), a further simplified and improved procedure for quantitation of HIV₁ using solid-enclosed template, has been designed. In principle, the assay sample is mixed with a reaction solution containing the radiolabeled substrate and other necessary components, one after the solid-enclosed template is added. Next the reaction proceeds for desired time, whereafter the product is separated from substrate by washing the solid phase with a salt solution. Then the incorporated radioactivity is directly measured in a counter. For the analyses of RT activity in crude specimens, containing disturbing substances or enzymes like DNase, TPase etc, the assay is improved by adding a primary step as follows: the specimen is first added to the solid-enclosed primer template and kept for 10-20 min at 4°C in order to let the RT bind to the template, next the disturbing factors are washed away, whereafter the amount of RT on the solid phase is determined by adding radiolabeled substrate and further proceeding as indicated above. Further, data showing that the assay can be improved by addition of ribonuclease inhibitors and addition of 50% will be given. Analyses using Sepharose or plastic beads as solid phase have been done, and a high recovery of activity from mixtures of recombinant HIV-1 with immunoprecipitated or crude clinical extracts was obtained. Further analysis of clinical specimen are given in abstr. ()

Th. C.P.85 CHARACTERIZATION OF AN HIV-2 RELATED VIRUS WITH A SMALLER SIZED ENVELOPE PROTEIN
Kozak, Ruzsa, Roy, M.A., Laurent, A.G., Gesteau, D., Monagnier, L. and Horvathian, A.S.
Unité d'Oncologie Virale, Institut Pasteur, Paris 15, France.

Objectif: A new cytopathic isolate of the human immunodeficiency virus (HIV) related to the HIV-2 strain was isolated (HIV-2 MAN) from peripheral blood lymphocytes of an Ivory Coast patient with AIDS.
Résultat: HIV-2 MAN could be differentiated by its envelope precursor and external glycoprotein which are 20kD molecular weight smaller than those of HIV-2 ROD isolate. Furthermore, the apparent molecular weight of the major core protein of HIV-2 MAN is 27kD instead of 36kD as in HIV-2 ROD isolate. In addition, the product of the *gag* gene which is a characteristic feature of the HIV-2 strain, is 14kD in precursor of HIV-2 MAN compared with 16kD in HIV-2 ROD. In contrast to these, the envelope of HIV-2 MAN is 27kD instead of 36kD as in HIV-2 ROD isolate. It is the case for HIV-2 ROD. In both cases the transmembrane proteins are 36kD and exist as homodimers of 36kD. No RT digestion experiments indicated that the 20kD difference between the two HIV-2 isolates is due to their polyepitopic moiety. Furthermore partial proteolytic with 1% protease gave two distinct polypeptide patterns, thus suggesting the difference between the external envelope proteins of the two HIV-2 isolates are due to their amino-acid composition. Accordingly, polyepitopic raised against HIV-2 ROD envelope do not recognize the corresponding envelope proteins of HIV-2 MAN by immunoblotting and immunoprecipitation assays.
Conclusion: These data illustrate that analysis of viral proteins could be useful for a rapid and an efficient method to characterize new HIV isolates.

Th. C.P.87 INFECTION AND REPLICATION OF HIV-1 IN HUMAN
NEURO-GLIAL AND PERIPHERAL
T-CELL RECEPTOR-MACROPHAGES

REIN, S., WILSON, D., PRINCE, R., GORVING, J.C.

Unité de Neurobiologie INSERM et les Unités de Neurologie Neurochimie (U-322) - Centre de l'Enfermé - 93 231 - 13200 NANTERRE Cedex, France

Objectif: To characterize the site of replication, localization and transmission of HIV in neurons - macrophages (CM).
Résultat: HIV-1 was found by plaque formation, *in vitro* trans-activator (Tat) gene and RNA detection in both CD4+ T-lymphocytes and in CD4+ macrophages (CM) from healthy donors and from infected *in vitro*. Cells were monitored for HIV by reverse transcriptase (RT), electron microscope (EM) and sensitive DNA detection techniques.

Conclusion: HIV virus expression monitored by RT, was never detected in striatum cultures of HLA-B2 microglial cells *in vitro* or *in vivo*. Structures with a sensitive cell line (CM) or normal PM-180 cells, after freezing - thawing the adherent cells, allowed virus detection. Efficient blockage of virus infection on PM-180 was obtained using low concentrations of human HIV neutralization sera and various monoclonal antibodies (mAb) against CM (13B-2). These mAbs directed against different CM epitopes are currently investigated. In the absence of a high amount of viral particles included into immunological vesicles of HLA-B2 while no mAb was present. Furthermore, no neuronal budding has been seen on the same cells. Preliminary results using Western analysis indicated that viral DNA was not incorporated in infected HLA-B2.

Th. C.P.89 EXPRESSION OF VIRAL AND CELLULAR GENES IN CELLS INFECTED BY THE HUMAN IMMUNODEFICIENCY VIRUS, HIV-1, AND THE SIMIAN IMMUNODEFICIENCY VIRUS, SIVmac.
Klein, R., Berman, R.S., Hoenes, R.L., Roy, K.J., Gray, L.J., Kay, M.A., I. Department of Microbiology, University of Washington, Seattle, Washington; Regional Primate Research Center, University of Washington, Y-10 of viral pathogenesis, NCI, Frederick Cancer Research Center, Frederick, Maryland, U.S.A.

The current study was undertaken to define the complex regulatory events occurring *in vivo* in CD4-positive lymphoid cells infected by HIV-1 and SIVmac. Initial efforts were directed at measuring viral and cellular mRNA and protein levels in HIV-infected CD4 cells. Northern blot analysis revealed that viral-specific mRNAs could be detected as early as 2 days after infection of CD4 cells by HIV-1. Maximal accumulation of the major species of viral mRNAs occurred by 5 days post-infection (PI). In accordance with these results, the synthesis of viral-specific proteins was readily detectable at 2 days PI and peaked essentially at 4 and 5 days PI. Immunofluorescence studies showed that >95% of CD4 cells are infected by 4 days PI. Cell viability studies, using trypan blue exclusion, demonstrated that 75% of infected cells were still viable at 4 and 5 days PI. We next examined the effects of HIV-1 infection on cellular mRNA and protein synthesis. The steady state levels of actin and GAPDH mRNAs steadily declined during virus infection with actin mRNA levels down ten-fold by 5 days PI in HIV-1 infected CD4 cells. There was a corresponding progressive decrease in cellular protein synthesis during infection at the time when viral protein synthesis was found to peak. In parallel studies, we examined the kinetics of viral protein synthesis in cells infected by SIVmac. In contrast to the results obtained with HIV-1, little or no viral protein synthesis was detectable in SIV-infected CD4 cells. However, in SIV-infected CD4 cells, high levels of the SIV-specific proteins were detectable by 2 days PI. As was the case in the HIV-1 system, overall levels of cellular protein synthesis declined during infection of CD4 cells. Efforts are in progress to delineate the mechanisms responsible for the decreases in cellular mRNA and protein levels in HIV- and SIV-infected cells.

Th. C.P.86 NEW TESTS USING SYNTHETIC PEPTIDES IN THE DIAGNOSIS AND TYPING OF HIV INFECTIONS IN HUMAN.

MAITIN, Jean-M., BERTHOUD, S., ADDA, O., TSAI, F.C.P., RICHARDSON, C., GOMAS, J.
*CLONATEC 40 Rue de Valenciennes 75008 Paris France
**SYNTO, S.A.R.L. 08020, CA, USA

Objectif: Monoclonal ELISA using 4 synthetic peptides derived from transmembrane glycoprotein of HIV-1 and HIV-2 were optimized. One shows no cross-reactivity (TOTAL HIV Ab (1-2)) and the other one allows to type specifically and HIV-1 and anti-HIV-2 antibodies (TYPING HIV AB (1 or 2)).
Method: The TOTAL HIV Ab assay involves microtiter wells coated with a blend of the two HIV-1 and HIV-2 peptides and the TYPING HIV AB involves microtiter wells coated with HIV-1 peptide only and assays coated with HIV-2 peptide only on the same plate. The duration of the test is 35 minutes long (15 min. serum incubation, 15 min. conjugate incubation and 5 min. color development).
Résultat: In a preliminary study, 302 sera were tested: 191 and HIV sera and 111 negative sera. Among the 191 positive sera: 122 samples are from Europe origin, 47 samples from Africa origin, 13 samples are from HIV-1 and 7 samples are anti-HIV-2 sera (Africa origin). Among the 111 negative sera: 60 samples from Europe origin, 41 samples Africa origin and 4 samples are from HIV-2 sera. The performance of TOTAL HIV AB and TYPING HIV AB are respectively of 99.16 and 99.36 for sensitivity and 100% 100% for specificity. The cross-reactivity of anti-TYPING HIV AB is 1.16 for anti-HIV-1 sera and 0.2% for HIV-2 sera.
Conclusion: These first results show the advantages of ELISA kits using synthetic peptides for detection of HIV antibodies and also to the infectious virus, this is a very important information for epidemiologic studies. We thank Dr. Ph. Poulety.

Th. C.P.88 ZIDOVUDINE SERUM LEVELS AND HALF-LIFE IN PATIENTS ON CHRONIC MAINTENANCE HEMODIALYSIS

Schilling, H.-J., Averhoff, H.
*Universitätsklinikum Hamburg Eppendorf, Hamburg; *Augusta-Viktoria-Krankenhaus, Berlin; FEDERAL REPUBLIC OF GERMANY

Objective: To determine zidovudine serum levels and half-life in HIV patients on chronic maintenance hemodialysis due to renal failure.

Method: Zidovudine serum levels were determined with an HPLC assay at 0, 60, 120 and 180 min. after single dose oral administration and during hemodialysis sessions. 2 patients with HIV-1 infection have entered the study so far. 1 pat. is ready for evaluation, 1 is still under study.

Patient characteristics:

age	sex	HIV risk cause	renal CD4+	p24 other
42	male	unknown	0.51	undetectable
50	male	transfus. IgA nephritis	0.15	>1000 U/ml

None of the patients had impaired hepatic function.
Results: Zidovudine peak levels were reached after 2 h following oral administration of 100-200 mg of AZI. They were within the therapeutic range (1.67 mg/ml). Half-life was not prolonged and was not significantly altered by hemodialysis in the first pat. studied so far. The results of both will be ready for presentation in detail.
Conclusion: Serum half-life of zidovudine may be normal in renal failure and patients on chronic hemodialysis. Delayed and low peak levels may be due to impaired absorption. Because of these results different from the observations of others (Dery et al. 1988) a pretherapeutic assessment of the basic pharmacokinetic parameters seems justified in this setting.

Th. C.P.90 IDENTIFICATION OF HIV-1 PACKAGING SIGNALS

Levy, Andrew; Gottlinger, M.; Haseltine, W.; Sodroski, J.
*Fred Hutchinson Cancer Institute, Harvard Medical School, Boston, MA U.S.A.

Objective: To define regions of the HIV-1 genome required for packaging HIV-1 RNA into virions.

Methods: Deletions in the area 3' to the splice donor and 5' to the *gag* ATG were made using site directed mutagenesis. Virion RNA content was determined by RNA dot-blot analysis.

Results: Deletions of as little as 19 base pairs in this region produced virions which produced abundant viral protein and morphologically normal virions as seen by EM. These virions displayed a characteristic replication defect and packaged virion RNA at an efficiency of 2% of wild-type virion.

Conclusions: A region important for packaging HIV-1 RNA into virions has been defined. Mutation of this region inhibits both cell free and cell to cell viral transmission.

Th.C.P.91 DIFFERENTIAL INHIBITION OF HIV VARIANTS INDUCED SYNTHESIS FORMATION BY SEROPOSITIVE PHAGOCYTES

Steinhausen, E.; Sempaphanlann, E.; Cahill, O. and Rubinstein, Arvo

Albert Einstein College of Medicine, Bronx, N.Y., U.S.A.

Objective: To assess the ability of sera from HIV seropositive children to inhibit *in vitro* synthesis of HIV-1 and HIV-2 variants.

Methods: Sera were incubated with supernatant from 8-9 cells productively infected either with HIV-1-1118 or -877. The virus-serum mixtures were inoculated into CEM-10 cells plated on poly-D-lysine coated 96-well plates. Syncytia were counted after 3 days incubation at 37°C.

Results: Each serum was initially tested for its ability to inhibit *in vitro* syncytium formation induced by HIV-1118. Four of the sera showed low inhibition (10-20%). Three other samples exhibited intermediate inhibition (40-60%) and the remaining 3 showed high neutralizing activity (80-100%). The same sera were subsequently tested for their ability to inhibit HIV-877 induced syncytium formation. The sera showed equivalent neutralization of both variants. Of the remaining 3 samples, 3 exhibited 2-fold increase in inhibition of 877 whereas the remaining 1 sample did not neutralize 877.

Conclusions: Sera from HIV seropositive children showed inhibition of HIV induced syncytium formation *in vitro*. Sixty percent of the samples showed equivalent neutralization of 2 different HIV-1 variants, whereas significant differences were observed in 40% of the samples. The development of HIV disease has been shown to correlate with the emergence of HIV-1 variants which, *in vitro*, are progressively more cytopathic. Neutralization of a range of HIV strains may be prognostic of improved clinical outcome.

Th.C.P.92 HIV-1 INFECTION OF HUMAN DENDRITIC CELLS: NEW EVIDENCE FOR SILENT INFECTION

Hahné, M.J., Albert, J.J., Verbeek, H.M., and Agt, W.H.

1. Department of Virology, Middelkade Institute and 2. Department of Virology, National Reference Laboratory, Stockholm, Sweden.

OBJECTIVE: To study HIV-1 infection of normal peripheral blood monocytes/macrophages.

METHODS: Monocyte cultures were prepared from untreated blood mononuclear cells (MNC) released by Ficoll-Paque gradient centrifugation. PBCs were cultured in RPMI medium containing 10% HIV negative human serum and 20% FCS. After five days non-adherent cells were discarded. The monocyte cultures were infected with viruses isolated from primary PBC of HIV-1 seropositive individuals. Two months after infection PMA-stimulated normal PBC were added to the monocyte foci in RPMI medium with 10% FCS. Virus infection was monitored by reverse transcriptase (RT) activity and presence of viral antigen (p24). In culture medium, as well as by immunofluorescence (IF) of infected cells.

RESULTS: HIV-1 replication in monocytes was transient and could be detected by antigen assay in 11 cultures and by RT assay only in 2 cultures (of 14). One if virus replication appeared to be short for up to ten months after infection. The presence of virus could be demonstrated in 12 of 18 monocyte cultures by co-cultivation with PMA-stimulated PBC.

CONCLUSION: Our results show that HIV-1 infection of normal monocytes/macrophages can lead to a silent latent infection. Such persistently infected, non-producing cells, may conceivably serve as infection reservoirs in the infected individual and spread infection to other susceptible cells for a long time.

Th.C.P.93 EFFECT OF CALCIUM CHANNEL BLOCKERS ON HIV-1 EXPRESSION IN LYMPHOID CELLS

Harrison, Gary*, Kim, D**, Baltimore, D**, and Hammer, D**

*New England Deaconess Hospital, Boston, MA, U.S.A.

**Whitehead Institute, Cambridge, MA, U.S.A.

Objective: To determine the effect of the calcium channel blockers (CCB's) verapamil (V), diltiazem (D) on the replication of HIV-1 and the expression of the HIV LTR in lymphoid cells.

Methods: CEM cells were exposed to CCB's at 0, 25, 50, and 75 µM for 1 hour before inoculation with HIV-1118 or medium control. Drug concentrations were included in the cultures, which were monitored for RT activity. Fixed cell immunofluorescence (IFA) for p24 antigen, and cell viability. The effect of CCB's on HIV LTR expression was determined by transfection of CEM cells with LTR-chloramphenicol acetyltransferase (CAT) plasmid constructs, exposure to 50 µM V or D for 48 hours, and assay of CAT activity.

Results: Peak RT and p24 IFA+ cells were seen 3-4 days earlier in V and D treated cultures vs controls. I had no effect. Results, day 8 post-infection:

	RT (log ₁₀ copies/ml)	p24+ Cells (%)	Viability (%)
V 75 µM	5.70	83	63
D 75 µM	5.70	82	80
Control	4.22	5	99

HIV LTR-CAT activity was 7 fold at 50 µM induced consistent 5-10-fold increases in CAT activity.

Conclusions: (1) CCB's can markedly enhance HIV-1 replication in lymphoid cells. (2) This effect may be related to activation of the HIV LTR. (3) Agents which affect signal transduction can be used to further our understanding of the control of HIV replication.

Th.C.P.94 A RAPID AND SENSITIVE PLAQUE ASSAY OF HIV-1 ON CR166 CELLS

Zhu, J.-P., Chan, J.-Y., Janda, R.A.,** and Brinkman, Benjamin*

*Children's Hospital, Harvard Medical School, Boston, MA, USA

**Chester Beatty Institute, London, England

Objective: To develop a sensitive and simple assay to measure the infectivity of human immunodeficiency virus (HIV-1).

Methods: A syncytial plaque assay was developed using CR166 cells (kindly supplied by E. Gallo), a CEM lymphocytic line derived from cord blood and superinfected with HIV-1. The cells were adhered to plastic with poly-D-lysine, infected, and overlaid with agarose. After 2-3 days' incubation, agarose gel was added in a 2nd overlay, and syncytial plaques were counted 8 hours later using low-power or dissecting microscopy.

Results: Two strains of HIV-1, 1118 and 877, were tested, and both produced giant cells large enough to be easily recognized as plaques after staining. There was a linear correlation between number of plaques and virus dilution. The sensitivity of the assay was almost identical to that of TIGD5 tests. Plaques were specifically inhibited by neutralizing antibody. Two of 3 new isolates of HIV obtained from pediatric AIDS cases exhibited focused plaques. The assay has been used to determine the neutralizing antibody titres in multiple serum specimens from children with HIV infection.

Conclusion: A plaque assay of HIV-1 on CR166 cells has been developed which rapidly permits the determination of infectivity in untreated and new clinical isolates and quantitation of neutralizing antibodies in human sera. The assay is rapid, sensitive, reproducible, and easy to perform.

Th.C.P.95 PROCESSING AND ASSEMBLY OF HIV-1 CORE ANTIGENS EXPRESSED BY RECOMBINANT VACCINIA VIRUS

Wu, Zhi-Ling¹, Travis, B.M.², Sridhar, P.², Dykers, T.²

Garrison, J.,¹ Drexler, G.²

Objective: To demonstrate processing and assembly of HIV-1 core antigens expressed by recombinant vaccinia virus and to study the effect of viral protease on these processes.

Methods: Recombinant vaccinia viruses have been constructed that contain the gag ORF and varying extents of the pol ORF of HIV-1. Biosynthesis of HIV-1 core antigens was studied by serological assays and the assembly of core structures detected by electron microscopy.

Results: HIV gag antigens are efficiently expressed by all recombinants tested. Recombinants lacking the protease-encoding region direct the synthesis of gag antigen precursor p55 and processing intermediate p40 only. Those containing the protease region direct synthesis of the processed products p24 and p17 as well. Surface fluorescence is detected by anti-p24 MAb in 10-15% of the infected cells and up to 15% of the core antigens synthesized is released into the media. Particles of 100nm diameter are present in recombinant-infected cells, even in the absence of viral protease functions.

Conclusions: HIV-1 core antigens are efficiently expressed and processed by recombinant vaccinia virus infected cells, indicating the presence of viral protease function are successful read-through of the gag and pol ORF. Recombinant-made gag antigens are assembled into viral core-like structures. This process is independent of any other HIV-specific functions, including that of the viral protease.

Th.C.P.96 CHARACTERIZATION OF HIV-1 PROTEINS EXPRESSED BY VACCINIA VIRUS AND E. COLI

Atsushi, Kazumi¹, Kei-ko, A.², Okamoto, T.³, Chiba, Y.⁴

¹Saito, T. and ²Kuroki, M. ³RIKEN Japan, ⁴RIKEN Japan.

* Nippon Zen Co., LTD., Kawasaki, Japan. ** NIH Japan, Tokyo, Japan. *** Natl. Cancer Center Inst., Tokyo, Japan.

Objective: To examine immunogenicity of HIV-1 gag proteins, p17 and p24, and reverse transcriptase (RT) and rF proteins. The DNA fragments representing p17 or p24 of gag protein, RT or rF protein as well as the sequences spanning from gag to rF were expressed both in recombinant E. coli and in recombinant vaccinia virus (RV). These sequences were prepared from a HIV-1 clone pH810 by restriction endonuclease digestion and/or site-directed mutagenesis and inserted into a bacterial expression plasmid pCR80 and vaccinia virus genome. HIV-specific proteins expressed from the recombinants were detected and identified by indirect fluorescence antibody (IFA) and western blot analyses, using polyclonal and monoclonal antibodies against HIV-1 proteins.

Results and conclusion: Expression of the proteins reacted with patients' sera and monoclonal antibodies was observed except for constructs in both RV-infected cells and E. coli transformed with recombinant plasmids. The production of HIV antigens was also demonstrated at the serum sites inoculated with RV by IFA. For preliminary immunological analysis, rabbits were inoculated with RV expressing p17 and serum samples were prepared for specific response for specific response. Indetectable levels of anti-p17 antibodies are not detected so far. Immunogenicity of other RV and E. coli-derived HIV proteins is presently under research.

Recherche fondamentale (biomédicale) Basic Research (Biomedical)

Th.C.P.103 SINGLE AMINO ACID SUBSTITUTIONS IDENTIFY AMINO ACIDS CRITICAL FOR RNAse H ACTIVITY IN REPLICATION OF HIV. Repard, Roy, Clancy, E. and Mauchly, T. D. LAM, MAED, National Institutes of Health, Bethesda, MD, U.S.A.

Objective. To identify amino acids in the HIV *gag* gene critical to the function of RNAse H. **Methods.** Site-directed mutagenesis was used to substitute either of two conserved retroviral *gag* amino acids (aspartic acids) in the putative RNAse H domain in a molecularly cloned infectious HIV (pNL4-3). HIV particles produced by SW480 cells following transfection of the mutant DNAs were harvested, evaluated for RT activity and for infectivity on A3201 cells. RT and RNAse H activities of the partially purified mutant RTs expressed in *E. coli* were determined. **Results.** SW480 cells transfected with the mutated pNL4-3 DNAs produced particles with normal protein and RNA content and slightly decreased RT activity. These particles were not infectious. Whereas RT activities of normal and mutant RTs expressed in *E. coli* were essentially the same, the RNAse H activity in mutant RTs was decreased more than 30 fold. **Conclusion.** Two conserved aspartic acid residues in RT are associated with RNAse H function and are critical for infectivity of pNL4-3.

Th.C.P.105 HIV-1 ANTIBODY SCREENING IN 1646 SEROPOS, HEMOPHILIACS, HEMOPHILICS AND BLOOD DONORS IN EDINBURGH, SCOTLAND. Waters, Leslie M.,** Thompson, J.C.,** Hay, P.A.,** Jordan, A.,** Townell, J.,*** Watt, R.,*** Edwards, R.,*** Edwards, R.,***

**Regional Virus Laboratory, City Hospital, EDINBURGH.
***National National Blood Transfusion Service, EDINBURGH.
****Scottish Reference Laboratory, University of Edinburgh.
*****Central Public Health Laboratory, LONDON, UNITED KINGDOM
Objective. To test for HIV-1 antibody titres in three high risk populations and new blood donors in an area where a high proportion of intravenous drug consumers (IUDCs) are HIV-1 positive. **Methods.** HIV-1 antibody tests were performed on sera from 300 IUDCs, 130 blood donor recipients (BDRCs) (100 haemophilic and 30 non haemophilic donors), 503 heterosexual or bisexual men and 500 new blood donors using Duoset HIV 1 ELISA. HIV antibody seropositivity rates in the groups studied were estimated. Confirmatory testing for HIV-1 antibody was by immunofluorescence (IF) against HIV-1 infected cells, particle agglutination assay for HIV-1 (F) (Ria) and immunoblotting. **Results.** 1 of 300 IUDCs, 1 of 130 blood donor recipients, 6 of 153 heterosexual or bisexual men and 1 of 500 new blood donors were positive by ELISA. Confirmatory testing was undertaken on the single positive IUDC and the individual was negative for HIV-1 by particle agglutination test, positive by IF and immunoblotting. This patient (who is HIV-1 antibody negative) may be infected with a retrovirus other than HIV-1 or HIV-2. The single positive haemophilic was of Japanese origin and was possibly infected by Japanese blood or blood products. Results from confirmatory testing are omitted in the single positive blood donor. **Conclusion.** HIV-1 appears in this initial survey not to have significantly infiltrated a population with a high rate of HIV antibody infection, nor in other high risk populations or new blood donors in the same city.

Th.C.P.107 FUSION OF SDGAN IMMUNOPRECIPITATION VIRUS (SIV_{SD}) WITH LIPIDOMES AND ERTHROCYTE GHOSTS. Lopez, Charles,** Alford, D.,** Yang, L.,** Lee, K.-D.,** McGrath, T.,** and Dinglasan, N.,** University of California, San Francisco, CA, USA. and **National Center for Human Research Center, Davis, CA, USA.

We investigated the kinetics of membrane fusion between SIV_{SD} and phospholipid vesicles, and the effects of various parameters on this process. SIV was purified by sucrose gradient and precipitation of cell-free supernatant followed by two sucrose density gradient centrifugations, and labeled with octadecyl rhodamine (B18). Fusion was monitored continuously as an increase of fluorescence intensity resulting from the dilution of the probe into target membranes. Ultrastructural analysis of the virus and fusion products was performed by electron microscopy. Viral fusion was strongly dependent upon the liposome composition. Pure cardiolipin (CL) vesicles fused with the virus at a fifty-fold greater rate than pure dioleoylphosphatidylcholine (DOPC) liposomes. SIV fusion with CL/DOPC (3/7) and phosphatidylserine (PS) vesicles was slower than that with pure CL. Calcium or reduced pH greatly enhanced the rate of SIV-CL fusion but did not affect that of SIV-DOPC fusion. SIV also fused with erythrocyte ghosts, and the rate of fusion increased in the presence of calcium or reduced pH. SIV fusion with model membranes is similar in some aspects to that of other lipid enveloped viruses. Our results indicate that SIV can fuse with biological and model membranes lacking the CD4 receptor. This assay system can be used to test inhibitors of the fusion activity of SIV.

Th.C.P.104 HIV RESISTANCE IN PLASMA OF PATIENTS WITH RETROVIR.

Deleens, J.,** Blanchet, A.,** Tourenq, J.A.,** Leclercq, D.,** Stane, M.,** Loussier, M.,** Wasth, M.,** Jadot, J.A.,** for the Laros HIV Study Group - Laros Institute 87 - 40 de Meuse - 7200 HAININ OISEL - Belgium

Measurement of the viral load in HIV disease is crucial for the management of antiretroviral patients (pts) especially to evaluate their response to current and future therapeutic trials. To assess the HIV production *in vivo*, we have developed an assay measuring directly cell-free virus in plasma. We cultured plasma (sent cells) from 20 HIV pts (10 AIDS and 10 asymptomatic pts) with an 14 cell control before and 3 month after start of AZT therapy (10µg/ml) * 10⁶ aliquots normal. 14 days prior to PMA and IL2 were cultured with 200 µl of HIV plasma or with 10⁶ HIV₉₀ in 12-well coated plates. 14 experiments were serially harvested for 30 days. 1 pt. was tested with an immune capture assay (Immocore). Cell cultures were 100% positive for HIV-1 RNA and antigenemia was absent. 14 patients were:

	before AZT	after AZT	before AZT	after AZT
Plasma culture	10 positive-3 positive	8 positive-3 positive	8 positive-3 positive	2 negative-1 positive
Antigenemia	11 positive-3 positive	7 positive-3 positive	11 positive-3 positive	2 negative-1 positive

These data demonstrate a significant decrease of plasma infectivity under earlier administration of AZT, and suggest that measurement of plasma HIV is a more valuable tool to evaluate the *in vivo* antiviral activity of chemical compounds than pH antigenemia. However, since these 2 parameters are not closely linked they are both useful for the management of HIV asymptomatic individuals.

Th.C.P.106 THE KILLING EFFECT OF 65°C TEMPERATURE ON HIV-1 IN DRIED BLOOD: DECONTAMINATION OF LAB. INSTRUMENTS/EQUIPMENTS. Boradon, Farzadmanesh,* W. Hardig,* K. Qataish,* B. Tappes,* P. Goldenbom,** A. Laak,* John Johns Hopkins Hospital of Hygiene and Public Health, Baltimore, MD. **Mectron-Dickinson, Johnson Laboratories, Towson, MD, U.S.A.

OBJECTIVE: To determine the efficacy of 65°C for inactivation of HIV-1. This information is valuable for industrial settings involved in repairing laboratory instruments/equipments contaminated with human blood. **METHODS:** HIV-1 (250-500 pg/ml) was mixed with normal blood. One tenth of 1 ml HIV-1 inoculated blood was placed on a sterile plastic slide (in duplicate) and air dried at room temperature for 24 hours. Dried blood samples were left in an oven heated to 65°C for 4, 8, 12, 16, 24 and 36 hours (intervals). After the specified time interval, samples were removed and blood was eluted in 5ml of RPMI. A sterile rubber police spatula was used to ensure removal of blood residues. (Slides were used for HIV-1 isolation using cocultivation with PHA-P treated normal PHW⁺ cells (SIIG⁺ cells) in a 125 cell flask in 1:1 containing RPMI culture media and monitored for viral growth. **RESULTS:** HIV-1 was isolated from blood samples not heated at 65°C. However, HIV-1 was not recovered during one month of follow-up from any blood samples that were incubated at 65°C for four hours or more. **CONCLUSIONS:** HIV-1 in dried blood does not survive four hours or more at 65°C. This low and safe temperature therefore could be applied for decontamination of laboratory instrument/equipment contaminated with human blood.

Th.C.P.108 MONOCLONAL ANTIBODIES TO HTLV I AND HTLV II GAG PROTEINS.

Hoffman-Barrett, Cathryn L.,** Bodner, A.J.,** Alexander, S.,** Salaudeen, Z.,** Lipsky, M.,** and Cortman, A.,**

**Hirsch Research Laboratories, Inc. Bethesda, MD

**NCI, National Institute of Cancer, Bethesda, MD.

**National Institute of Health, Bethesda, MD, U.S.A.

Objective. To generate specific and cross-reactive monoclonal antibodies (MoAb) to HTLV I and HTLV II gag proteins. **Methods.** Lymphocytes from Balb/c mice immunized with either HTLV I or HTLV II viruses were fused with NS-1 myeloma cells by the procedure of FCG. ELISA assays were utilized to select cells secreting anti-viral immunoglobulins. Cells were cloned by limiting dilution. ELISA results were confirmed and protein specificity determined by Western Blot and by RIBA. Immunoglobulin subclass was determined by Ouchterlony double diffusion. **Results.** MoAbs isolated from HTLV I immunized mice showed the following reactivities: (1) specificity for HTLV I p19, (2) specificity for HTLV I p24, (3) cross-reactive with HTLV I and HTLV II p24, and (4) cross-reactive with HTLV I p19 and HTLV II p22. The HTLV I p19 specific clone recognizes and cross-reacts with HTLV I p19 and HTLV II p22. The HTLV I p24 specific clone recognizes only p19. MoAbs isolated from HTLV II immunized mice were: (1) specific for HTLV II p22, (2) cross-reactive for HTLV I p19 and HTLV II p22, and (3) cross-reactive for HTLV I and HTLV II p24. All MoAbs were IgG₁ subclass. **Conclusion.** HTLV I and HTLV II p22 share a common epitope. The p19p22 and the p24 proteins of HTLV I and HTLV II have similar and differing antigenic epitopes.

Th.C.P.109 ADDITIONAL CHARACTERIZATION OF ORIGINAL HUMAN IMMUNODEFICIENCY ISOLATES FROM TWO CONTINENTS. ANT 70 AND ANT 70A
Bart Vandenbroucke, L. Eys, N. Vanden Bessende, B. Van Neerwyn, R.J. De Leyn. Zoogenetica N.V. Antwerpen, Belgium.

Objective: To assess the relationship between isolated ANT 70 and ANT 70A and other HIV and HIV strains and to determine the biological properties of the isolates.
Results: Dot-blot hybridization experiments were performed in order to evaluate the relationships of the isolate ANT 70 to other known human and simian immunodeficiency viruses. Hybridizations were carried out using probes derived from HIV-1 (gp120), HIV-2 (gp120), and ANT 70 (gp120). Under nonstringent conditions, crosshybridization was observed between virus types. However, a clear distinction could be made between ANT 70 and ANT 70A, and other virus types under stringent conditions. Although ANT 70 and ANT 70A have been shown to be indistinguishable by Western blotting or nucleic acid hybridization techniques, biological differences could be demonstrated between the two strains in terms of their preference for certain cell lines.
Conclusions: ANT 70 and ANT 70A differ significantly in their nucleic acid homology from prototype HIV-1 and HIV-2 strains, even in relatively highly conserved regions of the genome. The two isolates are highly related to each other but can be differentiated based on biological properties.

Th.C.P.111 DETECTION OF HIV GENOME IN SERONEGATIVE HOMOSEXUAL MEN
Perrille Nègre¹, Gerald-Jai P...Vonnest, N.-J. Gentili, J...Stuenkel, N.-J. and G...
¹Institute Infectious Disease, Policlinico Umberto I University of Rome, Rome, Italy

Objective. The aim of our investigation was to evaluate the presence of HIV latent infection and HIV genome in peripheral blood mononuclear cells (PBMCs) from 20 asymptomatic homosexual men with multiple sexual partners. All the subjects, non intravenous drug users, were seronegative for anti-HIV antibodies (ELISA test and Western Blot), for HIV antigens and RNA. The 74/70 cells ranged between 0.7% - 2.5%.
Methods. Cytocentrifuged PBMCs were "in situ" hybridized with three probes: 1) the HIV Δ8 plasmid containing the 9 kb full-length viral insert; 2) the pBR322 to reconstituent clone able to recognize both viral RNA and proviral DNA; 3) the pBR322 plasmid lacking viral insert. The probes were tagged by inserting an antigenic sulfone group in cytosine residues and visualized by the sandwich immunohistochemical reaction using a specific monoclonal antibody against the sulfone group and an anti-mouse alkaline phosphatase conjugate antibody (Chemie probe, Organon). The controls were performed by HIV non infected and infected 5 cell culture lines and PBMCs from 20 healthy heterosexual men.
Results. HIV genome sequences were observed in the cytoplasm of mononuclear cells of three subjects as a granular staining and in some cases a mild non clear positivity was found. The HIV genome was observed also in three cases.
Conclusions. Active homosexual and/or bisexual men are at risk of acquiring HIV infections.

Th.C.P.113 Sodium Pentosan Polysulfate (SP-54), an Anti-HIV Agent Also Enhances Lymphocyte Proliferative Activity and Synergism with AZT

HSA Ahmad, Sanyar Nayyar, Teresa A. Galvin, Carl R. Merrill, Llewellyn B. Bigelow¹, Laboratories of Biomedical Genetics and Clinical Brain Research, National Institute of Mental Health, Saint Elizabeths Hospital, Washington, DC U.S.A.

Objective. Sodium pentosan polysulfate (SP-54) was studied for its antiviral activity against HIV-1 and was compared with dextran sulfate (DS) and AZT.
Methods. Drug responses on the production of HIV-1 in normal human peripheral mononuclear cells were tested by reverse transcriptase (RT) assay, p24 antigen test and p24 radioimmunoassay.
Results. More than 90% of virus replication was inhibited with 5.0 mcg/ml of SP-54. Direct inhibitory effect of SP-54 was also observed on the HIV reverse transcriptase reaction in vitro. No toxicity was observed with SP-54 on PMNC cultures. In fact, it had proliferative effect on uninfected PMNC and protective effect on infected PMNC cultures at concentrations of 0.1 to 10.0 mcg/ml. In addition, SP-54 showed profound synergism with AZT. In the presence of 25 and 100 nM AZT, 2.0 mcg/ml of SP-54 reduced HIV-1 replication 110- to 176-fold as compared to 3- to 16-fold decrease in the presence of either drug.
Conclusions. SP-54, owing to its anti-HIV-1 activity, nontoxic nature, lymphocyte proliferative activity and synergism with AZT could prove to be a valuable agent in the chemopreventive intervention of AIDS.

Th.C.P.110 EXPRESSION OF THE GAG-POL GENE PRODUCTS OF HUMAN IMMUNODEFICIENCY VIRUS BY RECOMBINANT VACCINIA VIRUS VECTORS
Shioda, Tatsuo; Hirose, K.; Awada, H.; and Shioda, T.
Institute of Medical Science, University of Tsuyuki, Tsuyuki, Japan.

OBJECTIVE: To understand the molecular mechanisms of virion assembly and processing of the gag precursor. The gag-pol genes of the thymidine kinase gene of vaccinia virus (TK) were inserted into the thymidine kinase gene of CV-1 and 8240 cells infected with the recombinant vaccinia virus (RV) carrying the entire gag-pol region. The precursor gag protein was almost exclusively detected by immunoblot analysis using serum from an AIDS patient. However, in the culture fluids of infected 8240 cells, but not of infected CV-1 cells, we could clearly detect reverse transcriptase (RT) activity, even when the replication of vaccinia virus was suppressed by cytosine arabinoside. The highest RT activity was found at a density of 1.6 x 10⁶ cells and this fraction was revealed by immunoprecipitation with the cleaved gag proteins by immunoblot analysis, suggesting that particles containing the HIV RT and the cleaved gag protein were released from infected 8240 cells. The corresponding fraction prepared from the culture fluids of 8240 cells infected with another RV carrying only the gag gene contained exclusively the uncleaved gag precursor and lacked the RT activity, confirming that the processing of the gag precursor was mediated by the HIV protease encoded in the pol gene. Electron microscopic examination is now under way. **CONCLUSION:** Our results showed that only the gag gene products are sufficient for particle production and suggested that the particle formation is necessary for efficient processing of the gag precursor.

Th.C.P.112 A METHOD FOR QUANTITATING INFECTIOUS HIV PARTICLES

Tilgner, Egon and Grinde, B.
Department of Virology, National Institute of Public Health Oslo, Norway.

Objective. To develop a method for determining the number of infectious HIV particles in various preparations.
Method. M74 cells were incubated with the preparation containing HIV particles for 1 h. The cells were then mixed with a molten solution of agarose in a cell medium. The agarose was placed in the refrigerator for rapid solidification. Extra medium was added on top of the gel and the tubes incubated for four days with one medium change. The gels were then melted by heating, mixed with a salt solution and the cells rescued by centrifugation. After fixing, the cells were stained by immunofluorescence using an anti-HIV antiserum. The relative number of fluorescent cells were counted.
Results and Conclusion. Cultivating the infected cells in an agarose gel prevented the transfer of virus between cells. The number of HIV positive cells after the incubation should therefore reflect the concentration of infectious HIV particles in the original preparation. If the cells had been cultured without a gel, some cells would be expected to prevent antigen due to secondary infection. The present method is faster than traditional plaque assay.

Th.C.P.114 VIRAL GENE EXPRESSION ASSESSED BY PCR IN HIV-1

INFECTED BY HIV-1
Miyatake, T., Ruta, M., Geyer, S.J., Hawthorne, C., Ford and Drug Administration, Bethesda, MD, U.S.A.

Objective. To study early events of viral gene expression in HIV-1 infected cells by a sensitive gene amplification technique, polymerase chain reaction (PCR).
Methods. 89 cells were infected with HIV-1 (10⁶ infectious units/ml). At various times after infection (1, 6, 18, 24, 48, 72 and 144 hr), high molecular weight DNA and RNA were isolated from the cells. DNA and RNA were detected by co-amplification of primer pairs to gag, env, tat and pol regions of the viral genome using PCR. Reverse transcriptase (RT) activity was measured by direct assay of cell culture supernatants.
Results. HIV-1-specific sequences were first detected in genomic DNA of 89 cells 3 hrs. after HIV-1 infection, thereafter, these sequences increased in copy number. Synthesis of viral-specific RNA was detected at 6 hrs. after infection. Extracellular RT activity increased 35-fold, to 0.75 ng/ml T17hr/10⁶ cells 3 and 6 days after infection.
Conclusions. Results indicate that virus-specific DNA became integrated into host genome rapidly after HIV-1 infection, followed several hours later by synthesis of viral RNA's. Release of virus, signalled by increased extracellular RT, was delayed between 3 and 6 days. These results demonstrate that PCR is a useful technique to evaluate early events in replication of HIV-1 in target cells such as lymphocytes and macrophages.

Recherche fondamentale (biomédicale) Basic Research (Biomedical)

Th.C.P.115 PURIFICATION AND ANALYSES OF THE HTLV-I ENVELOPE GLYCOPROTEIN gp46 USING AN ANTI-CARBOXYLY-TERMINAL SYNTHETIC PEPTIDE SERUM.

Lilohol, Edik, Nguyen, A., Tu, C., Alexander, S.
Biotech Research Laboratories, Inc., Rockville, MD 20855, USA.

Objective: The objective was to isolate gp46 from HTLV-I transfected HUT102 cells by immunofluorescent chromatography.

Methods: A rabbit antiserum against a synthetic peptide corresponding to the carboxyl-terminus of gp46 (LPPFLSLSPVTLGSSSRK) was prepared and analyzed for reactivity with the native gp46 and precursor gp64 proteins by ELISA, Western blot and RIFA assays. An affinity column was used to purify gp46.

Results: The anti-peptide serum reacted with gp46 with apparent molecular weights of 46,000 on HTLV-I and HTLV-II virus Western blot strips. The specificity of this reaction was established by inhibition with the homologous but not an irrelevant peptide. Removal of N-linked carbohydrates with endoglycosidase F resulted in a decrease in molecular weight from 46,000 to 31,000. RIFA analysis using 13S5 methionine labeled HUT102 cell lysates revealed specific reactivity with the envelope precursor gp64 in addition to a smaller protein of approximately 30,000 daltons. gp46 was purified by immunofluorescent chromatography and shown to be reactive with sera from HTLV-I infected patients as well as monoclonal anti-HTLV-I gp46 antibody but not sera from uninfected individuals or monoclonal anti-HTLV-I gag (p19, p24) antibodies. False reactivity of the gp46 preparation with an antiserum against uninfected T lymphocytes revealed minor contamination with cellular proteins.

Conclusion: HTLV-I gp46 can be purified using an anti-peptide serum in a form suitable for evaluating envelope-antibody ELISA and Western blot assays.

Th.C.P.117 GLOBAL HETEROGENEITY OF HIV-1 ISOLATES IN U-937 CELLS, BOUTERIEUX, FERRAZZI, BOER, S., GELSTONER, R.**, and Fainberg, J.A.

*Lady Davis Institute for Medical Research, Sir Mortimer B. Davis - Jewish General Hospital, Department of Experimental Medicine and **Department of Immunology and Microbiology, McGill University, Montreal, Quebec, Canada.

Clines of U-937 cells were derived from a chronically-infected population by limiting dilution and micro-manipulation. We studied the expression of HIV-1 by immunofluorescence and reverse transcriptase assays in six of these clones. Four of them showed presence of the p24 viral antigen that correlated with normal mRNA expression and reverse transcriptase activity in the supernatants. These virus-containing supernatants were inoculated onto other cell types and were shown to differ in infectiousness. Western blot analysis revealed structural differences at the level of viral antigens which could account for a defect in viral budding and infectivity. The results clearly show heterogeneity of isolates recovered from U-937 clones and raise the question as to whether the expression of HIV-1 is influenced by the innate biological characteristics of these clones.

Th.C.P.119 SIMULTANEOUS DETECTION OF HIV-1 AND HTLV-I INFECTIONS BY CO-AMPLIFICATION USING PCR

Felix, Heltz, Hewitt, I.K., Hawthorne, C.A., and Tostevin, J.C.
Food and Drug Administration, Bethesda, MD, U.S.A.

Objective: To detect in the same PCR reaction, the presence of multiple viral infections.

Methods: Genomic DNA isolated from HIV-1 (89/HTLV-III) or HIV-1 (MC-2) infected cells was used as the template for gene amplification. PCR was performed in the presence of primer pairs to the gag and env genes of HIV-1 and the pol region of HTLV-1 primers were optimized for conditions of equal sensitivity.

Results: PCR performed by co-amplification of the HIV-1 gag and env regions was positive for both gene sequences in 21/21 high risk samples and 0/11 negative controls. In addition PCR performed on mixed genomic DNA (89/HTLV-III and MC-2) resulted in specific detection of each of the amplified targets with comparable sensitivity (20-40 gene copies each). **Conclusion:** Using co-amplification of multiple gene sequences it is possible to simultaneously detect and confirm the presence of HIV-1 in clinical samples. In reconstitution experiments the same method has been used to simultaneously detect HIV-1 and HTLV-1 predicting another clinical application.

Th.C.P.116 BIOLOGICAL HETEROGENEITY AMONG HIV-1 ISOLATES

Moore, Barbara E., Hart, Andrew R., and Clapp, Miles U.
Department of Microbiology, The University of Texas Medical Branch, Galveston, TX 77550 USA.

Objective: To biologically characterize HIV-1 isolates having variable tropism and cytopathogenicity.

Methods: The infection kinetics of 14 independent HIV-1 isolates were monitored in 8 cell lines. Viral replication was characterized with respect to RT activity, p24 production, and cell growth and viability.

Results: In the absence of preexisting transactivator activity, HIV-1 isolates adapted slowly in most cell cultures requiring from 8-14 days to achieve infection in 100% of the cell population. The viruses varied in their tropisms, with the degree of susceptibility of CD4-positive cell lines to infection varying as much as 100,000-fold. One isolate, HIV-1₁, infected the promonocytic cell line, U937, and T cell lines equally well; but it did not readily infect the H9cns neuroblastoma cell line. RT activity was an unreliable measure of viral replication. Some isolates yielded high RT, while others were consistently low. In addition, RT was always low in some cell lines even though high titres of infectious virus were produced. HIV-1 isolates varied in their ability to kill and/or fuse cells, however most isolates killed cells without syncytia formation.

Conclusions: HIV-1 isolates demonstrate considerable heterogeneity in their biological characteristics. Cell specific replication, and CPE within a given cell will be important parameters of virulence. The findings of this study should form a framework from which HIV genome sequence information may eventually be correlated with biological function.

Th.C.P.118 A RAPID, DIRECT ASSAY FOR REVERSE TRANSCRIPTASE ACTIVITY IN HIV-INFECTED CELL CULTURE SUPERNATANTS.

Greer, Sharon J. and Reising, J.S.

Food and Drug Administration, Bethesda, MD, U.S.A.

Objective: To develop a simple, rapid and sensitive assay for reverse transcriptase (RT) activity in HIV-infected cell culture supernatants.

Methods: The RT microassay reported by Miller *et al.* (J Clin Micro. 23:97,1987) was miniaturized and conditions for trapping the ³²P-products on glass fiber and DEAE filter mats were optimized for rapid collection and counting on a liquid scintillation counter. Briefly, 20ul of culture supernatant was transferred directly to a 96-well microtiter plate and virus coats were neutralized with 5ul buffer including 30E plucolase and 0.5E Triton X-100. 25ul containing 5mM ³²P-thymidine triphosphate (TP, 200Ci/mM, NEN), 0.45ul poly(A)oligo(dT)₁₂₋₁₈ (Pharmacia) and 10mM MgCl₂ were added to wells and incubated at 37°C. Reaction products were precipitated with 25mM ZnSO₄ buffer and 10E TBA and transferred to mats using a cell harvester (LKB). Mats were counted in a liquid scintillation counter (Beckman LS 5000TD). **Results:** The RT reaction was linear over a 100-fold range of RT concentrations during a 4h incubation at 37°C. 20ul of supernatant from 10⁶ HIV-1-infected U937 cells incorporated 1:1 pmol TTP/hr, 3.5 times the activity reported in the microtiter. RT activity in supernatant of 10⁷ 89 cells/ml rose 35-fold, to 0.75 pmol TTP/hr, 6 days after infection with approximately 10⁷ infectious units of HIV-1. The procedure of RT measurements in one 96-well plate required about 3 hr, while each additional plate added 20 min to total processing time. **Conclusion:** The procedure described for measuring RT activity in cell culture supernatants does not require isolation or concentration of virus and expresses a simple, sensitive and rapid assay for HIV replication **in vivo**.

Th.C.P.120 VARIABILITY OF HIV-1 COMPUTER ANALYSIS DATA BASE.

Whitcomb, D.L. Division of Biological Laboratories Science.

DAK-SAN, FUJITSU, Ltd., Shinjuku-ku, Tokyo, Jpn.

Objective: The activity of the reverse transcriptase (RT) depends on Mg ions, and the linker strand around RT may be very strong and may force the nucleic acid sequence to have a specific conformation. Some RT. The conformation of the linker strand of the nucleic acid sequence. I analyzed the data base (Los Alamos, 1988) with computer in Quebec.

Methods: The linker strand of the nucleic acid sequence was divided into four groups: New York, WMA, Haiti which contain nt, csk and if, and Africa. The variability was considered within each group, and was considered the constant dependency the variability of the neighborhood of position (N) or pyrimidine (P) or Y) was considered. When only one strain in a group was tested at the same point of the env gene sequence, this mutation was considered to calculate variabilities of aspartate. The variability of an aspartate in a group was defined as:

$$\frac{\text{sum of constant point mutations at the 2nd, 3rd and 4th bases of the aspartate in the group}}{\text{frequency of aspartate in the group}}$$

Results: The USA in the aspartate (ASD), csk and csk were overrepresented in the aspartate which have polarity and the mutation of these amino acids may be very advantageous to escape from the immune system of host. If the methionine coding were mutated, these amino acids may be very advantageous to escape from the immune system of host. The variabilities of ASD and csk were, however, the highest ones in the 64 possible aspartates, but that of csk was of about the average. This was common to the four groups. There were aspartates which showed similar variabilities among the four groups: the csk and csk, and some other aspartates showed distinct variabilities among the four groups. For example, that of csk decreased from the Africa group to the New York group.

Conclusion: These strongly suggest that the variability of the env gene depends on the context of the nucleic acid sequence (therefore on the conformation), and depends on RT of each group.

Recherche fondamentale (biomédicale) Basic Research (Biomedical)

Th.C.P.121 DEVELOPMENT OF A NOVEL QUANTITATIVE ASSAY TO STUDY MEMBRANE FUSION MEDIATED BY gp120gp41
Nelson, M.B., Wang, F.-H., Rekoh, D. and Hammarström, M.-L.
Departments of Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

A single vector (pSVX1) expressing the rat, rev and envelope proteins of HIV-1 was used to develop a quantitative fusion assay. This assay is based on the ability of the rat protein to transactivate the HIV LTR. CD4+ cells are transfected with a plasmid (LTR-CAT) in which the LTR is linked to the chloramphenicol acetyl-transferase gene and at the same time CV-1 cells are transfected with pSVX1. Twenty-four hours later these cells are mixed and after an additional twenty-four hours of incubation the cells are harvested, extracted and assayed for CAT activity. If fusion takes place, the rat protein produced in the CV-1 cell is able to transactivate the LTR. This is the only mechanism by which transactivation occurs in this system, since control experiments have ruled out leakage of rat from transfected cells and transactivation by uptake into the CD4+ cells. The sensitivity of this assay permits it to be performed using only a small number of cells in multi-well dishes. This assay has been used to analyze fusion inhibition by specific antisera and peptides.

Th.C.P.123 PURIFIED REVERSE TRANSCRIPTASE (RT) FROM HIV-1, HIV-2 AND EIAV SHARE STRUCTURAL AND IMMUNOLOGICAL PROPERTIES
Devico, Anthony, Copeland, T.**, Crowlson, S.**, Montalero, R.**, Gallo, R.**, and "HIV-1, S.D.S." *Biometric Research, Inc., Rockville, MD, **NIH-PCRP, Frederick, MD, ***La State Univ., Baton Rouge, LA ****MCI, NIH, Bethesda, MD, U.S.A.

Objective: To determine if sequence homology among the RT proteins of the lentiviruses is reflected in common structural and immunologic properties.
Method: A synthetic peptide derived from a C-terminal portion of HIV-1 RT which is conserved in all lentiviral RTs was used to raise rabbit monoclonic sera. Purified IgG was tested for RT inhibitory activity and as immunofluorescent adsorbent to purify RT from HIV-2 and EIAV.
Observations: Anti-peptide IgG directly inhibited RT from HIV-1, HIV-2 and EIAV RT and it provided a good chromatography matrix to purify RT from HIV-2 and EIAV. RT activity was associated with a pair of proteins - p66/p55 for HIV-2 and p66/p51 for EIAV. Sera of HIV-1 infected individuals had anti-RT antibody; EIAV-infected horses did not.
Conclusions: The RTs of HIV-1, HIV-2 and EIAV share structural similarities, being comprised of two associated proteins. However, high immunogenicity seems to be a feature of human lentiviral RTs. The broadly inhibitory nature of the antibody suggests that the peptide sequence represents a portion of the RT active site.

Th.C.P.125 KINETICS OF APPEARANCE AND SPECIFICITY OF NEUTRALIZING ANTIBODIES IN PATIENTS WITH PRIMARY HIV INFECTION

Albert, J.**, Ljunggren, K.**, Nag, K.**, Abrahamson, B.**, Paves, E.**,
*National Bacteriological Laboratory, Stockholm, Sweden.
**Karolinska Institute, Stockholm, Sweden.
***Hungarian Academy of Sciences, Budapest, Hungary.

Objective: To study the appearance of virus neutralizing antibodies in patients with symptomatic primary HIV-1 infection. To establish if these antibodies play a role in elimination of the initial viraemia; to an selection for the development of antigenically distinct HIV-1 strains in the infected individuals.
Methods: Sequential HIV isolates and serum samples were obtained from four patients during and after primary HIV infection. The neutralizing capacity of the sera from one individual was tested against sequential virus isolates from the same and other individuals.

Results: Preliminary results show that HIV neutralizing antibodies develop after HIV infection. The initial antibody response is strain-specific, but declines with time to include several strains.

Conclusions: The results will be important in understanding early events in HIV-1 infection and in vaccine studies.

Th.C.P.122 EXPRESSION AND CHARACTERIZATION OF HIV-1 ENVELOPE PROTEINS SYNTHESIZED FROM A SV40 VECTOR

Hammarström, Björn; Nelson, M.B.; Hammarström, M.-L.; and Rekoh, D.; Departments of Microbiology, Biochemistry and Oral Biology, State University of New York at Buffalo, Buffalo, N.Y. 14214, U.S.A.

We have used a SV40 late replacement vector system to express HIV-1 envelope proteins in COS cells. One construct produces gp160 which is efficiently processed to gp120 and gp41. Fusion assays utilizing transfected cells and CD4 expressing HeLa cells indicate that functional env proteins are inserted into the plasma membrane of the transfected cells. Approximately one third of the gp120 produced is found in the medium. This plasmid was modified to produce a soluble form of gp120 which is efficiently secreted into the culture medium. Other truncated forms of the envelope protein have also been made. We have started a systematic analysis of these proteins with regard to kinetics of cleavage and glycosylation, transport and oligomerization.

Th.C.P.124 CLONING, PRELIMINARY CHARACTERIZATION AND EXPRESSION OF GENIC FRAGMENTS OF A HUMAN HIV-2 ISOLATE (ARTV).
Farkas, David; Van den Heuvelde M.; Vanderschueren, J.; Driver, A.; Juvell, W.; and Highfield P. Wellcome Institute, Banbury, Oxon, OX2 9AT, *Immunogenetics, 65, 2000 Antwerpse, Belgium.

A Belgian AIDS patient, who had never visited Africa, was found to have a Western blot profile consistent with an HIV-2 infection. An HIV-2 (designated ARTV) was isolated from this patient and adapted to culture. An HIV antigen capture test on culture supernatants indicated that this was indeed an HIV type 2 (Vanderhoef, et al., 1988 Eur J Clin Microbiol Infect Dis 7: 816-8).

OBJECTIVE: To clone and sequence this isolate to determine its relationship to the African HIV-2 prototype R00 and to express ARTV3 genes in heterologous systems to obtain reagents for further research.
METHODS: Viral RNA from infected cell cultures was used to prepare cDNA clones either by standard methodology or by the use of PCR technology. Specific gene products were then expressed in prokaryotic (E. coli) and eukaryotic (insect cell) systems and analyzed immunologically.
RESULTS: Clones containing the major genes were obtained and preliminary sequence data has shown that ARTV3 is an HIV-2 isolate and is distinct from HIV-2 R00; the homology is between 70-90% at the amino acid level depending upon the particular gene compared. RT and gp120 polypeptides have been expressed both in E. coli and baculovirus systems and are reactive with anti-HIV-2 sera.
CONCLUSIONS: ARTV3 is an HIV-2 isolate related to but distinct from the African prototype R00. Recombinant viral gene products will be useful as research tools and as potential diagnostic and vaccine reagents.

Th.C.P.126 EVALUATION OF THREE METHODS FOR HIV DETECTION IN CULTURE OF BUCKINGHAMIA PATIENTS
S. S. Ghosh, D. Basak, J. Stewart, C.A. Steel, H.S.S. Ghosh, L. Laitala

*Department of Bacteriology, University of Edinburgh, 2, Department of Microbiology, Royal Infirmary of Edinburgh, 1, MEI Corporation unit, UNITED KINGDOM
*Department of Microbiology, University of Edinburgh, 2, Department of Microbiology, Royal Infirmary of Edinburgh, 1, MEI Corporation unit, UNITED KINGDOM
*Department of Microbiology, University of Edinburgh, 2, Department of Microbiology, Royal Infirmary of Edinburgh, 1, MEI Corporation unit, UNITED KINGDOM

OBJECTIVE: To evaluate 3 methods for HIV detection in cultures in HIV antibody positive hemophilia A patients.
METHODS: PMPs from 40ms of recipient blood were generated on a Ficol-pyrase gradient. The yield of the cells were cultured in RPMI 1640 in the presence of FCS, IL-2 and PHA. On the reacting cells a screening method was used for CD4 cell detection. Half of the generated PMPs from the CD4 negative donor were co-cultured with the cell line C-816 (p24 negative) and the other half were co-cultured with the cell line C-816 (p24 positive) PMPs from a virus HIV negative donor. The cultures were harvested at weekly intervals, supernatants were tested for the presence of p24 antigen using an antigen capture assay (Biorad). The p24 antigen was checked by flow cytometry (Becton Dickinson, Sector Cytometer).
RESULTS: The cytometry showed that the p24 antigen using an antigen capture assay (Biorad). Six out of 15 patients were investigated, 1 has consistently yielded a positive virus culture, 1 has had a positive culture on one occasion and a more than negative over a period of 2 years. The results are presented in the table below.

CD4 Status	Number of patients	Unscreened culture	co-culture of p24 negative PMPs with C-816
II	2	-	2
I	2	-	1
I/2	2	-	1
I/1	1	-	1

CONCLUSIONS: Co-cultivation of CD4+ depleted PMPs is a more sensitive method for HIV detection than simple culture of PMPs and the addition of normal CD4 cell may promote virus detection.
* FCS Fetal calf serum.

Recherche fondamentale (Biomédecine) Basic Research (Biomedical)

Th.C.P.133 QUANTITATIVE HIV RNAOCCURRANCES.
Maddala, Robert* Foster, A. Carter, C.S.* Burns,
D.L. & The Walter Reed Biodefensives Research Group
Walter Reed Institute of Research, *NSA Technology, Inc.,
Washington, D.C., U.S.A.

Objective: Quantitate the minimum number of patient peripheral blood mononuclear cells (PBMC's) required to isolate HIV in culture.
Methods: PBMC's from 12 untreated HIV seropositive patients were obtained by Ficoll-Hypaque separation of heparinized blood. Serial ten-fold dilution of cells (10^6 to 3×10^2) were inoculated into cultures of H9 and IL-2 stimulated normal donor tissue PBMC's. Culture fluids were monitored weekly for 4 weeks for HIV p24 antigen.
Results:

Initial Seed Size	Minimum # cells for positive
1 - 2	3
3 - 4	10^4 , 10^3 , 10^2
5 - 6	10^4 , 10^3 , 10^2 , 10^1

 HIV was also isolated in cultures from plasma from 5 of the 12 patients (* noted above). Serial exposures of cultures (7 days) in cultures using 3×10^6 patient cells correlated significantly ($p < 0.05$) with a high titer of circulating infectious virus (10^6 and with plasma viremia, and possibly ($p = 0.11$) with stage of illness.
Conclusions: Culture-positive blood HIV PBMC cultures approximately 100 infectious cells per cm³, with a range from 10 to 10,000 infected cells per cm³.

Th.C.P.135 INFECTION OF MESENCHYMAL CELLS WITH HIV-1 IN VITRO

Melzer, W., Knaemlich, A., Pest, H., Schmid, J., Wiser, A., Eder, Volker*
*GSF-Abteilung für Molekulare Zytobiologie, D-8542 Neuherberg, *Medizinische
Poliklinik der Universität München, D-8000 München, West-Germany.

Objective: Infection of mesenchymal cells of different origin (lung, skin, bone) with HIV-1 in vitro.
Methods: Infection of primary cell cultures and permanent cell lines with HIV-1 in vitro. Demonstration of virus infection and production by indirect immunoperoxidase staining (IP), in situ hybridization, reverse transcriptase activity (RT), electron microscopy and virus rescue.
Results: Different human cells of mesenchymal origin (primary skin fibroblasts, fetal lung cells, osteogenic cells) can be infected with HIV-1 in vitro. Especially in lung-derived cells, the infection was more pronounced, could be inhibited by anti-CD4 monoclonal antibodies and resulted in a persistent and productive infection similar to that of T-cells (RT activity, amount of infectious particles).
Conclusions: The productive and persistent infection of mesenchymal cells with HIV-1 indicates another potential virus reservoir in vivo which may contribute to local pathogenesis as for example in the lung (pneumonia).

Th.C.P.137 COMPARISON BETWEEN IMMUNOCYTOCHEMICAL ANALYSIS (ICF) AND IN SITU HYBRIDIZATION (ISH) IN DETECTION OF HIV INFECTION OF MONOCYTE-MACROPHAGES (MΦ).
Cohen, Suzanne; Elbak, T. Thomas, F. Ishaq, S. Olla, J. McGrath, W. San Francisco General Hospital/University of California, San Francisco, CA, California, U.S.A.

Objective: To compare the techniques of ICF and ISH in assessment of proportion of MΦ which contain HIV antigen and HIV RNA respectively.
Methods: MΦ were isolated from (1) peripheral blood (PB) of HIV seropositive donors (n=6) infected in vitro with HIV-1 at multiplicity of one; (2) PB of HIV-infected individuals (n=6). MΦ were stained with Mab directed against HIV p24 (provided by J. Carlson, U.C. Davis) and the proportion of cells expressing HIV was quantitated using an Ortho IIS cytofluorograph. Parallel samples of MΦ were spotted onto slides, fixed and ISH was performed with ³⁵S-labelled full-length HIV-1 RNA gene probe (provided by Chiron, CA). Slides were coded and examined by a blinded observer.
Results: In the 20 samples examined, the proportion of MΦ containing HIV antigen varied from 0-70% and the proportion of cells containing RNA varied from 0.001 - 881. Linear regression analysis showed a strong correlation between the two methods ($r = 0.77$). The calculated relationship between ICF and ISH is: $1 \text{ MΦ HIV positive (ISH)} = 0.8 \text{ ICF MΦ positive (ICF)} - 3.75$.
Conclusions: ICF and ISH correlate well in determining the proportion of MΦ within a population which contains HIV p24 antigen or HIV RNA respectively.

Th.C.P.134 A BROAD-RANGE MUTANT OF HIV WHICH CAN INFECT FIBROBLAST-LIKE CELLS DERIVED FROM HUMAN BRAIN.
Tateuchi, Yasuhiko and Hosono, H.
Gunze University, Maebashi, Gunma, Japan

Objective: It is not understood well what type of cells in the brain and what type of HIV have participated in the development of neurological disorders induced by HIV. In this study, we analyzed a mutant HIV which can infect fibroblast-like cells derived from human brain.
Methods: Fibroblast-like cells (BF cells) were readily cultivated from various types of human brain tumours. A mutant of HIV (HIV(GM-1)) highly infectious not only to T4⁺ T cells, but to BF cells was obtained by infection of BF cells with HIV(GM-1)₁, which is infectious to T4⁺ T cells, but almost not to BF cells. Genomes of HIV(GM-1)₁ and HIV(GM-1)₂ were cloned from DNA of HIV(GM-1)-infected M92-4 and DNA of HIV(GM-1)₁-infected BF cells, respectively. Various recombinant genomes were transfected to M92-4, and recombinant viruses were produced.
Results: Infectivity of recombinant viruses to BF cells were tested. Viruses containing a 2.3 kbp PstI (Pst-3) fragment derived from HIV(GM-1)₁ clones were infectious to BF cells, whereas viruses containing Pst-3 fragment from HIV(GM-1)₂ failed to express HIV-antigens in BF cells. The Pst-3 fragment contains the Pst-3 open reading frame and the Pst-3' region of the sequences of the Pst-3 fragments from the two viruses, we detected three nucleotide mutations.
Conclusions: Differences in infectivities of HIV(GM-1)₁ and HIV(GM-1)₂ to BF cells was coded for by the Pst-3 fragment. Some of the three nucleotide exchanges might determine the host-range differences.

Th.C.P.136 SYNTHETIC SELECTIVE INHIBITORS OF HIV PROTEASE
Micheals, Christopher J., Blumenstein, J.J., Copeland, T.D., Drayton, S.

BI-Basic Research Program, CMC-Friedrich Cancer Research Facility, Frederick, MD, U.S.A.

Retroviral protease, the enzyme which processes viral precursor polyproteins, is essential for virus replication and thus is an attractive target for chemotherapeutic treatment of retrovirus infections. We have designed and synthesized a structurally simple and versatile class of compounds, 1,3-epoxy alcohols, acids, and derivatives, and found several of them to be selective inhibitors of the HIV protease. The effect of these compounds on chemically synthesized HIV protease was conveniently studied by monitoring the cleavage of an antibiotic single peptide bond in a synthetic nonapeptide corresponding to a natural cleavage site in HIV-1 gag precursor polyprotein. The relative inhibitory effects of these compounds have afforded an insight to the structural characteristics which impart activity. Several compounds which inhibited the HIV protease showed negligible inhibitory effect on renin, a related neuronal aspartyl protease. Preliminary studies indicate that some of these synthetic compounds inhibit viral infectivity without substantial cytotoxicity. These compounds represent an entirely novel class of agents against HIV infection. (Research sponsored by the National Cancer Institute, DMS, under contract NO. N01-CO-7412) with Biotech Research, Inc.)

Th.C.P.138 QUANTITATION OF HIV-1 IN PLASMA AND PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) OF SEROPOSITIVE PERSONS.
Ho, Bruce J. Alan, M.J. Mowatt, T. Liu, S. UCLA School of Medicine and Cedars-Sinai Medical Center, Los Angeles, CA, U.S.A.

Objective: To quantify the titer of infectious HIV-1 in plasma and PBMC.
Methods: Plasma (2, 10, 40, 200, 1000 uL) and PBMC (2×10^6 to 2×10^7) were cultured with H9 and PM1C from normal donors. Virus titer was measured by suppressive p24 antigen assay weekly for up to 28 days. Infectious titers for plasma and PBMC were expressed as those cultures infective dose (TCID₅₀) per mL and TCID₅₀ per 10^6 cells, respectively.
Results:

	N	Serum p24 (ng/mL)		TCID ₅₀ /mL		PBMC HIV-1 titer (TCID ₅₀ / 10^6 cells)	
		mean	range	mean	range	mean	range
Healthy	12	0	0	0	0	2-50	23
ARC	8	140	434	25-500	196	50-5000	2675
AIDS	19	9-500	1812	5-5000	143	5-5000	1433

Conclusions: (1) Infectious HIV-1 was detected in the plasma of every seropositive person, suggesting that HIV-1 infective activity and not latent (2) Asymptomatic individuals have significantly more virus in plasma than asymptomatic individuals. (3) In 1 mL of blood, asymptomatic persons have approximately 15 TCID₅₀ of HIV-1 in plasma and 25 TCID₅₀ of HIV-1 in mononuclear cells, while ARC and AIDS patients have 165 TCID₅₀ in plasma and 1000 TCID₅₀ in cells. In fact, many asymptomatic patients harbor HIV-1 in 1 in 300 PBMC, which is a 100-fold increase in frequency over that previous reports suggesting that only 1 in 10^4 or 10^5 cells carry virus. (4) This quantitative culture has been successfully applied in patients receiving azidothymidine to demonstrate the in vivo antiviral effect.

Th.C.P.139 THE BINDING OF H5A₂g TO HUMAN T4 LYMPHOCYTES INDICATES THE POSSIBILITY OF THE ANTIGEN TO FUNCTION AS OLIGOPEPTIDE ANTIGENIC TO HIV PRIMARY INFECTION OF T4 LYMPHOCYTES.

Leung Seawen-Lai¹

National Research Institute of Health, P.O.Box 1202, Asele Avenue, Ethiopia

Objective: To evaluate if H5A₂g can bind on CD4 receptor of human T4 lymphocytes and to identify if it can function as oligopeptide antigenic to HIV primary infection of T4 lymphocytes.

Methods: H5A₂g positive sera samples, partially purified H5A₂g and highly purified H5A₂g were assayed for H5A₂g reactivity when tested with and without equal volumes of human T4 lymphocytes (2x10⁶ cells) using Oregon diagnostic kit for the detection of HIV-1.

Result: H5A₂g reactivity in the samples gave higher OD reading than tested with the T4 lymphocytes than the same samples tested without the T4 lymphocytes.

Conclusion: H5A₂g can bind on human T4 lymphocytes obviously on the CD4 receptor hence may function as oligopeptide antigenic to HIV primary infection of T4 lymphocytes. The application of oligopeptides of H5A₂g in preventing HIV primary infection of T4 lymphocytes should be investigated in the future.

Th.C.P.141 HUMAN MONOCLONAL ANTIBODY AGAINST HIV

Shimizu, Etsuko¹, Sasaki, K., Katagiri, K., Kubo, K., Katori, N. and Takayama, K.W.
Kurume University School of Medicine, Kurume, Fukuoka, Japan

Objective: Attemp. were made to produce monoclonal antibodies of human origin against HIV which have neutralizing antibody activity.

Methods: Monoclonal cells from peripheral blood of the patients with hemophilia showing sero-positive to HIV and the healthy sero-negative donors were cultivated with inactivated HIV and GDH antibody on an *in vitro* immunization for 4 days. On day 4, EBV was infected to the culture. After 2 to 3 weeks of cultivation the growth of EBV transformed B cell clusters was observed. Culture supernatant of propagated B cells through cloning procedure was tested for their antibody activity to HIV by using ELISA method, immunofluorescence method, and Western blot procedure.

Result: Series of experiments were performed on the monoclonal cells originated from 2 hemophilia B patients, 1 hemophilia A patient, and 2 healthy donors. Numbers of B cell clones were obtained from a hemophilia B patient in AHC stage, whereas no continuous propagation of B cells were observed on the cells from other donors. Some culture supernatants of the propagated B cell clones showed antibody activity to HIV by ELISA method. However, those positive reactivities have not been reproducible by immunofluorescence or western blot procedure.

Conclusion: A procedure to produce human monoclonal antibody against HIV by EBV transformed B cell method has been partially established. Cloning procedure and screening procedure have to be improved to obtain B cell clones consistently produce human monoclonal antibody to HIV.

Th.C.P.143 DECREASING PRODUCTION OF IgG, IgM, AND IgA ANTIBODIES AGAINST PHENOCYTIC CARININ ANTIGENS IN AIDS PATIENTS

MORSE, L. AND DE WETTING, BERT.

BAKER RD WILHELM, ANNE GRETE POLGREN, CLAUDE EODOP, BO HOFMAN, AND

PHILIPPE MOJUM,***

Stempejers Hospital, ***Statens Serum Institut and ***State University Hospital, Copenhagen, Denmark, ***University Claude Bernard, Lyon, France.

Objective: The study assesses IgG, IgM, and IgA production against major Hemocytin carinin (PC) antigens during the development of AIDS.

Methods: Eight hemocytin AIDS patients were included in the study. Six patients suffered from PC Pneumocystis during the period and two patients had Kaposi's sarcoma. Between 2 and 21 sera per patient were examined for specific antibodies. Twenty-nine healthy volunteers served as controls. The antibodies were assayed by ELISA and western blot using soluble PC-antigens.

Result: All patients, except one, had decreasing antibody level in all immunoglobulin classes. The level of IgG and IgM were in all patients below the level of the normal subjects. However, the IgA level was during the whole period above the level of the normal subjects. Western blot showed changes relative to the major antigenic components with molecular weights of 64,000 and 98,000 Dalton. IgG from normal controls did not react in the 98,000 Dalton antigen reaction. The reaction between the immunoglobulins and the antigenic components disappeared in the following order: IgG64, IgM98 and finally IgG98 or IgA98.

Conclusion: The humoral immunity against PC may serve as a marker for the degree of immunodeficiency in AIDS patients.

Th.C.P.140 ANALYSIS OF A FUNCTIONAL HIV-1 REV GENE Sylvia Paulina, M. Ennemas, and A. Cordonnier, Unité d'oncologie virale, Institut Pasteur, Paris, France

Objective: HIV-1 Rev is required for HIV-1 envelope protein expression. We have begun a functional and structural comparison of the *rev* gene of HIV-2 with that of HIV-1 in order to better understand their mechanism of action.

Results and Methods: We constructed a cDNA library from HIV-2 infected cells and cloned a cDNA encoding the *rev* gene. The sequence of the *rev* cDNA shows that the *rev* gene of HIV-2 is encoded on a message with four exons. The first, from R to the major splice donor, and the second, a 72 bp exon in the *pal* gene, are non-coding. The first coding exon begins between the ATG of the *pal* gene and the ATG of the *rev* gene and ends after the ATG of the *rev* gene. The second coding exon begins near the end of the *env* gene. The HIV-2 *rev* gene product is predicted to share 44% amino acid identity with that of HIV-1. To show that the HIV-2 *rev* cDNA was functional, co-transfections were done with another plasmid that encodes the envelope gene of HIV-2 from a plasmid vector was dependent on co-expression of the HIV-2 *rev* cDNA.

Conclusion: We have cloned a functional cDNA encoding the HIV-2 *rev* gene. The analysis of the specificity of the HIV-2 *rev* product with that of HIV-1 will be useful in defining the target site of the HIV *rev* products.

Th.C.P.142 CHARACTERIZATION OF MONOCLONAL ANTIBODIES REACTIVE WITH DIFFERENT PROTEINS OF HIV-1 - MDK STRAIN.

REISER, S., ROBERT V., VITKOVIC M. and GERMANN, J.-C.

Unité de Génétique Moléculaire, Ins. Pasteur (Unité Associée U-3221) - Centre de Lympho

- et de Cell. Humaines, Paris - FRANCE

To obtain to generate monoclonal antibodies (mAb) specific for the highly expressed strain HIV-1MDK. Until now, 8 mAb have been obtained: 3 mAb have been shown to react with epitopes of 28 (mAb: H1.4.73; H1.5.11.141; or gp120 (mAb: H1.16.74)) shared among several HIV-1 isolates. The 5 other mAb (3 of which react with epitopes of gp120 (mAb: H1.16.74 and H1.16.74) and 2 with an epitope of gp84 (mAb: H1.21.51)) apparently bind specifically HIV-1MDK proteins. Further characterization is in progress to evaluate the biological effects of these reactions on HIV-1 infection.

Th.C.P.144 B-CELL SYSTEM ACTIVATION AND HIV-1 INFECTION

MAHILLI, ALBERTO¹, ZANETTI, R.², VERONESI, M.L.¹, FRANCESCHI, L.²

1-IRCCS, ***; 2-IRCCS, *** and Chiao-Giuliano L.²

¹Institute of Oncology, University of Padova; Dept. of Infectious Diseases, ILSG 21, Padova²; ULSG 36, Mestre² - ITALY.

Objective: To better define B-cell activation during HIV-1 infection.

Methods: Limiting dilution assay of B-cell precursors spontaneously secreting HIV-1-specific and total Ig by absorption of culture supernatants with solid-phase HIV-1; effect of T-cell and monocyte removal, and interleukin addition, on *in vitro* spontaneous Ig synthesis.

Results: *In vitro* spontaneous Ig synthesis did not depend on T-cell presence, while monocyte removal caused a striking fall in spontaneous Ig production. IL-6 presence in culture was essential; antisera against IL-6 strongly reduced spontaneous Ig synthesis, which was partly restored by rIL-6 addition to monocyte-depleted populations. The frequency of B-cell precursors spontaneously producing HIV-1-specific Ab was about 1/3-1/4 of that of spontaneously activated, Ig-secreting precursors. However, after absorption with solid-phase HIV-1, about 30% of total Ig was removed from unstimulated culture supernatants.

Conclusion: HIV-1-specific B-cell activation is a major component of the overall B-cell activation in PB. In part seropositive subjects. This phenomenon can contribute to the virus-induced immune damage, and partly explain the increased frequency of AIDS-associated B-cell malignancies.

Th.C.P.145 FINE STRUCTURE OF INSIDE THE VIRAL ENVELOPE OF THE HIV-1 [John Tashmeh¹, A-W Lademann², W Tamao³, M S Schulz⁴].
¹Central Laboratory for Electron Microscopy, Teikyo University School of Medicine, Tokyo, Japan, ²Institut für Pathologische Anatomie, ³Max-Planck-Gesellschaft, ⁴Harvard University, Boston, MA, U.S.A.

OBJECTIVE: We presented an envelope surface model of HIV-1 using a computer image processor with negatively stained electron micrographs, namely, envelope structure of HIV-1 particle is constructed of 7-7 layers symmetric lamellae and 72 knob(gp120) are stuck into the envelope on the pentamer/hexamer clustering positions. Int. Conf. AIDS, abstract No. 1002, and J. AIDS to press). Our results support the studies presented by Goldbloom et al. In this study we will indicate some structures under the viral envelope.

METHODS: HIV-1 particles were obtained from HIV-producing M9-cells of the HT-lymphocyte line. The HIV-1 particles were negatively stained with 2% phosphotungstic acid (pH 6.6) and then dried in air to obtain well preserved structures.

RESULTS: From the electron microscopic observations following features will be suggested.

1) The core shell has a polyhedral structure.

2) The space between viral envelope and core shell is filled with fibrous structures.

We also show a three dimensional model.

Th.C.P.147 HIV-1 DOES NOT REPLICATE IN HUMAN VAGINAL EPITHELIAL CELL

Sanjour, James, Norrweber, C, and Sobel, J.
Wayne State University, Detroit, MI, USA 48201; Veterans Administration Med. Ctr., Allen Park, MI, USA 48101

OBJECTIVE: To determine the ability of HIV-1 to replicate in human vaginal epithelial cells, a potential cellular target to heterosexual transmission.

METHODS: Vaginal epithelial tissue explants obtained from HIV-seronegative women undergoing hysterectomies were seeded in tissue culture wells for 12 days. Cell-free supernatant from HIV/HTLV-III B-cells was added and adsorbed 2 hr. Explants were washed three times with saline, refed, and examined for morphological changes and supernatant HIV p24 antigen (Abdotest) at times 0, 2, 4, 8, 10, and 18 days following viral inoculation.

RESULTS: No morphological changes were detected for tissue explants inoculated with HIV when compared to uninoculated wells. Growing monolayers consisting of epithelial and/or fibroblasts were observed in all wells, and increased in size regularly. Supernatant p24 antigen levels were negative in all wells at the time points examined.

CONCLUSION: Human vaginal epithelial cell in contact support HIV replication when assessed for up to 18 days following inoculation with a lymphoblastoid-adapted strain of virus. Experiments are in progress to determine whether a macrophage-adapted strain of HIV can infect vaginal tissue explants.

Th.C.P.149 MOLECULAR CHARACTERIZATION OF A DEFECTIVE HUMAN

IMMUNODEFICIENCY VIRUS
M. Inoue, J. A. Hunkler, and E.P. Reddy*
*The Wistar Institute, Philadelphia, PA, USA; *Hospital of the University of Pennsylvania, Philadelphia, PA, U.S.A.

Prologed culture of HD919 cell line, chronically infected with HIV-1, resulted in the emergence of a variant cell line that was found to be defective for virus production. This cell line (M-III) was tested for the production of p24 antigen by ELISA and was found to be negative. Similar negative results were obtained when the cells were analyzed by FACS using monoclonal antibodies to p24. However, these cells were found to produce large quantities of HIV envelope gene product and were found to induce massive apoptosis when cocultured with SUPT-1 cell line which is a CD4+ T-lymphocytic leukemia cell line. Immunoprecipitation analysis of the labeled cell lysates revealed the synthesis of envelope gene products (gp160, gp120). As predicted, there was no synthesis of p24 antigen as well as gag precursor protein, p55. The Southern blotting analysis of the M-III cell DNA revealed the presence of a single proviral genome in cellular DNA. Following digestion with XbaI, which cleaves outside the proviral genome, the DNA was fractionated and cloned into a λ phage vector. A molecular analysis of the proviral genome aimed at understanding the nature of defect will be presented.

Th.C.P.146 SOME OBSERVATIONS ON THE LATEST HIV INFECTION PHASE

Paganella, M., Microni, M., Miceli, M., Rossi, M., Vescovi, H., and Mazzella, L.***
*** Institute Infectious Diseases, ¹Department of Obstetrics I, University of Rome -National Center for Blood Transfusion C.R.I.; ²Ospedale L. Spallanzani, Italy

Objective: To evaluate the latest HIV infection period, from January 1985 to December 1988 six seronegative regular sexual partners of HIV infected subjects have been studied.

Methods: The seronegative diagnosis has been based on the demonstration of the absence of specific serum antigen and antibodies to the viral proteins by EIA and Western Blot tests. The HIV latest infection has been evaluated by "in situ" hybridization on peripheral blood mononuclear cells (PBMC) using an SP 64 plasmid containing the full-length 9 kb viral insert flanked by 10 ribonuclease sites tagged with a sulfone group and visualized by double immunohistochemical antibody reaction. The controls were performed using HIV infected and non-infected 8 x culture cell lines and PBMC from healthy blood donors.

Results: The HIV genome was demonstrated, at first control, in the cytoplasm of mononuclear cells of all the seronegative subjects as a granular staining (kallium phosphatase). Five subjects showed a transient positivity for anti-p 24 and linear for specific HIV antigens. One subject seroconverted three months after first control.

Conclusions: The "in situ" hybridization is a useful technique to recognize HIV infection at very early stage.

Th.C.P.148 EXCRETION OF HUMAN IMMUNODEFICIENCY VIRUS IN BODY FLUIDS

Georday, Mark, Barrett, J., O' Shea, J., Stames, J., Gostowski, J., London, UK; Abbott Diagnostic Division.

OBJECTIVE: To evaluate techniques to assess HIV excretion patterns and specific antibody responses to body fluids.

METHODS: Peripheral blood, semen, saliva and female genital secretions from asymptomatic and symptomatic patients are being examined for infectious virus, viral antigens (EIA and flow cytometry), viral nucleic acid (PCR to follow) and antibodies (EIA and Western Blot).

RESULTS:

Sample	Infectious Virus	Antibodies	IgG	IgA
Saliva	0/31 (0%)	12/31 (38%)	17/31 (54%)	1/31 (3%)
Semen	3/12 (25%)	0/23	29/20 (84%)	11/13 (84%)
Saliva	0/12	0/18	12/23 (52%)	1/12 (8%)
Genital	0/10	0/5	0/5 (0%)	0/10

No positive/was tested

Positive cultures occurred within 3-7 days among asymptomatic and 7-28 days among asymptomatic patients. We have shown that flow cytometry provides an efficient method for analysis of cell populations in blood and female genital secretions; we have not yet detected expression of HIV antigens.

CONCLUSIONS: Infectious virus and viral antigens were detected less frequently in semen and saliva which may reflect the fact that they contain specific antibodies. These fluids probably represent a low risk for transmission of virus. Detection of positive cultures earlier among asymptomatic than among asymptomatic patients suggests higher virus load or rates that replicate more efficiently.

Th.C.P.150 HIV EARLY VIRUS-CELL INTERACTIONS

Greer, Cynthia Beck, A., Georday, M.R., Robert Koch-Institut, Berlin, FEDERAL REPUBLIC OF GERMANY

Objective: HIV infects CD4+ cells, mainly lymphocytes and macrocytes. Two entry mechanisms have been observed in different reports: 1. direct fusion of the viral envelope with the cell membrane, 2. receptor-mediated endocytosis via clathrin coated pits and vesicles.

Methods: Differentiated cells were incubated with purified virus and studied by EM at different time intervals and temperatures with regard to adsorption, fusion mechanisms and penetration of the core. Emission. Since fusion was seen not only within cytoplasmic vesicles but also the cell surface of both lymphocytes and macrophages, virus entry seems to be pH independent. The two layers of the viral envelope and the lipid bilayer of the cellular membranes usually fuse seamlessly within 1-3 min, but occasionally membrane ruptures may also occur, leading to rapid cytopathic effects, i.e. vacuolization and cytolysis. In the course of fusion at the cell surface, the viral envelope glycoprotein gp120 is integrated into the lipid bilayer of the cell membrane, where it can be visualized by immunoelectron microscopy. Free gp120, shed by the mature virus already before attachment to the cell, may also bind to the cell surface and is most frequently found within clathrin coated pits.

Formation of synaptia by cells studied with viral proteins was observed as early as after 1h of incubation with virus. SBL668(HIV-2) Syncytia reach a larger size than HTLV-III (HIV-1) Syncytia.

Conclusion: The rapid entry of HIV into its host cell as well as early cytopathic effects should be considered in attempts to block virus entry or replication.

C.513 A NEW EMPLOYED ASSAY FOR NEUTRALIZING ANTIBODIES TO HIV-1
MILLON, G.M.*; FISHER, R.*; POWLER, A.A.**; ARTHUR, L.*
HIV-1

*Program Resources, Inc., MCI-Fredrick Cancer Research Facility, Frederick, MD, USA; **NSA Laboratories, Rockville, MD, USA; *** Division of Cancer Etiology, NCI, Frederick, MD, USA; **** Developmental Therapeutics Program, Division of Cancer Treatment, MCI, Frederick, MD, USA.

Objective. To develop a simple, large-scale assay for the safe and rapid quantitation of antibodies which block HIV-1 infectivity.

Methods. The reduction of a new tetrazolium salt, NTZ, by viable T-lymphoblastoid cells to a soluble formazan was used to quantitate HIV cytopathic effects in a semi-automated 5-day microtiterum procedure for evaluation of neutralizing antibodies. Comparative methodologies included analysis by enzyme assay, quantitation of p24 synthesis, and anti-HIV-1 gp120/gp130 binding tests.

Results. The tetrazolium assay permitted screening large numbers of human and non-human primates sera including selected AIDS patient sera and sera from isocou- vaccinated chimpanzees and rhesus monkeys for antibodies to HIV-1. Sera from goats immunized with HIV gp120/gp130 were also evaluated for specificity of reactivity permitting development of a competition neutralization assay.

Conclusion. The soluble formazan based tetrazolium assay can be employed for large-scale screening of sera from a variety of species for neutralizing antibodies to HIV. This new assay eliminates manipulations associated with other tetrazolium assays and is sensitive enough to permit evaluation of antibody binding specificities. Supported in part by NCI-CA74102

C.514 ANTIBODY DEPENDENT CELL-MEDIATED CYTOTOXICITY (ADCC) IN RELATION TO CLINICAL PROGRESSION OF HIV-1 ASSOCIATED DISEASES IN HOMOBIOTICITY

Stclair, Anne J., Hoesbelen, J., Mail, L., Steele, N.* Jodan, C.** and Sinclair, A.G.
MRC Clinical Research Centre, Harrow, UK. **MRC Clinical Cytotoxicity Unit, Edinburgh, UK. *Scottish S.S. Regional Blood Transfusion, Middlesbrough, UK.

Objective. Evaluation of the ability of serum samples from a cohort of HIV-1 positive haemophiliacs to mediate ADCC, with study of the relationship of ADCC to clinical state and disease progression.
Method. HIV-1 isolate in the CEM cell line were used as target cells and peripheral blood mononuclear cells from selected normal donors as effector cells*. Comparison of serum samples from 36 HIV-1 positive haemophiliacs infected with the same contaminated factor VIII is described. Titres of antibody mediating HIV-1 specific ADCC are compared with the evolution and clinical stage of HIV-1 associated disease.

Results. Preliminary results show that 7/7 M/CPC patients with non-progressive disease have higher ADCC than 2/2 patients progressing to AIDS. Full results of 30 patients will be presented.
Conclusion. Our preliminary studies as well as those from other groups support a protective function of sera that can mediate HIV-1 specific ADCC. It is confirmed the findings will be of importance in design of HIV vaccines and therapeutic strategies.

*Reference: Stclair, A.J., Hoesbelen, J.H., Mail, L., Chandler, J., Forster S., Crickham, K. and Dalgleish, A.G. (1988) Antibody-dependent cell-mediated cytotoxicity: comparison between HIV-1 and HIV-1 assays. AIDS Journal, 2:465-472.

C.515 ANTISPERM ANTIBODY AS A RISK FACTOR FOR SEXUALLY TRANSMITTED HIV INFECTION
MILIN, Steven S. and Jordan, J.
Cornell University, Ithaca, New York, New York U.S.A.

Objective. To determine whether men with antisperm antibodies in their semen will be more likely than men who are not permitted to sperm to transmit HIV to their sexual partners. Men with a history of STDs and homosexual sex have a high incidence of antisperm antibodies.

Method. Semen from fresh ejaculates were tested for bound antibodies by the immunodiffusion assay. Spermatozoa from sperm cells were purified by ficoll-density gradient centrifugation and CD4 and CD8 T lymphocytes quantitated by immunofluorescence staining using monoclonal antibodies. Interferon gamma (IFN γ) in seminal fluid was measured by ELISA. The ability of sperm with or without bound antibodies to induce IFN γ production or immunosuppress allogeneic mononuclear cells was determined by cocultures.

Results. CD4 cells predominate over CD8 cells in semen from men with antibody-free sperm. In men with antibody-bound sperm there is a selective loss of CD8 cells so that CD4 cells now predominate. IFN γ is present in semen only from men with antibody-bound sperm. Antibody-bound sperm induces IFN γ from allogeneic lymphocytes while antibody-free sperm inhibits allogeneic lymphocyte proliferation.

Conclusion. CD8 cells normally predominate in semen and the male genital tract and sperm are immunocompetent. This inhibits replication of HIV-infected sperm cells. In men with antibodies to sperm, however, CD4 cells predominate in semen and their sperm are IFN γ inducers. This promotes replication of HIV-infected cells in the male and enhances viral infectivity.

C.516 MODULATION DE L'EXPRESSION DE CD4 PAR LE PMA ET INFECTION VIH IN VITRO
MARCHAL, Karim, Bercat, I. et Tourain, J. L.
Faculté de Médecine A. Carrel, INSERM ICM-CNRS URA 117, Lyon, France

Objectif. La liaison de la glycoprotéine 120 (gp120) à la molécule CD4 constitue l'un des événements principaux de l'infection de la cellule par le virus de l'immunodéficience humaine (VIH). Le modulation de l'expression de CD4 in vitro, par le phorbol myristate acétate (PMA), permet d'étudier les conditions d'infectivité de la cellule par le VIH.

Méthodes. Des cellules de lignée lymphoïde 845 sont prétraitées avec PMA (10⁻⁶M pendant 1,5 et 16h. Le phénotype CD4 de ces cellules est analysé en immunofluorescence avant l'infection par VIH in vitro. L'évaluation de l'infection virale est basée sur l'apparition d'un effet cytopathogène (CCP), l'expression intracytoplasmique de l'antigène viral p24 et d'une activité transcriptase inverse ou RT.

Résultats. Les cellules 845 sécrètent, 8 jours de 80%, la molécule CD4 et des conditions de leur infection in vitro par PMA ont été définies. Le traitement des 845 au PMA, pendant 1,5 et 16 h permet une forte réduction de l'expression CD4 associée à une absence d'CCP et de p24 intracytoplasmique. L'activité RT était absente après 1h d'incubation au PMA mais par contre détectable à 5 et 16 h de prétraitement au phorbol.

Conclusion. Ces résultats confirment que l'infectivité in vitro par VIH est associée avec le degré d'expression de la molécule CD4.

C.517 QUANTIFICATION OF HIV-BINDING TO CD4+ CELLS USING FLOW CYTOMETRY

Thiele, Bernhard*, Kunze, R.O.F.*, Gebauer, F., Ramirez, G., Gedenbom, H., Pauf, G., Abt, Vilhelm, Robert Koch-Institut and AIDS-Zentrum, BGM, Berlin.
*Max Planck-Gesellschaft, AG Rheumatologie, Universitätsklinik Erlangen-Nürnberg

The anti-CD4 antibody Leu 3a is able to inhibit HIV-virus binding to its receptor, the CD4-molecule. (Weiss et al., 1984). On fluorochrome-labeled Leu 3a in combination with Scatter-Plot analysis of flow cytometric data gives a good estimate of the average number of CD4 molecules per cell and of the corresponding affinity constants. Such the optimum Leu 3a concentration with the highest sensitivity to sterfing ligands can be used in further experiments. Human peripheral blood lymphocytes were incubated with supernatants of HIV-producing cell lines (Molt 4/B, H9), washed and fixed. The remaining binding capacity for Leu 3a was determined using a calibrated flow cytometer. The decreased fluorescence intensity compared to appropriate controls can be regarded as a measure of gp120 blocked CD4 and intact viruses. Ultraconjugation of HIV containing supernatants makes it possible to distinguish free gp120 from particle-associated glycoprotein and to estimate the content of viruses with ability to bind to cells. In all experiments performed receptor occupation by HIV-virions or their glycoprotein did not exceed 50% of the CD4 molecules which is in good agreement with theoretical considerations

C.518 SPONTANEOUS TMF-ALPHA PRODUCTION BY ALVEOLAR MACROPHAGES AND PERIPHERAL BLOOD MONONUCLEAR FROM PATIENTS WITH AIDS

Crickham, K., Vazir, M., Mitchell, J., and Pritchard, A.,
MRC Clinical Research Centre, Harrow, UK.

Objectives. To assess spontaneous and IFN induced TMF-alpha production by alveolar macrophages (AM) and peripheral blood mononuclear cells (PBMC) with and without IFN (alpha 2) after which supernatants were collected and assayed for TMF-alpha.

Group 1 - HIV positive patients with PCP (20/20)
Group 2 - HIV positive patients without PCP but with bacterial infection (LAC or AIDS) (20/20)
Group 3 - HIV negative patients with negative bacteriology for LAC or AIDS (20/20)

Results. Spontaneous TMF-alpha production was significantly higher in Group 1 patients with PCP compared to Group 2 patients without PCP but with bacterial infection. Spontaneous TMF-alpha production was significantly higher in Group 3 patients with negative bacteriology for LAC or AIDS compared to Group 2 patients without PCP but with bacterial infection.

Figure. are mean values of TMF α expressed as units/ml/10⁶ macrophages. Values lower than the limit of detection of the assay (25 units/ml) were assigned a value of 0.

Conclusion. AIDS patients with Pneumocystis carinii pneumonia, but not bacterial infection, showed increased spontaneous TMF-alpha production.

C.519 INDUCTION OF MAJOR HISTOCOMPATIBILITY (MHC) CLASS II ANTIGEN ON CELLS OF THE DEVELOPING HUMAN PERIPHERAL NERVOUS SYSTEM BY GAMMA-INTERFERON

Micha, A. and Wigdals, E.
Department of Microbiology and Immunology, The Pennsylvania State University College of Medicine, Hershey, PA 17033 USA

Objective: To examine the effect of gamma interferon (γ -IFN) on the level of MHC class II expression on cells isolated from the developing human fetal peripheral nervous system.

Methods: γ -IFN was used to study the induction of MHC class II antigen expression on the surface of cells obtained from dorsal root ganglia (DRG) derived from abnormal human fetal specimens between 13 and 16 weeks gestation. The induction of class II antigen expression by γ -IFN was also examined on U373 glioma cells. Fluorescence-activated flow cytometric analysis was performed on both live and fixed cells utilizing a primary monoclonal antibody specific for the HLA-DR (MHC class II) region-associated bimolecular complex in conjunction with a fluorescein-conjugated anti-mouse secondary monoclonal antibody.

Results: We have demonstrated that between 15 and 25% of human DRG neural cells isolated from abnormal human fetal specimens are HLA-DR antigen positive. However, human fetal DRG neural cells isolated from the same tissue were treated for 48 hr with γ -IFN (10 U/ml), the number of HLA-DR antigen positive cells increased to between 41 and 71%. Kinetic analysis of MHC class II antigen expression in the U373 glioma cell line after treatment with γ -IFN (100 U/ml), demonstrated an increase in the number of HLA-DR antigen-positive cells, reaching a maximum of 68-96% antigen-positive cells within 48 hr after exposure, declining thereafter, but remaining above pre-treatment levels 24 hr later.

Conclusion: γ -IFN enhances MHC class II expression on human fetal DRG neural cells. Future studies will examine the effects of HIV infection, HIV antigens, and factors secreted by HIV-infected cells on MHC class II expression in the developing human nervous system.

C.521 THE EFFECT OF HIV ON THE EXPRESSION OF HLA-DR AND CYTOSOLIC B-2-OXIDASE mRNA IN MONONUCLEAR CELLS

Cheln, C.T. and Henson, J.
Harvard Medical School and Brigham and Women's Hospital, Boston, MA, USA.

Objective: To determine if HIV infection can alter the expression of two DIFFERENT mRNA markers of mononuclear cell activation: 1. HLA-DR—the major histocompatibility antigen responsible for accessory cell function; and 2. Cytosolic B-2 heavy chain (cyt-b-2)—a component of the oxidase system responsible for mononuclear cell respiratory burst activity.

Methods: The HIV-1 strain was used to infect two human promonocytic cell lines, U937 and THP-1. At the time of peak reverse transcriptase activity, cells were divided into the following groups: non-stimulated cells; cells stimulated with 400 U/ml interferon (γ -IFN); and cells stimulated with 100 ng/ml lipopolysaccharide (LPS). Non-infected cells were treated identically and served as controls. After 24 hr, total RNA was extracted, electrophoresed and subjected to Northern blot using probes consisting of cDNA for HLA-DR and for cyt-b-2. An actin probe was used as an internal control.

Results: Expression of HLA-DR and cyt-b-2 mRNAs were decreased in non-stimulated, HIV-infected cells. γ -IFN stimulation resulted in increased levels of HLA-DR and cyt-b-2 mRNAs; however, these levels were diminished in the infected vs. the non-infected cells. LPS had no effect. Actin mRNA was equivalent in all groups and was not affected by either infection or stimulation.

Conclusion: HIV infection caused down-regulation of two markers of mononuclear cell activation at the transcriptional level. These alterations may play an important role in the pathogenesis of cellular immune dysfunction. γ -IFN partially reversed the HIV effects.

C.523 EARLY DEVELOPMENT OF ANTI-HIV IgG

Bahrén, B. Eriksson, P., Frolner, J., Nilner, E., Albert, E., Sandberg, E., and Eriksson, P.
National Bacteriological Laboratory, Stockholm, Sweden. **Ferring AB, Malmo, Sweden. ***South Hospital, Stockholm, Sweden.

Objective: To enhance the early seroreactivity in HIV infection/immunization.

Methods: Non-viral peptides covering the CD4 binding region of HIV were prepared by solid phase synthesis. All peptides were made to contain two cysteine residues in the same position and chemically oxidized. The sulphur bridges formed, restricts the peptides acritically.

Results: All patients ($n=100$) with established HIV-1 infection had an IgG1 response to one (J8-6) of two peptides representing the CD4 binding region. Subclasses IgG2, 3 and 4 appeared in 27, 60 and 33% respectively. In seroconverting persons ($n=10$) IgG1 and IgG2 antibodies to the peptide J8-6 developed within 3-4 weeks and paralleled total anti-viral IgG. The J8-6 sequence represents the C-terminal of the putative gp120 binding region.

Conclusion: The IgG1 seroreactivity of HIV-infected individuals is a chaotically modified peptide representing the CD4 binding region and the early seroconversion stage; primary infection implies a role for this peptide in vaccine development.

C.520 DECREASING ANTIBODY RESPONSES IN ASSOCIATION WITH AIDS

Roederly, B., Michalski, P., Katsanovich, D., McClellan, J.A.,* Sawyer, L.A.,* Wolick, L.C.,* Quintana, J.H.,* et al. *NIH, DV, Center for AIDS Evaluation and Research, FDA, Bethesda, MD, U.S.A. and **UCSD AIDS Core Study, San Diego, CA, U.S.A.

Objective: To identify HIV specific immune responses associated with the development of AIDS in HIV seropositive homosexual men.

Methods: Sera were obtained semi-annually from 20 asymptomatic HIV seropositive men in San Diego, 10 of whom developed AIDS and 10 remained stable. They were studied by quantitative Western Blot (WB) neutralizing antibody (NA) and antibody-dependent-cell-mediated cytotoxicity (ADCC) assays.

Results: Quantitative analysis of the IgG binding to individual proteins and glycoproteins of HIV W-81 demonstrated no differences between the groups at the initial visit. After 3-5 years, there was a significant decrease in antibodies against p24, p31, gp120, and p51 in the group with AIDS compared to the stable subjects ($p < .05$, Mann-Whitney). NA decreased in the AIDS group with AIDS and 2/10 stable subjects. Reciprocal geometric mean titers (GMT) of NA were identical in the two groups at presentation (1:10) subjects with AIDS and 1:100 in the stable group. In the AIDS group 17/20 subjects and there was no difference or change in ADCC titers between the two groups over the study period.

Conclusions: Development of AIDS in initially asymptomatic HIV seropositive homosexual men was associated with a decline in HIV specific antibodies against core antigens and NA but not ADCC or envelope binding antibodies as detected by WB.

C.522 MICROWAVE INDUCED SYNERGY IN HIV1 INFECTION: ACTIVITY OF SPECIFIC ANTIBODIES IN PARFIDIT SALIVA

Zelen, Zdenek, Anonhik, D.,* Pech, P.,* Havel, D.,* Dole, D.L., S.,* Melan, M.J.,* Rana, M.,* Harvard Univ., Boston, MA. *Univ. of Maryland, Baltimore, MD, U.S.A.

Objectives: To look for qualitative and quantitative properties of the specific antibodies in the period saliva of HIV1 infected people.

Methods: Human serum and periodical saliva was collected from 19 HIV1 infected individuals of different clinical stage: CDCII (7), CDCIII (8), CDCIV (3). The immunoglobulin IgA, IgG and IgM were separately diluted from the sera and saliva. The serological techniques used were the western blot, ELISA and neutralization test.

Results: Specific antibodies (Ab) to the HIV1 were found in the sera and saliva of all the people tested. They were found positive to both immunoblotting and ELISA. The immunoblotting revealed Ab to all major HIV1 antigens (env, pol and gag). The predominant Ig class of specific Ab toward env proteins in the serum was IgG, while in the saliva it was IgA class. Moreover IgA antibodies were found by ELISA in 14 of 18 saliva tested, while IgG antibodies were found in only 6 of 12 saliva samples. The level of Ab to the env antigens in the sera and saliva varied widely. Comparing level and class of IgA, we could not find any significant difference between the groups of asymptomatic, CDCII and AIDS affected people. The saliva IgA antibodies to the env proteins reacted more frequently compared to the serum IgA in 11 of 14 samples tested. The relative lower reactivity ranged from 2 to 65 times lower (mean=11). Neutralization assay revealed positive reaction in 3 of 7 sera tested in rather low titers (1:10-1:100). None of the 9 tested saliva nor their respective IgA demonstrated neutralization activity.

Conclusion: The current data revealed: A) Relatively low reactivity of saliva IgA compared to serum IgA. B) Lack of neutralization activity in the HIV1 antibodies of saliva. C) No correlation could be established between antibody reactivity and the 3 CDC HIV1 categories. These findings might suggest that the mucosal immune response in HIV1 infected people is impaired long before any subclinical symptoms of AIDS occur.

C.524 THE IMMUNE RESPONSE TO HIV-1 ENVELOPE PROTEIN IONOLVINS

2078 AIDS AND HIV
Y. Kikuchi, J. P. Ezzamel, M. McCaskey, A. Grondinakis, M. Berman, M.-P. Kieny, P. Sasmontelli, and L. Montagnier, Institut Pasteur, Paris, France, Strasbourg, France.

Objective: HIV protein specific cytotoxic effector cells, present in the peripheral blood of most HIV seropositive donors, have been characterized and shown to be HIV specific. HIV specific cytotoxic effector cells: Phenotypic studies and analysis of antigen processing were used to define these effector cells.

Methods: Recombinant gp120 anchored in the plasma membrane, soluble gp120, or an HIV precursor with deletion of the peptide signal or gp120 with deletion mutations were expressed in vaccinia. Autologous EBV transformed lymphoblastoid cells were infected with these recombinant vaccinia viruses and used as targets for primary cytotoxic effectors present in PBMC of HIV seropositive donors.

Results: The predominant HIV specific cytotoxicity in most HIV donors is mediated by ADCC effectors cells (CD8⁺, CD8⁺, CD8⁺, CD8⁺ and T_H1 cells can be blocked by antibody to human IgM. ADCC effectors cells are able to lyse only target cells that express the proteins on the cell surface as detected by surface immunofluorescence. However, CD8⁺ CTL are able to lyse target cells that do not express the whole env protein on the surface.

Conclusion: In the heterogeneous population of viral antigen specific effector cells in the peripheral blood of HIV seropositive donors, a major cytotoxic activity is HIV specific ADCC. However, in some individuals CTL activity or both ADCC and CTL activities are detectable.

C.525 TUMOR NECROSIS FACTOR (TNF) STIMULATES HIV-1 TRANSCRIPTION IN HUMAN T CELLS
Israel, Nicolas; Naran, U.J.; Alouf, J.J.; Bachelier, F.; Tranchesi-Milazzo, and Virelizier, E.
Institut Pasteur, Immunologie Virale, Paris, France.

Objective: We have examined whether TNF might stimulate HIV-1 transcription and we have analyzed the mechanism involved.
Methods and results: We transfected T_H then cell line (a subclone from Jurkat T cell line) with the plasmid LTR HIV-CAT which contains the HIV-1 LTR sequences upstream of the bacterial CAT gene. CAT activity was consistently increased 2 fold when transfected cells were treated with TNF. Subtransfection was enhanced: more than 20 fold when the RRE region of the LTR (nucleotides +158) was deleted. We have previously shown here that the enhancer (-108, -75) element, previously described to bind NF- κ B, is necessary for activation of the heterologous promoter. However, flanking sequences of this region are important for full transactivation. Using homologous assays, we show that this increased expression is accompanied by the induction or activation of an NF- κ B-like transcription factor. We show also that PMA and PHA have synergistic effects with TNF. Such a synergy was not due to superinduction or activation of this transcription factor and may be due to upregulation of TNF receptors by PMA or PHA.
Conclusion: Since TNF is secreted during most immunological and inflammatory reactions and has been indeed detected in the serum of AIDS patients, our observations suggest a possible role for TNF in the pathogenesis of AIDS through activation of HIV gene transcription.

C.527

C.529 HIGH LEVELS OF CELL-ASSOCIATED IL-1 IN CIRCULATING MONOCYTES FROM HIV-INFECTED INDIVIDUALS
Miles, Laurence; MacFarther-Cavillan, M.; Londe, M. and Kaschnick, R.
Unité d'Immunopathologie, Hôpital Brocauss, Paris, France.

Stimulation of normal monocytes results in transcription of IL-1 α and β genes and accumulation of cell-associated IL-1. Some but not all IL-1 inducers further trigger the extracellular release of IL-1 β . We have examined the production of cell-associated IL-1 *in vivo* and that of cell-associated and extracellular IL-1 *in vitro* in 30 infected individuals and 30 non-infected controls. Cell-associated IL-1 activity assessed using a cytotoxic thymocyte assay was significantly increased in patients with AIDS (80.6 \pm 19 U/ml (mean \pm SEM); n = 14) and HIV oligo-seropositive individuals (32.9 \pm 10.2 U/ml; n = 16) as compared with normals (4.4 \pm 1.6 U/ml; n = 30). Cell-associated levels of IL-1 α and β antigens were also elevated in HIV individuals. Serum-free culture of monocytes from HIV individuals in the absence of IL-1 inducers resulted in spontaneous release of IL-1 activity. IL-1 β and antigen. No IL-1 activity was released by cells from normal individuals cultured under the same conditions. LPS-stimulation of monocytes from HIV patients induced the release of both IL-1 and whereas monocytes from normal individuals exclusively released IL-1 β . However less IL-1 activity was released by LPS-stimulated cells from HIV patients as compared with normals. Thus, HIV-infection is associated with the chronic stimulation of monocytes to produce IL-1 *in vivo* and an alteration in the intracellular pathways regulating the extracellular release of IL-1 α .

646

C.526 HIV-1 AND HIV-2 SPECIFIC IgG SUBCLAS REACTIVITY TO env AND gag PEPTIDES
Holliday, Peg Andrea; Ottens, A.S.; Silver, E.R.; Trojnar, J.***; Norbury, E.S.*** and Labrecq, R.***
National Bacteriological Laboratory, Stockholm, Sweden, **Institut Pasteur de Côte D'Ivoire, Abidjan, Ivory Coast, ***Ferring AB, Malmo, Sweden, ****Karolinska Institute, Stockholm, Sweden

Objective: To evaluate and compare the HIV-1 and -2 specific IgG subclass reactivity to selected peptides.
Methods: Peptides representing five immunodominant regions of the HIV-1 and -2 env and gag proteins were used as antigens in IgG subclass ELISA assays. Sera from HIV-1 and -2 infected individuals were analysed.
Results: IgG was the dominant anti-HIV-1 subclass and was detected in 100% of the sera. The HIV peptides representing gp36-41 elicited the highest frequency of reactivity of all subclasses. The reactivity to the gp120 peptide was mainly restricted to IgG1 or IgG3. A high IgG3 reactivity was also seen directed to peptides representing the putative hypervariable loop region of gp120. Subclass response to peptides representing regions of gp7 and gp5 was restricted to IgG1+4 and IgG1+5 respectively. Sera from HIV-2 infected individuals showed a 90-100% reactivity to the corresponding HIV-2 peptides. Cross-reactivity was more frequent in the HIV-1 group to HIV-2 peptides than vice versa.
Conclusion: Differential restriction of the IgG subclass response was seen to regions of HIV representing the major structure proteins. The IgG3 response to envelop-representing peptides indicates frequent gp120 stimulation and development for neutralization.

C.528 RELATIONSHIPS BETWEEN THE PHYSIOLOGICAL FUNCTION OF CD4 AND ITS ROLE AS THE HIV RECEPTOR
Quarini I. Sattentau*, Merkenhausen, M***, Healey, D., Truneh, A**, Arthos, J**, Sweet, R.**, Beverley, P.C.L.***
The Academic Dept of Cell Medicine, UCMGSM, London, UK
**HTG, ICRF, UCMGSM, London, UK
***Smith, Klein and French Laboratories, King of Prussia, PA, USA

Objectives: To define with the use of monoclonal antibodies (mAb) to CD4 and their anti-idiotypes those sites on the CD4 antigen important in the physiological functions of this molecule in relation to their role in HIV reception.
Methods: The amino acid residues essential for the binding of a number of CD4 mAbs has been determined using forms of the CD4 antigen containing point mutations. These mAbs have also been used to probe the function of the CD4 antigen in terms of its HIV binding capacity and role in T-cell activation.
Results: We have defined those CD4 mAbs which react with residues most similar to the amino acids which gp120 requires for binding. These mAbs are highly effective at inhibiting T-lymphocyte responses to soluble recall antigens and mitogens in a soluble form, but are also capable of enhancing T-cell responses when cross-linked with CD3 mAb.
Conclusions: Antibodies against CD4 which inhibit HIV-induced synapsium formation require residues very similar to those required by gp120 for binding to CD4, and are also highly effective at modulating T-cell activation. We therefore conclude that the regions of CD4 reactive with HIV gp120 are important in the physiological function of CD4.

C.530 SPECIFICITY OF CD4+ T CELLS FROM CHROMOLUNG MACAQUE IMMUNIZED WITH HYBRID HIV P24/7Y VIRUS LIX PARTICLES
Killey, Kingston*, Barrow, A*, Adams, S**, Kingsman, S**, Kingsman, A** and Kitchin, P.**, FIBIG, ICRF, South Mimms, Hertsmere EN8 3QG, UK. **British Biotechnology Limited, Oxford, UK.

Objective: To assess the ability of a novel antigen presenting system to generate T-cell responses to HIV gag proteins in primates.
Methods: Specificity of virus particles of chromolung macaques immunized with recombinant HIV P24 protein expressed in yeast as hybrid P24/7Y virus like particles (VLP). Animals received 3 i.v. injections, at 8 week intervals, of 50 or 200ug of P24/7Y-VLP with or without adjuvant. Proliferative responses of peripheral blood lymphocytes were tested at 2 week intervals.
Results: Lymphocyte proliferative responses to P24/7Y-VLP and control 7Y-VLP were detected in all animals as soon as 2 weeks after immunisation. Responses were significantly greater in animals given the antigen with adjuvant. Lymphocytes from these animals also gave a significant response to recombinant gag alone or to whole HIV. Proliferation and IL-2 release by T-cell lines and clones in response to synthetic peptides from the P24 sequence demonstrated the presence of CD4+ T-cell epitopes on HIV-P24.
Conclusion: Hybrid HIV P24/7Y VLP are a useful antigen presenting system for the generation of proliferative T-cells to HIV gag proteins and have allowed us to identify determinants on P24 recognised by CD4+ T cells from chromolung macaques.

C.543 USE OF AUTOLOGOUS CD4+ T CELLS IN THE ASSAY OF HIV-1-SPECIFIC CYTOTOXIC T CELLS (HIV-CTL)

Magnan, C. and Drouot, J., Department of Medicine, University of Ottawa and Ottawa General Hospital, Ottawa, Ontario, Canada.

Objective. We have reported that the anti-HIV drug zalcitabine (CZP) and dextran sulfate (DS) induce the regeneration, within 3 days, of CD4+ T cells in lectin-stimulated cultures of blood lymphocytes from HIV+ patients. Based on this observation, we describe a method that permits the use of autologous CD4+ T cells as targets in the assay of HIV-specific cytotoxic T cells (HIV-CTL). **Method.** Blood mononuclear cells cultures are started with Con A, IL-2, to which are added CZP or DS (25 µg/ml). On day 3 the CD4+ cells are separated from CD8+ T cells by staining with anti-CD8 (CD8T) antibodies with post-exposure antibody conjugated to magnetic particles and separation of CD8+ T cells using a magnet. The separated cells are cultured for 3 to 4 days in a medium containing IL-2 and CZP or DS (25 µg/ml). A day before the CTL assay, the CD4+ cells are infected *in vitro* with prototype HIV-1 virus and incubated for 18 hours in a medium without anti-HIV drugs. The following day the CTL assay is carried out. **Results.** A systematic analysis of the method demonstrated that the proposed assay is reproducible and reliable. We have used autologous T cells in the cloning of HIV-CTL (3 experiments) and in the study of the HIV-CTL response in 5 HIV+ patients. A more detailed study of patients is now being carried out. **Conclusion.** The method proposed here should be of value in studies of the HIV-CTL response in the clinical as well as the research laboratory.

C.545 A CHEMICALLY SYNTHESIZED 104-MER PEPTIDE OF THE C-TERMINAL HALF OF HIV-1 P24 SUCCESSFULLY USED AS AN HIV INHIBITOR

Ghisoni, L., Baroni, P., Maggi, P., Di T. T., Tosti, G.E., G. M., Ghisoni, W.A. and Oates, A.H.

The London Hospital Medical College, London, UK. *London School of Pharmacy, London, UK.

Objective. To investigate the immunological properties of a chemically synthesized C-terminal half (104 residues) of HIV-1 p24 core protein. **Method.** The 104-mer peptide was prepared using an Applied Biosystems 430-A synthesizer employing t-boc chemistry and used in purified form in the subsequent work. T-cell response was studied by *in vitro* proliferation of antigen-activated splenic cells from mice previously primed with the peptide. Mice and rabbits were immunized subcutaneously with approx 100 µg peptide in Freund's incomplete adjuvant. Murine monoclonal antibodies were made using NS0 myelomas as partner. Antibody activity in sera from HIV-1 haemophilics and experimental animals was tested in ELISA and Western blot with the 104-mer and HIV-1 proteins. **Results.** A dose-dependent proliferative T-cell response in mice was found using the 104-mer as antigen. Antibodies from mice and rabbits reacted strongly with the 104-mer immunogen and also with the HIV p6 protein p24 and p50. Conversely, sera from HIV-1 seropositive humans reacted with the 104-mer. **Conclusion.** The synthetic 104-mer peptide elicited an anti-HIV-1 T- and B-cell response, indicating that some important epitopes are shared between this chemically synthesized molecule and the natural viral p24 protein. Immunologically useful HIV-1 proteins can now be prepared by chemical synthesis.

C.547 CARBOHYDRATE-DEPENDENT EPITOPES OF HIV-1 GP120

Belsand, A., Bissler, L., Bissler, L., and Giesecke, G., Department of Clinical Virology, University of Göttinge, Göttinge, Department of Virology, University of Göttinge, Göttinge, Germany.

Objective. Carbohydrate epitopes may decrease or increase the antigenic activity of viral glycoproteins. We present one half of the molecular weight of the carbohydrate content representing one half of the molecular weight of the six different N-linked oligosaccharides and their N-linked oligosaccharides: one modulating effects on the antigenic activity.

Methods. Secreted gp120 was covalently linked on microtiter plates and exposed to neuraminidase and increasing concentrations of periodate. As a control of sequential removal of peripheral monosaccharides an enzyme-linked lectin assay was used. The alteration in antigenicity, during the neuraminidase/periodate-treatment, was followed in ELISA with a panel of LAV-specific monoclonal antibodies.

Results. Removal of sialic acid and galactose from N-linked oligosaccharides on gp120 resulted in significant increase in antigenic epitopes, in the N-terminal region, previously masked by glycosylation.

Conclusion. Our results demonstrate that some epitopes of gp120 are modulated by the carbohydrate component. This phenomenon might, at least partly, be of importance for the ability of HIV to escape immune reactions.

C.544 CHEMICAL SYNTHESIS OF CHIMERIC PEPTIDES AND PEPTIDES FOR IMMUNOLOGICAL PURPOSES

Manganji, P., Datta, D.T., Trun, G.K., Gibbons, W.A., Baselin, L.R., Gell, S., and Oates, A.H.

* The School of Pharmacy, London, UK.

** The London Hospital Medical College, London, UK.

*** California Institute of Technology, California, USA.

Objective. To chemically synthesize a 104 amino-acid long peptide corresponding to the 273-377 sequence C terminal half of HIV-1 p24, and the hybrid peptides p24 (1-epitope)-limer-*env* (8 epitope) 44 mer and p24 (273-377)-limer-*env* (D-epitope) 136 mer.

Methods. The three polypeptides were synthesized using highly optimized custom protocols on an All-400 synthesizer. Crude peptides were dialyzed and purified by a combination of reverse phase, size exclusion and ion-exchange HPLC. Quality control included amino-acid analysis, protein sequencing, SDS-PAGE and IDP gel chromatography and P24-immunoprecipitation. The synthesis of the 104 mer peptide yielded three grams of crude peptide-*env*. After purification 20% (w/w) of the cleaved peptide was obtained and had a chemical composition which was consistent with the expected amino-acid sequence. Similar yields of homogeneous material were obtained for the chimeric peptides. Immunisation of mice with the peptide and proteins induced antibodies to HIV core and envelope proteins.

Conclusions. This work suggests that the chemical synthesis of long peptides is feasible and may have application in vaccine development.

C.546 MHC CLASS I-III ALLOTYPES IN PATIENTS WITH DISSEMINATED KAPOSI SARCOMA (KS), ARC/WRS, AND IN NORMAL CONTROLS

Gross, F., H. Kriehuber, F. Isel, C. Baudier, H. Kamber, C. Meis, and the ARC-IVIG Study-Group Cologne/Berlin

Dept. of Medical Microbiology, Virology, Internal Medicine II, Dermatology, Pathology, Biostatistics, Univ. of Cologne, 5000, Bad Mendenstrasse, City, St. Marien, Cologne, FRG; Centre Laboratory, Berlin and Bonn, Cologne, FRG.

Objective: Major histocompatibility complex (MHC) class I and II (HLA-A,B,C,DR) associations in HIV-infected patients has been controversial. Of the MHC coded polymorphic components C1, B2, C4A/C4B (MHC class III) allotypes of C2 and C4 have not yet been reported. CA alleles encode for major immunogenetic relevance for their potential differences in virus neutralizing capacity. In the present study 30 ARC/WRS patients from the ARC-IVIG project (Dr. Schappag-Schäfer et al.), 30 patients with disseminated KS, and 160 HIV-negative control individuals were compared for MHC class I to III allotypes.

Methods: All individuals were of West German origin. Diagnosis of ARC and KS (CDC and WHO criteria) was done by clinical and laboratory parameters. MHC testing by standard method: microlymphocytotoxicity assay for HLA-A,B,C,DR, electrophoretic and serologic tests for class III allotypes, Western Blots with poly- and monoclonal antibodies for C4A/B. **Results:** An increase in frequency ($p < 0.05$) was observed between ARC/WRS patients and controls for HLA-B35/CW4, DRW14, a decrease for B18, CW6/DR1. In KS CW6 was more frequent than in ARC/WRS patients. However, values were not significant if corrected for the number of tested antigens. No significant differences were seen between KS and ARC patients or controls for class III allotypes, nor for the previously reported associations e.g. of B2, DR1, and especially DR3, including the DR3-gp120 DRW11, 12.

Conclusions: The results indicate lack of strong MHC-associations with the investigated antigens in West German Caucasoids. The contrast of our data to previous findings for distinct, as well as disseminated KS supports the hypothesis of ethnic dependence of HIV-related diseases.

C.549 MODIFICATION DE LA SECRETION D'INTERLEUKINE 1 PAR L'EXPOSURE SAISONNIERE A L'INFECTION VIH

Domin Brillet*, Roland St. Omeron*, Litane P.
*Clinique Dermatologique - Hôtel Dieu, A. A. Renardes - AIDS UNIT
CROIX DU - FRANCE.

Objectif. Dans la série, la production spontanée d'interleukine 1 (IL1) augmente chez les patients VIH au début de l'infection, puis s'affaiblit au stade SIDA. Dans ce contexte, nous avons voulu vérifier si aux semaines quantitatives des cellules de lymphocytes (L) de l'épiderme s'associaient des modifications de la sécrétion d'interleukine 1 (IL1) épidermique produite normalement par les kératinocytes de ces cellules.

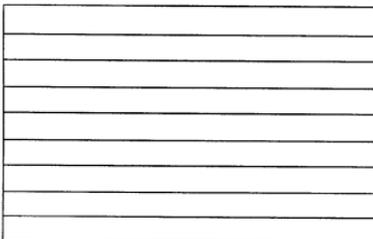

Méthodes. 37 patients VIH (11 au stade II, 10 au stade III et 16), 8 au stade III et 4 au stade IV, ainsi que 5 témoins séro-négatifs ont été étudiés. Les biopsies cutanées ont louches été réalisées au passé simple (free entrance de temps) avec un piquet-aspire au passé simple (coupe) au stade (free). Les techniques d'immunofluorescence indirectes sur coupes complètes avec un anticorps anti-IL1 (Elior et cell UI 1016, Immunotech) et des cellules (free) des témoins (Elior et cell UI 1016, Immunotech) ont été réalisées.

- au stade II et au passé simple de coupe, la sécrétion d'IL1 épidermique est supérieure avec un niveau normal de cellules de lymphocytes.

- au stade III et IV, elle est plus faible mais toujours supérieure à celle des témoins (L = 29,7%).

- au stade III et IV, elle est s'affaiblie avec chute des cellules L (12,3%).

Conclusion. Le travail confirme donc l'importance de l'entretien fonctionnelle du système immunologique noté par la VIH.

C.551

C.553 NATURALLY OCCURRING AUTO-ANTIBODIES TO CD4 AND THE HEC CLASS II MOLECULE IN HIV-DEPLETED INDIVIDUALS

ROBERTA ROBERTI, J. Baker, J. Payne, A.L. Sweet, R.J. Suckoff, J., and the Walter Reed Retrovirus Research Group, Walter Reed Army Medical Center, Washington, D.C., United States of America.
*Smith, Klein and French Laboratories, Philadelphia, Pa., United States of America

The natural ligand for CD4 is the HEC Class II molecule. Antibodies to the CD4 binding site of HIV could theoretically cross-react with HEC Class II as both bind to CD4. Such anti-HIV binding site antibodies could also result in anti-Idiotypic cross-reactive with CD4. Western blots of EDV-transformed B-cells rich in CD4 are demonstrated by a murine monoclonal were prepared. Sera from 25 HIV patients and 5 normal individuals do not exhibit or do so in such low titer as to be of no pathophysiologic relevance. Incubation soluble CD4 was utilized in a direct RIA to determine if antibodies to CD4 are detectable in HIV patients. 3/20 (15%) patients probably demonstrated reactivity compared to 0/5 normal individuals. EDV-transformed B-lymphocytes from patients continued to produce antibody to CD4 *in vitro* as measured by direct RIA and dot-blot. This indicates that a significant anti-CD4 response is present in HIV patients, possibly as a result of an anti-idiotypic response to gp120. These findings may have implications for the therapeutic use of soluble CD4.

C.550 SYNCTYMIUM FORMATION AND DESTRUCTION OF CD4+ BYSTANDER CELLS COCULTURED WITH PRESENTLY HIV-INFECTED T-CELLS, AS DEMONSTRATED BY FLOW CYTOMETRY

Dominique Schols, R. Pauwels, M. Baha, J. Desmet and E. De Clercq
Rage Institute for Medical Research, K.U.Leuven, B-3000 Leuven, Belgium

To investigate cell fusion and giant cell formation following fusion between HIV-1- or HIV-2-infected (HIV-78) cells and uninfected CD4+ MOLT-4 (clone 8) cells, the two cell populations were mixed and cultured at 37°C, stained with the appropriate monoclonal antibodies (mAbs) (FITC- or PE-conjugated), fixed and analyzed by flow cytometry.

At the moment that syncytium formation started, i.e. after 4-6 h incubation, the MOLT-4 cell number began to decrease and after a 24-hr incubation period all MOLT-4 cells had disappeared, as demonstrated with specific mAbs to antigens expressed on either MOLT-4 or HUT-78 cells. The formation of giant cells and the concomitant disappearance of MOLT-4 cells was blocked by OKT4/Leuck mAbs, and several parameters of cell fusion such as fusion index, percent of fusion inhibition and 30 f fusion inhibitory concentration of the mAbs could be accurately determined.

This flow cytometric method can be readily implemented to evaluate any agents for their capacity to block cell-cell fusion and the subsequent destruction of the bystander target cells. Our observations also reveal a mechanism by which a low HIV-infected cells may gradually deplete the pool of uninfected CD4+ cells *in vivo*.

C.552
DETECTION OF gp120 (HIV-1) AND ANTIBODIES TO DEFINED REGIONS OF gp120 IN HUMAN SERUM: CORRELATION WITH HIV-1 IMMUNIZATION

ROBERTA JOHN AND ROBERTING, J.A. (1)

Dept. Vet. Pathology, Glasgow, UK and

(2) Institute of Cancer Research, London, UK

We have developed ELISA-based methods for the detection of the HIV-1 surface glycoprotein gp120 in a subset of sera from HIV-1 infected individuals, and will describe data relating gp120 levels with those of p24 antigen, anti-gp120 antibodies and disease status. In this study, anti-gp120 antibodies are monitored using an extremely sensitive, sensitive and specific ELISA that can use a wide range of sources of gp120 as a capture antigen, including simple unpurified detergent extracts of divergent HIV-1 strains. We have also developed ELISAs that detect serum anti-gp120 antibodies (1) capable of blocking gp120 binding to CD4, and (2) that bind to the type-specific neutralizing loop (387-395). Data will be presented relating levels of these antibodies to neutralisation titres (see below).

Serum	Neutral. titre	Total gp120	Ab	CD4 blocking	Ab	anti-gp120	Ab
3	160	9000	270	250			
2	80	9000	470	300			
3	40	380	35	0			
4	40	900	70	20			
6	320	5700	680	600			
6	160	9000	900	200			

C.554
CELL-MEDIATED LYMPHOBLASTIC RESPONSES BY ADULTS AND CHILDREN TO RECOMBINANT HIV ENVELOPE AND CORE PEPTIDES.

*ROBERTING, M., Moore, T., Hraimel, H., Papageorgiou, N., New York University Medical Center, and Baltimore Hospital Center, New York, U.S.A.

Objectives. To determine if recombinant HIV antigens elicit cell-mediated immune responses in infected adults and children and to compare these responses to those of seronegative individuals.

Methods. Lymphocytes from individuals at risk for HIV infection were cultured with recombinant HIV envelope and core (ENV & COR) antigens, as well as diabetin or staphylococcus (S & TT). These with a stimulation index >> 0 were scored as responsive. The response rate among seronegative adults (N=6) and seronegative adults (N=6) was compared to that of seronegative children (N=6), seropositive children (N=6), and seropositive children (N=6).

RESULTS. POSITIVE RESPONSES TO HIV AND RECALL ANTIGENS (4)

STIMUL	ENV	COR	TT	IT
Infected	3/32 (9)	4/32 (13)	12/28 (43)	20/28 (69)
Uninfected	5/12 (42)	7/12 (58)	9/18 (50)	10/18 (61)
Uninfected	9/28 (32)	12/35 (34)	8/21 (38)	16/31 (52)
Uninfected	7/28 (25)	4/28 (14)	8/28 (29)	24/28 (86)
Uninfected	1/13 (8)	3/13 (23)	8/13 (62)	10/13 (77)

Conclusions: 1) Infected children are as likely to respond to ENV & COR as they are to recall antigens. 2) Infected children & seronegative children are more likely to respond to HIV antigens than are uninfected children (p<0.01). 3) One fourth of high risk seronegative adults respond to HIV envelope antigen, indicating either antigen sensitization or nonspecificity.

C.561

Evaluation of the role of the soluble CD8 and IL2 receptors (IL2R) in patients with Human Immunodeficiency Virus infection. L. Lichtig*, A. Chachona*, V. Molinari*, M. Rosen*, P. Rong*, P. Valadarias* et al. *New York University Medical Center, NY NY 10016, and *T Cell Sciences, Cambridge MA 02139 USA.

Objective: We evaluated the levels of soluble CD8 and IL2 receptors (IL2R) in patients with HIV infection. **Methods:** 63 patients with HIV infection and 7 normal controls were studied. Of these, 21 were seronegative asymptomatic (ASYM), 19 had ARC, 13 had KS and 10 had AIDS with opportunistic infection. In previous studies the T84 protein has been shown to be induced in direct proportion to the level of activation of T84 positive cells. Serum IL2R is a measure of the activated state of IL2R bearing cells. The levels of T84 and IL2R were compared with each other and with levels of plasma P24 antigen and T4/T8 ratio. Soluble CD8 and IL2R were measured using CellFlowTM Immunometry kits from T Cell Sciences. T4/T8 ratios were determined by standard techniques. **Results:** Soluble CD8 levels in plasma of patients with ASYM, KS, ARC, and AIDS were respectively 1029 ± 89, 1454 ± 131, 980 ± 118, and 771 ± 115 while normal controls were 592 ± 60 antibody (Mean ± SD). IL2R levels in serum of patients with ASYM, KS, ARC, and AIDS were respectively 783 ± 98, 970 ± 129, 1011 ± 119, and 1566 ± 157, normal controls were 482 ± 28 antibody. Using flow-cytometric analysis, comparing each patient with normal controls, the majority of low T84 patients were 59% of normal (p < 0.0001). IL2R was higher than T4/T8, T84, and P24 for discriminating ASYM from AIDS (p < 0.0001), ASYM from ARC (p < 0.002) and ARC from AIDS (p < 0.0001). Using a combination of both receptors in each patient group, a formula was derived which predicted between normal and ASYM patients. **Conclusion:** We conclude that there is an increase in soluble CD8 and IL2R in all patients with HIV infection compared to the normal control group. These data suggest that the measurement of levels of IL2R and soluble CD8 in HIV infected patients provide objective and quantitative parameters for clinical researchers studying changes in the immune system in ASYM, ARC, KS and AIDS and may serve as a surrogate marker of disease in ASYM patients.

C.563

CIRCULATING INTERFERON-GAMMA IN HIV-1 INFECTION

Puchs, Distmer, Hausen, A.; Reibnegger, G.; Werner, E.H.; Dierich, M.P. and Wachter, H. University of Innsbruck and Ludwig Boltzmann Institute of AIDS Research, Innsbruck, Austria

Objective: Progressive HIV-1 infection is associated with diminished in vitro production of lymphokines by T-cells upon antigenic and mitogenic stimulation. However, in vivo markers, e.g. neopterin, indicate hyperproduction of certain cytokines.

Methods: We measured serum concentrations of interferon gamma and neopterin in 43 HIV-1 seropositive individuals and 76 seronegative blood donors. A modified radioimmunoassay procedure for detection of interferon gamma was used with a detection limit of 18 U/l.

Results: 22 of the 43 seropositives exhibited increased serum interferon gamma concentrations. There was a significant association between serum interferon gamma concentrations and CDC-stages of the patients. CDC IV-C patients had the highest concentrations. Further, serum interferon gamma and serum neopterin concentrations were significantly correlated.

Conclusion: Circulating interferon gamma is increased in HIV-1 seropositives compared to seronegative blood donors. Diminished in vitro production of interferon gamma by T-lymphocytes on stimulation contrasts the in vivo findings.

C.565

C.562

AN INTERACTIVE RELATIONAL DATABASE FOR HIV AND THE IMMUNE SYSTEM

Rizova, G., Stanley, E. A., Flynn, James H. and Nelson, G. Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA

Objective: To organize the complex, changing information about HIV and the immune system in a visually oriented, user-friendly, interactive system. **Methods:** We are using HyperCard, an Apple Macintosh to create an interactive reference tool on HIV and the immune system. Information is presented on "cards," each of which contains a diagram and/or short description, as well as "buttons" which link the card to related cards. The "mouse" is used to click a button and move from card to card. For example, from the main card describing macrophages, the user can go to a card on the infection of macrophages and to other related subjects. Comment cards allow researchers to remark on contradictory results, difficulties with experiments, etc. **Results:** We see one of the primary stumbling blocks to an understanding of how the immune system is slowly destroyed by HIV to be the difficulty involved in organizing the information from experiments and studies on HIV and then organize it within the context of the immune system. This continually expanding relational database can be used by newcomers to the field to get up to speed, by AIDS researchers who are not immune system experts to understand the studies on HIV relative to the immune system, and by immune experts to organize the latest information.

Conclusion: This HyperCard system, although still incomplete, will provide AIDS researchers to develop new ways to organize the growing knowledge base. To obtain this experimental program send us three 20/20 microdisks: in return we would like comments on its utility, structure, and content.

C.564

B ENDOPHRIN, A.C.T.H. AND CORTISOL RELATIONSHIP WITH AIDS

LE GASTHER, J. J. and BOUTIER, C. ** TEXIER, F. **, OBER, F. **, MONTAGNER, L. **, LEFEBVRE, J. **, et al. * Institut PASTEUR - PARIS, ** COLLEGE DE FRANCE - PARIS, FRANCE

Objective: Study of B ENDOPHRIN, A.C.T.H., CORTISOL, plasma concentrations in homosexual HIV infected men groups.

Methods: 72 low drug-abuse men, 20-30 years old, 3 homosexual groups: AIDS-25, SERO-+15, SERO-15, one essential HYPOTENSIVE group as CONTROL with 2 blood samples daily (8 am-5 pm).

B endorphin and A.C.T.H. were evaluated by radio-immunoassay and Cortisol by chromatography. Data were analyzed by parametric and non parametric tests.

Results: 1) Both AIDS, SERO- and SERO- showed plasma B ENDOPHRIN/A.C.T.H. ratios were higher than age-matched/ ratio of CONTROL. 2) A low of normal A.C.T.H./TOTAL CORTISOL revealed and relative rise of free CORTISOL level. **Conclusion:** 1) The higher relative level of plasma B ENDOPHRIN suggests a possible role of HIV derived pituitary precursor (DOPC) processing in the role in immunity. 2) The striking normal and neuroendocrine pattern of the 2 homosexual groups SERO- and SERO- (living together) suggest either latest HIV infection in SERO- patients or other causes factor to these two groups. 3) Possibility to link the higher ratio of B ENDOPHRIN to A.C.T.H. as an early sign of HIV infection will be discussed.

C.566

SUPPRESSIVE EFFECTS OF IMMUNODEFICIENCY VIRUSES ON THE IN VITRO STIMULATION OF HUMAN LYMPHOCYTES

Lieber, Johannes; Benita, I.; König, H.; Kurtz, R. Paul-Ehrlich-Institut, Frankfurt am Main, FRG

Objective: Antial retroviruses exert a suppressive effect on the in vitro stimulation of lymphocytes. The equivalent effect of primate immunodeficiency viruses (HIV-1, HIV-2) and human T-cell lymphotropic virus type II (HTLV-II) on the in vitro stimulation of human lymphocytes should be studied and the responsible viral components should be identified.

Methods: In the lymphocyte stimulation assay, PBMCs are incubated with uv irradiated whole virus or with viral components (purified p24 and glycoprotein) and stimulated with PHA. After two days, the ³H-thymidine uptake is measured. After solubilization, viral glycoprotein complexes are isolated by chromatography on lentil lectin and heparin columns.

Results: The most important variable in the lymphocyte stimulation assays is the origin of the human lymphocytes. Depending on the donor a more or less profound inhibition by inactivated HIV-1 can be observed. The extent of inhibition varies between 20% and 80%. However, the effect of HIV-2 and the SIV is very small, often negligible. Purified glycoproteins give the same results.

Conclusion: The inhibitory effect of different immunodeficiency viruses in the lymphocyte stimulation assay may well be due to differences in the pathogenesis of these virus strains. Therefore, it may play a role in the pathogenesis of AIDS. In addition, lymphocytes of different donors are differently susceptible to this effect. Whether this observation can explain, at least in part, the differences in the time course of the disease in different individuals is an area of further investigation.

C.573 LYMPHOCYTE STIMULATION IN ARC/WRS PATIENTS DURING INTRAVENOUS IMMUNOGLOBULIN (IVIG) TREATMENT
H. Krichbaum, G. Metz, Th. Mennig, G. Meisner, and the ARC-IVIG Study-Group Cologne/Berlin
Department of Medical Microbiology, Hygiene, Internal, Medicine II, Dermatology, Rheumatology, Usher, of Cologne, FRG; Central Laboratory, Peter Badt (Food Production Service), Bonn, Federal Republic

Objective: In a randomized, controlled double blind study 15 ARC/WRS patients were compared during 6 months 6g/kg IVIG treatment with 15 placebo treated patients. The protocol has been described elsewhere (cf. Schupp-Bäcker et al.). Our study was aimed at lymphocyte response to T- and B-cell mitogens.
Methods: ³H-thymidine uptake was determined after stimulation with the specific mitogen PHA, PWM, formalinized *S. aureus* - Cowan 1 (SAC), and with the antigens PPD, and Herpes simplex virus (HSV) at the onset, on day 85 and 181; antibodies against HSV were measured by ELISA and CFT. In addition, 30 untreated HIV-negative control individuals were tested.
Results: For T-cell mitogen PHA, T-7-cell mitogen PWM, and B-cell mitogen SAC no differences between the 2 patient groups was observed at day 1, 85 and 181, but stimulation was significantly lower as compared to the control group (p<0.05) on day 1. Lymphocytes of 4 patients and 5 HIV-negative control individuals showed PPD response. All patients had IgG-antibodies against HSV (ELISA). In the IVIG-group 8 patients' lymphocytes responded to HSV at some time during treatment, 13 had positive CFT titres in the placebo group only 3 patients' lymphocytes responded to HSV, 10 had positive CFT titres. Seven HIV-negative individuals showed positive HSV-lymphocyte response, 19 with ELISA/CFT titres.
Conclusions: In spite of some clinical improvement regarding fever and fatigue during IVIG treatment, there was no influence on T-7-cell stimulation by specific mitogens. All patients having experienced HSV infections, lymphocyte reactivity to HSV, although statistically not significant, was predominantly seen in the IVIG-patient group.

C.575 IMMUNO-ADHERENCE OF *MYCOBACTERIUM AVIUM* (M. AVIUM) TO U937 IS ENHANCED BY HIV-1 INFECTION
Bakker, Leendertz, J.; Meitaz, HJ; Van Strijp, JAG; Visser, NM; Eijssels, HJ; Verhaar, J.
Lab. of Microbiology, State University of Utrecht, Utrecht, The Netherlands.

Objective: To investigate the effect of HIV-1 infection on the function of monoclonal phagocytes. In this study, the interaction of uninfected or HIV-1 infected U937 cells with opsonized *M. avium* was compared.
Methods: *M. avium* was directly labeled with FITC, and opsonized with normal human pooled serum (HPS, HIV-negative), or with heat-inactivated HPS. U937 and U937/HIV-1 cells were incubated with opsonized *M. avium*, washed and cell fluorescence was measured using flow-cytometry and fluorescence microscopy.
Results: Flow-cytometry showed a 10-fold (10,7x±5) increase in fluorescence of uninfected U937 with HPS-opsonized *M. avium* as compared to non-opsonized *M. avium*. Heat-inactivation of HPS reversed this effect. Fluorescence using HPS-opsonized *M. avium* was significantly higher with U937/HIV-1 (1,8x±4; p<0.02) than with uninfected U937, while non-opsonized or heated-opsonized *M. avium* showed no difference. Microscopy showed that *M. avium* was attached to the cells. Since the increase was complement dependent, complement receptor (CR1 and CR3) expression on U937 was measured. Both were significantly higher on U937/HIV-1 (1,8x±1 and 1,4x±1 resp.). Inducers of cell-differentiation (PMA, retinoic acid) up-regulated immunoenhancement of cell-adherence of *M. avium* to uninfected U937.
Conclusions: Immunoenhancement of mycobacterium *avium* to U937 is enhanced by HIV-1 infection. This enhancement may be due to upregulation of complement-receptors on U937 induced by HIV-1 infection.

C.577

C.574 "ACTIVE LIPIDS" (AL) IN VITRO: LOSS OF DETECTABLE T- AND B-CELL SURFACE ANTIGEN

Bommer, Johannes R., Matsuecha A., Heinrich B., Pöhl H., Geoböl P.; Universität München, Med Poliklinik, FRG

OBJECTIVE: AL have been shown in vivo to increase the percentage of lymphocytes detectable neither by T- nor B-cell markers "unstained cells" (UNST) (Steedholm 1981). We have investigated if this effect can also be observed in vitro.

METHOD: Blood from patients with AIDS (n=4) and healthy controls (n=3) was incubated without (1) and with (2) a mixture of lipids similar to AL 721 (triglycerides, phosphatidylcholine, phosphatidylethanolamine) for one hour at 37°C. PBMC were stained with anti-CD3, CD4, CD8, CD19 and MLA DR after and prior to incubation with AL and analyzed with two-color flow cytometry.

RESULTS: 2 versus 1 resulted in a significant increase of UNST (mean ±1,7x±0,19) and reduction of all other cells (mean ±0,67-fold ±0,17). In contrast, 2 did not differ significantly from 1 (UNST 0,97fold ±0,13, other subsets 1,03fold ±0,19) when AL incubation was performed after antibody incubation, difference after/prior p<0,01. The effect occurred in all 7 subjects without regard to diagnosis.

CONCLUSION: Our results show that in vitro incubation of lymphocytes with "active lipids" unspecifically lowers detectability of cell surface markers by monoclonals. Physiologic lymphocyte function or virus binding might be altered by AL.

C.578

A HUMAN anti-LIKE PROTEIN: POSSIBLE RELEVANCE IN HIV INFECTION

Stzanski-Fabio, De Santis, C.; Beretta, A.; Gullberg, M. and Ericard, A.B. Dipartimento di Biologia e Diagnostica per la Scienze Mediche, Università di Milano, Italia, Unità for Applied Cell and Molecular Biology, University of Umeå, Sweden.

Objective: To characterize a human env-like protein.
Results: A 45 kDa human lymphocyte activation-associated protein sharing an epitope with env gp120 has been described and named HELP (human env-like protein). Two monoclonal antibodies reactive with HELP have been produced: one of them (M8) is reactive with both the cellular protein and env gp120, the other (L31) binds only the human molecule, but its binding can be inhibited by M8, probably because of steric hindrance. The two Mabs have different effects on lymphocyte functions: M8 inhibits proliferation by antigen presentation whereas L31 inhibits IL-2 production by cross-linked CD3 stimulated lymphocytes. Since HELP acts in negative signalling and an autoimmune response against it induces HIV infection could be deleterious for the patient, we are now searching for M8- or L31-like specificities in sera from infected individuals to evaluate a possible prognostic significance.
Conclusion: HELP is involved in more than one physiological immune function. Autoimmune responses against it are likely to be deleterious to the AIDS patient.

CHARACTERIZATION OF TANNINS CONTAINING ANTI-HIV ACTIVITY.
 Kikukawa, Robert L.* Cheng, Y. C.* Lee, K.-H.* and Boster, A.L.*
 *Hirsch Research Laboratories, Inc., Rockville, MD 20850, USA.
 *University of North Carolina, Chapel Hill, NC 27599, USA.

Objective: To characterize anti-HIV activity of purified tannins.
Methods: Tannins were purified from commercial tannic acid by chromatography through Sephadex LH-20 and preparative high performance liquid chromatography with reverse phase column. HIV-1 reverse transcriptase was purified by immunoaffinity chromatography. Enzyme activity was measured using poly (A)-oligo (d) U as the template. HIV-1 replication was assayed after infection of H9 lymphocytes. A p24 antigen capture test was used to detect viruses released into culture supernatants after a three day incubation following HIV-1 infection. Drug cytotoxicity was evaluated by cell count after a three day incubation with uninfected H9 cells.
Results: Four new tetrahydroxyquinone acids were isolated which inhibit purified reverse transcriptase by 85-90% at 100 µg/ml and 60-70% at 30 µM. They inhibit HIV-1 replication in H9 lymphocytes by at least 50% at 1.5 µM without cytotoxicity to uninfected H9 cells. Drugs were cytotoxic approximately 50% growth inhibition) at 25-50 µM. Inhibition of HIV-1 replication in H9 cells by tetrahydroxyquinone acid was assayed in the presence of either AZT or ddC. Inhibition by the combination of drugs was additive at all concentrations of AZT and ddC tested.
Conclusion: A new class of plant products which inhibit purified reverse transcriptase and HIV-1 replication *in vitro* has been isolated and characterized.

C.586

TREATMENT OF AIDS ASSOCIATED CRYPTOSPORIDIOSIS WITH HYPER-
 IMMUNE COLONUM FROM COWS VACCINATED WITH CRYPTOSPORIDIUM
 J. Nodji, F. Ma, C.D. Tackes, D. DiJohn, S. Lippert, S. Sahar,
 C. Shieh, St. Vincent's Hosp. & Med. Ctr. of New York, Div. of Maryland, Dept.
 of Medicine, Royal College of Surgeons, New York, N.Y.

Objective: To assess the efficacy of hyperimmune bovine colostrum against
 Cryptosporidiosis in asymptomatic AIDS patients.
Methods: Bovine colostrum was obtained from cows hyperimmunized with Cryptosporidium antigen. 5 AIDS patients with diarrhea and Cryptosporidiosis were
 given the colostrum by continuous infusion via feeding tube in a double blind,
 placebo controlled pilot study. Stool was analyzed for vel. frequency &
 consistency. Quant. cryptosporidial oocysts counts were determined by Cold
 Kinyoun stained smears. Antibody titer of colostrum was assayed by IFA.
Results: Antibody Titer Conc. of Oocyte/ml Stool
 Patient of Colostrum 1st day Last day

A	125:600	1.4 x 10 ⁷	2.2 x 10 ⁶	Improved (2 wks.)
B	13200	8.4 x 10 ⁴	2.0 x 10 ³	Resolved (6 mos.)
E	1200	1.6 x 10 ⁶	1.8 x 10 ⁶	No Change
C	Placebo	2.0 x 10 ⁷	6.0 x 10 ⁶	No Change
F	Placebo	4.2 x 10 ⁶	4.0 x 10 ⁶	No Change

Conclusion: Placebo showed no effect on the diarrhea. Two of three patients
 receiving hyperimmune colostrum showed clinical improvement/resolution
 accompanied by a reduction of oocysts in the stool. The patient receiving the
 hyperimmune colostrum failed to respond. A combination of low antibody titer
 and high oocyst concentration may be responsible. Therefore, higher antibody
 titers may be required for treatment of high oocyst concentration.

C.587

THE EFFECT OF CIGARETTE(S) ON LYMPHOCYTE POPULATIONS IN NORMAL
 AND HIV-1 INFECTED BLOOD.

Wessels, Kenneth* Meyers, D.* Vora, J.* Baker, J.R.*
 ** Henry H Jackson Foundation, Rockville, MD. ***National Naval Medical
 Center, Bethesda, MD. ****Walter Reed Army Medical Center, Washington, DC *

Objective: Measure the effect of varying CD concentrations on lymphocytes in
 whole blood from an uninfected and a Walter Reed Stage 2 HIV patient.
Methods: Separated whole blood samples were exposed in triplicate to 0, 10, 20,
 40, 80 and 160 µg/ml with an oxygen control. Coded, blinded blood samples
 were gently agitated for 18 min. and incubated for 1 hr. at 37 C. Monoclonal
 cells were separated using Ficoll-type density gradients and stained for
 FACS analysis using labeled monoclonal antibodies.
Results: CD had no effect on lymphocyte populations of the uninfected donor
 as numbers of total T cells, CD4, CD8, and T cell subpopulations did not
 change. In contrast, there were marked changes in the lymphocyte popula-
 tions of the HIV positive donor with increasing CD11.

(6.1)	T cells	CD4	CD8	T4/T8	CD positive [†]	CD8 positive [†]	CD4/CD8 [†]
(%)	CD3	CD4	CD8	T	T	T	T
0	8.5	82	34	43	81	13.3	1.8
20	8.6	79	34	41	85	14.9	8.8
40	8.4	82	48	38	1.18	18.3	15.5
80	6.3	83	42	34	1.28	7.8	8.2

Conclusion: Osmotic CD concentrations previously shown to inactivate HIV,
 may alter lymphocyte surface markers in HIV infected patients. Further
 studies are indicated to assess this effect.

C.588

DEC AND PER CAPITA AIDS CASES
 IN THE UNITED STATES

Werner, David* Kirschbaum, D.* Courby, M. AIDS Coalition
 to Unleash Power, New York, New York, USA.

Objective: Administration of the antiretroviral/immunomodulator
 Zidovudine (ZDV) to HIV-1 infected patients has been reported to
 interfere with human immunodeficiency virus (HIV) replication. This
 suggests that ZDV is concentrated in brain tissue. The present
 study examines, on a country-by-country basis, the relationship
 between Zidovudine control programs involving administration of
 ZDV and per capita reported AIDS cases.

Methods: Numbers of known AIDS cases (WHO 2/88) in each of 161
 countries were reported in articles were combined with population
 data to obtain per capita figures for known AIDS cases. The
 countries were listed into 3 subgroups according to their
 status: Group A, no evidence of Zidovudine (ZDV) control;
 Group B, ZDV control program in place; Group C, ZDV control
 program in place but no data on ZDV control program. The
 null hypothesis was that the null hypothesis was that the use of
 ZDV is associated with fewer per capita AIDS cases.

Results: The null hypothesis was rejected (a) when group 2
 (p=0.01) and (b) when group 3 (p=0.005) were compared against
 group 1 (p=0.005).

Conclusion: These preliminary observations suggest that the
 effect of ZDV on HIV infection warrants additional study.

C.589

C.590

WOMEN UNDERREPRESENTED IN AIDS CLINICAL TRIALS

Kelly, John* Kirschbaum, D.* Courby, M. AIDS Coalition
 to Unleash Power, New York, New York, USA.

Objective: To monitor the access of women to experimental AIDS
 treatments in the United States. **Method:** We collected data on women
 enrolled in U.S. Government AIDS clinical trials to identify barriers to
 health care. **Results:** Current Food and Drug Administration (FDA)
 policy restricts access of all patients to experimental treatments for
 AIDS on the theory that many women will prevent patients from
 entering trials. Yet historically, many women have been prohibited from
 participating in clinical trials. Even AIDS, the most HIV drug
 approved in the U.S., has not been adequately tested in women to show
 beneficial as well as adverse reactions as required by the FDA. Although
 in November 1988 women represented 9% of CDC-defined AIDS cases, women at
 all stages of disease comprised only 5.8% of total trial enrollment. In
 February 1987, 142 women were enrolled in AIDS trials; by August 1988
 200 women were enrolled. Over 60% of women in AIDS trials are enrolled
 in AIDS trial 018 which is testing AZV versus AZV in asymptomatic for
 HIV-infected subjects. As of December 1988, 52% of women with AIDS in
 the U.S. were infected through IV drug use. Nationally, 70% of women
 with AIDS are black and Hispanic. Most of these women are poor and have
 access only to public hospitals. **Conclusions:** Government and medical
 establishment policies restrict the access of women to experimental
 treatments. These results imply inadequate drug approval policies, poor
 health care on the local level, and many unvoiced biomedical issues.

IN VITRO EVALUATION OF EFFECTS OF LP1985 ON HIV INFECTED CELLS, ALONE OR IN ASSOCIATION WITH ANTIVIRALS.

D. G. Klapper, G. M. Clayton, J. D. Miller, G. M. L. Liang, G. C. and Damon, D. L. J.
 (1) Centre de Recherches de Santé des Amér. Commun. à l'Énergie Atomique, Pasteur-Ann. Sures, France. (2) Institut Pasteur, Paris, France.

Objectives: To determine the cellular target of an immune modulator drug, LP1985, in HIV infected PBL and cell lines, and to evaluate potential interactions with antivirals.
Methods: Interactions of LP1985 with thymocyte membrane have been studied by Spin Label Method and competitive assays between monoclonal anti-CD4 antibodies and LP1985 (immunofluorescence). Dose response curves of LP1985 action on HIV Reverse Transcriptase activity have been established (only 10-100 nM). In vitro toxicity of the drug on normal human PBL has been determined. Effects of LP1985 on cell growth and HIV replication has been reported using RT assay on cell culture supernatants. Potential interactions between LP1985 and AZT have been investigated by measurement of toxicity in suspensions of cell cultures which were doublet treated with both drugs at different concentrations.
Results: Biological effects of LP1985, such major interactions with the external part of cell membrane has been demonstrated, and acute cytolysis like the antiviral effect observed in low HIV infected PBL cultures, and the competition with anti-CD4 antibodies seem to amount 100 per cent of healthy donors. No direct and reverse transcriptase effects could be demonstrated for LP1985. Immune modulating concentrations of LP1985 do not exhibit either cellular toxicity or reproductive antiviral effects, as demonstrated in IL2 stimulated HIV infected PBL cultures. However, some inhibition of HIV replication was noted in a cell line of monocyte origin. LP1985 does not interact with antiviral effect of didanosine or zalcitabine. Furthermore, a normal cell growth in cell cultures treated with a 100 per cent antiviral dose of AZT.
Conclusion: LP1985 is an immune modulator drug which cellular target is the cell membrane. A despite the lack of direct antiviral effect, this drug might be used in association with didanosine/zalcitabine, as a complement of the antiviral cellular toxicity.

C.593

BIOCHEMICAL PHARMACOLOGY OF AZT IN HUMAN T-LYMPHOBLASTOID CELLS (CEM).

J. M. Estévez, W. M. Mackinnon, Edward Compton & John S. Holmberg, Children's Hospital of Los Angeles, Los Angeles, CA, U.S.A.

The purpose of this study was to investigate the biochemical pharmacology of AZT and to examine the effect of AZT on nucleoside triphosphate pool in virus-free human T-lymphoid line (CEM) cultured *in vitro*. Although the inhibitory concentration 50% (IC₅₀) of AZT in this cell line averaged 3.90 ± 2.5 μM (n = 3 determinations ± S.D.), the readily obtained plasma concentration of AZT in patients (1 μM) was used in these studies. CEM cells were incubated with 1 μM of [³H]AZT for 24 hr. In 100% and at various times relative to depletion of 10% cells were removed and extracted with perchloric acid for nucleoside and metabolites of AZT. The extract were assayed by HPLC. 54% of cultures for nucleoside, adenosine, deoxy, and triphosphates nucleoside of [³H]AZT. The cellular concentration of AZT ranged from 0.98 to 1.8 μM (mean 1.28 ± 0.3 μM) throughout the 24 hr experiment. The [³H]AZTMP cellular concentrations averaged 1.3 μM at 2 hr and declined gradually to 0.12 μM by 18 hr. The [³H]AZTDP was on average 17.5 ± 11.4 fold lower than the AZTMP, strongly indicating that a rate-limiting step in the activation of AZTMP to AZTDP exists at the AZTMP kinase level. The intracellular [³H]AZTDP pool of 4 hr after initiation of drug treatment at 14.5 nM in CEM cells declined exponentially with a t_{1/2} of 5.3 hr and a t_{1/2} of 18.1 hr. NTP cellular concentrations declined rapidly in the cells after exposure to AZT and by 9 hr reached a nadir of 21.8% CTP, 8.1% UTP, 13.3% ATP and 14.6% GTP, in comparison to control values. Consequently, phosphorylation of AZT to AZTMP and AZTMP to AZTDP declined 2.9- and 2.4-fold, respectively. The depletion of NTP pools may be responsible for the host toxicity that has been observed in patients. The amount of AZT metabolite incorporated into purified DNA peaked at 0.66 pmol/mg of DNA 1 hr after AZT treatment and declined with a t_{1/2} of 12 hr. We conclude that 1 μM AZT is sufficient for activation to the triphosphate which is associated with depletion of NTP pools and is incorporated into DNA.

C.595

DIFFERENTIAL ANTIVIRAL ACTIVITY OF DEKSTAN SULFATE, PENTOSAN POLYSULFATE AND HEPARIN AGAINST HIV-1 (HTLV-III₂) AND HIV-2 (HTLV-III₁)

M. Baba, D. Schmidt, J. Balzarini, J. Dewayer, and B. H. Huisman, K. Institute for Medical Research, E. v. Leuven, B-3000 Leuven, Belgium.

Objectives: Since sulfated polysaccharides interfere with the interaction of the highly variable envelope glycoproteins of HIV with the cellular receptor, we wondered whether these compounds may have differential effects on different HIV-1 and HIV-2 strains.
Methods: Anti-HIV activity was determined 3 days post-infection by a tetra-sulfate stability assay. All HIV strains were used at the same multiplicity of infection and all experiments were done in 96 wells.
Results: 20 ± 3 effective doses (ED₅₀) except for AZT (nM).

	Anti-Human-pulvita	Pentosan-Polysulfate	Heparin
HIV-1(III ₂)	0.0018	0.1	0.1
HIV-2(III ₁)	0.0013	0.05	0.1
HIV-1(III ₁)	0.0018	0.1	0.1

Conclusion: Whereas AZT was equally effective against both HIV-1 and HIV-2, dectan sulfate and pentosan polysulfate were significantly more inhibitory to HIV-2 than HIV-1. Heparin, however, was more inhibitory to HIV-1 than HIV-2. These findings point to a specific interaction of sulfated polysaccharides with the HIV envelope glycoproteins. As pentosan polysulfate is acid and dectan sulfate could be detected in the renal range by using HIV-2(III₂) as the challenge virus, the HIV-2(III₁) system could be used as a bioassay for the detection of these compounds in biological systems.

INHIBITION OF HIV-1 AND HIV-2 REPLICATION IN FRESH AND CHRONICALLY INFECTED CELLS WITH ANTIVIRAL AGENTS

S. D. Baxby, K. L. F. Farrant, D. G. M. Thornton, A. H. J. Fullen, J. J. Sheahan, S. J. G. and Sarin, P. S.
 (1) University of Toray Cell Biology, National Cancer Institute, Bethesda, Maryland. (2) New Jersey State Department of Health, Trenton, New Jersey, U.S.A.

We have examined and compared the inhibition of HIV-1 and HIV-2 replication in fresh and chronically infected cell cultures by a number of drugs directed towards various stages in the virus life cycle. We have evaluated the effect of these drugs, including AZT, ddC, foscarnet, amphotericin methyl ester (AME) on HIV-1 and HIV-2 replication in freshly infected and chronically infected Molt-3 and H9 cells. It appears that some drugs can inhibit both HIV-1 and HIV-2 replication at similar drug concentrations, whereas others require a higher drug concentration to inhibit HIV-2. Similar differences were observed between the potency of these drugs on freshly infected cells as compared to chronically infected cells. These findings indicate that it may be extremely important to select antiviral agents which are equally active on both freshly infected and chronically infected cells for the treatment of AIDS.

GLQ223: AN INHIBITOR OF HIV REPLICATION IN ACUTELY AND CHRONICALLY INFECTED T CELLS AND MACROPHAGES

McGosh, M.P., Hwang, E.M.P., Caldwell, S.H., O'Brien, P., Luk, K.C.M., Linton, R.P., et al.
 *San Francisco General Hospital, San Francisco, California, U.S.A. *Onsite Incorporated, Redwood City, California, U.S.A.

OBJECTIVE: To evaluate GLQ223 for ability to inhibit HIV replication in acutely and chronically infected cells and cells of both thymocyte and monocyte/macrophage lineage.
METHODS: GLQ223 is a highly purified dimer derived protein used in crude form, in traditional buffer medium for a variety of clinical indications. GLQ223 was tested for ability to inhibit HIV replication in assays systems employing target cells of both thymocyte and monocyte/macrophage lineage, in acute and chronic infection models. Viral replication in treated cultures labeled with laboratory indicator of HIV was assayed by effects of GLQ223 on cultured cells from HIV-infected donors. Viral replication was monitored by flow cytographic immunofluorescence analysis, antigen capture immunosay of culture supernatant, and northern blot analysis.

RESULTS: GLQ223 showed concentration dependent inhibition of HIV replication in acute infectivity assays with a 50% T cell line as target. Complete inhibition of viral replication was obtained at concentrations of GLQ223 which were one tenth to parallel cultures of uninfected cells. Northern blot analysis showed a selective proportional decrease in the amount of viral RNA compared to levels of a representative cellular RNA species in treated cultures. Treatment of chronically HIV-infected monocyte/macrophage cultures also showed selective inhibition of HIV antigen expression. A single 3 hour exposure of whole blood from HIV-infected donors to GLQ223 was sufficient to prevent the expansion of HIV antigen which occurred upon subsequent culture when the cells were not treated.

CONCLUSION: GLQ223 is a compound with encouragingly to virus anti-HIV activity in both acute and chronic infection, in both T cells and monocyte/macrophages. The mechanism of action is under investigation.

- C.603** **NM-1 IN THE TREATMENT OF AIDS.**
REPORT ON 172 TREATED PATIENTS.
Shafiq-Abadi¹, Larkhan²,***, Nase, M.***, Wayne, J.***,
¹Cairo University, Cairo, Egypt;
²***, ***, *** University of Kinshasa, Kinshasa, Zaïre.

The result of treatment of 172 AIDS patients with NM-1, an antiviral drug, is presented. Twenty AIDS patients were treated with the standard treatment for opportunistic infections and were considered as controls. Patients were monitored for clinical and laboratory changes before, during and after treatment. NM-1 was given in a dose of 0.07 mg/kg body weight, one injection every other day for 10 injections, and every third day for another 10 injections. Of the 172 patients treated with NM-1, 24 died; 6 of cryptococcal meningitis, 8 of electrolyte imbalance from diarrhea, and 10 of Kaposi's sarcoma. Improvement achieved in 148 patients. Follow-up varied from 4 to 14 months. NM-1 showed no side effects except fever after each of the first 3 injections. The patients showed clinical improvement and immunologic restoration to normal. The 20 control patients died within the follow-up period.

C.605

- C.607** **INHIBITION OF HIV REPLICATION BY NYLAN-POLYHYDROGENSULFATE: HOE/BAY 946, A NEW ANTIVIRAL COMPOUND IN CLINICAL TRIAL.**

Lothar Blasser¹, H. Saharoun², J. Wenker³, E. Schinner⁴, H.-D. Schlumberger⁵, H. Rübmann-Wiegmann⁶,
¹Chemothérapeutisches Forschungsinstitut Georg-Spoyler-Haus, Frankfurt, FRG,
²Hoechst AG, Frankfurt, FRG, ***Bayer AG, Wuppertal, FRG.

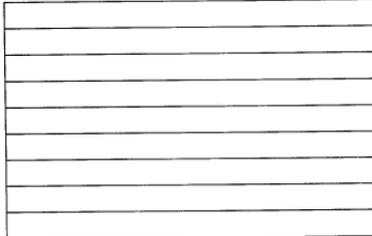

Objective: HOE/BAY 946, a styrenopy-hydrogenosulfate disodium salt, inhibited HIV-1 and HIV-2 replication and virus-induced cell fusion in lymphocyte cultures at concentrations above 25 µg/ml (4.2 µmol/l) totally. The drug was found to be an inhibitor of the HIV-enzyme reverse transcriptase. Experiments were performed to find out which step of the virus life cycle was inhibited by the drug in the living cell.

Methods: HIV-infection of lymphocytes was detected by determination of syncytia formation, reverse transcriptase activity and antigen release.

Results: 1) An inhibiting effect of the compound for free viruses could not be demonstrated. 2) Lymphocytes incubated with HIV in the presence of 100 µg/ml HOE/BAY 946 followed by the removal of both the drug and unbound virus were found to be infected. Thus, inhibition of virus adhesion to the cells may not be sufficient to avoid further infection. 3) Several experiments showed that the permanent presence of the drug was necessary for its full antiviral activity. 4) Treatment of a permanently HIV-infected monocyte cell resulted in a drastic reduction of virus shedding and points to an additional mode of action. It is discussed that HOE/BAY 946 has an influence on virus assembly or virus release.

Conclusions: Based on the anti-HIV activity of the compound, a clinical pilot study with HOE/BAY 946 was started recently in Germany with AIDS-patients and asymptomatic virus carriers.

C.604

- C.606** **INHIBITION OF EXPRESSION OF NATURAL UAC SUPPRESSOR GLUTAMINE tRNA IN HIV- AND MOLONEY VIRUS-INFECTED HUMAN PB3 CELLS IN VITRO BY AVANAC.**

Müller, Werner E. C., Kuchino, Y., Schröder, W. C.,
¹Institut für Physiologische Chemie, Universität, Duesbergweg, 6500 Mainz, West Germany, ** Biophysics Division, National Cancer Center Research Institute, Chou-ku, Tokyo 106, Japan.

Objective: To study the mode of action of the anti-HIV compound Avanol. **Methods:** Human T cells (HT), infected with HIV-1 and NIH-3T3 cells, infected with Moloney Murine Leukemia Virus (Mo-MuLV) have been used for the studies. **Results:** Avanol is a squariterpenoid hydroquinone, which causes a strong antiviral effect on HIV and Mo-MuLV in vitro. It was found that in HIV- or Mo-MuLV-infected cells a high level of the UAC suppressor glutamine tRNA-UAG is present. In Mo-MuLV-infected cells this tRNA is required for the synthesis of the RNA, coding for the viral proteins; the function of this tRNA in HIV-infected cells is not yet known. Avanol causes at virostatic concentrations a reduction of the virus-induced UAC suppressor tRNA to normal levels. The functional consequence of this event is an inhibition of the processing of the viral polyprotein, very likely due to an inhibition of the readthrough of the Mo-MuLV process gene; in the HIV system the molecular explanation is not yet possible. **Conclusion:** This study demonstrates that an inhibition of HIV production can be achieved also by a selective inhibition of the expression of a cellular gene. C.608

- Hypericin mediates Anti-HIV Effects in Vitro:**
D. M. Stasick¹, P. O. Lavee², W. V. Williams³, D. Lavee⁴, M.I. Greene¹, D. Muroto², Department of Pathology¹, Department of Medicine², University of Pennsylvania, Philadelphia PA, 19104-6082., Department of Pathology and Kaplan Cancer Center³, New York University Medical Center, 550 1st Avenue, New York, NY 10016, The Weizmann Institute of Science, Rehovot 76100, Israel.

Objective: To examine the ability of two aromatic polycyclic dyes hypericin and pseudohypericin to control HIV infection in vitro. **Methods:** Evaluation of syncytia formation, reverse transcriptase activity, viral RNA production, biochemical as well as electron microscopic studies of HIV-1 and HIV-2 have been studied. **Conclusions:** The low in vitro and in vivo toxicity of these compounds, the ability to interfere with infectious virus particle production, the fact that humans have been treated with these compounds with no serious side effects as well as the widespread availability of these agents, suggest further examination of hypericin for future AIDS patient therapeutic regimens may be warranted. **Discussion:** Both HIV-1 and HIV-2 were sensitive to the effects of hypericin. Hypericin possesses at least two different active components and syncytia and blocking of viral infectivity. Morphological examination demonstrates a significant difference in the number of virus particles exhibiting the mature HIV-1 virus phenotype after hypericin treatment. Hypericins does not have direct effects on several commercially available viral reverse transcriptase and viral integrase activities. Studies in our laboratory have demonstrated synergistic anti-viral effects between this class of compounds and other inhibitors of HIV infectivity. Further examination of the mechanism of anti-viral effects of these compounds is in progress.

C.609 EVALUATION OF erythro-9-(2-hydroxy-3-oxo)adenine (EHNA) TREATMENT ON HIV-1 REPLICATION

Yoshitani Sei¹, I. Tsuboi², M.M. Tokuyama³, and Prince K. Arora⁴
¹Laboratory of Neurovirology, NIDDK, National Institutes of Health, Bethesda, MD, U.S.A.
²Department of Immunology, Kurume University School of Medicine, Japan.

Objective: To evaluate the efficacy of EHNA treatment on viral replication in HIV-1 infected cell lines *in vitro*.

Methods: HIV-1 infected or uninfected H9 cell lines were treated with varying concentrations of erythro-9-(2-hydroxy-3-oxo)adenine (EHNA), an inhibitor of the common Adenosine deaminase (ADA) [enzymes/ADA and ADA1-CP]. Several different concentrations of deoxythymidine (dCT) were also added to the cell cultures. Cell viability was assessed by vital dye exclusion. Reverse transcriptase (RT) activity in the supernatants and in the cell lysates was determined by standard RT activity assays. Finally, RT activity in the supernatants was inhibited by assay 9PS in EHNA-treated HIV-1 infected H9 cells, when compared with the untreated but infected H9 cells. There was also a significant decrease in cell viability, but this was reversed following the addition of dCT to these cultures. This combined treatment had an effect on RT activity in the cell lysates, suggesting an inhibition of HIV-1 replication, and release from the infected cultures. This combined treatment was also effective in suppressing HIV-1 release of HIV-1 from infected U937 cells.

Conclusions: The treated treatment with EHNA+CT may be an means of suppressing viral replication in HIV-1 infected cells. Also, since EHNA inhibits adenosine deaminase, HIV-1 release from infected cells may be regulated by purine metabolic pathways.

CONTROLLED EVALUATION OF THE EFFICACY OF ZIDOVUDINE ON NEUROPSYCHOLOGICAL TEST PERFORMANCE IN GUC GROUP BY HIV INFECTED INDIVIDUALS
 Boudreau, A., Vermeiren, S., Charu, J., Hubert, M., Pature, B., Plamondon, J.
 Psychology Department and Neurology Dept., St. Mary's Hospital, London, ON, CAN.

Objective: To evaluate the effectiveness of Zidovudine in reversing cognitive impairment in GUC Group HIV infected patients and to judge the speed of drug effectiveness.

Methods: Monthly evaluation on a battery of neuropsychological tests was carried out on Zidovudine treated patients (ZID) and control groups: (1) HIV infected GUC patients treated for non-neurological aetiology (N=10) (2) GUC Group HIV patients treated with AZDT (N=10) (3) HIV seronegatives. Tests used included (COWAT), Trail-Making, Mark Flattery, Rey Auditory Verbal Learning and St. Mary's Departmental Hall Attention Task. Multivariate analysis of variance was used to look at change over testing sessions for each of the groups.

Results: On an overall impairment score calculated by summing standardized (z-scores) over the individual tests there was a significant (p<0.05) interaction between group and improvement on testing. This was mainly due to greater initial improvements in the Zidovudine treated group as compared to the other groups. They did not however continue to improve in all cases. Further follow-up is continuing.

Conclusions: Zidovudine does appear to improve overall neuropsychological test performance in those with AIDS. More improvement is seen it is likely to be greatest in the first few months of treatment.

C.612

ANTI-HIV-1 ACTIVITIES OF SULFATED MONOSACCHARIDES (SMS) AND POLYSACCHARIDES (SPS); THERAPEUTIC STRATEGIES (T1)

Bassey, Umar; Lischner, R.W.; Halligan, G.E.; Shino, N.
 Univ. of Medicine and Dentistry of New Jersey, Camden, NJ; Temple Univ. Sch. of Med. and St. Christopher's Hosp. for Children, Philadelphia, PA, USA.

Objective: To compare the T1 in vitro of anti-HIV SMS and SPS.

Methods: SPS including dextran sulfates (DS) of various mw, heparin, heparin sulfate, chondroitin sulfate (ChS) and heparan pentosan polysulfate, fucoidin, and carrageenan as well as SMS including D-glucosamine 2 sulfate, D-glucosamine 6 sulfate, D-glucosamine 2,6 disulfates and monofucosyl hexasulfate were examined for their direct inhibitory effects on HIV-1 reverse transcriptase, spycyctic formation (SF), and infection of pretreated target cells as well as on partial thromboplastin and prothrombin times.

Results: (1) All of the SPS inhibited HIV reverse transcriptase (25-99%) at 50 µg/ml of the SMS, only glucosamine 6 sulfate had significant anti-SF activity (50%). (2) Spycyctic formation was inhibited by as low as 6 µg of 5% carrageenan, fucoidin and pentosan polysulfate. D-glucosamine 6 sulfate completely inhibited SF at 50 µg/ml. Other SMS had no significant anti-HIV activity at this concentration. (3) All SPS had significant anticoagulant activity, whereas SMS had no anticoagulant activity up to 1 mg/ml concentration except heparin hexasulfate. **Conclusions:** SPS have broader and more consistent anti-HIV activity but POTENTIAL LOW T1 because of anticoagulant activity. SMS, particularly glucose 6 sulfate, have higher *in vitro* T1 and deserve clinical trial.

C.613

BLOCKING OF HIV-1 BINDING SITE BY LECTIN

Hasegawa, Osamu; Reine, R.; Whittle, P.; Lischner, R.
 Temple Univ., University of Medicine and Dentistry of New Jersey -SOM, Camden, NJ, USA; Temple Univ., Philadelphia, PA, USA.

Objective: Blockade of the interaction of HIV-1 gp120 molecule with CD4-ligands is one of the many strategies for blocking HIV-1 infection and possibly cytopathicity. The use of purified lectins, which are specific for one or two sugars, as a blocking agent may provide a rather simple way of HIV-neutralization.

Methods: (1) Sup-T7 cells (CD4+ cell line) were pre-incubated with various lectins, washed, and degree of inhibition of HIV-CD4-ligands (OCT4, OKT4, lectin) was evaluated by flow-cytometry and microscopy. (2) Anti-HIV activation of various lectins was examined by a spycyctic-inhibition assay using Sup-T7 and HIVIIII cells (2Zidov. Dis). (3) Western blot analysis were performed to determine the possible site of binding of the lectins.

Results: (1) Five lectins: VVA, DBA, RAA, WPA and SMA completely or partially blocked the binding sites of HIV-1. (2) VVA, DBA, RAA, WPA, PMA, PMA, ConA, PMA and WPA blocked spycyctic formation. (3) Western blot analysis revealed that two lectins, VVA and PMA have affinity for certain components of HIV-1.

Conclusion: (1) Lectins have specificity for a certain sugar or oligo-saccharide. Therefore, they can be used as a simple agent(s) for "anti-spycyc" which will block the "critical" HIV-CD4 site. (2) Theoretically, such sugars can be used to block HIV-1 from binding to CD4 and has therapeutic potential.

- C.627** BACULOVIRUS DIRECTED CELL-SURFACE EXPRESSION AND PURIFICATION OF CD4 IN INSECT CELLS
 Webb, J.C., Felt, P.S., Brumstad, D.R., Saeed, I., Summers, M.D., Nicolson, C.
 *Texas A&M University, College Station, Texas, USA; **Genzyme Corporation, Cottage Station, Texas, USA; ***College of Medicine, Houston, Texas, USA.

Infection by the human immunodeficiency virus (HIV), the causative agent of acquired immune deficiency syndrome (AIDS) is mediated by the binding of the viral envelope glycoprotein, gp120, to CD4, a glycoprotein expressed on the surface of HIV-susceptible cells, most notably T helper lymphocytes (Gautschi and Weiss, 1988). In a recent report, we described the stable insertion of CD4 derived from human lymphocytes into rat blood cells and its interaction with HIV-1 and HIV-1-infected HeLa cells (Nicolas et al., J. Cell Biochem. 33, 234, 1988). The potential use of a CD4-erythrocyte complex as a therapeutic agent for AIDS requires large amounts of CD4 which contains the bicyclic hexamer-spanning region. To do this, we have produced a baculovirus expression vector (Lusick and Summers, 1988) for the abundant production of full-length CD4 in insect cells. We show that the recombinant protein expressed on the surface of insect cells is chemically, immunologically and biologically similar to CD4 expressed in human cells.

C.629

- C.631** CELLULAR PHARMACOLOGY OF 3-AZIDO-2'-3'-DIDEOXY-URIDINE (AZDUI) IN HUMAN PRIMARY CELLS: EVIDENCE OF A NOVEL METABOLITE
 Zhou, Z., Srinivas, R.P.F., Edson, B.F.H., Chu, C.K., Williams, G.L., and Remington, J.P.

Univ. of Alabama at Birmingham, Birmingham, AL, Veterans Admin. Med. Ctr., and Emory Univ., Sch. of Med., Atlanta, GA; Univ. of GA, Athens, GA; and Tibco Biociences, Inc., Alameda, CA, USA*

Objective: To investigate the cellular pharmacology of AZDUI (CS-87) and 3-azido-2'-3'-dideoxythymidine (AZT) in human bone marrow (BM) and peripheral blood mononuclear (PBMC) cells. **Methods:** Human PHA-stimulated PBMC or BM cells (2×10^6 cells/ml) were exposed to 10 μ M (10) AZT or (10) AZDUI from 2 to 16 hrs. The 80% methanol-soluble fraction of the cell lysate was analyzed by HPLC using a Parted 10-SAX column. **Results:** Within 2 hrs AZT-MP accumulated for 80% (87 to 92%) of intracellular metabolites in increased within 48 hrs to 5.2 and 6.1 percent of cells in PBMC and BM cells, respectively. AZDUI-MP accumulated at a slower rate reaching 5 to 10 fold lower levels compared to AZT-MP and represented approximately 50 to 80% of intracellular radioactivity in both PBMC and BM cells at all times. AZDUI-DP represented similar concentrations compared to AZT-DP in both cell systems, while AZDUI-TP had 5-10 fold lower levels than AZT-TP in PBMC cells. In contrast to AZT, an unknown metabolite analogous of AZDUI labeled with AZDUI-MP and DP with a different retention time from AZT-MP and DP in both cell systems. This AZDUI metabolite increased over time and represented as much as 20% of intracellular radioactivity in BM cells following a 48 hr exposure. The metabolite was resistant to 5'-phosphatase, but was a substrate for 5'-phosphodiesterase, yielding AZDUI-MP with the same retention time as the analog, suggesting formation of a AZDUI-5'-diphosphate base. **Conclusions:** The metabolite of AZDUI to AZDUI-DP, hence its primary human cells, especially in BM cells, may contribute to the decreased toxicity of the anti-HIV drug when compared to AZT.

- C.628** ESSAIS CONTRÔLES EN DOUBLE INSU DU LF 1695 CHEZ DES PATIENTS VIH-1
 Livraghi, Jac-Michel, *; Cimet, D.**, Kienast, J.L., **; Touraine, F. **, Touraine, J.L., **
 *Division Hospital E. Herriot, Lyon, France; ** Laboratoire Fournier, Dijon, France; *** Hôpital Neurologique, Lyon, France.

Objectifs: Evaluer et comparer l'efficacité de 2 poologies d'un immunomodulateur, le LF 1695 (Lab. FOURNIER) parmi 38 patients au stade de LPJ ou d'ARC. **Méthodes:** Dans un essai contrôlé randomisé en double insu, 20 patients ont reçu 1 g/jule quotidien de 120 mg de LF 1695, 15 jours par mois pendant 3 mois, puis 1 g/jule de placebo en continu les 3 mois suivants; 18 patients ont reçu une g/jule de placebo 15 jours sur 30 pendant 3 mois puis une g/jule de 120 mg de LF 1695 en continu les 3 mois suivants. Une évaluation clinique et biologique (NF, CD3+, CD4+, CD8+) a été réalisée tous les 3 mois. A la fin de l'étude randomisée, les patients ont été traités par placebo ou LF 1695 en continu ou en discontinuation selon un arbre de décision (variation de +/- 20 % du nombre de CD4+ au cours de l'étude randomisée).

Résultats: La composition des profils de lymphocytes CD4+ au cours de la phase initiale ne montre pas de différence significative entre le groupe placebo et le groupe placebo, seule une tendance vers une augmentation à la fin de l'étude. En revanche, lors du protocole de suivi, le nombre de lymphocytes CD4+ et significativement augmenté parmi les patients traités en discontinuation (de 400 à 200 à 630 à la dernière visite) par rapport aux patients traités en continu (de 411 à 310 à 344 à la dernière visite), ou par rapport aux patients (de 426 à 310 et 376 à la dernière visite). **Conclusions:** Le LF 1695 à la dose de 120 mg par jour, 15 jours par mois, présente un intérêt thérapeutique. Il devra être confirmé dans un nouvel essai randomisé.

C.630

- C.630** IN VITRO ANTI-HIV ACTIVITY OF A NEW CLASS OF POLYMERS.
 Lemelle, Michel; Boyer, B.**, Roque, J.-P.**, Lamly, G.**, Montagnier, L.**, and Lericq, A.***
 *Univ.-Paul Sabatier, Research Center, F-31062 Vilry-Cedex, **Université des Sciences et des Techniques de LangueDoc, 34090 Montpellier-Cedex, France, ***Institut Pasteur, Viral Oncology, Paris, France.

Objective: We have synthesized a new class of polymers and tested their ability to act as HIV inhibitors. **Methods:** We have tested these compounds as HIV replication inhibitors in Molt-4 (T8 cells) and in human peripheral blood lymphocytes (PBMC). We have measured the reduction of cytopathic effect (CPE) induced by HIV-1 (LAI-89 strain) - WT assay, and reduction of reverse transcriptase (RT) activity in supernatants. **Results:** Two polymers PS and PC were active. The EC₅₀ were 1-3 μ g/ml and 2-5 μ g/ml respectively in CDM (1 and 14 days after infection respectively) and the EC₅₀ of PS was 0 μ g/ml in PBMC. The CDM were in all cases superior to 100 μ g/ml. Both products were active when added to the cells 2 h, post infection. In these conditions the EC₅₀ in CDM were 5 and 10 μ g/ml respectively for PS and PC. RT were 2-10 μ g/ml (PS) and when injected i.v. in mice (1 dose), the LD₅₀ were 0.10 mg/kg (PS) and 5 days was well tolerated. **Conclusions:** Our new compounds were active as in vitro HIV inhibitors at doses similar to those reported for clinically used compounds.

- C.632** IMMUNOTOXICOLOGICAL EFFECTS OF BETA-CAROTENE ON T-CELL ACTIVATION MARKERS AND NK CELLS IN HIV INFECTED PATIENTS.
 Stigum, Ronald B., Coombs, R.W., *; Aouf, N.M., *; Freiberg, M., *; Allen, V.**, Dob, C.**, Hirsch, M.J.**, et al.
 *University of Arizona, **Veterans Administration Medical Center, Tucson, Arizona, USA.

Objective: Study the effect of beta-carotene on lymphocytes from patients with AIDS, based on its immunological effects in normal subjects. **Methods:** Eleven HIV infected patients were given 30 mg/day of beta carotene for 4 months. Samples of heparinized peripheral blood were collected prior to, during, and after cessation of supplementation. Changes in the number and percentage of mononuclear cells with various markers were measured with monoclonal antibodies and flow cytometry.

Results: After 3 months of treatment the percentage of cells with markers of NK cells increased significantly (from $3.2 \pm 2.8\%$ to $19.4 \pm 13.6\%$) in HIV infected patients. The percentage of cells expressing CD-28, transferrin receptor, and HLA-Dr antigens was increased from 3.6 ± 4.8 to 16.8 ± 18.3 ; from 3.4 ± 3.1 to 23.2 ± 16.9 ; from 36.5 ± 9.3 to 61.1 ± 13.3 respectively by the treatment of beta-carotene for 3 months in HIV infected patients. No significant changes in T-lymphocytes, T-suppressor or total T-cells were observed during the treatment. Similar changes were seen in the number of these cells with each antigen. The maximum response was reached after 1 month, and had declined since by 4 months of treatment. These results are all qualitatively similar to those previously observed by us in normal subjects. No toxicity attributable to the drug was observed and the effects of cessation of supplementation were also assessed.

Conclusions: Beta-carotene produces an increase in the number of cells with NK markers and markers of activation (CD-28, transferrin receptor). Clinical studies are warranted to assess if these findings will be of clinical benefit in AIDS or AIDS-related diseases. Supported in part by grants from Wallace Centers and NIH AA-08073.

EFFECT OF p24 ANTIGEN IN AIDS CD4+ T-LYMPHOCYTES WITH NO ZIDOVUDINE AND PROGRESSION TO AIDS

THOMAS¹, GILLI², THOMAS³, NICHOLSON⁴, GARDNER⁵, HARTLOW⁶, ST. THOMAS⁷ HOSPITAL, PHOENIX, AZ; ²UNIVERSITY OF ARIZONA, TUCSON, AZ; ³UNIVERSITY OF ARIZONA, TUCSON, AZ; ⁴UNIVERSITY OF ARIZONA, TUCSON, AZ; ⁵UNIVERSITY OF ARIZONA, TUCSON, AZ; ⁶UNIVERSITY OF ARIZONA, TUCSON, AZ; ⁷UNIVERSITY OF ARIZONA, TUCSON, AZ.

Objective: To study the effect of 1200 and 800 mg zidovudine given in 4 or 12 15 day courses in patients with AIDS CD4+ T-lymphocytes. **Methods:** 36 asymptomatic patients (AIDS CD4+ T-lymphocytes) were randomized to receive either zidovudine or Placebo on a double-blind basis. The results of the first 18 are shown.

Table 1

	No. of patients	Weeks 1-6	Weeks 7-12
A Zidovudine	7	600 mg qds	600 mg bid
B Zidovudine	5	200 mg qds	200 mg qds
C Placebo	3	6 caps qds	2 caps qds
D Placebo	3	3 caps qds	2 caps qds

Mean age was 35 years, average IB at entry 14.5 g/dl (range 11.8-17.0) and median CD4 cell count 800 cells/mm³ (range 100-2000).

Results: The mean percentage reduction of p24 antigen level was 62% (range 37-78%) in group A, 28% (range 8-47%) in group B and 0% in the Placebo groups. Mean percentage reduction of p24 antigen in the combined treatment group was statistically significant ($P=0.01$, Mann-Whitney U test), with no difference between groups A and B. Treatment was well tolerated since few side effects were reported. All patients were followed up for a minimum of 9 months after cessation of therapy. 7 (5 treated, 2 placebo) had continued with zidovudine 250 mg or 500 mg bid and remain well. 7 (5 treated, 2 placebo) have progressed to AIDS or NEC. The remaining 4 patients remain well. Conclusions: Short-term zidovudine given 600 mg and 400 mg bid reduces p24 antigen levels but may not influence progression of disease.

C.635

DEXTRAN SULFATE DECREASES CELL SURFACE GP120, BUT DOES NOT INTERFERE WITH GP120-CD4 INTERACTIONS

CATHAN, L., PHAN, M. and HOGAN, M.A.

Food and Drug Administration, Bethesda, MD, 20895, USA

Objective: Dextran sulfate has been reported to block virus binding to CD4+ cells. To determine if this effect is due to receptor blockade, we examined the effect of dextran sulfate on gp120 to CD4 binding and cell surface gp120 expression.

Methods: GP120 binding to CD4 was measured by incubating recombinant gp120(Genentech) with Meth-4 T-cells followed by monoclonal anti-envelope antibody and fluorescently-labelled goat antibody to mouse Ig. Binding was also measured in an ELISA format by incubating soluble CD4(PharMing) with gp120 coated plates, developing with anti-CD4 monoclonals. The effect of dextran sulfate on cell surface expression of gp120 on HIV-infected cells was quantitated by immunofluorescence and flow cytometry analysis.

Results: Anti-viral concentrations of dextran sulfate from 10µg/ml to 10 mg/ml were without significant effect on gp120-CD4 binding in both cell surface binding and ELISA assays. In contrast, HIV-1 chronically infected cells treated with dextran sulfate show marked decreases in gp120 surface staining, while CD3 remained constant.

Conclusion: Dextran sulfate does not directly block gp120-CD4 interactions. The rapid decrease in the amount of gp120 on the surface of infected cells suggests that the effects of dextran sulfate include the disruption of gp120 cell surface expression resulting in inhibition of synctia formation.

C.637

Effect of the polyene macrolide group of antibiotics on inhibition of human Immunodeficiency Virus (HIV) replication in cell culture

DENNIS, R., BENTLEY, S.R., SHARIF, I., DIANE RUBERTSCHER, I., LEVIN SWIATEK, DANEY K.L. SUN, P. RAN, S. SARIN

New Jersey State Department of Health, Trenton, New Jersey

Objective: The polyene macrolide family of antibiotics contain several potent antiviral compounds and act by binding to a sterol niche in the membrane of cells. They have recently been shown to be effective inhibitors of HIV RNA virus due to the presence of a high cholesterol:phospholipid ratio in this virus. These antibiotics are grouped according to the number of conjugated double bonds in their lipophilic hydrocarbon region. A number of these compounds including the trime, tetraene, pentane, hexane and heptane groups were examined for their cytotoxicity and activity against HIV. Of the compounds tested amphotericin B, its methylated derivative AMB, nystatin and the methylated derivative of amphotericin proved to be effective inhibitors of HIV-1 replication at non-cytotoxic dose levels. The other compounds tested were not active against HIV at non-cytotoxic dose levels. The results show the importance of structural modification as a means of reducing toxicity of current compounds in search for effective compounds for the treatment of AIDS. Current studies show that derivatives of amphotericin B are much less toxic compared to the parent compound without any loss of antiviral activity.

C.634

PULMONARY FUNCTION IN INDIVIDUALS WITH AIDS RECEIVING AZENKIDOLYD PIPROVEDINE (AZ) FOR PNEUMOCYSTIS CARINI

PERINAKA (CI) PHARMACEUTICALS, NEW YORK, N.Y.; KILMARTIN, S.A.; BLAS, A. *Community Research Institute, New York, U.S.A.

Objective: To monitor pulmonary function in 205 patients with AIDS enrolled in a 1-year trial of the doses of AZ for prophylaxis of PCP, which was fully enrolled by 8/2/88. 75.4% of study participants had experienced a prior episode of PCP.

Methods: Pulmonary function tests (PFTs) including measurements of TLC, FEV₁, and FVC, were performed at entry, at 4-6 months, and at 12 months after entry. Spirometry were obtained and physical examinations done at the same time.

Results: 125 patients were tested after 4-6 months (mean = 5.1 months). The mean values for FEV₁ and FVC did not differ at both times, nor were there significant differences in the distributions for both tests when the first repeat set of tests was compared to baseline. The 125 patients showed an increase in mean value on the second test: 73.2% (n=82) of the population showed an improvement in TLC when retested after a mean period of 4.6 months on AZ. The degree of improvement correlated inversely with the time elapsed since diagnosis of a prior episode of PCP. ($r = -0.214$, $p = .047$).

Conclusion: No deterioration in pulmonary function could be shown in this study. Whether AZ hastens improvement in patients who had a mean of 4.6 months at this study.

C.636

Effect of amphotericin B and its methyl ester (AMB) on human immunodeficiency virus infection and phagocytosis in macrophage cultures.

D.K. SUN, B. WOLF, P. RYAN, S.I. SHARIF, J. BROWN, J. ROSEN, C.P. FLESCIA, C.P. SCHIFFER and T.S. BERTIN, U.S.A.

Objective: The antifungal amphotericin B and its methyl ester AMB were tested in the continuous macrophage cell line DM37 for activity against HIV-1. At non-cytotoxic dose levels the expression of HIV-1 was inhibited as shown by the measurement of p24 antigen expression with immunofluorescence. At 10 µg/ml there was complete inhibition of virus activity.

To examine the effect of these drugs on the enhancement of macrophage activity, phagocytosis was measured using primary murine adherent cells. Either Sheep red blood cells, latex or coated with antibody, or listeria monocytogenes were added to the cultures which had been inoculated in the presence of each drug at concentrations of 0.1, 1, and 10 µg/ml. Furtuin was added as a positive control. With both systems a significant increase in phagocytic activity was observed in the presence of AMB and amphotericin B.

Conclusion: These studies suggest that both AMB and amphotericin B could be very useful in the treatment of AIDS due to their inhibition of HIV-1 replication in T cells and macrophages.

These compounds may provide an alternative to AIDS therapies due to their multifunctional cellular activities.

C.638

MECHANISTIC ASSAYS FOR NATURAL PRODUCT ANTI-HIV ACTIVITY

MULLIGAN, JAMES; WATSON, O.K.; KIE, R.W.; OLAHOSKI, R.A.; WARREN, J.; GUSTAFSON, K.F.; BADER, J. and BOYD, M.

*Developmental Therapeutics Program, DCR, Wyngate Research, Inc., NCI-FCRF, Frederick, MD, USA.

Objective: To develop rapid quantitative assays to study the mechanism of action of compounds with anti-HIV activity isolated from natural products.

Methods: Microculture procedures were utilized to define the various steps of HIV infection in T-lymphoblastoid cells. Quantitative readouts of these assays included several novel colorimetric, enzymatic, and fluorescent endpoints. Interactive laser cytometry was also used to study the effects of anti-HIV compounds at the single cell level.

Results: In addition to developing quantitative tetraacetyl and fluorescent assays for the overall cytopathic effects of HIV, microculture assays measuring the effects of compounds on virus/target cell interactions, reverse transcriptase and infectious viral release were also developed. Quantitative measurements of viral antigen expression at the single cell level was accomplished using immunocytofluorescent methods. Antiviral compounds with known mechanisms of action and comparative methodologies were used for assay validation.

Conclusions: Several rapid quantitative assays have been developed and/or modified which allow for the large-scale mechanistic screening and/or analysis of AIDS antiviral activity of natural products. These investigations attempt to determine where in the life cycle of HIV natural products exert their activity. Understanding the mechanism of action of antiviral compounds will aid in the selection and prioritization of novel anti-HIV agents for clinical trials.

A TRIAL OF AZIDOGLUCOSYL PENTAMIDINE (AP) FOR PROPHYLAXIS OF PNEUMOCYSTIS CARINI PNEUMONIA (PCP) IN AIDS.
Joseph Bilmeser, S.J.; Fieischer, T.; Community Research Initiative, New York, U.S.A.

Objective. To investigate the safety of 100 and 150mg of AP during biweekly to individuals with AIDS, as well as the efficacy of these dosages in the prevention of PCP.

Methods. Eligible participants who had CDC-defined AIDS, were randomized to receive either 100 or 150mg of AP biweekly using the Neupogen randomized 2 numberizer, in a 1-year trial fully enrolled by 6/28/88.

Results. 212 subjects were enrolled, for 191 of whom demographic data was available: 71.5% white, 5.3% black, 11.2% Hispanic, 2.4% women. 63.9% had a prior episode of PCP (mean of 7.6 months before entry). 83.4% were gay/bisexual men, 4.5% intravenous drug users, 1.8% blood transfusion recipients. As of 1/89, 46% had discontinued participation (26.4% voluntary withdrawal, 15.8% non-compliance, 11.3% infectious illness, 25.9% death). AP was well tolerated with no significant side effects, and results of pulmonary function tests (FVC, MLD, FEV1) showed no deleterious effect after a mean of 4.6 months. The number of cases of proven PCP was far less than anticipated for this population.

Conclusion. AP (100 & 150mg) biweekly demonstrated no systemic or localized pulmonary toxicity. The recurrence rate of PCP in those who had experienced a prior episode appeared to be considerably lower than that anticipated for 2nd episode cases.

C.640

A CRITIQUE OF THE U.S. GOVERNMENT AIDS CLINICAL TRIAL PROGRAM
Lynn Lutz; Kirschbaum, D. and Barf, R. AIDS Coalition to Unleash Power, New York, New York, U.S.A.

Objective. To evaluate accessibility of experimental treatments in the AIDS Clinical Trial Group (ACTG) Program to HIV-infected people.
Methods. In January 1989, this program had enrolled over 5,700 subjects in trials at 35 sites and 11 pediatric centers. Government documents related to these trials were reviewed periodically.

Results. There were 24 agents under study and 45 trials open. Twelve trials were closed and 2 completed. There were 12 ACT trials in which 4,625 subjects (80% of total program enrollment) were enrolled. AZT was being tested at many different stages of the disease. There were also 16 trials of AZT in combination with other drugs, with a total program enrollment of 78. Antivirals other than AZT were in 12 preliminary Phase I or pharmacokinetic trials and had enrolled 349 subjects (4% of total program enrollment). Enrollment by sex: Male 94.2%, female 5.8%. Enrollment by race: white 82.94, black 6.94 and Hispanic 8.94. Enrollment by IV drug use history: never used 84.3%, previously used 11.0% and currently using 0.3%.

Conclusion. The main drug tested in the program is AZT alone or in combination. Access to trials testing other antivirals besides AZT or in combination with AZT is very limited. Women, people of color, children, hemophiliacs and prisoners are not represented to the extent that they are HIV-infected. All recently diagnosed people with AIDS have few clinical trial options.

C.641

SPECIFIC INTERACTION OF ADENINETRICARBOXYLIC ACID WITH THE HIV/CD4 RECEPTOR

Dominique Sordet, N. Balm, E. Kowalek, J. Demptier and E. De Clercq
Rega Institute for Medical Research, K.U. Leuven, B-3000 Leuven, Belgium

Considering the essential role of the CD4 receptor in the replicative cycle of HIV, it would seem important to find appropriate marker molecules that specifically interact with the CD4 receptor and thereby block HIV attachment to the cell.

CD4⁺ cells (M1, U-937, peripheral blood lymphocytes and monocytes) were incubated in the presence or absence of the test compounds, stained with various monoclonal antibodies (mAbs), washed, fixed and examined by flow cytometry. To investigate virus-cell binding, HIV cells were exposed to radio-labeled HIV-1 virions in the presence or absence of the test compounds.

The triphosphathene derivative aurtitricarboxylic acid (ATA), but not surin, selectively prevented the binding of (D6TA)Leu3a mAb, and, to a lesser extent, (2E9) mAb to the CD4 receptor of all four cell types at a concentration of 10 µM. The effect was rapid (1 minute), dose-dependent and reversible. It could be neutralized by surin. ATA also prevented the attachment of radio-labeled HIV-1 virions to HIV-1 cells, presumably as the result of its specific binding to the CD4 receptor.

These unusual properties of a small molecule of non-immunological origin may have important implications for the study of CD4, HIV, AIDS pathogenesis, and, possibly, therapy and prophylaxis.

VARIABILITE DES SEQUENCES DU VIRUS DU SIDA
F. GARDYETZ, P. BONHOUD, S. HAZOUTI, A.J. VALLERON
INSERM U163, 2 INSERM U163, Institut Pasteur, Paris, France

Objectif. La variabilité génétique du virus du SIDA peut être utilisée comme un outil d'analyse des processus de migration et de sélection quantitative sélective. L'objectif de ce travail est, après avoir conclu statistiquement à la non-homogénéité du taux de substitution par site, de caractériser dans les séquences différents ensembles de régions de haut de substitution proche. Les données utilisées sont les séquences publiées de la protéine de l'enveloppe.

Méthodes. À partir de l'alignement multiple des séquences HIV-1, HIV-2 et SIV, on construit d'abord une séquence consensus avec les acides aminés les plus fréquents à chaque site; on calcule ensuite le taux de substitutions par rapport au consensus le long de la séquence, ceci constituant la fonction de variabilité. Un ensemble de tests statistiques est effectué sur cette fonction afin de vérifier l'existence de régions homogènes.

Résultats. L'analyse statistique a permis de classer l'ensemble des régions en trois groupes de variabilité et de composition nucléotidique (en position 1 des codons) différentes.

Régions

	type	variabilité	variabilité	consensus	nb sites
Longueur en Ac.Am.		33	326	446	818
Longueur (%)		4.0	41.9	54.7	100

Taux moyen (%) de substitutions par site

	type	variabilité	variabilité	consensus	nb sites
Taux en base A/G		65.2	23.7	40.0	27.1
base T/C		84.1	28.7	15.0	19.2
		18.5	18.5	18.5	18.5

Le découpage de la séquence en régions ne se révèle significatif que pour des tailles inférieures à 15 résidus.

Conclusion. L'analyse des séquences à l'aide d'une telle partition constitue une étape nécessaire qui peut être discutée en termes de relation structure-fonction.

- C.645 DIFFERENCES IN LONG TERMINAL REPEAT ACTIVITY OF TWO HUMAN IMMUNODEFICIENCY VIRUS-1 VARIANTS FROM THE VIRAL STRAIN**
 M. L. Li, G. and Volosky, D.J.
 Molecular Virology Lab, St. Luke's/Roosevelt Hosp, Ctr. and College of Physicians and Surgeons, Columbia University, New York, NY, U.S.A.
- Objective.** To compare transcriptional activity of long terminal repeats (LTR) of different HIV-1 variants.
- Methods.** LTR activity was analyzed by transient chloramphenicol acetyltransferase expression assay or by measuring production of p24 protein.
- Results.** Two HIV-1 variants, derived from a single parental isolate and termed HIV-1₁ and HIV-1₂, differ substantially in their ability to replicate in CD4-positive cells. We show that the LTR of the better-replicating HIV-1₁ virus has a 3-5 fold higher capacity than HIV-1₂ to direct gene expression in T cells. The higher activity of HIV-1₁ LTR is due to a combined effect of two mutations: 1) a point mutation in position -94 (relative to the CAP site), which is located between the two subunits of HIV-1 enhancer 1) a duplication of 24 base pair in positions -128 to -132, which has not been known to be involved in any regulatory mechanism. Presence of these mutations increases the basal level of the LTR-driven gene expression and does not influence the degree of induction caused by the viral tat gene product or by cell activation. Conclusions: HIV-1 LTR is one of the sites which may determine functional heterogeneity of HIV-1.

- C.647 EXPRESSION OF GAP PROTEINS OF HUMAN IMMUNODEFICIENCY VIRUS USING RECOMBINANT ADENO24 VECTORS**
 Katherine L. Molinar-Kramer, Robert Mastroeni, Suresh K. Dheer, Robert B. Franch, Chantal M. Franch, Alan B. Alan B. Davis, and Paul P. Nung, Biotechnology and Microbiology Division, Wyeth-Ayerst Research, P.O. Box 8299, Philadelphia, PA USA 19101-1245.
- To develop Ad24-HIV recombinant adenovirus type 2 vaccine candidates, the gag-pol gene of Human Immunodeficiency Virus was inserted into the Ad24 E3 region. In attempts to generate a new late transcription factor, an oligomer which contained 32 bp of the splice acceptor from the L5 transcription factor was inserted upstream of the gag-pol gene followed by a large E3 deletion and an intact EBV polyadenylation signal. The recombinant adenovirus, Ad24GAGPOL, synthesized gag p55 protein both early and late during infection. Although the protease gene was intact, no protease activity was detectable. The expression of the gag proteins was approximately 500 lower than expression of the hepatitis B virus envelope proteins using Ad24 E3-based vectors. Recent reports suggest that the expression of the gag-pol proteins is positively regulated by the presence of rev. The mechanism will be discussed.

- C.649 CONSTRUCTION OF HIV-1 INTER-ISOLATE RECOMBINANTS**
 York, D.A., Barisano, L.,* Bauer, D.,* Chang-Mayer, Cecilia**,
 Levy, J.M.,* Wain, D.*
- *Chiron Corporation, Emeryville, CA, USA, **University of California- San Francisco, San Francisco, CA, USA.

Objective. Construction of inter-isolate recombinant HIV-1 viruses using molecularly cloned DNA from viruses with distinct biological properties was undertaken to identify the genes determining these specific biological properties.

Methods. The HIV-1 isolates SF-2 and SF-3 differ biologically in their ability to form plaques in the MT-4 cell line (possibly related to their cytopathicity) and their host range. The SF-2 isolate replicates in peripheral blood lymphocytes and CEM-established T-cell lines such as HUT 78 and CEM, whereas the SF-3 isolate additionally replicates in human and baboon peripheral mononuclear cells as well as human fibroblasts such as HOS. By making constructs exchanging specific regions between the two molecularly cloned HIV-1 genomes, it should be possible to follow the biological characteristics. The construction series was transfected into cells and infectious virus was rescued from all combinations for comparison studies.

Results. Biologic assays performed on the recombinant viruses indicate that plasmids in MT-4 cells and cytopathicity segregate with the env-3'orf region of the genome. Host range specificity is being examined.

Conclusions. The env-3'orf region of the HIV genome appears to be directly responsible for the cytopathicity characteristic of the isolate.

- C.646 DELAYED & SLOW EXPRESSION OF HIV-1 RNA & tat PROTEIN DURING INFECTION WITH A NON-CYTOPATHIC HIV-1 VIRUS STRAIN**
 Sakali, Kelli Ma, X-Y Shiang, J. P. and Volosky, D.J.
 St. Luke's/Roosevelt Hospital Center, College of Physicians and Surgeons, Columbia University, New York City, NY, U.S.A.
- Objective:** To study the mechanism of infection with a non-cytopathic isolate of HIV-1.
- Methods.** The non-cytopathic and cytopathic HIV-1 isolates HIV-1₁ and HIV-1₂, respectively, were obtained from the virus-producer CD4/HIV-1/MT cell line by molecular cloning. Virus entry was measured as a function of the virus-cell fusion by the membrane fluorescence dequenching assay. Viral RNA was detected in crude cell lysates with HIV-1 RNA probe from the pol gene. tat and rev proteins, and LTR functions, were tested by CAT assay.
- Results:** HIV-1₁ and HIV-1₂ entered CD4-positive target cells with equal efficiency by virus-cell fusion. The expression of HIV-1₁ genome was delayed and characterized by slow kinetics, resulting in low levels of HIV-1 RNA, structural proteins, and tat protein during the first 7-10 days after virus entry. In contrast, cells infected with the same dose of the cytopathic HIV-1₂ virus began to express high levels of HIV-1 RNA structural proteins and tat protein with a kinetics similar to that of infection; the expression peaked on day 5, followed by complete cell lysis. Both HIV-1₁ and HIV-1₂ viruses replicated well in chronically-infected cells. Conclusions: Our results show that slow kinetics of HIV-1₁ expression during early stages after virus entry is an important determinant in a non-cytopathic infection.

- C.648 ISOELECTRIC FOCUSING OF RECOMBINANT HIV PROTEINS BY ISOELECTRIC FOCUSING.**
 Chant, Albert*, Winkler, E.,* Stafford, A.*, Saaz, J.*, Siaw, M.,* Van Winkle, M.*
 St. Louis, MO. *Beckman Instruments, Inc. 92421, and **SmithKline Beecham, King of Prussia, PA, U.S.A.
- A preparative isoelectric focusing (IEF) method using a commercial available apparatus was applied to the purification of recombinant HIV proteins expressed in E. coli. Proteins representing env, gag and pol domains were extracted from inclusion bodies and initially purified through various sequences of ion-exchange and molecular sieving chromatography. Proteins obtained from the primary purification were desalted and subjected to isoelectric focusing separation. Appropriately solubilized proteins in the presence of various non-ionic surfactants and polylysines were focused at their isoelectric points (pI). Proteins were harvested in fractions after reaching equilibrium. Each fraction was analysed electrophoretically for purity and further identified by western blot using specific monoclonal antibodies. The results of ELISA testing for HIV antibodies using the IEF proteins showed significantly increased activity and specificity. Our work shows that IEF methodology can yield significant quantities of effectively purified recombinant proteins in a simple, efficient and cost effective process.

- C.650 IN VITRO DETECTION OF HIV ANTIBODY IN SERUMEDITHYLSULFIDE BY USING RECOMBINANT ANTIGENIC PEPTIDES**
 Saperstein, P.,* Hwang, J.,* Lewis, M.,* Pittsitt, M.P.,* Berman, C.,* Hershkov, I.*
 * Institute of Biological Research - University of Texas - Dallas
 ** Institute of Biological Research - University of Texas - Dallas

Objective. To validate the data on serum antibodies in seropositive individuals, detecting HIV RNA by polymerase chain reaction (PCR) technique.

Methods. We collected 94 HIV sera and 10 peripheral blood sera from HIV seropositive HIV subjects. The HIV RNA was amplified in the sera and blood by PCR. HIV RNA was amplified by using specific PCR primers. The PCR products were directly used for the PCR. HIV RNA was amplified by using specific PCR primers. The PCR products were directly used for the PCR. HIV RNA was amplified by using specific PCR primers. The PCR products were directly used for the PCR.

Results. The PCR products were directly used for the PCR. HIV RNA was amplified by using specific PCR primers. The PCR products were directly used for the PCR. HIV RNA was amplified by using specific PCR primers. The PCR products were directly used for the PCR.

Conclusions. The absence of prolamellar aggregation in all serum specimens, in the presence of HIV-1 RNA in the blood, and of HIV-1 amplification in the sera, is in accord with the important of detecting through this study. Our results confirm the potential utility of the PCR technique in complementing existing virus isolation procedures as a routine means of determining the presence of HIV in blood cells.

EPI TOPE MAPPING OF THE HUMAN IMMUNODEFICIENCY VIRUS *gag* GENE PRODUCTS p24 AND p26 WITH MONOCLONAL ANTIBODIES:
 Brian J. Young, T. Crowl-Hickson, S. J. Swerdlow, S. J. Younger, R. P. and Lockwood, S. A. Biostatistics Research Institute, Rockville, MD, *Organon Teknika Corporation, Durham, NC, USA.

Objective: To map immunogenic domains of HIV-1 p24 and HIV-2 p26 using specific monoclonal antibodies and to define epitopes conserved between the two proteins.

Methods: Overlapping synthetic and recombinant peptides of p24 were prepared and tested for reactivity with each monoclonal antibody (Mab) using ELISA and Western blotting techniques.

Results: Sixteen murine monoclonal antibodies reactive against native viral p24 were also reactive with a full-length recombinant clone of p24 generated from a cDNA library of HIV-1. The Mab map within four discrete regions along the 230 amino acid length of p24:

Mab Group:	(within an open reading frame)
A	264-344
B	244-362
C	143-209
D	133-242

In addition, two of the Mab are cross-reactive with HIV-2 p26. Three of the Mab have proven useful in a sandwich ELISA for the detection of p24 and p26 in sera/plasma from infected patients and cell culture supernatants.

Conclusion: A large variety of epitope specificities are represented by the Mab and this has proven useful for the development of an in vitro assay.

C.665

ENZYME IMMUNOASSAY OF RECOMBINANT HIV PROTEINS.
 Lewis, Stephen, Bofinger, G., Kost, M., Ballard, M. and Lee, H. H. (Rockwell Instruments, Inc., Irvine, CA, U.S.A.)

Three enzyme immunoassays were developed to specifically quantitate & recombinant p17 protein in support of our development of A5U-HIV assay for antibody to HIV.

- Using a direct solid phase sandwich technique, antigen under study was presented in microtiter plate wells and reacted with specific mouse monoclonal antibody (mAb). After incubation in turn with rabbit anti-mouse alk. phos. conjugate and pNPP substrate, antigen was quantitated photometrically at 410 nm.

- In the second method, soluble antigen was studied using a competitive sandwich technique. This assay used precoated control antigens to react simultaneously with antigen specific Mab and the soluble antigen under study. Competition between soluble and bound antigen for Mab generated signal which was inversely correlated with concentration of soluble antigen.

- Finally, a more complex solid phase direct sandwich method was developed which featured the use of 1) avidin/biotin enhancement; 2) Mab to HIV proteins of both G1 and G2 subtypes and 3) rabbit alkaline phosphatase conjugated antibody to the mouse monoclonal subtypes. The competitive assay was needed to speed analysis by alleviating the need to precoat plates with the antigens under test. The multistep avidin/biotin technique was employed when competitive displacement curves were difficult to obtain.

C.667

STUDIES ON THE MECHANISM OF ENHANCEMENT OF HIV-ENVELOPE (ENV) EXPRESSION BY HIV-*tax* GENE USING ADENOVIORAL EXPRESSION VECTORS.
 Dhat, Sheer, Chanda, P., Natar, R., Chodolofsky, S., Nelson, B., Morin, J., Diner, S., Molar-Kramer, K., Luback, M., Mizutani, S., Davis, A., Hunt, P. Biotechnology and Microbiology Division, Hyatt-Ayerst Research, P.O. Box 8299, Philadelphia, PA U.S.A.

The enhanced expression (30-70 fold) of HIV-env gene in human cell line, by co-infection of adeno virus recombinants (A67-*gus* and A67-*gus*) to a good vector system to explore the direct mechanism mediated by HIV-*tax* gene, since other HIV-proviral gene(s) are present in these vectors. By comparing the study levels of mRNA isolated from A67-*gus* and also after co-infection with A67-*gus*, revealed that: 1) the *gus*-specific mRNA(s) present in the cytoplasmic fraction after the co-infection with A67-*gus*, were qualitatively and quantitatively different from that in A67-*gus* recombinant; 2) however, in the nuclear fraction of the above experiment, the *gus*-mRNA(s) showed only a qualitative difference. Addition of actinomycin D, 20 hr post-infection with A67-env for 1-6 hr prior to mRNA extraction, resulted in a significant reduction in the cytoplasmic *gus*-mRNA(s). In a similar experiment, but in presence of *tax*, there was no decrease in the cytoplasmic *gus*-mRNA(s). Using these recombinant adeno virus recombinants is understanding the direct interaction of *tax* on *gus*-mRNA processing will be discussed.

C.664

HIV INFECTION OF THE GASTROINTESTINAL TRACT: COMPARISON OF THE SENSITIVITY OF HYBRIDIZATION AND IMMUNOASSAY

Enler, Donald P., Ecks, P., Cossin, W., Clayton P., Flux CH **, S. L. Blau's Roosevelt Hospital Center, New York; *Lance Hill Hospital, New York; **Laboratory of Immunogenetics, NIH, Bethesda, MD, U.S.A.

Objective: To use hybridization and immunology for detecting evidence of HIV in rectal smears; to compare the results with histopathologic features in the tissue.

Methods: Rectal biopsies from 25 HIV seropositive subjects (19 AIDS, 6 ARC) were examined by RNA in situ hybridization, polymerase chain reaction (PCR), a quantitative p24 ELISA, and p24 immunohistologic stains. Coded sections were examined for specific histologic features.

Results: Positive results were obtained by in situ hybridization in 34%, by PCR in 70%, by quantitative p24 ELISA in 70%, and by p24 immunoperoxidase stains in 80%. Only one AIDS patient was negative by all methods used. In situ RNA hybridization was demonstrated only in lamina propria lymphocytes and macrophages by immunoperoxidase. p24 antigen could be detected in lamina propria lymphocytes and macrophages in 64% of cases. Antigen also could be detected in epithelial cells in 40% and immunohistopathologic features in 26%. There were no correlations between the presence of HIV nucleic acids or tissue p24 content and specific histopathologic features.

Conclusions: Evidence of HIV in rectal smears is common. Of the methods used, in situ hybridization with viral RNA was the most sensitive technique for detecting viruses. PCR was the most sensitive method for detecting viral genes. Methods to detect p24 antigen in mucosal homogenates or in tissue sections also use sensitive means of revealing evidence of HIV infection in the tissues.

PROTEOLYTIC CLEAVAGE OF THE 66-KD FORM OF THE HIV-1 REVERSE TRANSCRIPTASE.
 Enayati, M., Strydom, P., Hizi, A., Pichantans, S., Bahr, L., Craik, C., Shawalter, S.D., **** and Hughes, S.H., *

BRI-Basic Research Program, **Program Resources, Inc., MCI-Fredrick Cancer Research Facility, Frederick, Maryland, USA, **Sackler School of Medicine, Tel Aviv University, Ramat Aviv, Israel, ***University of California, San Francisco, San Francisco, California, USA.

Objective: We wished to test the ability of viral and non-viral proteases to convert purified 66-kD reverse transcriptase (RT) to the 51-kD form. The 66-kD form of HIV-1 RT and the viral protease were separately purified to homogeneity from two recombinant strains of *E. coli*. Proteolytic cleavage sites on HIV-1 RT were mapped using a battery of monoclonal antibodies that recognize known positions in HIV-1 RT.

Results: Using a viral protease produced in *E. coli* we have been able to react a condition that contains only HIV-1 RT and the protease. However, this poses the question of whether the specificity of cleavage resides in the protease or in the structure of the properly folded 66-kD form of RT. We have found that certain other proteases produce cleavage products closely related to the 51-kD protein produced by the viral protease.

Conclusions: Of the tested proteases, the viral protease most closely reproduces the cleavage event seen in viruses; however, unrelated proteases make similar cleavages suggesting that the structure of the 66-kD form of the RT plays a significant role in defining the site of protease cleavage.

C.668

HIGH LEVEL EXPRESSION OF THE ENVELOPE GLYCOPROTEINS OF THE HUMAN IMMUNODEFICIENCY VIRUS (HIV) USING RECOMBINANT ADENOVIORUS VECTORS.
 Prasad, K., Chanda, P., Natar, R., Wark, Lydia Greenberg, Bruce B. Hanson, Sheer Dhat, Saravada S., Diner, John E. Morin, Catherine L. Molnar-Kramer, Michael D. Luback, Satosh Mizutani, Alan R. Davis, and Paul P. Hunt. Biotechnology and Microbiology Division, Hyatt-Ayerst Research, P.O. Box 8299, Philadelphia, PA, U.S.A.

Recombinant adeno viruses containing either the envelope (env) or the rev (rev/rt) genes of the human immunodeficiency virus type 1 (HIV) were constructed by inserting the genes into a cassette which contained adeno virus major late promoter, tripartite leader containing intervening sequence and the poly(A). The cassette was then inserted between the *gus* and *ITR* region on adeno virus genome. A649 cells infected with the env recombinant virus produced the envelope glycoproteins gp160, gp120, and gp125. HIV envelope gene expression made by the env-adeno virus recombinant can be greatly enhanced (30-70 fold) in A649 cells that were simultaneously infected with the rev-adeno virus recombinant as measured by ELISA, western blotting, and immunoperoxidase staining of infected cells. A double recombinant adeno virus which contains both rev and env genes was also constructed by inserting the rev gene in the deleted E2 region and the env gene in the terminal cassette. This double recombinant virus was able to infect A649 cells in 100% of cells similar to that expressed by cells that were doubly infected with both the env and rev recombinant viruses.

SELECTION OF PRIMERS OF HUMAN MONOCLONAL FOR THE EXPRESSION OF HUMAN IMMUNODEFICIENCY VIRUS SEQUENCES USING THE POLYMERASE CHAIN REACTION.

Robertson, R. and G. G. Stevenson. *Journal of Virology*, 61: 1966-1970, 1987.
 *Molecular Virology Laboratory, Laboratory Center for Disease Control, National Center for Zoonosis and Vector-borne Diseases, Institut Armand-Frappier, Ville de Québec, Québec, Canada; *Molecular Research Institute, National Research Council of Canada, Montreal, Québec, Canada.

Most of the oligonucleotide primers which have been proposed for the detection of human immunodeficiency virus (HIV) sequences using the polymerase chain reaction (PCR) contain sites known to cause an increase in specificity and sensitivity of the PCR. However, the use of such primers is dependent on the prevalence of the mismatched strains the use of different proportions of false negative results. Our objective was to optimize the design of primers according to their degree of homology to all available HIV sequences. In particular, we have been interested in the design of primers suitable for the amplification of Hind III fragments. Algorithms and computer programs were developed to determine the optimal alignment for the detection of the longest regions of homology within groups of sequences. The results of these algorithms are presented. The longest regions of maximum homology among all complete sequences available for HIV are presented.

Based on this information we identified and synthesized a pair of Hind III restriction primers which allow the PCR reconstruction of specific HIV sequences. The primers were used for the detection of HIV sequences in clinical specimens.

USE OF A CASSETTE EXPRESSION VECTOR FOR THE EXPRESSION OF HUMAN IMMUNODEFICIENCY VIRUS SEQUENCES IN CHO CELLS

O'Shaughnessy, M.Y. and Campbell-Pineda, D.
 *Bureau of Laboratories and Research Services, Federal Center for AIDS Health Protection Branch, Ottawa, Ontario, Canada; *Centre de Recherches en Virologie, Institut Armand-Frappier, Ville de Québec, Québec, Canada; *Molecular Virology Laboratory, Laboratory Center for Disease Control, National Center for Zoonosis and Vector-borne Diseases, Institut Armand-Frappier, Ville de Québec, Québec, Canada.

Human immunodeficiency virus (HIV) has already been expressed in vitro using different expression systems. We have chosen the pSVcat cassette vector expression system which contains a powerful cytomegalovirus (CMV) promoter to express the entire *gag* in mammalian cells. Our design required the excision of a 2.9 kb *Bst* I fragment of HIV-1 RNA from plasmid pSHIV1. This fragment contains the entire open reading frame in the *gag* region of the genome. The *Bst* I enzyme cuts the genome 1.6 kb before the *gag* stop codon in the *gag* open reading frame. This 2.9 *Bst* I fragment was ligated with a 1.5 kb promoter containing the CMV promoter. The fragments were added. The new *Bst* I fragment was cloned into the EcoRI site in the open reading frame of the insert was in frame with the first ATG after the coding site of the CMV promoter. Cells expressing the HIV-1 *gag* are being tested as target cells for immunoprecipitation assays. Dr. M. Harper (N.I.H., Bethesda, MD) is making available the pSHIVcat construct. He is interested in our work to produce the HIV-1 expression vector system and Dr. H. Melnick's (Institute of Protein Research, Academy of Sciences of the U.S.S.R., Moscow Section) for his kind gift of restriction enzyme *Bst* I.

C.677

SYNTHESIS AND PROCESSING OF HIV RNA IN THE PRESENCE OF ANTIVIRAL AGENTS

Chiu, J.A. and Crumpacker, C.S.
 Beth Israel Hospital/Harvard Medical School, Boston, MA, USA.
Objective. Several antiviral agents inhibit the replication of HIV in vitro. Ribavirin (RBV) has been shown to interfere with post-transcriptional processing in vesicles. We assessed effects of RBV in combination with other antiviral agents on the size and amount of RNA synthesized in infected cells. *Methods.* Cytoplastic (HIV) RNA isolated from HIV infected cells treated with RBV was analyzed by northern blot using a ³²P labelled RNA probe. Virus replication was assayed in cultured lymphocytes using the p24 antigen assay. *Results.* Previous data has shown that RBV treatment of HIV infected T cells suppresses viral protein synthesis and DNA replication (Crumpacker et al. Abstr. Int. Conf. AIDS 1985). Envelope proteins are expressed by 70% in the presence of 20 µg/ml RBV. An HIV *gag* gene probe was used to measure the size and abundance of HIV cytoplasmic RNA isolated from infected cells synthesized in the presence of increasing concentrations of RBV. A marked decrease in the amount of 3.5 kb *gag* RNA occurred with increasing concentrations of RBV. In addition, there was a dramatic increase in the 385 genomic RNA species in RBV treated cells as compared to non-treated cells. When ddA was used in conjunction with RBV, a similar decrease in *gag* specific RNA occurred with only 20% the RBV concentration as when used alone. *Conclusion.* RBV and other drugs may result in altered amount and size of HIV RNA. Direct measurement of viral RNA is useful to study effects of antiviral agents. The combined effects of RBV and other anti-viral agents on transcription and translation of *gag* and *gag* RNA species in vitro, are being studied to better understand the mechanism of action of these agents.

A MOUSE MONOCLONAL ANTIBODY AGAINST THE REV-PROTEIN OF HIV-1

Voll, R., Amann, Christian, Krapp, F., Fleckenstein, B., and Haidich, H.
 Institut für Klinische Immunologie und Rheumatologie der Universität Erlangen-Nürnberg, D-8520 Erlangen, FRG

The rev-protein of immunodeficiency viruses has an important function in structural gene expression. A 9-kilodalton fusion-protein containing the amino-terminal part of the fusionprotein was synthesized in *E. coli*. It was used to raise a rev-specific immune response in mice. A monoclonal anti-rev fusion with the SP2/O cell line stable hybridoma clones were established. Clones were isolated that secreted monoclonal antibodies specifically recognizing the rev part of the fusionprotein. They were identified by ELISA and Western blot. Data demonstrating recognition of the subviral protein and intracellular localization will be presented.

C.680

CHARACTERIZATION OF AN HIV-1 POINT MUTANT BLOCKED IN ENVELOPE GLYCOPROTEIN CLEAVAGE

Pel, B., Galla, R.C., Bell, M.S. Jr.,
 *National Cancer Institute, Bethesda, Maryland, USA
 *Biometric Research Laboratory, Inc., Bethesda, Maryland, USA

The envelope proteins of retroviruses are derived from a polyprotein precursor protein by cleavage adjacent to a cluster of basic amino acids. Site specific autolysis was used to construct a mutant of the human immunodeficiency virus type 1 (HIV-1) in which the arginine residue at the carboxy terminus of the gp120 was changed to a threonine residue. This single substitution was sufficient to abolish all detectable cleavage of the gp120 envelope precursor polyprotein. Immunofluorescence assays showed that gp120 was transported to the surface of transfected CD4+ Hela cells. No envelope proteins of known size could be detected in the media of cells transfected with the mutant virus, suggesting that functional virion release was impaired. Binding of the mutant gp120 to the CD4 receptor molecule was unimpaired. In spite of this and the presence of gp120 on the cell surface, neither growth of virus-transfected CD4+ Hela cells nor cocultivation of transfected cos-1 cells with H9 cells resulted in significant syncytium formation. The data indicate that the carboxy terminal arginine residue of HIV-1 gp120 is necessary for envelope protein cleavage, and suggest that a lack of cleavage inhibits the virus life cycle at the steps of both virus release and membrane fusion.

- C. 661** COMPARISON OF REVERSE TRANSCRIPTASE OF HIV-1, HIV-2 AND SIV
 Lori, Franco*, Achilli, G.**, Cattaneo, E.**, Serin, P. S.,**
 and Barilanti, J.***
 *IGR/CMR, Pavia, Italy, **IRCCS Poli. S. Matteo, Pavia, Italy, ***National
 Cancer Institute, Bethesda, Maryland, USA.

Objective. To compare the structural and biochemical properties of reverse transcriptase of HIV-1, HIV-2 and SIV.

Methods. An activity gel method was used allowing identification of the active components of reverse transcriptase on polyacrylamide gel, after electrophoresis under denaturing conditions.

Results. We have confirmed the presence of three active polypeptides of 166, 68 and 31 kDa in HIV-1 reverse transcriptase (P. Lori et al, AIDS Res. and Hum. Retrov. 4: 393, 1988). A similar three active band pattern was also observed for RT from HIV-2 (with sizes of 176, 75 and 62 kDa) and SIV (with sizes of 175, 70 and 59 kDa). The migration and the band intensity of the high and the low reverse transcriptase forms of HIV-2 and SIV appear to be closer than those of HIV-1.

Conclusion. In all three AIDS related retroviruses a high M_r putative precursor and two lower active peptides of reverse transcriptase are present. The structural properties of reverse transcriptase from HIV-2 and SIV are similar and tend to differ from those of HIV-1.

- C. 663** HIGH LEVEL EXPRESSION OF HIV PROTEASE IN *E. COLI*
 Olsen, R.K.; Rockenbach, S.K.; Tomaselli, A. and Iwashita, Shin-ichi.*
 The Upjohn Company, Kalamazoo, Michigan 49007, USA

We have obtained high level expression of the HIV protease in *E. coli* using the *gag* promoter and a runaway vector. Upon induction of the runaway function to increase plasmid copy number, the protease production results in the accumulation of inclusion bodies. In a pBR322-derived vector, the expression level is greatly decreased. Fusion of the protease to its pro-peptide, to β -galactosidase, or to bovine growth hormone gene only low level accumulation of the product as the fusion form or the auto-processed form. Low level expression was also obtained by fusion of the protease to a *E. coli* signal peptide to expression the protease by secretion.

To monitor expression and to test if the HIV protease made in *E. coli* is active *in vivo*, two truncations of the HIV *gag* protein containing parts of the *p6* region were used as substrates. These *gag* truncations have been expressed to high levels using the *gag* promoter in a pBR322-derived vector. The sequence coding for protease was placed immediately downstream of the *gag* sequence in an open fusion arrangement. Activity of the protease can be directly measured by its ability to cleave the *gag* protein into the product *p6* which is detected by Western analysis.

Inclusion bodies containing HIV protease were dissolved in urea or guanidine-HCl. Upon dilution of the chaotropic agent, the protease is active on synthetic peptide substrates. For comparison, the *E. coli*-derived *gag* truncations are being tested as substrates.

C. 665

- C. 662** BIOPHYSICAL CHARACTERIZATION OF REVERSE TRANSCRIPTASE (RT) FROM HIV
 Schalken, Gerard; Hillebrandt, R.; Kopke, M.L. and Dickerson, R.E.
 Molecular Biology Institute, UCLA, Los Angeles, CA 90024, U.S.A.

Objective. In order to find conditions for the growth of single crystals suitable for x-ray structure analysis, various experimental techniques were applied to characterize the properties of RT in solution, especially with regard to dimerization equilibria.

Method and Results. Protein preparations from *E. coli* cultures carrying a plasmid with the full p66 sequence were analyzed, comparing pure p66 samples with p66-p51 mixtures. Analytical ultracentrifugation shows 2 species at 3.95 and 5.95 in a p66 solution. Chemical crosslinking with Dimethylsuberinate indicates strong dimer-formation in p66-p66 mixtures, and weaker dimer-formation with more higher aggregates in pure p66 samples. FPLC runs on a size-exclusion column give one peak for p66-p66 samples and 2 clearly separated peaks for pure p66. Both peaks show high activity in a specific assay for reverse transcription activity, and yield a single band under denaturing conditions on PAGE with SDS. Fraction of each of these peaks give the corresponding single peak when relectrodesed with respect to concentration.

Conclusion. In solutions of pure p66 RT homodimers coexist with monomeric species in a slow equilibrium. Under similar conditions, mixtures of p61 and p66 form heterodimers with significantly stronger affinity.

- C. 664** A GENE FAMILY WITH HIV-LIKE POTENTIAL REVERSE TRANSCRIPTASE
 Forsythe, Donald; Blum, S.; Sideris, D.P. and Forsythe, M.E.
 Department of Biochemistry, Queen's University, Kingston, Ontario, Canada K7L 3N6

Objectives. To understand the molecular basis by which HIV establishes, maintains and escapes from, latency. To identify genes in T-lymphocytes which regulate, are regulated by, or are coregulated with HIV.

Methods. "Latent" peripheral blood lymphocytes in the G0 phase of the cell cycle were activated by culturing with lectin and cycloheximide for 2h. cDNA libraries enriched for 60S11 switch (60S) genes were screened by differential cDNA hybridization (Forsythe, 1988; *Biochem. Biophys. Res. Comm.* 123: 619-625).

Results. Among the 60S11 switch ones, 60319, is the first identified human homolog of the mouse "activation gene" family (MIP, J. Virol. 61: 1804-1811; *Immuno.* 11: 481-483) and is identical to ID78 (Obara et al. 1986; *J. Biol. Chem.* 261: 885-894). We have identified 3 genes in Lambda Charon 35 libraries which hybridize with 60319 cDNA. Three of these have been restricted mapped and two sequenced. One has the identical sequence to the cDNA. Of particular interest are two sequences in the 3' non-coding region which are conserved in MIP: (1) TTTTGGATTATTTT which differs only by a purine transition from a 3'UTR pal sequence and (ii) GGACTCTTC which differs only by 2 pyrimidine transitions from the NF8-binding HIV 5' enhancer.

Conclusion. We speculate that genes conserved with latency in HIV and in G0 lymphocytes are coregulated by similar interacting factors. (Supported by the American Foundation for AIDS Research)

C. 666

NEEDLE/SYRINGE EXCHANGE SCHEME BASED ON COMMUNITY PHARMACIES, TRONDHEIM, NORWAY
 Hvalstad, Hans-Joel; Jarvold, E. (Hennel); Hvalstad, T.; Trondheim Health Board, Norway

Objective. To evaluate exchange schemes based on community pharmacies and local AIDS clinic during 10 months trial period. Injection equipment could otherwise be purchased by ordinary sales from all pharmacies. The exchange scheme involves exchanging or sold carries a label illustrating the importance of sterile equipment. Together with an introduction to the scheme. No. of syringes sold or exchanged were recorded. Questionnaires were presented to IVDA and pharmacy employees. Results: Total no. of syringes/needles showed no increase during the trial period, while the return rate increased to 19%. Pharmacies reported no conflicts. IVDA reported a positive attitude to the scheme, but showed no significant change in risk behaviour. No significant change in the incidence of HIV and HIV were reported. No syringes were returned to the AIDS clinic. Conclusion: An exchange scheme based on community pharmacies were favoured by IVDA to specialised clinics run by HDN. Only marginal effect on the prevention of HIV and HBV transmission can be expected where syringes are already easily available.

LYMPHOKINES IN DIFFERENT STAGES OF HIV INFECTION
 Kasaoli, Teresa; Pignera, T.; Quer, J.; Garcia, X.; Caragall, I. and Ocaña, J., I.S. Vall de Hebron, Barcelona, Spain.

HIV causes a progressive loss of CD4 cells and their functions, subsequently IL-2 synthesis is decreased in the disease. Although monocytes are also infected there is no cytotoxicity of these cells, and they were interested to know the synthesis of IL-1 in different stages of this infection and the relation with other lymphokines.

We have measured the synthesis of IL-1, IL-2 and β 2M in 36 HIV-1 drug-naïve in different stages of HIV infection and 10 controls. Lymphokines were produced by PHA cultures stimulated with 10% of 24 h, (IL-1) or PHA/40 h (IL-2 and β 2M) and measured on the supernatants with ELISA and RIA methods respectively. Lymphocyte subsets Ig levels and lymphocyte blastogenic responses to PHA and PWM were also studied in these patients.

IL-1 synthesis is very high until advanced stages of immunodeficiency, and is also high in unstimulated cultures in the first stages of the infection. There is some correlation between these levels and clinical symptoms.

IL-2 and β 2M synthesis decreases more rapidly with the progression of the disease and, together with other immunological parameters, has prognostic value.

Therapeutic protocols to modulate lymphokine synthesis must be taken into consideration to improve clinical conditions of these patients.

C.707

SUPPRESSOR EFFECT OF CELL SUPERNATANTS FROM HIV-0 POSITIVE PATIENTS ON NORMAL LYMPHOCYTE REACTIONS.
 Alvarez, María Elena; Merini, L.; Goico, M.A.; Falcaro, Y.; Diaz, S.A. and Sm., J.

Sección Inmunología Oncológica, Instituto de Investigaciones Neoplasias, Academia Nacional de Medicina, Buenos Aires, Argentina.

Objective: The aim of the study was to determine if ConA can induce an increase of the NK cell activity of HIV-infected subjects (IS) similar to that of normal subjects (NS). Also, we investigated if the factors that normally regulate the NK function, released by cells from IS differ from those released by NS cells.

Methods: We studied 13 IS and 19 NS. Mononuclear cells were incubated with and without ConA (50µg/ml) at 37°C for 18-20h. The cell supernatants (SN) were stored; the cells were stained and the NK activity measured by the 51Cr release assay using K562 cells as target.

Results: The NK function and response to ConA of IS cells were similar to NS cells. In 8 out of 15 cells the normal NK activity, in 5 without ConA suppressed ($p < 0.05$) 3/5 + 24 and 5 with ConA 34/5 + 11. On the contrary, 5 without ConA of normal cells did not modify normal NK activity while 5 with ConA increased the NK function (24/5 + 8).

Conclusion: The results indicate that NK effector cell function of IS does not differ from NS. However, the mononuclear cells from IS spontaneously release NK suppressor factors and although ConA can increase the NK effector function, it can not modify the release of suppressor factors. The altered release of soluble factors in prior to the decrease of the NK activity observed in IS may contribute to the development of opportunistic tumors.

C.709

CHARACTERIZATION OF HUMAN B CELL (H2) AND PROMONOCYTE (H37) AFTER HIV-1 EXPOSURE
 Tomalin, J.G. Deane*, and Priscilla E. Arnes *

*Laboratory of Neurosciences, NIDDK, National Institutes of Health, Bethesda, MD, U.S.A.
 *Department of Neoplastic Diseases, Mount Sinai School of Medicine, New York, NY, U.S.A.

Objective: Comparison of HIV-1 infection kinetics among human B (H2), promonocyte (H37), T-8 hybrid (CD4/74), and T890 cell lines.

Methods: SupT1 (HIV1 susceptible CD4+T7) cells were used to analyze syncytia induction capacity of vesicular cell lines. Reverse transcriptase (RT) activity in the supernatant (sRT) and in the cell lysates (iRT) was determined by standard RT activity assays.

Results: CD4/74 and H9 cells indicated strong syncytia inducing capacity against SupT1 and high extracellular RT (eRT) and H37 exhibited syncytia inducing capacity at 3 days. Intracellular RT (iRT) became detectable at 10-15 days but eRT appeared much later. The syncytia inducing capacity and intracellular RT rate were also observed in chronically infected H9CD4+T890 (H2) and subclone of H37/H9. Further, coculture of H9 with H2/H9 (which exhibit no detectable iRT) showed measurable increase in eRT with significant increase of T-8 double marker hybrid (H9-H2-H9).

Conclusions: Our results suggest that B cells and/or monocytes may acquire fusing capacity against CD4+T7 cells in early stages of the infection, and that these cells to cell interactions may lead to reduction in the number of CD4+T7 cells. Further, since T-8 and T-8 monocyte hybrids may serve as temporal sites for viral replication. These in vitro studies may provide clues to the possible immunopathological roles of HIV-1 infected cells and monocytes and may help in understanding the mechanisms of viral burden on an infected host.

C.706

HIV-2 CHRONIC INFECTION OF PROMONOCYTES (H2)
 Tronchetti, Patricia; Brian J.P.; Baccari C.; Seligson J.M.
 Virology Laboratory, Centre Hospitalier universitaire, Genève, France

Objective: To establish chronic infection in cells of the monocytic progenitor system, with HIV-2 we covered (1) to HIV-1 infection; to study the phenotypic variations throughout the infection.

Methods: We clones of the promonocytic cell line U937, with 30 to 35% of CD4+ cells, respectively, were each infected with HIV-2 HD strain and with HD1 (HD) strain (multiplicity of infection: 10 CD4+ per 10⁶ cells). Cell cultures were studied for > 30 days in terms of cytopathic effect, and presence of p24 and RT activity in the supernatant. The expression of p24 in cells was assessed by immunofluorescence and, when necessary, viral genome detection was carried out with the polymerase chain reaction. Fluorescence was used to measure the expression of CD4. Results data are summarized in the following table.

U 937 & CD4	HIV-2				HD-1			
	01	07	021	042	01	07	021	042
Clon 1	30	0.0	>2.5	>2.5	0.0	0.0	>2.5	>2.5
Clon 2	30	0.0	0.0	>2.5	>2.5	1.2	>2.5	0.0

Although a same amount of virus was used to infect cells, a latent period before the production of p24 by HD1 was only observed with HIV-2. Chronic infection was obtained with HIV-2 without the CD4 percentage, as opposed to HIV-1.

Conclusions: This study showed that, in monocyte cells, there was a difference in the pattern of multiplication between HIV-2 and HIV-1, which seemed to be independent of the amount of CD4 in the case of HIV-2.

C.708

AIDS - PARANETIC INFELIA AND PATHOPHYSIOLOGICAL MECHANISM
 Anbar, Michael* and Sheppard, H.* *Viral and
 Bacterioid Diseases Laboratory, Department of Health Services,
 *California Public Health Foundation, Berkeley, CA, USA.

We propose a model whereby HIV component(s) cause immune dysfunction by mimicry of the physiologic ligands of CD4+ molecules of the Major Histocompatibility Complex (MHC), binding to CD4 molecules and causing lymphocyte activation of a generalized and uncontrolled nature (paranety). The symptoms of mediator disease, autoimmune phenomena, lymphadenopathy and hyperglobulinemia are obvious manifestations of such activation. The energy spent early in HIV infection prior to T cell depletion can be attributed to functional desensitization through this T cell receptor pathway. Continuous activation signals in the form of HIV component(s) finally disrupt T cell homeostasis by the interference with filling of memory cells resulting in clonal selection and net T cell loss (anemia). Thus, HIV disrupts immune function by violating the rules of MHC restriction and the adverse result of this interaction establishes the significance and underlying purpose of MHC restriction.

The model can account for the findings of both AIDS-related-complex and frank AIDS without widespread T cell infection, is consistent with a prolonged "incubation period" and provides a role for antigen specific co-factors. In contrast to immunosuppressive approaches, therapy aimed at suppression of aberrant activation via the CD4 molecule and/or the generation of resting cells may have beneficial effects in HIV disease.

C.710

DETECTION OF CD40CD EXPRESSION ON HIV INFECTED T CELL CULTURES
 M.F. McClane, Lee, T.H.; Ho, S.T.; Wolf, A.A.; Fetter, G.H. III* and Essex, M.* Harvard Univ., Boston, MA USA ** PHLS, Witshire, UK

Objective: The study describes the expression of CD40CD on T cell culture lines at early and chronic stages of infection.

Methods: We examined T cell cultures by the techniques of dual color immunofluorescence flow cytometry, ferritin labelling for electron microscopy visualization and reverse transcriptase for virus expression.

Results: CD4 expressed markers remained depressed at post-infection as predicted previously and into the chronic stages. RT activity and absolute number of virus particles being generated did not significantly influence the surface markers once the culture was infected. CD8 when co-expressed remained demonstrable.

Conclusions: Using quantitative doses of HIV strains we find the variation of expressed membrane markers can be separate elements from cell function and maturation of the virus. We are presently using cytokines in modulating surface marker activation and virus induction.

- C.711** BIOLOGICAL ROLE OF COCAINE IN THE DEVELOPMENT AND EXPRESSION OF AIDS
HAEGHEBAERT P. FURMAN, L.J.*** Department of Microbiology* and Department of Medicine** University of Medicine and Dentistry of New Jersey, Camden, New Jersey, U.S.A.

Objective. To determine the effect of cocaine on the immune system.
Methods. In order to obtain a better understanding of the effects of cocaine on immune function, inbred male rats were treated daily for ten days with 1.25, 2.5 or 5.0 mg/kg of cocaine. Rats were then immunized with T-helper independent (TI) and T-helper dependent (TD) antigens. Splenic plaque-forming cell (PFC) and serum antibody responses were measured 5 days post-immunization.

Results. The ability of rats treated with cocaine to mount primary PFC and antibody responses to TI were elevated several fold when compared to control animals. The magnitude of the elevation was directly related to the dose of cocaine administered. Antibody responses to TD antigens were increased at lower concentrations of cocaine (1.25 and 2.5 mg/kg) and were suppressed at the higher concentration of the drug (5.0 mg/kg). Exposure of isolated lymphocytes from rats and humans to cocaine *in vitro* did not result in a stimulation of B-cell populations indicating that a metabolite of cocaine or the release of some other host factor(s) was responsible for the observed immunomodulation.

Conclusion. The prevalence of AIDS in substance abusers is very high. It is also well documented that activation of CD4 cells in HIV-1 individuals also activates proviral (latent) stages of AIDS. The present studies provide data to indicate that the immune system is stimulated by cocaine.

- C.713** PRESENCE OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) IN THE ALVEOLAR MACROPHAGES AND FROM SPERMATOCYTES/LYMPHOCYTES (SAL) AIDS
MARGONEN, OLVIN C. JR., Swanson, R.P., Fross, P.T., Floyd, R., Depts. of Medicine, Pathology and Laboratory Medicine, University of Cincinnati Medical Center, Ohio, U.S.A.

Previous work in our laboratory has shown that HIV can be recovered from the BAL fluid of all patients with AIDS, but has only detected p24 antigen directly in the BAL fluid of a patient with lymphocytic interstitial pneumonia. To determine which cells in the BAL fluid contain the virus, BAL cells were separated into glass adherent (alveolar macrophages) and non-adherent populations and were cultured in random donor peripheral blood mononuclear cell cultures. Five consecutive AIDS patients were cultured and the BAL fluid from all were positive for HIV. Both adherent and non-adherent cells contained HIV, but adherent cell cultures were either positive before non-adherent or had higher levels of p24 antigen on days 6-8. Only one non-adherent patient has been cultured and, in contrast to the AIDS patients, HIV was not recovered. These studies suggest that HIV appears at levels detectable by culture in the bronchoalveolar secretions of HIV infected patients later in the natural history of the infection, and, even though virus can be recovered from both BAL and lymphocytes, it appears to be in higher titer in macrophages. Studies on the effects of HIV infections of AM on macrophage function are underway. Production of tumor necrosis factor (TNF) by HIV infected AM has been evaluated. Spontaneous release of TNF was detected from AM of 2 of 5 AIDS patients, while all 5 released normal amounts of TNF when stimulated with lipopolysaccharide.

- C.715** HIV-1 INFECTION OF HUMAN FETAL THYMOCYTES
JANKA-BATHANY, BACH, V.; BATHANY, W.; RUBINSTEIN, A.; WEISS, I.; and LIPMAN, V.D. Albert Einstein College of Medicine, Bronx, NY, USA

Objective. Since infants with congenital HIV-1 infection are immunocompromised, it is felt appropriate to examine those infected by HIV-1 resulting in immune dysfunction. To examine this hypothesis, normal human thymocytes were established in culture with HIV-1. The potential for this virus to affect thymocytes was determined by measuring ³H/5 and functional assays. Thymocytes were exposed to either infectious or heat-inactivated HIV-1 isolates. The presence of HIV-1 infection was determined by immunocytochemistry, molecular hybridization and an infectious cell center (ICC) assay using the GEM-25 cell line. Treated cultures were analyzed by flow cytometry and functional assays.
Results. Increased thymocytes responded to T_H but not to B-cell associated antigens and were comprised of over 90% double (CD4⁺CD8⁺) positive cells. After 5-7 days in culture, immunocytochemistry revealed the presence of p24 in the HIV-1 exposed cells and the ICC assay was positive. In addition, there was a significant change in the subset ratios of infected cells. Furthermore, thymocyte infection was observed in a dose dependent fashion, upon the titer of the HIV-1 inoculum.
Conclusion. Culture of thymocytes with HIV-1 and the ICC assay of this infection causes significant cytopathology. As a model, this system may permit a better understanding of the pathogenesis of pediatric AIDS. (Supported, in part, by NCI, # 55283, DA 05363, NS 11920, AT 20473, and the Diamond Foundation).

- C.712** CHARACTERISTICS OF HIV-1 IN MONOCYTE-MACROPHAGES
SHIBUI, MITSUO;* GÖTHLUND, M.†; NILSSON, K.†; FENYK, M.* and WÄGELIN, H.†**

*National Institute, Stockholm, Sweden. **Univ. of Uppsala, Uppsala, Sweden.

Objective. To investigate infectivity and localization of HIV in monocyte-macrophages.
Methods. HIV-1-infected producing cells, D897 subclone, T.H.P.1 and T cell lines were by measuring reverse transcriptase activity and the amount of p24. Infectivity of HIV-1 in the solution was determined by infecting HIV-1 sensitive T cells, MT-2 and MOLT-4. Infection of the infected cells was checked by cytopathic effect and amount of p24 in culture supernatant.

Results. Solution obtained by freezing-thawing of monocyte lines showed higher reverse transcriptase activity and larger amount of p24 compared with T cell lines. The solution showed high infectivity to T cell lines.

Conclusion. Monocyte-Macrophage can harbour large amount of infectious virus inside the cells.
 Localization of the virus will be also discussed.

- C.714** POSSIBLE ROLE OF GENETIC, IMMUNOLOGICAL AND VIRAL FACTORS IN THE ACQUISITION AND/OR PROGRESSION OF HIV INFECTION

PURVIS, RAY†; KOSCI, M.A.††; MICHEL, M.†; KIROLO, M.†††; PASSELLI, M.††† and SENSILLA, E.†††

† National Center for Blood Transfusion and Cell Therapy, Hospital for Infectious Diseases, †† Institute Infectious Diseases, University of Rome, Italy

Objective. To evaluate the role of genetic, immunological and viral factors in the acquisition and/or progression of HIV infection.

Methods. Five seronegative regular sexual partners of HIV seropositive subjects and 5 HIV seropositive patients without HIV infection progression (during the last 3 years, were included in our study. We carried out HLA-A,B,C,D,RN antigen phenotyping and surface phenotypes of PBMC; we also performed *in situ* hybridization, P.C.R. and *in vitro* response to recall Ag, PHA and PWM.

Results. A higher frequency of HLA-2 Ag in seronegative and in HIV seropositive subjects without infection progression was found; an increase of CD4⁺ cells in HIV seropositive was also observed. All seronegative subjects were positive *in situ* hybridization and, at performed follow-up, the seronegativity has been lasting for more than one year.

Conclusions. Could HLA-A antigens and CD4⁺ cells play a role in the acquisition and/or progression of HIV infection?

- C.716** AIDS IS A NON-INFECTIOUS "OCCUPATIONAL" SYNDROME
MARRINO LOCA MORELLI,† Instituto de Terapia Plasma y Sindrome Infecciosa de Guatemala, Caracas, D.F., Venezuela

Objective. To find answers to the following questions: a) Is AIDS an infectious disease? b) Can it be considered a sexually transmitted disease? c) Is HIV the etiologic agent? d) What is the prophylaxis for AIDS? e) What is the possible cure for people at high risk for AIDS, with PGL, ABC or AIDS? **Methods.** Three years research conducted through: a) study and analysis of more than 5,000 AIDS research studies; b) study and analysis of the U.S. AIDS cumulative statistical official data during the period 1981-1988; c) study and analysis of clinical aspects and results in groups at high risk; d) study and analysis of the components and properties of the clotting factors and heroin and fecal material; e) analysis of the AIDS epidemiology between industrialized and developing countries. **Results.** These studies have shown that: a) AIDS is a non-infectious syndrome. b) HIV is not the etiologic agent. c) How the cause/effect factors of AIDS made possible the misunderstanding of HIV as the etiologic agent of AIDS. d) What are the causative factors of AIDS.

Conclusions. a) A new postulate for the AIDS pathogenesis: what are the causative factors and how they work. b) A new postulate for AIDS prevention. c) A new postulate for the cure of PGL, ABC, and AIDS.

THE COURSE OF IgG REACTIVITY WITH SYNTHETIC PEPTIDES DERIVED FROM HIV-1 GAG AND ENV IN HIV-1 SEROPOSITIVE INDIVIDUALS.

Johan Blomberg (1), Per Johan Klenck (1), Rüdiger Pipkern (2) Bernd Ljungberg (2), Bertil Christenson (2) and Bo Strandberg (2) Section of Virology, Dept Med Microbiol (1), Dept Infect Dis (2) Lund, Sweden, Zentrum f. Molekulare Biologie, Heidelberg/FRG (3)

OBJECTIVE: To evaluate the development of the immune response to epitopes simulated by synthetic peptides during the course of HIV-1 infection.

METHODS: [I₂₅I] with synthetic peptides from HIV-1 gag (1-20, 320-338, 335-355) and env (503-520, 581-599, 583-599, 606-620, 622-627, 658-663) were performed on consecutive sera from 39 HIV seropositive persons. A time period of 0.5 - 5 years was covered. Results were correlated with clinical status.

RESULTS: As previously noted by us, the pattern of reactivity with HIV peptides was individual. However, also a temporal pattern of variability was observed. Antibodies to certain peptides increased rapidly after an acute HIV infection, and then declined rather rapidly. Antibodies to some epitopes varied more, independently of other HIV antibody parameters. Antibodies to env 583-599 were more frequent in asymptomatic individuals than in patients with HIV-related disease. In individuals with more advanced disease, several peptide antibody parameters, both from gag and env, were low. The independent temporal variability among epitopes can be both abandoned and reconstituted during HIV-1 infection. Absorption by antigen, opsonin, also contributes.

C.719

A RAPID AND IMPROVED 2',5'A SYNTHETASE ASSAY BY POLYACRYLAMIDE GEL ELECTROPHORESIS

Henry C. Lee, Mary Beth Hiale, and Dal-Keo Lu.

Department of Pharmacology, The Pennsylvania State University, College of Medicine, Hershey, Pa. 17033, USA

Induction of 2',5'oligoadenylate (2,5A) synthetase activity is an accurate and sensitive parameter for viral infection of mammalian cells. It could be used clinically to monitor circulating interferences. The enzymatic assay ideally involves chromatographic separation of 2,5A, which range from di- to oligomers, from each other and from the unincorporated substrate of radiolabeled ATP. However, this procedure is not done routinely, and the enzymatic activity is measured instead by the amount of radiolabeled AMP incorporated into total 2',5'A. We developed a rapid and improved assay using a 0.3- μ m denaturing 20% polyacrylamide gel to separate the different species of [³²P]-labeled 2,5A from each other, and from the substrate [³²P]ATP. 2,5A species were visualized by autoradiography and the amount of incorporated [³²P] can be quantitated. To confirm the 2',5' linkage of the reaction products, the predominant species which coigrated with a tracer standard was shown to be resistant to 72 Hase but readily digested by phosphodiesterase. The current method is sensitive, fast and can assay a large number of samples simultaneously. Host cells we examined, including human T cell lines CEM and HP, had a low 2,5A synthetase activity. HIV infection of HP cells did not induce this enzymatic activity. This assay will be useful clinically to monitor circulating interferences in AIDS patients before and after therapy.

C.721

TROPICAL SPASTIC PARAPARESIS: SEROLOGIC AND HISTOLOGIC ANALYSIS

Canavaggio, M., Leckie, G.,* Chi, L.,* Madrid, R.E.,**

Lee, Helan,* and Van Gelder, R. Light and Electron Microscopy, *WESBOTE Laboratories, North Chicago, IL, 60064, USA, **SUNY State Center at Brooklyn, Brooklyn, NY

OBJECTIVE: To identify and further characterize by sural nerve biopsies, **MSWSP** in a neurological patient population from New York City.

METHODS: Serum and CSF from 150 patients were assayed for antibodies to HIV-1 by EIA. Repeat biopsies were confirmed by Western blot and SDS-PAGE. Sural Nerve was also performed on paired EIA positive serum and CSF. Sural nerve biopsies were performed on 17 TSP patients; these were analyzed by immunofluorescence, and light and electron microscopy.

RESULTS: 15 patients were HIV-1 seropositive; 12 of these had clinical features of **MSWSP** and all except one (black patient from S. Carolina) originated from the Caribbean. No differences in MB banding patterns were observed in matched serum and CSF. Surprisingly, a sensorimotor peripheral neuropathy was observed in 7 of the TSP patients. Two of the nerve biopsies revealed epineural and endoneurial inflammatory lesions containing plasma cells, but no giant or multinucleated cells. A myelin demyelinating process and abnormal giant axonal mitochondria were observed.

CONCLUSIONS: TSP is prevalent in the U.S. among Caribbean migrants and African-Americans. Repeat biopsies were performed to detect if intrathecal synthesis of anti-HIV-1 Ab was observed when comparing CSF and serum by MB. Nerve biopsies provide one means to assess the role of HIV-1 in the pathogenesis of myelopathy.

PATHOGENESIS NK DEFICIENCY IN AIDS

Maria Caterina Sirtanni, F. Tagliavini, F. Alati Dept. of Allergy and Clinical Immunology, University of Rome, Rome, Italy.

OBJECTIVE: To give a model explaining NK defect in AIDS.
METHODS: PBMC from AIDS patients were assessed for NK activity on the D1C7 labelled K562 cell line. Cytoxicole tubulin polarization in these conjugates was studied by monoclonal antibodies (wAb) and immunofluorescence. Tubulin is responsible for an effective NK lysis. Results from these experiments were compared with those obtained on PBMC from normal donors, which were treated, before the assays with an anti-CD16 wAb.
RESULTS: NK activity and tubulin polarization were deficient in PBMC from AIDS patients as well as in normal controls, pre-treated with anti-CD16 wAb.
CONCLUSION: Pathogenesis of NK deficiency in AIDS may be explained on the basis of this model, assuming that some HIV-1 env proteins mimic the action of anti-CD16 wAb.

C.720

KINETICS OF HIV INFECTED CELL-TO-CELL FUSION

Graham, Barry and Rowland, J. Vanderbilt University School of Medicine, Nashville, TN, USA.

Objective: To define the mechanism and timing of the cell-to-cell fusion process important in the pathogenesis of AIDS.
Methods: A cytoxic effect assay to measure serum fusion inhibition activity has been developed that utilizes HR23T-HIV as fusion partner and the CD4+ cell line, M12, as target for spycytium formation. Serum is added to wells containing cells in viable culture (Titer A340 - virus control A340 - virus control A340) X 100. The kinetics of the fusion process was investigated by adding a dilution of serum known to have fusion inhibition activity in wells simultaneously, and 15, 30, 60, 90, 120, 180, and 360 minutes after wells were mixed. An equivalent dilution of non-immune serum was added to another series of wells mixed by repeated pipetting at the same intervals. Control wells included non-immune serum without mixing and immune serum with mixing. Assays were done in triplicate. Results: Anti-fusion activity of serum was unchanged when added simultaneously or 15 to 120 minutes after cell mixing. However, at 180 minutes there was a diminished anti-fusion effect and at 360 minutes there was an anti-fusion effect when the assay was terminated at 20 hours. Mechanical disruption of cells retarded the onset of mechanical formation on fusion inhibition was diminished when performed at the 360 minute time point. Non immune serum had no protective effect.
Conclusions: There is a point in the fusion process at which antibody is unable to inhibit syncytium formation. The data suggest that in the fusion process there are evolving cell-to-cell interactions that attain sufficient stability to diminish antibody interference by 6 hours and to resist mechanical disruption by 6 hours.

C.722

HIST IMMNOGLOBULIN MOLECULES ARE ON THE SURFACE OF PHAGOCYTES CARINII

Blumenfeld, Walter and Griffin, J. Melech Veterans Administration Medical Center, University of California, San Francisco, San Francisco, California, U.S.A.

Objective: To define the organ and/or host factors that explain the pathogenesis of P. carinii pneumonia in humans.
Methods: (1) Immunofluorescent labeling of whole organism preparations of P. carinii in bronchoalveolar lavage fluid separated with enzyme-labeled polyclonal and monoclonal antibodies to human immunoglobulins and to P. carinii. (2) Analysis of electrophoretically sedimented components of density gradient-purified P. carinii from human antibodies as well as whole organisms in 3/2 preparations. Monoclonal antibody to the Fab fragment of human IgG also labeled whole organisms. Anti-human IgG, one of the two monoclonal antibodies to the Fc fragment of human IgG, and a monoclonal antibody to P. carinii all labeled a 40k band that was present in (a) purified preparations of P. carinii, (b) 4/4 bronchoalveolar lavage fluid supernatants from patients with (2) and without (3) AIDS, and (c) IgG purified from 2/2 human sera (1 HIV-, 1 HIV+).

Conclusions: A host-derived IgG fragment is present on the surface of P. carinii. Its role in the pathogenesis of P. carinii pneumonia in AIDS is currently unknown. It may conceivably interfere with the ability of an already compromised immune system to clear the organism or recognize it as foreign.

C.723 INFECTION OF MONOCYTES WITH A T CELL TROPIC CLONE OF HIV. Janssens, Jean, S., Foka, T.M., Orensanz, J. and Fauci, A.S. IIR, NIAID, NIH, Bethesda, MD, U.S.A.

Objective: To determine if an HIV clone derived from infected T cells can infect normal human macrophages in vivo.

Methods: The HIV infectious clone (pNL4-3) was developed by combining the 5' GAG-POL region of the NY5 strain construct and the 3' ENV region of the LAV-1 strain construct. The pNL4-3 construct was transfected into SW640 (colony carcinoma) cells, with a subsequent passage onto a T cell tumor line (A31). Elutriated monocytes were infected with the passaged pNL4-3 clone. The monocytes passaged pNL4-3 and original clone were equilibrated by reverse transcriptase levels (RT) and stained onto monocytes and PHA blasts.

Results: The initial passage of pNL4-3 onto elutriated monocytes resulted in RT positivity on day 30 post infection. The culture remained RT positive through day 65 when the experiment was ended. Infection of these cells revealed virus particles budding intracellularly as well as from the plasma membrane. pNL4-3 showed a much greater ability to replicate in PHA blasts than in monocytes. Of particular note, a single passage onto monocyte culture resulted in an increased (3 log infectious units) ability of the virus to replicate in monocytes. In parallel, a 3 log decrease in ability to infect PHA blasts was noted with this single passage HIV.

Conclusions: A T cell tropic HIV clone can infect monocytes. Moreover, a single passage of the clone onto monocytes is sufficient to markedly increase the tropism of the virus for macrophages at the same time as it decreases the tropism for T cells.

C.724 MONOCYTE CHEMOTACTIC ACTIVITY IN THE SUPERNATANTS OF IN VITRO INFECTED HUMAN MACROPHAGES. Jouis L., LAKELINE E., Alieri* and R.S. Melitzer**

*Research Laboratory†, PHARMACOLOGICAL DIVISION, CIBA-GEIGY Ltd. CH-4002 Basel, Switzerland.
**Walter Reed Army Institute of Research, WMAI, WANC, Washington DC 20307 USA.

Macrophages (MΦ) are an important target for HIV infection and probably play a major role in the establishment and propagation of AIDS. Following infection, the virus is found in tissue MΦ and blood monocytes. As present, the mechanism of infection and spreading of HIV in these cells is not known.

We present results that address this issue. Human blood monocytes cultured in presence of 1,000 units of Colony Stimulating Factor-1 (CSF-1) differentiate into macrophages and are permissive to the infection with HIV-1 (ADA strain). Following infection, viral replication with minimal cytopathic effect can be demonstrated. When supernatant from infected MΦ were assayed for their ability to attract freshly isolated non infected blood monocytes, they were found active at levels comparable to the supernatant with optimal concentration of the standard chemotactant F-Met-Leu-Phe. Control supernatants obtained from non infected MΦ did not show this activity. A 48-microwell chemotaxis chamber was used for the measurements. These results can be of relevance to explain the initial rapid spread of the virus from primarily infected MΦ to circulating monocytes.

C.725 DETECTION OF HTLV-1 IN ALVEOLAR LYMPHOCYTES OF PATIENTS WITH TROPICAL SPASTIC PARAPARESIS (TSP) WITH BRONCHOVULVAR LYMPHOMAS.

Claude Desmet†, Coedat J.L.**, Norza N.A., Cabaret†† and Vermet J.C.***
INSERM U 271, Lyon; * Service de Pneumologie, Hôpital, St. Simeon; ** Service de Neurologie, Hôpital La Meynard, France, Montpellier, France.

Objective: To study the type of alveolar cells draining HTLV-1 genome in the TSP patients with bronchovulvar lymphomas.

Methods: After bronchoalveolar washing of TSP patients serologically HTLV-1 associated with bronchovulvar lymphomas, the adherent and non-adherent cells were separated, identified and HTLV-1 genome was detected in the different cell populations.

- by Polymerase Chain Reaction (PCR) after cellular DNA extraction of each cell population.
- by coculture of the two alveolar cell populations with lymphocytes of HTLV-1 seronegative subjects.

Results: PCR was done with two different types of primers in pol and pX regions; HTLV-1 genome was present only in lymphocytes and never in adherent cells. After coculture, we observed immunolabelled TSP cells producing complete HTLV-1 only with the alveolar lymphocytes and never with the alveolar adherent macrophages.

The immunolabelling of TSP cells will be presented and these cell lines will be phenotypically and virologically characterized. The biological properties of the HTLV-1 isolated from alveolar lymphocytes and from peripheral lymphocytes of the same patient will be analysed.

Conclusions: HTLV-1 is detected in alveolar lymphocytes and never in alveolar macrophages of these TSP patients, while in HIV infected patients with bronchovulvar pathogenesis, HIV genome is currently present in the two types of alveolar cells.

C.726 PLASMA VALUES OF FIBRONECTIN (FN) AND ANGIOTENSIN CONVERTING ENZYME (ACE) IN KAPOSI'S SARCOMA (Ks)-RELATED AND CLASSICAL (KS).

Palanis A.† and Korte P.†
† STD Clinic, ** Haematology and *** Biochemistry laboratories, Hôpital Saint-Louis, Paris, France.

Objective: To investigate plasma values of FN and ACE as putative markers of endothelial proliferation in HIV-related and classical Kaposi's sarcoma (KS).
Methods: Plasma FN (ELISA, Stago Lab) and ACE (Radiochemical technique of Rohrbach) were determined in patients with AIDS-related KS, classical KS and the lymphoedematous syndrome (LAS).

RESULTS	FN (ng/ml)	SE	p	ACE (mg/ml/min)±SE	p		
CONTROLS	138	± 28	n=30	12.5	± 3.5	n=20	
LAS	153	± 75	n=18	KS	21.4	± 10.1	n=14
HIV-KS	227	± 80	n=21	CLASSICAL KS	16.9	± 6.1	n=3
				15.9	± 5.5	n=15	

The increase in plasma values of FN is highly significant in both HIV-related and classical KS (P<10⁻³). Plasma Von Willebrand Factor (VWF) gave similar results (Santur J. Invest. Dermatol. 1988; 90, 703). On the other hand, ACE increase is highly significant in LAS patients (p<10⁻³) and moderate in both forms of KS (p<0.01 and p<0.05).

Conclusion: Fibronectin and ACE are both partly released by endothelial cells. They are both, besides VWF, markers of endothelial damage or proliferation in KS. Their prognostic significance in LAS patients remains to be ascertained.

C.727 CD4- CELL HELPER AND SUPPRESSOR FUNCTIONS OF HIV INFECTED PATIENTS

Wetzel, Hol†(1), Bissel, Y.†(2); Schweighofer, Th.†(3); Scheller, G.†(4) and Opelitz, G.†(5).

†(1)Institute of Immunology, University of Heidelberg, and (2)Rehabilitation Hospital and Hematology Center, Metelberg, FR Germany

Objective: To investigate helper and suppressor functions of CD4+ T cells in HIV infected hemophilia patients.

Methods: We assessed T cell functions in 61 hemophilia patients (22 HIV-Group 1; 27 HIV without AIDS; Group 2); 13 ARC/AIDS patients, Group 3). PWM-stimulated allogeneic cocultures of CD4+ T cells and control B cells were evaluated by assessment of immunoglobulin secreting cells (ISC) in a reverse hemolytic plaque assay and by ELISA-determination of IgM and IgG secretion.

Results: We found no significant differences between HIV- patients and controls whereas CD4+ cells of HIV patients showed reduced helper activity for generation of ISC (p<0.01, Group 2; p<0.001, Group 3), IgM (p<0.005, Group 2; p<0.001, Group 3) and IgG secretion (p<0.02, Groups 2,3). CD4+ cell suppressor activity was enhanced with respect to ISC generation (p<0.01, Group 2; p<0.0001, Group 3) and IgM secretion (p<0.02, Groups 2,3). Preliminary data in 38 patients show that autoantibodies against CD4+ cells were associated with CD4+ cell helper defects (p<0.01).

Conclusion: Considering the central role of CD4+ cells in the immune response CD4+ cell dysfunction may play a role in the development of immunodeficiency state of ARC/AIDS patients. CD4+ cell autoantibodies might be involved in the pathogenesis of CD4+ cell helper defects.

C.726	
RESULTS	FN (ng/ml)
CONTROLS	138 ± 28 n=30
LAS	153 ± 75 n=18
HIV-KS	227 ± 80 n=21
CLASSICAL KS	21.4 ± 10.1 n=14
	16.9 ± 6.1 n=3
	15.9 ± 5.5 n=15

GROWTH OF HIV IN CELLS FROM VARIOUS DONORS
O. Yamada, T. Matsumoto, H. Saitoh and T. Kurimura,
Department of Virology, Tohoku University School of
Medicine, Yonegi 581, Japan

Peripheral blood mononuclear cell (PBMC) preparations were prepared from 27 individuals and the growth of Japanese HIV isolates, J90/1 and J90/2, in these PBMC preparations was studied. There was significant diversity in infectious virus yield among PBMC preparations. The virus yield did not correlate with the ratio of CD4 lymphocytes in PBMC or growth ability of the cells. In some PBMC preparations, p24 antigen levels did not correlate with infectious virus yield. Mean E-rosette forming cells were used instead of whole PBMC. Similar phenomena were observed, but the production of p24 antigen was much reduced without decrease of infectious virus yield. These results indicate that each individual donor has lymphocytes with capacity to allow the growth of HIV different from others, and that E-rosette forming cell-depleted PBMC produces excess p24 antigen.

C.754

DETECTION BY POLYMERASE CHAIN REACTION OF HIV-1 DNA IN
HOMODUPLEXES, HETEROLOGUES, AND AIDS PATIENTS IN TAIWAN
H. Dou¹, C. T. Chang², M. C. Shiao³, M. C. Lin⁴, Y. C. C.
Kuo⁵, C. H. Chiu⁶ and Kenneth B. S. Chien⁷ National Center Institute, NCH
Taiwan; ²National Taiwan University College of Medicine, Taipei,
Taiwan; ³Center for Venereal Disease Control, Taipei, Taiwan; and
⁴Shanghai Medical College, Shanghai, Taiwan.

Objective: To detect HIV-1 proviral sequences by polymerase chain reaction (PCR) with DNA samples obtained from seropositive Taiwanese subjects.
Methods: Peripheral lymphoid cells from an AIDS patient, an asymptomatic homosexual male, and two hemophiliacs, as well as formalized spleen tissues from two autopsied AIDS patients were tested. The presence of proviral sequence in the Southern blot was detected by specific probes following PCR-amplification procedures. **Results:** All of the 6 samples exhibited a positive reaction when primer pairs from gag region and splI domain of gag region were used. Primer pairs derived from a relatively conserved region of splII domain of gag region also functioned to produce amplified fragments for all samples. However, when primer pairs covering splII through splI domain were used, only four samples gave a definite amplified band, and one yielded a faint band. When primer pairs derived from gag and 3' LTR regions were used, all were negative. The degree of hybridization signal intensity for each of the samples PCR-amplified at gag region did not correlate exactly with those PCR-amplified at various gag regions.
Conclusion: The results suggest that these six samples contain various copy numbers of HIV-1 proviral sequences which exhibit heterogeneity in their gag sequences, divergent from those of HXB-2 clone of HIV-1.

C.755

CONSTRUCTION OF A RECOMBINANT RETROVIRAL INTERFERING PAR-
TICLES CONTAINING A DEFECTIVE HIV-1 GENE
Ferdinando, Maurizio; Taddeo, S.M.L.; Orsacchia, A.; Sabbatini,
L.; Carletti, F.; Veroni, F.; Rossi, G.S.
Laboratory of Virology, Istituto Superiore di Sanità, Rome, Italy.

Objective: By infecting Huc-78 cells with an RT positive supernatant of P81 from an AIDS patient, we have isolated a non-productive HIV-infected cell clone (P17), which exhibits a viral RNA pattern superimposable with that of productive cell clones, and shows resistance to HIV-1 or HIV-2 superinfection. In order to study the phenomenon of viral interference, the whole genome will be transferred in HIV-sensitive cell lines via transfection of a retroviral vector construct in an amphotropic packaging line.

Methods: From an λ gt10 genomic library of P17 clone we have molecularly cloned the whole provirus in pUC-19 and then subcloned it in retroviral vectors bearing the G418 resistance gene such as pL2 (CMV LTR promoter), pS (hyaluronidase kinase promoter) and HIV (SV40 promoter).

Results: The pL2 construct has been transfected in an amphotropic retrovirus containing the provirus originally integrated in P17 clone. More than 30 G418-resistant P4311 clones have been obtained. Indirect IFA analysis using a pool of human positive sera was clearly positive in two P4311 clones also showing an integrated construct by Southern Blot. A more detailed molecular characterization will be discussed.

REPLICATION OF A LETHAL VARIANT OF HIV/SIV IN MACAQUE PBMC
IN THE ABSENCE OF EXOGENOUS IL-2 OR ACTIVATION BY MITOGENS
Parks, Patricia; McClure, H.; Anderson, D.
Yerkes Regional Primate Research Center and Department of Pathology, Emory
University, Atlanta, GA, USA.

Objective: To identify mechanisms by which HIV/SIV(PB₁) replicates in and induces proliferation of PBMC from normal macaques and mangabey monkeys.

Methods: Resting or PHA-stimulated PBMC from normal monkeys, chimpanzees or humans were infected with SIV(PB₁) or the parent, HIV/SIV-9; cultures were monitored for RT activity, cell viability, total cell number, percentage of cells expressing the IL-2 receptor, and production of various cytokines.

Results: Infection of PBMC from pithecioid macaques or mangabey, but not from chimpanzees or humans, with HIV/SIV(PB₁) resulted in as much as 5-fold increases in total viable cells. This phenomenon was not observed in parallel cultures infected with the parent HIV/SIV-9. In addition, SIV(PB₁) but not SIV-9, replicated in and induced proliferation of resting macaque PBMC, irrespective of whether exogenous IL-2 was added to the medium. The proliferative response paralleled virus accumulation in culture medium and increases in IL-2 receptors. Experiments are in progress to assess the possible roles of various cellular activation pathways in the proliferative response to SIV(PB₁).

Conclusion: SIV(PB₁) has escaped the requirement that cells be activated before productive infection can occur. Also, the induction of cell proliferation during *in vitro* infection is manifest as lymphoid hyperplasia *in vivo*, leading to the speculation that the gag gene product, which has some sequence homology with and functions similar to p60-*src* and v-Src-*src*, has acquired mutation(s) that render it "oncogenic-like." (PFR 88-00163)

C.765 SCREENING ET TYPAGE HIV-1 ET HIV-2 GRACE A UN TEST RAPIDE 15 MINUTES UTILISANT DES PEPTIDES SYNTHETIQUES (CLONATEC TARGET HIV TEST).

Sylvie Bergeron, Gilles Laroche, S. Bettiger, A. Dangereux, G.M. Gerety-Danet, M. Denis, J. Département Virologie, France, C. Clonatec, Paris, France, Institut Pasteur, Côte d'Ivoire.

Objectif : Evaluation d'un test rapide (3 minutes) utilisant des peptides synthétiques HIV-1 et HIV-2 dérivés de la séquence de la glycoprotéine transmembranaire de chacun des deux virus HIV-1 et HIV-2.

Matériaux et Méthodes : 208 sérums provenant de sujets vivants en Afrique de l'Ouest.

Résultats : L'étude a porté sur 237 sérums provenant de sujets vivants en Afrique de l'Ouest. Les résultats obtenus ont été filtrés à travers une membrane sur laquelle ont été déposés chaque peptide HIV-1 et HIV-2. Après addition du conjugé (anti IgG humaine couplé à la peroxydase) et lavage, on ajoute le substrat (TMB). Le résultat (spot blanc) est visible à l'œil en une minute environ.

Résumé :

WR	TOTAL	HIV-1	PEPTIDES	PEPTIDES	Négatif
1	7	1	HV-2		
2	72	2	1	48	3
1+2	12	12	1	8	3
Non	186	2	-	-	-

Conclusion : Les résultats montrent une bonne sensibilité (HIV-1 : 94% et HIV-2 : 92,5%) et une très bonne spécificité (HIV-1 : 98,6% et HIV-2 : 100%). Ces résultats, très intéressants pour un test rapide, sont encourageants, une augmentation de la sensibilité doit pouvoir être obtenue.

C.767 INFLUENCE OF BLOOD VOLUME AND TEMPERATURE ON HIV CULTURES IN INFANTS AND CHILDREN

Barthelemy, P., Wessely, J.L., Jodar, A.M., Gilchrist, S.A., Sweeney, P., Burke, D.S., the Walter Reed Retrovirus Research Group, Walter Reed Army Medical Center, Walter Reed Army Institute of Research, Washington, D.C., Institute of Research.

Objectif : To determine the influence of blood volume and specimen transport on pediatric HIV cultures.

Méthode : Blood cultures for HIV were obtained with 1-3 cc of heparinized whole blood from 26 patients (PO-9) with an age range of 3 mos. to 31 yrs. Each culture was enveloped with a standard number of the patient's macrophage cells (10⁶) and a lesser number of cells (10⁵) using a modification of the method of D. Gallo, et al. Laboratory personnel were blinded to the patient's age and origin of specimen.

Résultats : Cultures from 9 children were positive and all asymptomatic infants and seropositive children had positive cultures. Eight of 9 had positive cultures with 10⁶ and 10⁵ cells. One child had a positive culture with 10⁶ cells only. Most cultures were positive at 7 days incubation and 7 of 8 were parallel samples were positive at the same time intervals. Six specimens were paraffin sealed (one of heparinized blood) and cultured over 24 hrs. after phlebotomy. Cultures from 3 of these 6 patients were positive. Conclusion : Prompt and reliable diagnosis of HIV infection in infants is a valuable diagnostic tool despite a small volume of blood (1-3ml) and delay between phlebotomy and culture processing.

C.769 HUMAN IMMUNODEFICIENCY VIRUS (HIV) MUTLIPLES IN PRIMARY CULTURES OF HUMAN KUPFFER CELLS

SCHMITT, Marie-Françoise, STEFFAN, A.M., JAECK, D., GENDRAULT, J.L., DE KINK, A., Département de Médecine Générale et Endocrinologie, Faculty of Medicine, U.P., STRASBOURG, FRANCE

OBJECTIVE: Given their localization in the liver sinusoid, the Kupffer cells (KC), which represent the largest reservoir of fixed macrophages in the body, are ready candidates for early infection following a blood transfusion. However, until now, the role of KC in HIV infection has never been studied and no attempt has ever been made to infect KC in culture.

METHOD: Isolation was carried out according to the method we have previously described (Krivt et al., C.R. Acad. Sci. Paris, 1980, 291, 249). The purity of the cell culture attested 90%. Primary cultures of 24- to 72-hour-old KC were infected with HIV 1 (isolate LAV 1 - Rev).

RESULTS: In 3 different experiments syncytia detectable under optical microscopy appeared between 4 and 10 days. Di observations showed typical HIV particles released either in vacuoles or outside the cell as well as characteristic budding figures. Except from the syncytia, no obvious cytopathic effect could be found. Furthermore, a reverse transcriptase activity increasing with the time of infection was demonstrated in the supernatant of the infected KC.

CONCLUSION: Our results, which demonstrate that KC may constitute a target for HIV, suggest that these cells may play a crucial role in the physiopathology of the disease. They may not only constitute a reservoir for the virus but, given that strategic position in the liver lobule, they may also be involved actively in the dissemination of the viruses.

C.766 ABSENCE OF P24 ANTIGEN AND ANTI P24 ANTIBODY DECREASING IN AFRICAN AIDS - COMPARISON BETWEEN EUROPEAN AND WEST AFRICAN POPULATIONS.

Guy Léopold, P.Wainreb***, M.Mouner*, G.M.Gerety-Danet***, F.Bari***, F. Delbecq***, M. Denis** et le sélectio desse des Groupes HIV Linoges France, Institut Pasteur Abidjan Côte d'Ivoire, Virologie CHU Tours France.

Objective : to compare virological pronostic factors (p24 antigenemia, anti p24 antibody titer) in European and west African patients. Materials and Methods : 508 HIV positive patients from Limoges France (106 sera) and Abidjan Côte d'Ivoire (402 sera) were tested for p24 antigenemia by Abbott HIV-1 antigen p24 assay and for anti p24 by recombinant EIA/RIA Abbott.

Virus Area	Cl. Status	Anti p24 % (n)	Ag p24 % (n)	20-50 % positivity	
HIV-1	AF	HEALTHY(146)	7%	91%	9%
	EUR	ARC(10)	20%	80%	20%
HIV-2	AF	HEALTHY(12)	2%	77%	4%
	EUR	ARC(20)	4%	58%	0%
HIV-1/2	AF	HEALTHY(12)	2%	100%	0%
	EUR	ARC(20)	2%	100%	0%

Conclusion : AIDS African patients have higher titers of core antibodies than European individuals. The pronostic value of HIV antigenemia is not the same for seropositive patients in Europe and in west Africa.

C.768 PRIMARY ISOLATION OF HIV FROM LYMPHOCYTES, MONOCYTES, AND MACROPHAGES WITH A PERMANENT T-CELL LINE AS A MODEL TO STUDY VIRUS REPLICATION AND CELL PROTEIN 24 EXPRESSION.

Barthelme, Andreas, Ehrmann, U. and Jahn, G., Institut für Klinische und Molekulare Virologie der Universität Erlangen-Nürnberg, D-8520 Erlangen, FRG.

Objective: To establish a standardized HIV isolation procedure where PMBC can be replaced by a permanent T-cell line in order to study primary HIV replication and transmission of HIV from monocytes/macrophages to T-cells.

Méthode: Under optimal conditions primary HIV isolation gave an overall positive result in 44%. Using the permanent T-cell line SupT1 as the cocultivating system, instead of negative donor PMBC, HIV isolation was positive in 68% of cases. In contrast to SupT1, negative donor PMBC's showed suppressive influence on primary virus isolation in vitro. Direct transmission of HIV from infected patients blood monocytes to SupT1 was observed in 9 out of 20 isolations. However, the monocytes had to be stimulated with CD-3/CF. In one case the virus could be isolated directly from alveolar macrophages to the permanent T-cell line.

Conclusion: SupT1 as a cocultivating system in primary HIV isolation are not as sensitive as PMBC, but revealed to be a good model to study virus replication and cell tropism of HIV wild isolates in vitro.

C.770 PRODUCTIVE INFECTION OF PRIMARY CULTURES OF HUMAN HEPATIC ENDOTHELIAL CELLS (EC) BY HUMAN IMMUNODEFICIENCY VIRUS (HIV).

STEFFAN, Anne-Marie, SCHMITT, M.P., GENDRAULT, J.L., JAECK, D., DE KINK, A., Département de Médecine Générale et Endocrinologie, Faculty of Medicine, U.P., STRASBOURG, FRANCE

OBJECTIVE: The presence of CD 4 antigens on the surface of human liver EC prevents them susceptible to infection by HIV. Hepatic EC were isolated from liver specimens obtained after liver resection in second liver cancer by a method we developed several years ago (Steffan et al., C.R. Acad. Sci. Paris, 1981, 292, 809). The cells were purified by centrifugal elutriation. The well flattened out EC could be easily characterized under SEM by their typical fenestration. RESULTS: Primary cultures of 24-hour-old EC were infected with HIV 1 (isolate LAV 1 - Rev) for 3, 5 and 6 days and processed for SEM and TEM. Under SEM, a great number of virus particles were detected at the plasma membrane as early as 3 days after infection. One or two days later, the number of viruses in close contact with the plasma membrane or in the vicinity of the cell had considerably increased. Moreover, numerous pictures strongly suggestive of virus budding were observed. TEM observations confirmed these results and demonstrated the presence of typical virus particles as well as the different steps of virus budding.

CONCLUSION: These results demonstrate that liver EC in culture may be infected with HIV and are able to produce large amounts of virions. This suggests that the EC could play an important role in the dissemination of HIV particles.

**A HUMAN MONOCLONAL ANTIBODY AGAINST HIV-1
 TRANSMEMBRANE GLYCOPROTEIN GENERATES
 COMPLEMENT-MEDIATED, ANTIBODY-DEPENDENT
 ENHANCED (C-ADE) OF HIV-1 INFECTION *IN VITRO*.**

W.F. Robinson, Jr., M.K. Gornzy, J.-Y. Xue, D.C. Montefiori¹, W.M. Mitchell¹, and T. Zolla-Pazner²

¹Dept. of Pathology, Vanderbilt University, Nashville, TN USA 37232
²Dept. of Pathology, New York University, New York, NY USA 10016

Neyers Administration Medical Center, New York, NY USA 10010

Objective: To evaluate ten human monoclonal antibodies (mAb) against HIV-1 for their abilities to neutralize or enhance HIV-1 infection *in vitro*

Methods: Ten human hybridoma cell lines producing mAb against HIV-1

were generated *in vitro* by infection of peripheral blood lymphocytes from HIV-1 seropositive subjects with Epstein-Barr virus. All ten IgG were tested in an MT-2 cell microtiter infection assay for HIV-1 neutralizing and enhancing activities.

Results: Of the ten, 4 mAbs reacted with gag protein (gp24) and 6 reacted with env protein (gp41), by radioimmuno-precipitation. None of the mAbs were neutralizing. It was determined that one mAb, 120-16, could enhance HIV-1 infection to a division of 1.648 (approximately 25 ng/ml). This mAb is an IgG₁ which recognizes gp41 and is directed against an immunodominant region of the virus. Enhanced HIV-1 infections were characterized by increased cytopathic effect, reverse transcriptase release, antigen synthesis, and progeny virus production.

Conclusions: Since only 1 of 6 human mAb tested mediated C-ADE of HIV-1 infection *in vitro*, this phenomenon probably depends on recognition of one or more specific epitopes. The epitope(s) can be mapped and should, perhaps, be eliminated from recombinant vaccines.

C.772

**IDENTIFICATION OF PROTEIN INTERMEDIATES IN THE PROCESSING
 OF THE p55 HIV-1 gag PRECURSOR.**

Shaharraz D. Gowde, B.S. Stala, and E.G. Englemann, Stanford University School of Medicine, Palo Alto, CA 94304, USA.

Objective: To analyze the cleavage pathway of the 55 kDa (p55) HIV-1 gag precursor.

Methods: HIV-1 gag proteins isolated from [³H]leucine labeled, recombinant HIV-1/vaccinia virus infected M1 lymphocytes by immunoprecipitation with anti-p24, anti-p17 or anti-p6 antibodies were subjected to one- and two-dimensional SDS-PAGE.

Results: SDS-PAGE analysis revealed that the initial cleavage of the p55 gag precursor gives rise to three processing intermediates (p41, p41 and p39), p41 and p39 proteins contain the p17 and p24 protein segments, and p41 is comprised of p24 and p15 proteins.

Two-dimensional gels, these intermediates as well as the mature p24 and p17 proteins were separated as distinct species. The tryptic acid labeling of the HIV-1 gag proteins revealed that in addition to p55 and p17, the p41 and p39 intermediates, but not p41, are glycosylated, confirming that glycosylation occurs at the N-terminus before cleavage of the p55 precursor.

Conclusion: The glycosylated HIV-1 gag p55 precursor is initially cleaved in a random either at the p17/p24 junction or at two sites between p24 and p15 proteins, resulting in three intermediates which are subsequently cleaved to yield mature gag proteins.

C.773

**EARLY DIAGNOSIS OF HIV INFECTION IN CHILDREN AND NEWBORN
 BY LYMPHOCYTE CULTURES AND DNA/RNA DETECTION IN THE
 POLYMERASE CHAIN REACTION (PCR).**

Basch, Senta¹, Polinger, J.M., Riser, J.M., Chaste, O.***, Bagatell, L*, and Tzipori, C.*

¹ NIDDKM U 271, Lysa; **Newman Hospital, Lysa; *** Rockefeller University, Lysa; **** Elster Hospital, Lysa, Germany.

Objective: In order to diagnose early HIV infection in newborns and children from seropositive mothers, we have looked for HIV in their peripheral blood mononuclear cells (PBMC).

Methods: 14 seropositive children were studied, age one day to 3 years and HIV was detected in lymphocyte cultures by P24 Ag ELISA (Abbott). HIV DNA and RNA in PBMC was demonstrated by PCR.

Results: HIV was isolated from lymphocytes in 5/14 cases (in 2/5 the first day of life). HIV DNA was detected in 13/14 children with two pairs of primers. HIV RNA was found in PBMC in 8/14 cases including the five with a positive HIV culture.

Furthermore HIV RNA was present in 6/8 cases of children with clinical and/or immunological abnormalities but only in 2/8 of those with no clinical or biological changes.

Conclusion: PCR appears as the most sensitive method to diagnose HIV infection anytime after birth. Since HIV RNA detection in isolated children does not correlate with immunological abnormalities and possibility of lymphocyte culture, it is likely that it may also be due to the assessment of active HIV replication and therefore of prognostic value in newborn HIV infection.

C.776

**HIGH CAPACITY DRUG SCREEN FOR INHIBITORS OF HIV
 TAT TRANSCRIPTION: EFFECT OF INTERFERONS**

Leo Bacheler and Bob Nardone, Medical Products Department, ELDuPore de Neuros and Co. Inc., Experimental Station, Wilmington DE 19800-0400, USA.

Transactivation of the HIV LTR by the virally encoded tat protein is an essential step in virus replication. As such, tat transactivation is an attractive target for antiviral therapy. Transfection of HeLa cells with recombinant DNA plasmids expressing the HIV tat protein and linking EcoRI/beta-galactosidase to the HIV LTR has been used to generate human cell lines which express high levels of *in situ* beta-galactosidase activity from a tat transactivated HIV LTR. One such cell line, 389, expresses sufficient beta galactosidase to allow the detection of the activity from 2000-5000 cells grown in a microtiter well. A high through put, virus free, microtiter format based drug discovery screen has been devised using the 389 cell line, and is being used to search for inhibitors of HIV tat transactivation. Compounds which inhibited HIV tat transactivation of the HIV LTR would be expected to reduce *in situ* beta galactosidase expression in this cell line.

Alpha, beta, and gamma interferons are potent inhibitors of beta galactosidase expression in this assay. In order to differentiate between effects of interferons and other active compounds on tat transactivation and other effects which result in reduced beta-galactosidase expression, we derived a control cell line which expresses significant levels of beta-galactosidase from a different promoter, unrelated to HIV and not subject to transactivation by HIV tat. The effects of interferons and other "nuclear" compounds on the expression of *in situ* beta galactosidase in this control cell line, as well as the effect on transactivation of a second LTR linked indicator gene introduced by transient transfection will be described.

C.775

**COMPARISON OF SINGLE AND DOUBLE-LABELLING OF SLB1 AND MT2
 CELLS IN THE DETECTION OF HTLV-1 ANTIBODIES BY RADIOIMMUNOPRECIPITATION (RIP) AND IN VITRO INFECTION (IVIF).**

Marian T. Sullivan¹, Richard A. Johnson, and D.J. Slamon², ¹American Red Cross, Rockville, MD, USA, ²UCLA School of Medicine, Los Angeles, CA, USA.

OBJECTIVE: To determine if the sensitivity to HTLV-1 antibodies can be enhanced by a double-labelled lysate or infected cells. To evaluate Leu 5 as a substitute for Cys 1 in the labelling of viral antigens. To compare RIPA profiles from MT2 cells to a cell line of non-activator origin (SLB1).

METHODS: Samples known to display varying patterns of antibody reactivity were combined with either ¹²⁵I-Cys 1 labelled MT2 or SLB1 lysate, ¹²⁵I-Leu 5 or ¹²⁵I-Cys 1 labelled SLB1 lysate or ³²P-UTP of both ³²P-Cys 1 and ³²P-Met labelled SLB1 lysate. Antigen-antibody complexes were precipitated by protein A-Sepharose. Pellets were electrophoresed by SDS-PAGE and autoradiographed.

RESULTS: No samples displayed any additional antibody reactivities with Cys-Met than with Cys alone, and there was no observable difference in the intensity of bands. Lanes representing double-label treatment had greater non-specific background. Leu 5 substituted for Cys did not improve the detection of any viral-specific antibodies, despite the fact that Leu 5 is 5 times as common in the coding sequence. Using SLB1 viral products p24, p40, p55, and gp67 were present; MT2 did not produce detectable p40, p41, and gp67 but exhibited p24, p55 and gp68. The representation of viral antibodies in 25 positive samples was 20%/100%, 40%/70%, 65%/25%, and 66%/100%.

CONCLUSION: 1. ¹²⁵I-Cys-labelled-lysate is as effective in the detection of HTLV-1-specific antibodies as is ¹²⁵I-Leu or Cys-Met. 2. The SLB1 cell line provides better detection of anti-p24s than MT2.

C.777 SEROLOGIC ANALYSIS OF PROTEINS ASSOCIATED WITH AND PREVALENCE SEROEPIDEMIOLOGIC STUDIES OF TWO NOVEL RETROVIRUSES ISOLATED FROM AIDS-ASSOCIATED LYMPHOMAS.

No. Virella L., Khayat-Bassif F., Marsh J. and McGinn MS.
 University of California, San Francisco, and San Francisco General Hospital, San Francisco, California, USA.

Objectives: To determine the serologic relationship of the proteins associated with two novel retroviruses, 27F and 10C9, isolated from primary AIDS-associated lymphoma tissue to other known retroviruses, and to determine prevalence of exposure to these viruses in various populations at risk for retroviral infection.

Method: Immunoblot.

Results: Purified 27F, 10C9, HTLV-I (QIVP), and bovine leukemia virus (BLV) proteins were used as antigen sources for immunoblotting. Antibodies raised against 27F/10C9 p27 (candidate major virus core proteins) recognized HTLV-I p24, and antisera raised against HTLV-I envelope proteins recognized 50 kd proteins present in 27F/10C9 virus preparations. A small subset of each had limited reactivity with HTLV-I virus core proteins and BLV envelope proteins (p55G1), and did not react with HIV-1 proteins.

Conclusions: These results demonstrate that the 27F/10C9 viruses are serologically related to oncoviruses, not to leukemia, and provide evidence that exposure to these viruses has occurred in individuals in groups at risk for retroviral infection.

C.779 HIV-SPECIFIC HIV P24 ANTIGEN REACTION DUE TO BACTERIAL CONTAMINATION OF HIV ANTISERA

BARBARA B. PHILIPS, BR. LEWIS, A. J. JAMES, A. M. AND SPYRID. 87*
 *Tulane Medical Center School of Medicine, New Orleans, LA, U.S.A.
 *Tulane Medical Center School of Medicine, New Orleans, LA, U.S.A.

OBJECTIVE: To determine the source of HIV p24 reactivity in a series of tissue culture growth medium (TCM) used as matrix negative control in capture assay. **RESULTS:** A positive antigenic containment in a seronegativity clear TCM was amplified at 37°C for 48 hrs. The culture was reactivated in antigen-capture and the isolate was grown in fresh sterile TCM. P24 antigen reactivity was determined with commercial (Behring) kits in the test prior to and after centrifugation (100g, 30min), and in the filtrate (0.45 µm) centrifuge. P24 reactivity was also evaluated in samples from a culture of *ESCHERICHIA COLI* strains in TCM. P24 specificity test was as per 101 envelope.

RESULTS: The contaminant in the original TCM was identified as *ALCALIGES FACIOLIS*. The centrifugate and filtrate derived from the TCM with the microbial growth had p24 reactivities of 324 and 424 gpa/ml respectively. P24 reactivity of 110 gpa/ml was noted with the centrifugate from TCM with *E. COLI* growth. In specificity reactions with the centrifugate from TCM with *E. COLI* growth, in specificity reactions with the sample from the bacterial culture, no effect on the p24 reactivities associated with the sample from the bacterial culture. **CONCLUSIONS:** false positive HIV p24 reactivity in the antigen-capture assay may be related to microbial growth in test samples. Measurement of p24 antigenemia in samples from HIV-infected patients should be adequately controlled for possible bacterial contamination.

C.781 BIOLOGICAL FACTORS AFFECTING TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS

Robertson JL, Shillington CA, Davidson DJ, & Babus S, Jr
 University of Pittsburgh Medical Center
 Pittsburgh Drug Addiction Study, Pittsburgh, PA
 Biomedical Research Institute of Pittsburgh
 UNIV. OF PITTSBURGH

OBJECTIVE: To examine biological factors which affect heterosexual transmission of HIV, with particular reference to biological markers of infectivity.

RESULTS: Couples were identified whose sex partner (10 male, 2 female) was infected with HIV, and the other partner seronegative. The couples were followed for 12 months. The seronegative partner was exposed to the infected partner by vaginal intercourse. There was no evidence of barrier methods of contraception. All infections were acquired at least once in the 12 month period. In 11 cases, tests were carried out using commercial kits.

RESULTS: Virus was detected in lymphocyte cultures from 5 index cases, of whom 3 (60%) also had p24 antigen. One other index case also showed antigen but no virus. Among their sexual contacts 3 seroconverted during the study period 2 and 6 months after virus was first detected in culture. A third patient also yielded virus on culture and later had evidence of HIV DNA on immunoblotting but 12 months after the original test is still HIV antibody negative. In 2 out of 3 couples where transmission occurred the index patient was antiseronegative and all 3 index cases yielded virus from lymphocyte cultures on one of each occasion. In all 3 cases who showed evidence of seroconversion, virus detection was the earliest marker of infection.

CONCLUSIONS: In all 3 cases who showed evidence of seroconversion, virus detection was the earliest marker of infection. Virus detection in lymphocyte culture during the study period, and the presence of HIV DNA on immunoblotting, p24 seroconversion. Virus isolation was present in all transmitted, p24 seroconversion. The use of p24 antigenemia as an early indicator of infection (before antibody detection) is important, and the implications for subsequent heterosexual spread are discussed.

C.778 BUDDING FEATURES OF DIFFERENT MORPHOLOGIES OF HIV-1 PARTICLES FROM CELL CLONES ISOLATED FROM HIV-1-INFECTED MT-4 CELLS

GOTO Toshiyuki, IUTA M, ZHANG, J, JIWAHITO, S, and KAKAI, H*
 Osaka Medical College, Osaka, Japan, 426, and *University, Osaka, Japan,***Shaanxi Anti-epidemic Station, Xia, China.

Objective: To elucidate the viral maturation process. **RESULTS:** Cell clones were isolated from HIV-1-infected MT-4 cells. Cloned cells were observed by electron microscopy, and immunoelectron microscopy was also carried out using monoclonal antibodies and HIV-1-seropositive serum.

Results: The cell clones produced particles with different kinds of morphologies. Normal particles were produced from the cell surface by a budding process in which crescent-shaped structures first appeared beneath the cell membrane, and subsequently matured to a complete form with an electron dense core just before being released from the cell surface. Doughnut-shaped and teardrop-shaped particles were respectively produced by budding of the crescent shape with double-layers from the cell surface, and by the budding of a teardrop form with an electron dense core from the cell surface.

Conclusion: The morphological maturation of HIV-1 particles appeared to be complete just before their release from the cell surface in several cell clones producing differently shaped particles.

C.780 MACROPHAGE CULTURES DO NOT INCREASE FREQUENCY OF HIV ISOLATION OVER LYMPHOCYTES FROM HEMOPHILIACS

LEONARD BLOOM, RICHARD S. HANSEN, S.R. S. ANDERSON, A. AND HYNOP JR., N.E.
 Tulane University School of Medicine, New Orleans, LA, USA.

OBJECTIVE: To determine whether macrophages (MΦ) of hemophiliacs preferentially harbor HIV, since the frequency of virus isolation from hemophiliacs in many studies is lower than that from infected asymptomatic homosexuals.

Methods: Monocytes and lymphocytes from asymptomatic seropositive hemophiliacs and homosexual controls in PICOI-lysozyme fractionated blood mononuclear cells were separated by adherence to plastic culture dishes and panning of the unattached cells. The MΦ fraction was subjected to complement-mediated lysis with MAb Lea 50 to remove residual T cells. The two populations of cells were cocultured with GM-CSF treated MΦ or PHA-stimulated lymphocytes from seronegative donors. Harvests from the cultures obtained weekly for 4 weeks were tested for p24 by the antigen-capture assay.

Results: Under comparable cultural conditions, HIV recovery from the blood mononuclear cells of 5 homosexual controls and 5 hemophiliacs studied was as shown.

Conclusions: The reported lower frequency of HIV recovery from hemophiliacs is unlikely to be due to the virus being preferentially harbored by the monocytes.

	Monocytes	Lymphocytes
Controls	4/5 (80%)	3/5 (60%)
Hemophiliacs	1/5 (20%)	2/5 (40%)

C.782 EXPRESSION AND TRANSCRIPTION OF HIV PROMOTER IN BACTERIA

Wood, Charles and Kambhosi, F.
 Department of Microbiology, University of Kansas, Lawrence, Kansas, 66045 U.S.A.

Objective: To study the expression and transactivation of HIV long terminal repeats (LTR) in a bacterial system.

Methods: A recombinant plasmid construct of the HIV-LTR linked to an indicator gene, chromosomal acetyl transferase (CAT), was transformed into *E. coli*. The expression and transactivation of the HIV promoter in the presence and absence of tat, was followed by assaying the level of CAT enzyme.

RESULTS: We have demonstrated that HIV-LTR can also function as a promoter in *E. coli*. The HIV-CAT plasmid can express the enzyme efficiently upon transformation into bacteria. The bacterial transcriptional start site was mapped by using base nuclease analysis. HIV-LTR, besides being fully functional in *E. coli*, can also be specifically transactivated by the HIV-tat gene product. Transactivation can be demonstrated by an increase in CAT enzyme activity as well as an increase in the level of CAT mRNA. **Conclusion:** This specific transactivation of HIV-LTR by tat protein in bacteria will provide a useful system to further investigate the specific interaction between the tat protein with the HIV-LTR and the mechanisms used for transactivation.

C.783 IMPORTANCE OF STRUCTURAL ELEMENTS OF HIV GP120 ON CD4-BINDING ABILITY
 Hoshino, Anna¹, Holmseth, A.¹, Flodby, P.¹, Lundberg, L.¹, and Oldeman, P.²
¹Department of Clinical Virology, University of Örebro, Örebro, ²Department of Immunology, Karolinska Institute, Stockholm, Sweden
 Biochemistry and Biophysics, Chalmers University Technology, Örebro, Sweden.

Abstract: The CD4-binding region of HIV gp120 has been mapped to a peptide stretch situated between aa 376 and aa 440. The aim of this study is to identify structures within this region, which are important for the ability of gp120 to bind to the CD4-receptor.

Analysis: Site-directed mutagenesis was used to introduce mutations within the CD4-binding region of gp120. Target structures were 1) cysteines, which are very conserved among HIV-1 isolates, hence indicating that they could be involved in disulfide bonds important for the three-dimensional conformation of the protein; 2) glycosylation sites, which surround the putative binding loop of gp120, thereby maybe protecting the binding region. Mutants were analysed in vitro by detecting a gp120 expression vector, containing the mutant gene, onto CW-1 cells. CD4-binding ability was examined in an *in vitro* assay.

Results: Changing cysteines to a serine resulted in a protein unable to bind to CD4-receptor in the *in vitro* assay. Moreover, the protein had an altered electrophoretic mobility probably due to structural changes in the protein. In conclusion, the ability to bind to CD4-receptor is dependent on the presence of cysteines and glycosylation sites. Cysteine mutation or its caused indirectly by protease.

Conclusions: Cysteines are important for the three-dimensional conformation and hence the biological function of gp120. Our results show that gp120, which has low glycosylation, is extremely sensitive to changes in its conformation, since mutating only two cysteines results in a protein susceptible to protease attack.

C.784 HUMAN IMMUNODEFICIENCY VIRUS (HIV) EXAMINED BY NEGATIVE STAINING: MORPHOLOGY AND ANTIGENICITY.
 Gattell, Ian¹, Barilak, Jane E., and Bartlett, J.S. Department of Virology, Dental Medical and Dental Schools of Guy's and St Thomas', St Vincent & Carsons, London, United Kingdom

negative staining EM has proved less rewarding than thin sectioning in the study of HIV morphology and antigenic structure. This may, in part, be due to the clinical need of HIV with the propagating cell making it difficult to obtain good preparations of isolated virus. However, when HIV-1 infected cells (CD 4-2/CD45) are gently homogenised in a Triton-bead-type classification homogeniser surface located virus is sheared off and can be concentrated by simple differential centrifugation. The particles so obtained are neatly clumped and very little internal morphology is visible. However the greater number of particles isolated make it possible to classify the immature virus particle which contains a spherical, detergent shaped core.

Optimal treatment of the semi-purified virus with a mixture of detergent (Sorbitol 140) and glutaraldehyde both releases and stabilises the 22' outer coat shaped component. Concentrations of both detergent and amount of antigenically reactive cores are available for immun EM. These HIV-2 cores react positively with their corresponding human antibodies giving rise to classical immune complexes. These complexes contain various aberrant forms of the cone shaped core ranging from a sheet like form to classical elongated rods. Their presence within the aggregates establishes that, antigenically, they are similar to, if not identical with, the standard cone shaped internal component. The isolated cores also reacted positively with a mouse monoclonal antibody directed against p16 (HIV-1) which reacts also with p16 (HIV-2).

C.786 FAILURE TO DETECT HIV-1 PROTEINS AND DNA IN
 ENTOZOAEMA HISTOLYTICA STRAINS ISOLATED FROM
 PATIENTS WITH HIV-1 INFECTION

Chr. C. Meyer¹, G.D. Burchard², F.T. Hufen², D. Berzow¹, H. Schmitz¹

¹Type of Virology, Bernhard-Noke-Institut für Tropische Medizin, Hamburg, F.R.G.

²Clinical Dept., Bernhard-Noke-Institut für Tropische Medizin, Hamburg, F.R.G.

Objective: To detect HIV proteins and proviral HIV DNA in Entamoeba histolytica strains isolated from patients with HIV-1 infection and from E. histolytica cultures fed with HIV-1 infected lymphoblasts. In order to characterize E. histolytica strains from HIV infected patients, it is important to know, whether these strains are HIV-1 positive. To answer this question, we characterized 3 E. histolytica strains isolated from 3 patients with HIV-1 infection and tried to detect E. histolytica cultures (DNA) by using three well known HIV-1 related lymphoblast (LH), human/lymphoblast antigenometry and the polymerase chain reaction for the detection of viral protein and proviral DNA were applied.

Methods: Isolated E. histolytica strains were cultured in TY296 medium, HEM-1 was cultured in TY293 medium.

Immunofluorescence microscopy was applied to detect viral antigenic material in the amoebae.

For the Polymerase Chain Reaction (PCR) DNA was extracted from blood cells and from E. histolytica, both

from HIV-1 infected patients. For the DNA amplification we used different regions of the HIV-1 genome for general detection (gap region: 8K 12, 8K 20/22) and virus region (8K 7a, 8K 8/9) according to the

primer and primer described by Ch et al. Amplification was performed within 30 cycles. DNA was demonstrated at 5'p C.

Results: By immunofluorescence microscopy viral proteins were not detectable neither in the isolated strains nor

in E. histolytica cultures, fed with HIV-1 infected LH cells after two weeks of cultivation. Applying the PCR, we could not find out, that all three primers were positive using the gap (8K 12) and the virus (8K 7a) gene fragments

as a target. However, no proviral DNA could be detected in DNA samples extracted from E. histolytica, isolated

from three patients in the interest E. histolytica cultures.

Conclusion: E. histolytica can be excluded from transmission routes of HIV-1 and occurs also as possible HIV

transmission by E. histolytica is not justified.

C.787

RELATIONSHIP OF OTHER INFECTIONS TO PROGRESSION OF DISEASE
IN HIV INFECTED MEN

Lesch, C., Jentink, Roger, Giorgi, J., English, P., and Cherry, J., University of California at Los Angeles (UCLA) Schools of Public Health and Medicine, Los Angeles, California, U.S.A.

To determine the relationship of other infections to changes in immune status and risk of AIDS, specimens for isolation attempts for CMV, HSV-2, adenovirus, *Streptococcus urealitidis*, and *Mycobacterium hominis* were collected 6 months apart in 222 HIV-1 antibody positive men participating in a cohort study of HIV-1 infection since 1984. Corresponding antibody titers to CMV (IgG and IgM), HSV-2, adenovirus, HSV, *Chlamydia*, HIV, and measles are being determined. At baseline, CMV was isolated from 63% of semen specimens, 5% of urine specimens, 5% of rectal swabs, and 5% of buffy coat cells. Isolation of CMV from semen at the baseline visit was associated with receptive anal intercourse, but not with isolations of HSV, *M. hominis*, U. urealitidis, HIV or adenovirus. The mean number of CD-4 cells and the mean CD-4/CD-8 ratio was significantly lower among HIV antibody positive men who shed CMV in their semen than in men who did not (p<0.005), but there was only a weak correlation between the titer of CMV virus in the semen and number of CD-4 cells. Semen excretion of CMV has persisted for six months in most men with positive cultures at baseline. Rates of isolation of HSV-2, adenovirus, U. urealitidis and *M. hominis* were low. Results of serologic and isolation studies at both visits will be presented in relation to other factors in these men. Implications of the association of low levels of CD-4 cells with isolations of CMV from semen will be discussed.

C.788

C.789

REGULATION OF REPLICATION OF HIV-1.
 Haselme, William. Dana-Farber Cancer Institute, Harvard
 Medical School, Boston, MA USA

Regulated growth of the Human Immune Deficiency Virus Type-1 (HIV-1) is the hallmark of infection with this virus. Prolific replication followed by a prolonged period of controlled replication followed once again by prolific replication is characteristic of most HIV-1 infections. The controlled aspect of the HIV-1 infection represents interactions between the virus and host immune system as well as viral regulatory genes which determine where, when and how much virus will be produced within a particular cell lineage. A systematic discussion of these interactions which occur at the level of control of synthesis and processing of messenger RNA, and of virion assembly and budding, and of the specific infectivity of the viral particle will be presented. Specifically the role of the *zif*, *zra*, *rat*, *rxr* and *raf* genes in the control of viral replication will be explored.

M.D.0.7

EPIDEMIOLOGY OF AIDS IN ADOLESCENTS, U.S.A.
Carli, Holmes, Reiser, P., Roper, M.
Centers for Disease Control (CDC), Atlanta, GA, USA

Objective. To describe the epidemiology of AIDS in adolescents in the United States.

Methods. We analyzed demographic features and transmission categories for adolescents (13-19) with AIDS reported to CDC.

Results. Adolescents aged 19 years or younger comprise 0.4% of the total reported AIDS cases; 50% of these cases have been diagnosed since 1986. Most of the adolescent AIDS cases (54%) were reported from 5 states and Puerto Rico and 74% from urban areas with populations greater than 1,000,000 inhabitants. Eighty-two percent of adolescents with AIDS are male and 51% are black or Hispanic. Overall, 54% of cases were attributed to sexual contact or intravenous (IV) drug use, 39% to exposure to blood or blood products and 4% to undetermined exposure. Heterosexual contact was the most frequent route of transmission for females. Accounting for 3% of cases, sexual contact or drug use accounted for 37% of cases for blacks and Hispanics and 40% for whites. The proportion of cases due to sexual contact or IV drug use increased from 10% for 13-14 year olds to 56% for 17-19 year olds.

Conclusions. Although adolescents comprise 1% of all AIDS cases, many adolescents may be at risk for HIV infection now and in the future. Our findings suggest that urban youth, particularly minorities may be at highest risk of exposure to HIV infection. Targeting interventions to adolescents with behaviors that place them at high risk of HIV infection is important. Helping all adolescents to develop safe sexual behaviors and avoiding drug use will have a major impact on the future of the AIDS epidemic.

M.D.0.9

THE SIGNIFICANCE OF THE AIDS PARADOX FOR HOMELESS ADOLESCENTS
Lynch, S., Galanter, Brown, N.C. and Rosenbaum, R.
*University of California, San Francisco, California, USA
**Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil

Objective. This paper reviews social epidemiological research on AIDS related attitudes, beliefs, and behaviors among street youth in the Western United States and in Rio de Janeiro, Brazil. This discussion will focus on the risk of HIV infection among street youth in developing countries, within the context of the larger world problem.

Methods. Ethnography and participant observation, structured and unstructured interviews with street youth and service providers in natural and institutional settings in Los Angeles, San Francisco, Seattle and Rio de Janeiro.

Results. While the majority of youth in the United States live above or with their families, Brazilian youth leave their homes because of extreme poverty and familial misery to make what living they can on the streets. Many through prostitution. Street youth in Rio, especially those from the slum areas of favelas, lack the long history of health education in schools, the community, and the media as compared to the United States. They are at risk for HIV infection because of their perception that AIDS is only a homosexual disease, concurrent exposure and discomfort they associate with condom use, and subsequent unprotected sexual activity. Bilingual activity and small intercourses are common among both heterosexual and homosexual street adolescents in Brazil, while cultural beliefs would dictate otherwise.

Conclusions. International collaboration and emergency economic support can assist greatly in the development of education material and outreach to prevent HIV among the growing number of street youth in the developing world.

M.D.0.11

Sex, Drugs and AIDS: Two Innovative Approaches to HIV/AIDS Prevention and Outreach for Minority Adolescents.
Troiano, Adelman*, Ball, J.V.**

*Newark Department of Health, Newark, N.J., USA; **NYC Health and Hospitals Corp., New York, NY & Greater Brooklyn Youth Council, Inc., Brooklyn, NY, USA.

Objective. To provide HIV/AIDS educational and outreach services to minority adolescents and to evaluate the effectiveness of these services and the beliefs concerning sex, drugs and HIV/AIDS through two innovative programs in Newark, New Jersey and Brooklyn, New York.

Methods. The Newark Department of Health program has four components. Three directly involve adolescents which are: (1) a original "Rap Off" contest on sex, drugs and AIDS; (2) a "Street Theater" program in which a professional production company will perform a teen theatre company which will perform an original scripted production on sex, drugs and AIDS for teens; and (3) peer counseling will be provided for adolescents. The fourth component, a professional video production will document the prior 3 components. The Brooklyn-Brownsville program trains 10 peer educators in sexuality, substance abuse, HIV/AIDS information and risk reduction strategies, and improvisational theatre techniques. Peer educators present role plays and skits on sex, drugs and HIV/AIDS to youth groups, organizations, community centers and parent associations. KANB surveys are distributed by both groups.

Results. Initial results indicate that minority adolescents (1) are concerned about their risks of HIV/AIDS; (2) have some AIDS specific knowledge but also have misconceptions and (3) want to help educate their peers regarding HIV/AIDS. Culturally sensitive and relevant HIV/AIDS information for minority adolescents must use innovative approaches to educate them on risks.

M.D.0.8

ADOLESCENTS AT RISK OF HIV INFECTION

Radford, Jagan*, Warren, V.P.* and King, A.*

*Queen's University, Kingston, Ontario, Canada.

Objective. To describe the AIDS-related knowledge and attitudes, and the risk-taking behaviours, of youth who had dropped out of school and lived on the streets of large Canadian cities.

Methods. Over 1,000 "dropouts" and over 700 "street youth" across Canada were interviewed by telephone and face-to-face, respectively. The data were analysed to assess the extent to which they were at risk of HIV infection.

Results. Many of these young people were knowledgeable, yet anxious, about AIDS, intolerance of homosexuality, sexually repressed and highly active sexually, and some of them were using illicit drugs.

Conclusions. The high incidence of unprotected sexual intercourse with numerous partners and the sharing of injection-drug needles indicate that these young people are at risk of HIV infection. Persuading them to abandon behaviours that are integral to their lifestyles will be difficult, but must be attempted.

M.D.0.10

INFECTION WITH HIV AND HIV IN ADOLESCENTS LOGGED IN SECURITY INSTITUTES OF BRASIL
Ribeiro, L.C., Cruz, A. & Almeida, M.C.

*Hospital de Ginecologia, São Paulo, São Paulo, Brazil
**National Directorate for the Promotion of Youth and Family, *Ministério Federal de Administração, **Departamento de Microbiologia, School of Medicine, Saõ Paulo, Saõ Paulo, Brazil.

Objective. To determine the prevalence of infection with HIV and HIV in adolescents lodged in Security Institutes and relate it to different risk factors.

Methods. The sera of all adolescents lodged in 3 national Institutes of Saõ Paulo from October 1987 to July 1988 were studied. In every case there was previous consent of the adolescent, as well as from the entity which legally protects them, to detect anti-HIV and HIV antibodies and to fill in the questionnaire about the risk factors. Anti-HIV and HIV antibodies were studied by ELISA method, anti-HIV were confirmed by Western blot.

Results. 158 adolescents (64 females and 94 males) whose ages ranged between 13 and 20 years were studied. 26.6% were positive for HIV and 26.6% for IgG. When 100% of both cases 13% were HIV positive and 52.9% non-HIV positive while there was a prevalence of 2.3% for HIV and 10.2% for HIV among non-adolescents or non-internation students. Of all the adolescents studied, 14 stated they were non-adolescents of which one was HIV positive and 2.9% positive.

	Number	HIV+	HIV-	Total
IVA	71	39/71 (55%)	32/71 (45%)	71
Non-adolescent or non-IVA	86	2/86 (2.3%)	84/86 (97.7%)	86
TOTAL	158	40/158 (25.4%)	118/158 (74.6%)	158

Conclusion. HIV antibodies were detected in 1/6 and HIV in 1/3 of the adolescent population in Security Institutes. Of the total population 40% used TDAM and this was, by far, the main risk factor found for infection with HIV and HBV.

M.D.0.12

THE DEVELOPMENT OF A STREET BASED OUTREACH PROGRAMME TO REACH YOUTH MALE, FEMALE AND TRANSGENDER, STREET BASED PROSTITUTES IN SYDNEY, AUSTRALIA

Crane, S., Toomey, M., Allen, S., Gold, J., Tarbit, P., Ryan, P., Reddy, P., et al.

Albion Street (AUS), New South Wales, Sydney Australia

Objective. (a) To ascertain the prevalence of HIV infection within a group of street based male, female and transsexual prostitutes; and (b) To develop an intervention programme to minimise transmission of HIV by this group. **Methods.** In November 1985 a mobile outreach bus program was established to provide HIV screening, counselling, education and the provision of free condoms, needles and syringes to street based prostitutes. The programme operates 365 nights a year, early evenings to early mornings in the streets of Sydney's "Red Light" districts. The outreach service is staffed by nurses and counsellors. **Results.** As at December 1988, 213 clients had been screened for HIV. 19 were HIV antibody positive (15 male prostitutes, 1 female prostitute, 3 transsexual prostitutes). 187 had used IV drug, 155 were current users, 17 were HIV antibody positive. Five clients re-screened during the 3 year period. An average of 2,000 condoms and 1,500 needles/syringes are given out per week. This paper will discuss the risk factors associated with the client group and highlight educational issues raised by the seroconversions. **Conclusions.** A street based outreach program is an effective way of minimizing transmission and providing client support who are otherwise disfranchised from existing health services due to, illiteracy, low socio-economic grouping and general alienation from established health services.

Colloque Symposium

Le SIDA et l'individu AIDS and the Individual

Détenus : contraintes et défis Prisoners: Constraints and Challenges

T.D.O.1 RAY IN PRISON - A TEST CASE FOR HUMAN RIGHTS
T. Harding
University Institute of Legal Medicine, Geneva,
Switzerland.

The AIDS epidemic has revealed grave deficiencies in prison health care. Prisoners are a vulnerable group, subject to an authoritarian regime and with little public sympathy. In over half the countries surveyed in a European study, inappropriate management of HIV-infected prisoners was described as routine: segregation, limited access to work places, lack of confidentiality. Compulsory screening of prisoners is also carried out in many countries, and results are frequently communicated to prison administrations without the prisoner's consent or knowledge.

Prisoners have a right to preventive and curative health care on the same level as in the community.

All prisoners should (i) receive adequate information on HIV/AIDS, (ii) be free to request or refuse HIV-testing, after counselling.

(iii) benefit from pre-release education and guidance.

HIV carriers should (i) receive appropriate psychosocial support, (ii) be housed and treated as other prisoners, (iii) benefit from normal parole procedures.

Prisoners with AIDS should (i) receive adequate care, (ii) be considered for early release, (iii) be allowed to die in dignity.

The degree to which prisoners' human rights are respected will demonstrate the authenticity of governmental commitment to human rights promotion in AIDS-related activities.

T.D.O.3 AIDS AND INTRAVENOUS DRUG USERS: THE CHALLENGE FOR THE JAIL ADMINISTRATOR
THOMAS, STEVEN G., DEPARTMENT OF CORRECTION
NEW YORK, NEW YORK

An administrator of a correctional system is confronted with a difficult challenge to provide appropriate AIDS prevention and treatment services to a large number of inmates with a history of IV drug abuse, without compromising the operation of a secure correctional setting.

One 6th of New York City's jail population abuses illicit drugs and/or alcohol regularly, and about 30% of them have used drugs intravenously. Given these extraordinary rates of drug abuse and addiction, an estimated 20% of the inmates are infected with HIV.

The New York City Department of Correction has implemented an extensive range of AIDS and drug prevention and treatment services, which reflects a willingness to respond to this epidemic in a creative and flexible manner. The use of illicit drugs in the jails is prohibited and strict enforcement measures are used to ensure compliance by both staff and inmates. In addition, the Department offers methadone detoxification and methadone maintenance programs for opiate addicts and an array of intervention programs (including acupuncture) for crack/cocaine abusers.

Although significant, the services for intravenous drug users provided by the New York City Correctional system are only as effective as the long-term treatment and other services available in the community. More inmates leave jail and return to the same high-risk activities because no alternative treatment and other preventive services are available.

T.D.O.5

APPROACHES TO THE SEROPOSITIVE PRISONER
Lester, Elizabeth, Medical Director, San Francisco County Jails; University of California, San Francisco, USA

OBJECTIVE To review current practices in the identification and management of seropositive prisoners. To suggest a rational, safe and humane approach.

METHODS A review of current policies in United States correctional facilities of screening and testing inmates for HIV antibody will be undertaken with reference to National Institute of Justice and American Civil Liberties Union surveys. Policies and procedures for special management of identified seropositive prisoners will be reviewed, with the National Institute for the study of segregation. A review of the San Francisco jail policy and procedures will be presented.

RESULTS In the prison environment, limited resources tend to be directed either towards procedures of testing and serological testing, or towards education and counselling. Variables for policies of segregation are frequently correctional rather than medical. Proper correctional classification and supervision of prisoners are essential for a safe prison environment.

CONCLUSIONS The essential information which AIDS education programs impart. HIV infection may be prevented by safe behavior, HIV is not causally transmitted, are contradicted by policies of segregation. Policies should be based upon medical rather than correctional reasoning.

T.D.O.2 RISK BEHAVIOUR IN PRISON: SEXUAL ACTIVITY MEASURED IN PRISON
Crawley, Bruno, Service Médico-psychologique
régional, Lyon (FRANCE), FRANCE.

T.D.O.4 CONSTRAINTS ON IMPLEMENTATION OF PREVENTIVE MEASURES IN PRISON

Bray, P. J., Deputy Director of Prison Medical Services,
England and Wales, Home Office, London.

The factors which influence AIDS prevention strategies for prison systems, and how they are implemented, will be discussed by reference to experience in England and Wales.

The environment.

The population.

Attitudes of prisoners (uninfected and infected) to AIDS/HIV.

Attitudes of staff.

Attitudes and preoccupations of management.

Limits to confidentiality.

Credibility of information and education.

The law and the prison discipline code.

The closed single sex institution.

Recherches sur le comportement (partie 2)

Behavioural Research (Part 2)

T.D.O.6 RECEIVED NEED FOR BEHAVIORAL CHANGE: DETERMINING BARRIER CONCEPTS AT RISK OF HIV INFECTION BY A LONGITUDINAL COHORT OF GAY AND BISEXUAL MEN. **John D. Coates, Richard B. St. O'Neill, Ph.D., James P. B. Rowe, Ph.D., James Coates, Ph.D., Centers for Disease Control, Atlanta, GA., USA.**

Objective: In a longitudinal cohort study of gay and bisexual men, to assess the relationship of perceived need for behavioral change with knowledge, attitudes and beliefs (KAB), and with actual modifications of high-risk sexual behavior.
Methods: A questionnaire assessing HIV risk behavior and KAB was administered to study participants at initial visit and six month intervals. From December 1986 through December 1988, 700 men were enrolled, of whom 226 had returned for at least 3 visits. Subjects were grouped according to their perceived need for change at each of 3 time points, and those falling in the extreme categories (those most to change [MC] versus as need to change [NC]) were selected for analysis. Between group comparisons were made regarding risk-related behaviors and discriminant function analysis was used to determine the discriminating KAB characteristics of each group.
Results: The MC group had 2.7 times as many sexual partners at each time point (p<0.001) and used condom less frequently than did the NC group (p<0.001). Discriminant analysis of KAB successfully classified 80% of subjects into the MC or NC groups. Factors which discriminated MC from NC included lack of perceived validity of education from local gay organizations, difficulty seeing one's need, absence of assertiveness and communication regarding safe sex practices, concern over drug/alcohol use, and need for condom during anal intercourse.
Conclusions: Gay men are able to correctly assess personal risk of HIV infection and it is possible to predict those who need to change their high-risk behavior by assessment of KAB systems. Specific behavioral interventions targeting motivation, communication skills, and coping should address issues that predispose to high-risk sexual behaviors.

T.D.O.8 RISKY SEX RELAPSE: THE NEXT CHALLENGE FOR AIDS PREVENTION PROGRAMS: THE AIDS BEHAVIORAL RESEARCH PROJECT
Estimation: J.J. Gelles, L.J. and McQuaid, L., Center for AIDS Prevention Studies, San Francisco, CA., U.S.A.

Objective: Research on other health-related behaviors such as smoking, drinking and weight loss has shown that initial health behavior change is often followed by relapse. This study was designed to examine the stability of individual behavior change following initial adoption of safe sex as well as psychosocial predictors of relapse.
Method: A sample of 483 gay and bisexual men was followed annually from 1984 to 1987. High risk sex was defined as unprotected anal intercourse with multiple partners. Predictor variables included social support, personal efficacy, sexual self control, knowledge of health guidelines, and openness about one's sexual orientation. These were examined in a multiple logistic regression comparing subjects who relapsed to those who were able to maintain low risk behaviors over time following initial behavior change.
Results: The individual behaviors over time were grouped into the following behavior patterns:

BEHAVIOR PATTERN	PERCENT
Stable low risk throughout the study	50.8%
Changed to and maintained low risk behaviors	29.8%
Relapsed after initial behavior change	19.7%
Stable high risk throughout the study	9.8%

Subjects who relapsed reported lower levels of self efficacy and less social support for safe sex behaviors than did subjects who were able to maintain safe sex behaviors.
Conclusion: It is clear from these data that future AIDS prevention programs need to include relapse prevention components to increase the likelihood that behavior change will be maintained over time. The predictor analysis suggests that it may be beneficial to address social support and self efficacy issues in these interventions.

T.D.O.10 TENSION REDUCTION EXPECTANCIES UNDERLIE THE EFFECT OF ALCOHOL USE ON AIDS-RISK BEHAVIOR AMONG BISEXUAL MALES
Estimation: David L. Reardon, Ph.D., *University of Illinois at Chicago, **University of Alabama at Birmingham, USA

Objective: Alcohol use is associated with AIDS-risk sexual behavior. Also, but "disinhibiting" in the sense underlying this association, but has not been well defined. We found tension reduction expectancies of alcohol effects to be related to risk for substance abuse and sexual risk. We hypothesized that such expectancies would also underlie the sexually disinhibiting effects of alcohol. Our objective was thus to assess the co-occurrence of alcohol and high risk sex, and to examine the role of such expectancies in mediating this relationship.
Methods: A large (n=2600) diverse sample of homosexual men were given an anonymous survey regarding alcohol use, sexual behavior, and psychosocial variables. This was accompanied by a smaller (n=67) in-depth interviewee sample.
Results & Conclusions: 54% of respondents reported some unsafe sex. A majority of these respondents reported alcohol disinhibition, an incident that was independent of "passion" or other factors. Alcohol problems, intoxication rates, alcohol use in sexual contexts, and tension reduction expectancies consistently predicted number of sexual partners and unsafe sexual practices. Tension reduction expectancies were strongly related to alcohol use in sexual contexts, with either habitual or new partners. Finally, alcohol use variables were consistently associated with expectancies in predicting unsafe sex, consistent with the hypothesis. These findings suggest a mechanism of alcohol disinhibition, and an avenue for prevention or intervention.

T.D.O.7 SITUATIONAL FACTORS ASSOCIATED WITH AND RATIONALIZATIONS EMPLOYED TO JUSTIFY UNPROTECTED INTERCOURSE IN GAY MEN
Gold, R., Skinner, M., Grant, D., and Plummer, D.
*Cairns University, Victoria, Australia, **Victoria AIDS Council, Melbourne, Victoria, Australia, ***Monash University, Melbourne, Victoria, Australia**

Objective: Investigate (a) the situational variables that distinguish between sexual encounters in which gay men (n) engaged in (1) abstinent from, unprotected anal intercourse; and (2) the rationalizations these men employ at the time to justify unprotected intercourse.
Methods: Gay men were asked to recall two sexual encounters in the past year one in which they had unprotected intercourse ("unsafe encounter" or UE) and one in which they remained a strong desire to do so the "safe encounter" or SE). For each encounter the respondent was asked when it took place and with whom. Each encounter was then divided into (a) when the "evening" (or morning) etc began; (b) when the respondent met his partner; (c) at the start of sex; (d) during sex. For each of these, the respondent was asked about location, his feelings, alcohol and drug consumption, and whether the question of safe sex was raised. For UE the respondent also identified any rationalizations he used for unprotected intercourse.
Results: Key findings were: (a) For respondents who described both SE and UE (n = 181) the latter was more likely with a lover, the former with a casual partner. (b) With the difference controlled for (100), factors which distinguished UE from SE were in UE there was a greater desire for unprotected sex from the start of the evening, greater feeling of being alert and relaxed by reflex and desiring excitement, greater physical attraction and less communication about safe sex. Consumption of alcohol and drugs did not distinguish UE from SE. (c) Respondents reporting UE (n = 139) employed only risk rationalizations, the most common being the thought that intercourse would take place without ejaculation.
Conclusion: The findings can be used to inform AIDS education strategies.

T.D.O.9 PSYCHOLOGICAL STATUS AND RISK BEHAVIOR IN MEN SEEKING HIV TESTING
Psychologist: Fishman, R.; Perry, S.; Jacobson, B.L. and Ryan, J., Cornell University Medical College, New York, NY, USA

Objective: To examine the hypothesized relationships between HIV risk behavior, psychological variables and effects of HIV testing.
Methods: 154 psychologically asymptomatic gay men voluntarily sought HIV testing and were evaluated with clinical ratings of psychiatric diagnosis (SCID-R), and self-report measures of risk behavior, hardiness, social support, attributional style and distress (Beck Depression, Brief Symptom, and Spillanberg Inventory Inventories). Risk behavior and distress measures were reported 9 weeks after notification and counseling.
Results: 132 subjects (86%) reported no unprotected Anal Sex (UAS) in the 3 week period to HIV testing; of 79 subjects seen 9 weeks later (28 HIV+), 75 continued to abstain from UAS. 23 subjects (14%) engaged in UAS in the month prior to testing; of 11 subjects seen 9 weeks later (27 HIV+), all had abstained from UAS in the past month. Psychological variables and serological status did not distinguish the two behavior groups at either measurement point.
Conclusions: Most participants ceased high risk behavior at least one month prior to HIV testing. This "floor effect" impeded determining the relation between risk behaviors, psychological variables, and effects of HIV testing and counseling. This study documents the need for prospective studies to determine if risk reduction surrounding HIV testing is sustained over time, and low psychological factors and known HIV status predict possible relapse.

T.D.O.11 HIV RISK BEHAVIOR SCREENING: CONCURRENCE BETWEEN ASSESSMENTS THROUGH INTERVIEWS AND QUESTIONNAIRES
Estimation: Roger Levy, James H. Stewart, Ph.D., Centers for Disease Control, Atlanta, Georgia, USA

Objective: To determine level of agreement between assessments by self-administered questionnaire and face-to-face interview, of HIV risk behaviors in two groups and individuals.
Methods: A sample of 336 women attending a family planning clinic responded to the same questions through a self-administered questionnaire and a face-to-face interview, for each HIV interview coded reasons for discrepancies between the two responses were recorded.
Results: 1. Prevalence of HIV risk behaviors in the group, as determined by the two methods were remarkably similar; the maximum difference between the two estimates for any risk behavior was 1.3 percentage points, for the proportion of individuals reporting more than 3 partners in the last 10 years. 2. Individuals' risk behaviors were assessed with less agreement between the two methods; 15 women (4%) reported risk behaviors on the questionnaire which they denied during the interview; 6 women (2%) did the reverse. Also, twice as many women (8%) reported greater numbers of sex partners during the interview compared to those who reported greater numbers on the questionnaire (4%). 3. Discrepancies between assessments did not differ by demographic characteristics.
Conclusions: Prevalence of HIV risk behaviors in a group are similarly assessed by self-administered questionnaires and face-to-face interviews. However, these two methods can yield highly discrepant findings in assessments of individuals' risk behaviors.

T.D.O.12 IDENTIFICATION, RECRUITMENT AND RETENTION OF BLACK AND LATIN COMMUNITY LEADERS IN AIDS PREVENTION RESEARCH

Monica Edwards and Fulvia, Review: Hunter's Point Foundation and Center for AIDS Prevention Studies, University of California-San Francisco, CA, USA.

Multicultural Inquiry and Research on AIDS, Bayview Hunter's Point Foundation and Center for AIDS Prevention Studies, University of California-San Francisco, CA, USA. **Objectives: This presentation examines the issues related to identification, recruitment and retention of Black and Latin community leaders in a research effort designed to evaluate the impact of AIDS education on the AIDS-related activity level of these leaders.

Methods: A list of Black and Latin community leaders in San Francisco was compiled consisting of elected officials, directors and administrators, appointed officials, clergy, and persons who were acknowledged as community leaders by two or more persons of the other categories. Subjects were contacted by letter with a follow-up telephone call to solicit participation. Reasons for not participating were recorded. Those agreeing to participate were randomly assigned to one of two conditions, a four session workshop on AIDS in their respective communities (Black or Latin) or receiving an AIDS information manual. **Results:** Of the 168 leaders identified, 84 (50%) agreed to participate; of those 46 (57%) formally entered the trial, of whom 22 were Black and 24 were Latin. Reasons for non-participation were examined and included: reluctance to be involved with an AIDS activity, "burnout" from AIDS work, has against people with AIDS and reluctance to commit time to the research activity.

Conclusions: While it is widely agreed that increased involvement of Black and Latin community leaders would improve prevention and education activities, this study identified major obstacles to their involvement. Minority community leaders may not see AIDS as a pressing issue and may have biases against people with AIDS. These attitudes require recognition in developing AIDS prevention activities.

T.D.O.14 INVOLVEMENT OF NATIVE HEALTH-CARE PROVIDERS IN DEVELOPING AIDS PREVENTION STRATEGIES FOR NATIVE PEOPLES

Morgan, J., Rekart, M.,* Harris, D.***

*Division of STD Control, British Columbia, Vancouver, British Columbia, **Vancouver Indian Centre Society, Vancouver, British Columbia, Canada

Objective: To develop an AIDS prevention strategy for Native population of the Province of British Columbia.

Methods: A representative Planning Group of Native health-care and human services providers from around the province was convened to develop a proposal for an effective AIDS program for the Native community. A "non-political" approach was taken in choosing Native providers rather than Native policy-makers to develop the program. A strategy was developed through meetings of the Planning Group. Funding, logistical and advisory support was provided by the provincial and federal governments.

Results: Consensus was reached on several general principles to be established as a basis for the strategy. The program would be 1) Native developed, implemented and owned, 2) designed to reach all Natives irrespective of status or place of residence, 3) generic in graphic design while remaining recognizably Native, 4) focused on AIDS while also addressing other forms of social malaise in the Native community and, 5) followed by a sustained AIDS prevention resource. Based on these guidelines a proposal was developed that included videos, posters and pamphlets, community presentations and workshops, and a large conference. **Conclusions:** Giving the task to health-care providers from the Native community is an effective way to develop AIDS prevention strategy for the Native population.

T.D.O.16 REACH OUTREACH PROGRAMS TO AIDS

Dillon, E.J., Barr, Dr. G.**, Perreault, Y.***

Ontario Association of the Deaf, Toronto, Ontario, Canada, *Canadian Hearing Society, Toronto, Ontario, Canada

***AIDS Committee of Toronto, Toronto, Ontario, Canada

Objective: To describe the formation and development of a joint project on AIDS and Deafness established to enable the deaf community to access AIDS information.

Methods: Information gathered during the initial phase of the project revealed: 1) 18,000 profoundly deaf persons in Toronto whose primary language is American Sign Language generally have limited English skills, usually below grade 4 level. Thus, current AIDS materials are inaccessible. 2) AIDS information is passed socially from 1 deaf person to another rather than through mass media. Misconceptions are spread quickly and are extremely difficult to challenge without direct access to deaf social networks. 3) Models of community development used by most AIDS organizations are not appropriate for the deaf community. Evaluation with key deaf leaders led to the restructuring of the project design.

Results: The service delivery model developed is congruent with the structure and needs of the deaf community and utilizes a cross-cultural approach of mediation, advocacy and culture-brokering. 14 deaf men and women from a variety of social groups (deaf gay networks, sports groups, clubs and informal groups based on ethnicity, communication modality and educational background) are trained as paid consultants to provide actual services.

Conclusions: Consistent liaison between the deaf community is critical to the development of a culturally-relevant, cost-effective and efficient AIDS and Deafness Program.

T.D.O.13 AMERICAN INDIANS/ALASKA NATIVES: ARE THEY AT HIGHER RISK OF HIV INFECTION?

Hewitt, Ronald M., Tafaya, T., Beaulieu, L., Green Rush, A. National Native American AIDS Prevention Center, Oakland, CA, USA

Objective: To highlight the risk factors which make American Indians and Alaska Natives particularly vulnerable to HIV infection.

Method: The National Native American AIDS Prevention Center has gathered secondary data from the U.S. Centers for Disease Control on rates of primary and secondary syphilis and gonorrhea and conducted knowledge, attitudes and behavior surveys of Native people in substance abuse programs at national pop-over and other venues; and conducted structured interviews concerning sexual behavior among Native Americans and of Native American people with AIDS.

Results: Sexually transmitted diseases rates are from 2 to 10 times higher for Native Americans in some geographical areas than for the non-Indian population as a whole. Interviews with substance abuse providers, tribal officials and youth indicate a growing but unmeasured problem with intravenous drug use. Although comprehensive sexual behavior research has not yet been done, preliminary findings indicate a higher rate of biennially than among any other American ethnic group.

Conclusions: American Indians/Alaska Natives are at high risk for infection.

T.D.O.15 A VIDEO AIDS PREVENTION TRAINING PROGRAM FOR PEOPLE WHO ARE MENTALLY RETARDED/DEVELOPMENTALLY DISABLED

Samowitz, P., Levy, P., Ph.D., Levy, J., Jacobs, Raymond, Young Adult Institute, New York, N.Y., U.S.A.

Objective: To teach adults who are mentally retarded/developmentally disabled (MR/DD) to better protect themselves from AIDS through the practice of safer sex.

Methods: A video training program with a staff training manual was developed by the Young Adult Institute to change sexual behaviors for people who require a multi-sensory mode of learning due to their impaired learning abilities. Participants who functioned in the mild and moderate range of MR were taught in small groups: 1.What AIDS is; 2.How it is sexually transmitted; 3.How to put on and take off a condom; 4.How to negotiate safer sex when pressured to have unsafe sex.

Results: The video training program was presented to 113 of our clients in small groups. Staff conducted a survey 2 months after their clients were educated, which revealed that 82% of our clients in the mild range of MR retained crucial information taught in the session. Additionally, before the training, our clients were not using condoms. Subsequently, 52% of those clients who are sexually active asked for condoms now being supplied in the program.

Conclusion: This study indicates that people with MR/DD do need protection from AIDS and can learn through education specifically designed for their learning needs.

T.D.O.17 AN AIDS EDUCATION PROGRAM FOR BLACK AND LATINA WOMEN

Fleisher, Jacquelyn M., Rymaszak, M. University of California, Los Angeles, CA, United States

Objective: To test the effects of an AIDS education & prevention program on the knowledge, attitudes & practices of low income Black & Latina women. **Method:** The study used a pretest-posttest nonequivalent control group design with a 2-3 month stretch of the experimental group. The sample consisted of 256 control Black women & 105 control Black women & 101 control Latina women who were clients of the Public Health Foundation Nutrition Program for Women, Infants & Children in Los Angeles. The program consisted of a slide-tape presentation, educational and resource brochures, knowledge, attitudes, sexual & drug use practices were measured using a structured pretest, posttest & retreat that was developed in both English & Spanish languages. Content validity of the questionnaire was established & it was pilot tested on each group. Reliability was determined using Cronbach's alpha.

Results: Using a 2-way repeated measures ANOVA, there were significant differences in pretest-posttest knowledge, attitudes & practices for both racial/ethnic experimental groups that were retained on retreat. Control groups did not show significant pretest-posttest differences. Blacks & Latinas differed on pretest knowledge & attitudes but not practices. Blacks had more knowledge & positive attitudes on pretest. The posttest improvements for both knowledge & attitudes were greater in Latinas than in Blacks. Multiple regression analysis revealed the best predictors of knowledge, positive attitudes & practices.

Conclusions: A didactic audio-visual program can positively affect the knowledge, attitudes & practices of participants that are retained over time.

T.D.O.18 THE WORRIED WELL: IDENTIFICATION BY SIMPLE CHECKLIST
Hedge, Barbara¹; Acton, T.²; Miller, D.³ et al.,**
¹St. Mary's Hospital, London, England, ²Westfield Hospital
London, England.

OBJECTIVE: The "Worried Well", who misattribute somatic symptoms to HIV infection despite repeated negative clinical and serological investigations, can benefit more from appropriate coping/life-behaviour intervention than from further medical investigations and reassurance. The development of a checklist to aid identification of the "Worried Well" for alternative intervention is described.

METHODS: Patients presenting to a gynaecology/primary care clinic seeking counselling with respect to anxiety about having contracted HIV infection were scored on items relating to presenting symptoms, style of presentation and psychosocial history. Differences between those accepting the negative results of clinical and serological investigations and those continuing to believe they are infected were examined. A checklist based on these differences was constructed and its ability to predict the "Worried Well" assessed using a further sample of forty similar patients.

RESULTS: The "Worried Well" group was characterized by a number of items, particularly presentation of symptoms and psychosocial history. The checklist developed using these items demonstrated a high predictive ability, high test-retest reliability and good inter-rater reliability.
CONCLUSION: It is possible to identify the "Worried Well" accurately and reliably using a simple checklist. The potential usefulness of early identification is discussed.

T.D.O.20 MODIFICATIONS OF SEXUAL BEHAVIOUR DUE TO AIDS IN
MIDDLE-CLASS HOMOSEXUAL "AT-RISK" POPULATION

Mouton, Jean-Paul (1), Favre, J. (2), Bajou, N. (3), Méraud, C. (2),
Sérand, C. (2).
(1) INSERM Unit #240, Paris, France. (2) French Committee for Health Education (CFES)-
(3) INSERM Unit #31, Marseille, France.

A survey has been carried out in France by CFES in a national sample (n = 1 000, Sept. 1988) of "sexual outpatients": identification of individuals recognizing a priori that they had more than one sexual partner during the last six months was done using a random walk procedure; a questionnaire was then administered to those on their personal interview.

45.9 % of the sample declared use of condoms (10.3 % declaring systematic use); 38.7 % of users were new users of the last six months, mainly motivated by fear of Aids; 33.5 % of sexual outpatients declared that they made some change of sexual behaviour because of Aids but 41.7 % of these only quoted "being more careful in choice of partners" without any condom use. Condom use was significantly more frequent for men (53.3 %) than women (41.6 %) (p < 0.01), and for individuals under 35 years of age.

Multivariate analysis (using logistic regression model) shows that the following factors are the main predictors of condom use in this population: High school level of education [OR = 1.32 - 95% IC = 1.03 - 1.74], being single [OR = 1.42 - 95% IC = 1.10 - 1.83], and [OR for women = 0.64 - 95% IC = 0.49 - 0.83], knowing HIV carrier in personal relations [OR = 2.04 - IC = 1.55 - 2.69], having voluntarily undergone a HIV test [OR = 2.91 - 95% IC = 1.90 - 4.44].

Although interpretation of results is limited by the absence of data on the real degree of exposure to sexual transmission of HIV in such French population of sexual outpatients, conclusions will be drawn for information campaigns about condoms and screening policies.

T.D.O.22 HIV-POSITIVE GAY MEN: SEXUAL DYSFUNCTIONS
Meyer-Rabuhny, Helmo F.L., Berberet, A.A., Gorman, J.M.,
and Goldstein, M., New York, N.Y., USA.

HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, N.Y., USA.
Objective: To evaluate HIV positive men for sexual functioning expected to be impaired because of the emotional, systemic, and/or neurological effects of HIV disease.

Methods: 120 HIV-positive gay men with no or few symptoms and 80 HIV-negative gay men (all mostly white, middle class, age range 18-59 years) underwent a detailed semi-structured interview, the Sexual Risk Behavior Assessment Schedule (SRBAS-A-RBM-1), Meyer-Rabuhny et al., 1988).

Results: Preliminary analyses show high interindividual variability in frequency and practices of sexual behavior. Two-fifths of the men reported distasteful sexual activities, more than half some degree of negative feelings during sex, and about one-third some degree of sexual erection. As to classical sexual dysfunctions as listed in DSM-III-R, about one-fifth of the men reported the presence of hyposexual sexual desire, two-fifths some degree of erectile failure, one-half some degree of retarded orgasm, one-fifth some degree of premature orgasm, and one-quarter other sexual dysfunctions.

Conclusions: The prevalence of sexual dysfunctions among HIV-positive gay men with no or few symptoms of HIV disease appears to be relatively high.

T.D.D.19

SOCIAL SUPPORT, HIV SYMPTOMS AND DEPRESSION AMONG GAY MEN
Black, Robert; Turner, H.; Cassano, J.; Mandel, J.; and Coates, T.
Center for AIDS Prevention Studies, University of California, San Francisco, California, USA.

Objective: To examine the impact of objective HIV status, knowledge of HIV status and AIDS-related symptomatology on depression among a community sample of gay men and identify which of three types of social support (emotional, informational, practical) most effectively buffered that depression.

Methods: Longitudinal questionnaire data come from 455 gay and bisexual men who participated in 1986 and 1987 waves of the San Francisco Men's Health Study, a population-based sample drawn from the census tracts with the highest AIDS incidence in 1984.

Results: The number of AIDS-related symptoms experienced significantly predicted depression cross-sectionally ($r = .25$) and one year later ($r = .17$). Objective HIV status and knowledge of one's status were not significantly associated with depression. The three types of social support were not significantly associated with depression. The three types of social support were not significantly associated with depression. The three types of social support were not significantly associated with depression. The three types of social support were not significantly associated with depression.

Conclusions: Gay men are at higher risk for depression when they begin to experience AIDS-related symptoms. While all types of social support are associated with reduced depression, informational support may be especially beneficial for those in early stages of disease progression.

T.D.O.21 THE PREVALENCE OF AIDS-RISK RELATED SEXUAL BEHAVIORS AMONG
WHITE, MIDDLE-CLASS, URBAN AMERICAN ADULTS: A SURVEY OF
RESEARCH FROM KANSAS TO THE PRESENT

J.M. Reinisch, Stephen A. Sanders, and M. Zimba Davis
The Kinsey Institute for Research in Sex, Gender, and Reproduction, Indiana University, Bloomington, IN USA

Objective: To provide a comprehensive view of sexual behavior patterns among American men and women, data from recent studies were combined to provide estimates of the prevalence of behaviors implicated in the transmission of Human Immunodeficiency Virus (HIV).

Methods: Drawing from 17 of the most thoughtfully designed scientific investigations and the largest, most comprehensive cross-sectional studies published between 1948 and 1984, we derived estimates of the prevalence of AIDS risk-related behaviors for White, middle-class, minority well-educated, primarily urban Americans between 20 and 50 years of age. These estimates are conservative. They represent weighted means derived by multiplying the results from each of the relevant studies by the sample size, remaining across studies, and dividing this sum by the total number of subjects across all studies.

Results: Results indicate that a substantial proportion of the participants in the studies reviewed had engaged in (a) conventional sexual intercourse, (b) and intercourse, (c) sex with prostitutes, (d) sexual intercourse across nonsexually distant sexual orientation groups, and (e) sexual contacts during visits to cities with a high prevalence of HIV.

Conclusions: Accurate data on sexual behavior and the attitudes related to these behaviors are essential to the development of behavior change programs that to stem the tide of AIDS. In the absence of sufficiently large and unbiased samples, our estimates based on 17 scientific and cross-sectional studies provide important insights into the prevalence of sexual behaviors which place Americans at risk for infection with HIV.

T.D.O.23 CHANGES IN LYMPHOCTY PEHNOTYPE AND FUNCTION IN HIV
SEROPOSITIVE HOMOSEXUAL MEN FOLLOWING THE DEATH OF A PARTNER

Kempy, Margaret, E., Durk, Robert, J., Visccher, B., and Fahny, J.L.,** UCLA Center of Medicine and
UCLA Department of Psychology, Los Angeles, CA, USA

Objective: To determine whether immune parameters relevant to HIV infection were altered in HIV+ homosexual men following the death of an intimate partner. HIV+ homosexual men were studied as a comparison group.

Methods: 25 subjects whose intimate partners had died over the past year were selected from among participants in the UCLA Multi-Center AIDS Cohort Study (MACS). Blood samples drawn prior to and following the death of the partner were compared. Age- and HIV serostatus-matched non-bereaved subjects provided blood samples over an equivalent time period. Immune parameters relevant to HIV progression were evaluated (e.g., CD4 cell levels; measures of immune activation such as the percent of CD8 cells expressing DR).

Results: Preliminary results from phenotypic analyses indicated that there was a significant increase in the percent of CD8 cells expressing DR following the death of the partner among HIV+ subjects; this change over time was not seen in the non-bereaved subjects. This change was also not seen among HIV-

Conclusions: The loss of a partner in HIV seropositive homosexual men was associated with increased evidence of immune activation. This pattern was not seen among the HIV- men who had lost a partner. Immune activation is relevant to progression of HIV infection.

T.D.O.30 TRAINING INMATES AS HIV PEER SUPPORT COUNSELLORS IN GAOZ
Lynas, M.*; English, L.; McClellan, L.; Cooley, J.; ...
*National Wallace Street AIDS Centre, Sydney
Hospital, Sydney, Australia. **NSW Department Corrective Services.

Objectives: To develop a programme to train inmates as HIV peer support counsellors and establish a network of inmates throughout goals who are available on HIV peer counselling and education.
Methods: Inmates collaborated with HIV workers in the design and implementation of the programme. Topics covered included: counselling and psycho-social issues. Topics were presented by visiting specialists and information delivered in a variety of ways including lectures, group discussions, role plays and videos. The course was evaluated through interviews and by questionnaires.
Results: The evaluation process involved collecting qualitative and quantitative information. Questionnaires were used to compare participants' AIDS knowledge (pre and post) and their attitudes towards AIDS. Results showed that inmates who had attended a higher general AIDS knowledge (p<0.001) and higher positive attitudes scores (p<0.05). As a result of the course, inmates produced an educational play and video on safe needle use for the internal television network of the inmates. They were involved in HIV peer education and counselling of other inmates.
Conclusion: The success of the programme is directly attributable to the active involvement of the inmates in its planning and implementation. The programme demonstrates the practical and economic value in using inmates as HIV peer educators and counsellors in goals.

T.D.O.32 PROBLEMS WITH COUNSELLING UNDEREDUCATED PEOPLE REGARDING HIV-1 SEROLOGIC RESULTS
Rivara, M.*; Adrien, M.*; Boulos, R.*; Halsey, M.*; Abdallah, M.*; Kinsinger, J.*
*Centres for HIV and AIDS, Port-au-Prince, Haiti
*Johns Hopkins University, Baltimore, MD, USA

Objective: To describe the difficulties in counselling undereducated men and women in an impoverished Haitian slum about HIV-1 infections and AIDS.
Methods: Women attending prenatal clinics were tested for HIV-1 by ELISA and WB. Men with signs and symptoms suggestive of HIV-1 infections were tested in an STD clinic. Counseling was provided by physicians and social workers.
Results: Of 1992 women, 49.7% had received no formal education and 75% had attended primary school for 4 or fewer years. Of 14 to 19 year old pregnant women, 68 to 98 have been HIV-1 seropositive each year during 1986 through 1988. Adverse reactions to learning that they were HIV-1 seropositive included destruction of household goods, physical threats to the STD clinic physician, hopelessness, anger, despair, and confusion.
Conclusion: Undereducation, illiteracy, and lack of general information about AIDS in the community make counseling regarding serologic status and the complex aspects of HIV-1 infections very difficult. Adolescent girls are acquiring HIV-1 infections soon after becoming sexually active. Education programs and changes in sexual behavior are urgently needed.

T.D.O.34 SPECIAL PROBLEMS INVOLVED IN COUNSELLING HIV-INFECTED HOMOSEXUALS AND BIPHOBICS
Matschek, Ginter*; Drasch, M.*; Sutar, G.*; Seitz, O.*; Schneider, M.*; Hahn, F.*; Schram, W.*
*Dept. of Psychosomatics at the Psychiatric Hospital, University of Munich, Munich, Federal Republic of Germany.
*Psychosomatic Unit, University of Munich, Munich, Fed. Rep. of Germany.
** Dept. of Semanticsology at the Medical Hospital "Immanuel", University of Munich, Munich, Federal Republic of Germany.

Objective: Descriptive problems involved in counselling of HIV-infected homosexuals and biphobics.
Methods: The coping behaviour of HIV-infected homosexuals and biphobics is descriptively analyzed, resulting from records of over 2000 counselling contacts over a period of 3 years.
Results: It was observed that an important prerequisite for an adequate coping with the HIV-infection (minimizing denial, guiltfeelings, depression, feeling victimized and isolated) is the person's successful coping with his group-specific stress factor: homosexuality or biphobia. For clients who demonstrated a deficiency in this coping ability, sensitive and non-confronting counselling led many cases to greater self-acceptance and more ease in dealing with the HIV-infection.
Conclusion: In counselling HIV-infected homosexuals and biphobics the task is, with a large number of clients, to help them accept themselves as homosexuals or biphobics as well as to cope with the HIV-infection of the partner. But even when it is ignoring the personal and social implications of homosexuality and biphobia is forced confrontation with these issues at the wrong time.

T.D.O.31 OPTIMIZING INNER CITY PRENATAL AIDS COUNSELLING (AC)
Menden, C.; Tarras*, Lischner, R.N.*; Saphel, J.A.*; Olson, M.H.*; Cohen, A.V.*; Steinberg, J.M.*; et al. *Temple Univ., Univ. of Pennsylvania; **Epidemiol Hosp., Philadelphia, Pa, USA.

Objective: To compare the effectiveness of 4 approaches to prenatally sensitive acceptance of preventive AC and HIV antibody testing (ABT), minimize client stress and permit the gathering of risk-behavior data.
Methods: The 4 approaches to AC were pilot-tested in 2 clinics serving predominantly Black and Hispanic women who have an average incidence of perinatal HIV infection of about 0.3% by anonymous umbilical cord blood screening. 1) Of 97 women who received flyers which described AIDS risk activities and offered AC, 29% requested AC and 18% requested ABT. 2) Out of 169 women interviewed directly by a social worker (SW) for consent to join a research program for anonymous risk assessment and ABT, 36% agreed. 3) Out of 42 women interviewed by the SW without prior mention of risk behaviors, 57% requested AC and less decrease was verbalized. 4) Out of 34 additional women approached as in method 3) but asked for verbal presentation to complete an anonymous risk assessment form, 35% requested AC. Regardless of the initial approach, confidential risk-assessment interviews were permitted during post-test AC and the resulting data were more complete than, though sometimes discrepant from, those from anonymous questionnaires.
Conclusion: As proposed by Menden et al. (New Eng J Med 319:1108, 1988), the initial focus in prenatal and perinatal AC should be on the danger of HIV infection to the infant and not on risk behavior. The consensus of observing professionals, soon to be tested, was that this AC would be most effective if conducted as part of multifocus SW or nursing interviews.

T.D.O.33 ARE PATIENTS GETTING THE AIDS EDUCATION THEY WANT FROM THEIR PHYSICIANS?
Richard, Barbara; Magnus, and Costes, T. University of California at San Francisco, San Francisco, California, United States.

Objective: Physicians are positioned in the health care system to counsel patients about risk reduction. We completed a population-based survey of United States residents to find out the extent to which physicians talk to them about AIDS and to assess their desire for AIDS prevention counseling during their medical visits.
Methods: Telephone interviews were conducted in July and August 1988 with 2000 English-speaking, United States adults using a representative national sample generated by random digit dialing. A 75% response rate was achieved.
Results: Only 15% of respondents had talked with their physicians about AIDS, and in most instances (78%) the patient had initiated the discussion. Most respondents (79%) had never been asked by their doctor about their sexual behavior. Among those who had not discussed AIDS with their physician, only 17% did not want such a discussion. Physicians were rated as the most credible source of AIDS prevention information.
Conclusion: AIDS prevention is not routinely discussed by physicians with their patients. Because patients are not aware of such counseling, we suggest additional research to identify barriers to AIDS prevention counseling in the medical encounter and strategies to increase such counseling.
Funded by NIMH & NIDA Center grant #MH4245 and the Universitywide Task Force on AIDS.

T.D.O.35 CONDOM USE AND ASSOCIATED HIV SEROCONVERSION FOLLOWING SEXUAL INTERCOURSE WITH HIGH RISK INDIVIDUALS
Mills, A.*; Bhatnagar, S.*; Bhatnagar, S.*; Haines, E.*; ...
*AIDS Unit, University of California, San Francisco, CA, USA.

Objective: To prospectively determine condom use and subsequent HIV seroconversion following sexual intercourse with high risk individuals. HIV seroconversion was defined as the presence of HIV-1 antibody in the serum. HIV-1 infection was confirmed by Western blot analysis. HIV-1 infection was confirmed by Western blot analysis. HIV-1 infection was confirmed by Western blot analysis.
Methods: 100 individuals were followed up for 12 months. HIV-1 antibody was tested at baseline and at 1, 2, 3, 4, 6, 8, 10, and 12 months. HIV-1 antibody was tested at baseline and at 1, 2, 3, 4, 6, 8, 10, and 12 months. HIV-1 antibody was tested at baseline and at 1, 2, 3, 4, 6, 8, 10, and 12 months.
Results: 100 individuals were followed up for 12 months. HIV-1 antibody was tested at baseline and at 1, 2, 3, 4, 6, 8, 10, and 12 months. HIV-1 antibody was tested at baseline and at 1, 2, 3, 4, 6, 8, 10, and 12 months. HIV-1 antibody was tested at baseline and at 1, 2, 3, 4, 6, 8, 10, and 12 months.
Conclusion: Condom use significantly reduces the seroconversion rate in sexually active individuals. An intensive counselling programme has been shown to increase condom use by 11% of 100% of couples. A practicing attorney was not following during all couple's visits. A significant decrease in seroconversion rate was noted to meet SC and led to seroconversion changes in sexual behavior.

Séance thématique Specialty Session

Women

W.D.O.1 HIV INFECTION AMONG WOMEN ATTENDING WOMEN'S HEALTH CLINICS IN THE UNITED STATES, 1988-89
Primary: Pattillo,¹ Allen, W.R., Goewert, J.,² and State and Local Health Department, Centers for Disease Control, Atlanta, GA, USA

Objective: To evaluate HIV seroprevalence in women attending family planning, prenatal care and abortion clinics in the United States.

Methods: In 1988 and 1989, binned surveys are being conducted in clinics providing services to women of reproductive age. After testing blood for routine purposes, individual identifiers are removed and consecutive sera are tested for antibodies to HIV. Age group, race, ethnicity, and type of clinic will be collected on over 100,000 women from 137 clinics in 30 metropolitan areas.

Results: Preliminary results for 10,164 women in 8 areas indicate that the highest seroprevalence rates are in prenatal and family planning clinic clients in densely populated cities. HIV seroprevalence ranged from 0-6.2% (median 0%) in prenatal, 0-4.3% (median 0%) in family planning and 0-0.16% (median 0.1%) in abortion clinics. Rates were 1.0% in black compared to 0.11% in white and 0% in Hispanic women. Seroprevalence was highest in the 25-29 year age group and lower among adolescent and older women.

Conclusions: These results suggest that HIV seroprevalence rates in women attending family planning, prenatal, and abortion clinics vary, but are generally low. Rates are higher in black women and in more populated areas. Surveillance of HIV seroprevalence in women of reproductive age is essential in directing programs to prevent perinatal and heterosexual transmission and to evaluate the effectiveness of such programs. These programs may need to focus on educating minority and adolescent women.

W.D.O.2 RELATIONSHIP BETWEEN HIV AWARENESS, PARTNER SELECTION CRITERIA, AND EARLY RELATIONSHIP FORMATION IN TWO GROUPS OF SAN FRANCISCO BAR PATRONS

McKusick, Lepp, and Hoff, C.C.
 Department of Medicine, Center for AIDS Prevention Studies, University of California San Francisco, USA.

Objective: To investigate the interaction between awareness of HIV and interpersonal relationship seeking and formation in adult heterosexual women and homosexual men.

Methods: San Francisco bar patrons were chosen, bars being places where awareness of HIV is likely to be high and where a sexual encounter with an HIV antibody seropositive may occur. 50 heterosexual women and 50 homosexuals men filled out questionnaires and were interviewed. Twenty five of each group were in an early relationship and 25 were single. Data was gathered on three HIV aware behavioral strategies: 1) assessment of partner characteristics and behavior, 2) safe sex practices, and 3) determination of HIV antibody status of partner. Additional data was gathered on partner selection and relationship criteria, awareness of AIDS, sexual behavior, and relationship history and satisfaction.

Results: Single heterosexual women were more likely than single homosexual men to assess partner characteristics of potential partners as an HIV avoidance strategy. Homosexual men were more likely than heterosexual women to know their own HIV antibody status and, for those in early relationships, to know the antibody status of the partner. Single homosexual men were also more likely to engage in safe sex practices than single heterosexual women. Those women who practiced safe sex early in relationship formation suspended the practice upon the establishment of trust that their partner was monogamous.

Conclusions: Psychological factors associated with relationship formation can interfere with effective HIV protection strategies, particularly in single heterosexual women.

W.D.O.3

W.D.O.4 GENDER RULES AS BARRIERS TO RISK REDUCTION FOR BLACK WOMEN

Fallone, Mundy, Pullimore, R., Haynes, K. and Cross, S.A.
 Multicultural Inquiry and Research on AIDS of the UICAR Center AIDS Prevention Studies and the Bayview-Hunter's Point Foundation, San Francisco, CA, USA.

Objective: This study was designed to examine gender rules that affect black women in their adoption of risk reduction behaviors. In particular, the study compared drug-using and non-drug-using women's comments about rules for sexual behaviors, drug use, and subordination within relationships.

Method: In order to examine the attitudes, beliefs and practices of women in the drug-using world, we conducted 12 focus groups with 75 black teenage and adult women, drug-users and non-drug-users, representing middle-, working- and uneducated black women residing in Bayview-Hunter's Point, a black ghetto in San Francisco. The focus groups asked women participants to discuss sexual practices and drug-related behaviors.

Results: The women in our focus groups were able to state explicitly what they believed to be the rules of their environment. The rules for behavior reflected an awareness of strict gender roles in which women were subservient to men and had fewer privileges than men. The gender rules varied with age, socioeconomic status and drug use. Of the women who participated, those addicted to crack cocaine appeared to face not only the highest risk for infection with HIV, but also the most severely limited options for behavior change.

Conclusions: Risk reduction must take into account black women's perception of acceptable gender behaviors. To the extent that these rules support subservience to men, women may be limited in their ability to initiate and maintain prevention activities. The degree to which this perception reflects reality, and the corresponding views of black men, deserve further study.

W.D.O.5 BARRIERS TO AIDS INTERVENTIONS AMONG SEXUAL PARTNERS OF HIV DRUG USERS
Smith, Chen, M.P., Frederick, S.P., Sofian, M.P., Stephenson, R.T., De Jureth, OC**
 *Narcotics and Drug Research, Inc., New York, NY, USA; **NY State Div of Substance Abuse Services, New York, NY, USA

Objective: (1) To develop strategies to locate sexual partners (SP) of drug users so they can receive AIDS education and be enrolled in research studies. (2) To determine barriers to sexual partners' participation in these activities.

Method: Under the direction of an ethnographer, a team of outreach workers attempted to locate and recruit SP. Barriers to recruiting SPs were identified through (1) conducting in-depth interviews with SPs who were recruited about the reasons that led to their status and that deterred their friends, and (2) casual feedback between the ethnographer and the outreach workers about what obstacles they discussed in their attempts to recruit SPs.

Results: Most SPs are women. The key barriers to their participation are denial, dependency, social isolation, and opposition from their drug using partners. Many SPs deny their partners' drug use and hope they will eventually stop using drugs. They are emotionally, and sometimes economically, dependent on their drug using partner. Thus, they want to hold on to the relationship, especially if they have children. SPs often contact with friends whom they do not want to have know about their partner's drug use. The drug users do not want the SPs to talk with outsiders about their drug use because they are ashamed of their drug use or because they fear these conversations may give the SPs social support to break the relationship.

Conclusions: Outreach based on ethnography facilitates locating sexual partners and identifying barriers to participation. Efforts to reduce HIV infection of SPs can use network techniques to locate SPs. Ways to overcome dependency, denial, and social isolation of female SPs, and to neutralize their drug using partners' opposition, must be developed. Theoretically promising ideas include group processes and counseling that lead to empowerment and collective identity.

W.D.O.6 CONTRACEPTIVE UTILIZATION AND REPRODUCTIVE DESIRES IN A GROUP OF HIV-POSITIVE WOMEN IN KINSHASA
Hemba, Bassia, E.P.,¹ Duppaigne, A.P.,² Piriel, L.,³ Moore, H.,⁴ ⁵
¹Ryher H.V.,⁶ ⁷Bertrand H.V.,⁸ ⁹Kashala T.D.,¹⁰
¹¹Zaire School of Public Health, Kinshasa, Zaire; ¹²Tulane University, New Orleans, USA; ¹³Beaujeu Cosmeceutic du Zaire, Kinshasa, Zaire; ¹⁴Projet SIDA, Kinshasa, Zaire.

Objective: To determine contraceptive utilization and future reproductive desires of women identified as HIV-positive. Methods: A working population and their spouses were treated for HIV and contraceptive/reproductive data collected.

Results: Fifty-eight (4.3%) of the 1299 women tested were HIV+. Ninety-one % of HIV+ women were married, and 7% currently use modern contraception. No differences in age (33.0/33.2 years), number of children (2.9/4.4) or condom usage (28/12) were found between HIV+ and HIV- women. HIV+ women were significantly more likely to use "rhythm" for contraception (26% vs 9%, p=0.0003). Of HIV+ women, 71% wanted more children within the next 2 years (mean desired family size = 5.2), and 5% were pregnant. A majority of women expressed a desire for more accessible contraception options.

Conclusions: Counseling services for HIV+ women in Kinshasa must be prepared to address the current low level of contraceptive usage and the definite pro-natalist sentiment in the population reflected by the high levels of desired and actual completed fertility.

Th.D.0.7 THE IMPACT OF AN EDUCATIONAL PROGRAM ON HIV INFECTION AMONG PROSTITUTES.

James R. Foret***, A. Tejeda*, J. Alarcón*, J. Piscayo*, and L. Varela**.
**Universidad Nacional Mayor de San Marcos, Lima, Peru.
***The Population Council, New York, New York, USA.

Objective: To determine the impact of a reproductive health program on the prevention of AIDS among registered prostitutes in El Callao, Peru.
Methods: A reproductive health program with an educational component was implemented in a STD clinic serving almost 600 prostitutes. The program's impact is being evaluated through successive surveys, program participation, changes in condom use and lab tests to detect seroconversion to HIV and infection with other STD's.

Results: To date 783 women have participated in program activities, 463 of them consistently, in the average every woman has attended 4 educational sessions. Changes in attitudes towards condoms have taken place. For instance, higher fees for sex when condoms are used are no longer charged, and condoms are now used in oral sex. More women participating in the program know the correct use of condoms (72% VS 52% among those not participating). The demand for condoms has increased from 1,010 in August 1988 to 32,445 in October of 1988. In addition, the demand has remained low with no seroconversion between April and November of 1988. In the same period prevalence of gonorrhoea decreased from 2.75 to 0.175 and candida infections from 85 to 35.

Conclusions: The program has had an impact on the social behavior of prostitutes, reflected mainly in an increased demand for condoms. Low and stable HIV seroconversion risk, and reduction of gonorrhoea and candida infection.

Th.D.0.9 WOMEN WORKING AS PROSTITUTES: PARTICIPATION/CONSENSUS-BASED PLANNING FOR PROVISION OF HIGHER PREVENTION, AIDS REDUCTION, AND SEROPREVALENCE ACTIVITIES

Stephanie P. Clay*, Adam R. E. Gross, M.J.

AIDS Office, Massachusetts Department of Public Health, Boston, MA USA. 02111

Problem: Provision of educational and risk reduction services and seroprevalence studies within the field of women working as prostitutes raises ethical, scientific, and political concerns. Women in general and sex workers in specific have little trust in the "good intentions" of outsiders. Public Health Departments (PHDs) and community-based organizations (CBOs) often lack credibility with prostitutes. Client distrust may lead to difficulty in reaching target populations, low utilization, and biased outcomes.

Model: Participatory/consensus-based planning minimizes conflict and increases cooperation among clients, project staff, and funding agency.

Application: The AIDS Office of MPHV received funding from CDC for a 22-month outreach, education, and risk reduction project for women working as prostitutes to be conducted by a CBO at the site. Consensus groups were formed consisting of AIDS/HIV service providers and women sex workers. Meetings jointly and separately, the groups seek consensus on program design and procedures, sites, hours of operation, and staffing. The providers and the AD staff seek consensus concerning contractual obligations and political concerns.
Conclusion: The participatory/consensus model offers an alternative to traditional planning and design. This model involves clients in a strong voice; CBO's input into issues of local concerns; realization of criminal justice issues; and increased access to technical support and funding. In partnership, this model seeks most needs without sacrifice of client anonymity, ethical considerations, or scientific quality.

Th.D.0.11 EVALUATION OF KEY MESSAGES TO INCREASE THE USE OF CONDOMS IN SEX WORKERS: AN AGRI-EXPERIMENTAL STUDY.

Xaldemaini-Jaak*, Izquierdo J.A.*, Sepúlveda S., Ramah M**.

Quetz** *General Directorate of Epidemiology, Ministry of Health, Mexico.

Objective: To identify and evaluate key messages and channels of distribution of educational strategies in prostitutes in Mexico to rapidly increase the use of condoms.

Methodology: The end goal took place in Toluca, Mexico (border city with California, USA) where approximately 50,000 prostitutes live. A randomly selected survey was undertaken, which investigated sociodemographic characteristics of persons and attitudes, a blood sample for HIV-1 was also drawn. Upon the data of the survey, key messages and adequate channels of distribution were identified. Educational material (posters, tracts, and comics) was pre-evaluated through local media and distributed. The final material was distributed by 15,000 prostitutes, with their active participation. Six months after the first survey, a second survey in a random sample was undertaken to evaluate changes.

Results: Women under study have an average age of 27 years, with a second grade elementary school level. 89% have children, no STD was reported, 87% are afraid of acquiring AIDS, and 10% use condoms. The usage of condoms is set: attractive women, prostitutes for social reasons and mothers worried for their children's health. Key messages were: 1) HIV is a STD; 2) Condom prevents infection; 3) When avoiding sexual transmission, perfect transmission is prevented; 4) Prostitutes who use condoms are responsible mothers. The use of condom increased 88% (incl. oral) after 6 months. The messages transmitted to the population considered to be the educational material. Seroprevalence of infection by HIV-1 was <1.0% in both serosurveys.
Conclusion: The identification of adequate key messages and channels of distribution improves the efficiency of educational programs of AIDS on female sex workers. This strategy must be evaluated in an educational program for prostitutes abroad.

Th.D.0.8 YOUNG MALE PROSTITUTES: SAFE AND UNSAFE SEX AND AIDS KNOWLEDGE

Frank Edelstein*, and Meyer Balthus, M.P.H.
HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, New York, United States.

Objective: To assess sexual behavior and AIDS awareness in young male prostitutes, a group at particularly great risk for acquiring and disseminating infection with the etiologic agent of AIDS.

Methods: 50 New York male prostitutes (for men), aged 14-27, were recruited by their operating locations (streets or bars and theaters) and systematically interviewed for 2.5 hours using semi-structured instruments to assess demographic, detailed sexual behavior, and knowledge and attitudes about AIDS/HIV.

Results: Preliminary results show an average age of 20.7 years. In erotic fantasy, 50% were predominantly homosexual, 20% bisexual, and 30% predominantly heterosexual. Only one reported being HIV antibody positive. The subject's sexual behavior with their male customers for pay included rates of condom use of 50% with fellatio and 85% with anal intercourse. With their non-paying male partners these rates fell to 25% with fellatio and 50% with anal intercourse, and fell further with their (non-paying) female partners to 21% with fellatio and 12% with vaginal intercourse. The safety of their sexual behavior did not appear to be related to their knowledge and awareness of AIDS/HIV, which was quite high overall. Distances between the street and the bathhouse/hustlers exist, with street hustlers being younger, less knowledgeable about AIDS/HIV, less likely to use condoms with women, and more likely to use drugs.

Conclusion: Male prostitutes' sexual behavior is related (in part) to their 'higher-end activities' with their male customers, where perceived threat is highest, and most unsafe with female partners where perceived threat is lowest. Knowledge of AIDS, while quite high, appears unrelated to awareness of sexual behavior.

Th.D.0.10 THE ACQUISITIVE APPROACH TO JOHN STD/AIDS PREVENTION AND CONTROL IN FEMALE SEX WORKERS: THE DOMINICAN REPUBLIC

Rosario, S.; Suterro, Ernesto; De Moya, I.A.; Velquez, C.

Alcántara, E. PROCTIS, Ministry of Public Health, Santo Domingo, Dominican Republic.

Objective: To describe and analyze the conceptual approach to STD/AIDS prevention in Dominican female sex workers (FSW), as well as the detection, diagnosis and treatment strategies and their results from 1987 to mid 1989.

Methods: On the basis of an agglutinating approach that incorporates FSW law fees selected by their peers to the National Struggle against AIDS, sex workers receive educational preventive training, at least monthly physical exams, laboratory tests and treatment for STD, in 12 new sentinel points in the Dominican Republic. FSW receive 50 condoms gratis in each visit.
Results: As of December 1988, 22,000 medical exams have been delivered to 5,000 FSW; 121 have been treated for syphilis and 111 for gonorrhoea. Out of 3,000 voluntary HIV tests, 2,155 have been seropositive.

Conclusion: Aggressive control of genital ulcer disease (GUD) through joint peer/professional intervention provides an unique opportunity for educating sex workers, detecting STD at an early stage, treating these diseases opportunistically, and reducing the risk of HIV infection.

Th.D.0.12 THE DEVELOPMENT OF VIDEO-INTERVIEWS AS SOME ALTERNATIVES FOR FEMALE SEX WORKERS IN THE DOMINICAN REPUBLIC

Alcántara, E.; Suterro, Ernesto; De Moya, I.A.

PROCTIS, Ministry of Public Health, Santo Domingo, Dominican Republic.

Objective: To describe the approach to HIV seropositive female sex workers (FSW) counseling and provision of training for profitable work alternatives through the Ministry of Public Health and a specialized Catholic Organization of women.

Methods: FSW who voluntarily demand HIV testing and refer seropositive are offered counselling services by State psychologists, who treat these women to the "Marianas Adoradoras", an International Catholic Organization of women specialized in developing work alternatives for female sex workers.

Results: From the start of this program in 1988, 56 HIV positive FSW have been recruited for psychological counselling, social support, and training for low risk work alternatives. Twenty-one of them have been able to support themselves and their children without resuming sex work.

Conclusion: HIV seropositive FSW in the Dominican Republic, when provided with appropriate professional counselling, social support and technical training, can have developed work alternatives capable of providing an income to support themselves and their children without resorting to sex work.

Séance thématique Specialty Session

Le SIDA et l'individu AIDS and the Individual

Consommateurs de drogues par voie intraveineuse (partie 2) Injection Drug Users (Part 2)

Th.D.0.13 DRUG USE TRENDS AMONG PARTICIPANTS IN THE TACOMA BYRNGE EXCHANGE
 HUGH HENDER, D.C. De Sales¹, D. Proctor², T. J. Reed³, B. R. Friedman⁴,
¹Tacoma Pierce County Health Dept., Tacoma, WA, ²Wash. Nat. State Division of Substance Abuse Services, ³Port Defiance AIDS Project, Tacoma, WA, ⁴Harvard and Drug Research, Inc., Boston, MA

OBJECTIVE: To examine the relationship between frequency of drug use and participation in a syringe exchange (SE). One of the arguments against SE programs has been that they will promote drug abuse and that the availability of equipment will cause injecting drug users to inject more often.

METHODS: Retrospective data were collected regarding drug injection frequency on 48 randomly selected SE users, using a standardized interview. Comparisons between the time periods just prior to first using the SE (PRE-SE), and since starting to use the SE (POST-SE) are reported as mean number of times each drug was used per month.

RESULTS: The majority of participants had used the SE for 3 months. Trends show no differences in the frequency of injection of heroin and cocaine between PRE-SE and POST-SE (66 vs. 64), heroin PRE-SE (56 vs. 56), crack PRE-SE (45 vs. 45), POST-SE (45 vs. 45), amphetamine PRE-SE (3.5, POST-SE 3.7, p=0.4). Looking at drug use that did not involve injection, no changes were noted in the use of snuff (heroin PRE-SE 0.01, POST-SE 0.01), snuff (cocaine PRE-SE 0.3, POST-SE 0.4), smoking crack (PRE-SE 0.3, POST-SE 0.8), or in the use of non-injection methadone or marfanin (all p > 0.5). Overall, 50% of SE users report injecting less, 15% the same and 35% inject more frequently since using the exchange. The mean age of SE users is 30, and 4 (9%) had been injecting drug use more than 5 yrs, 11 (23%) age, and 80% first injected more than 5 yrs ago. No other changes were noted during the time since the SE was used.

DISCUSSION: Clearly, the majority of SE users have a long history of drug use, and the availability of clean equipment is not restricting individuals who were once users. No increases were seen on the frequency of use of injected or non-injected substances. The finding that more SE users decreased than increased drug injection is consistent with earlier data from the same and other SE programs, but long-term study is needed to determine trends in drug use with prolonged SE use.

Th.D.0.15 REDUCING HIV TRANSMISSION AMONG RECOVERING FEMALE DRUG USERS
 Robert J. R. Anderson, M.D., Ph.D., Robert C. Gardner, M.D., and Nicholas L. S. ¹Columbia University School of Social Work, New York City, USA, ²Albert Einstein College of Medicine, Bronx, New York, USA

OBJECTIVE: To study the effect of a skills-building approach to reducing rates of HIV transmission among recovering IV drug users. Methods: Drawing on extant research and findings of an earlier descriptive study, the authors developed a multi-session group approach to reducing high risk behavior among a cohort of women enrolled in New York City area clinics. A controlled trial carried out by social workers in drug treatment settings involved random assignment to intervention- or skills-building conditions. Results: Outcome analyses demonstrated that participants in an information-only condition regularly attended in the clinic made fewer gains than skills-building participants in behavior related to HIV transmission. Participants in the skills-building condition were significantly more likely to carry condoms, talk about and initiate discussions around safer sex, and feel comfortable talking about discussing safer sex with IV drug users. Discussion: As follow-up data have not yet been collected, these modest preliminary findings must be viewed with a degree of caution. Nevertheless, ongoing research and support to the viability of skills-building strategies to reduce relapse and AIDS risk associated with recovering drug use.

Th.D.0.17 HIV IN PRISONS: A DESCRIPTION AND EVALUATION OF A PROJECT DESIGNED SPECIFICALLY FOR WORK WITH IVDA'S IN PRISON
 Barbara J. G. Anderson, Muriel Shover, and John S. Sorenson
 Ann Jensen, Dep. of AIDS Prevention, Ohio City Health and Environment Dep. Agency

OBJECTIVES: IVDA's constitute a large proportion of the prison population in Norwegian prisons. There is a need for new methods in preventive and supportive work among inmates. In 1987 the Department of AIDS Prevention employed a doctor, a psychologist, a registered nurse and a pedagogue, two of whom are also active in the prison. The project is a project to answer the following: - How do you give adequate information? - Under what circumstances can change of risk behavior take place? - How do you give adequate psychosocial support in a prison? - How can you best run support groups in a prison? The project works in the four prisons in the Oslo area with a total of 750 inmates.

METHODS: The project is, and is perceived by the inmates as, independent of the regular health service and authorities of the prisons, and information received from the inmates is kept confidential. Notwithstanding this separation from the prison system, contact with, and education of, prison employees has been an essential part of the work. The methods employed with the IVDA's are: - individual counselling, psychological support and medical examinations - counselling of the inmates' social partners - support groups for former IVDA's - take one's own responsibility - information meetings. The methods are continuously evaluated, and the activities give in themselves knowledge about the "anthropology of prison life".

RESULTS: The project has been in contact with 48 hiv positive inmates. This constitutes 20% of the registered hiv positive IVDA's in Norway. A qualitative evaluation of the methods used will be presented at the paper.

Th.D.0.14 THE PREVALENCE OF HIGH RISK SEXUAL BEHAVIOR IN MALE METROPOLITAN IV DRUG USERS
 Linda Gross¹, J. Walters, J.K. Cline², C. Case³,
¹University of California, Santa Cruz, California, U.S.A., ²University of California, San Francisco, California, U.S.A., ³Urban Health Services, San Francisco, California, U.S.A.

OBJECTIVE: To determine the prevalence of high risk sexual behavior in male intravenous drug users (IVDU) who are female sexual partners.

Methods: One hundred forty-nine IVDU's (70 whites and 79 blacks) with stable partners were interviewed in early 1987.

Results: During the previous year, 83% had more than 1 female partner and 31% had 4 or more female partners. The median number of female sexual partners was 3 for whites and 2 for blacks. Eleven percent (16/148) had sexual contact with men, with no significant difference between whites and blacks (7% or 5/70 vs. 14% or 17/120 respectively, p = 1.6). Heterosexual and intercourse were reported by 20% (50/148), with whites more likely than blacks to report this behavior. (ie. 46% (32/70) vs. 20% (24/70) respectively, p = .01). Reports of new sexual contacts between men and women were reported by 17% for the 2 groups of men. Of the 128 men who reported whether their steady female partners injected drugs, 40% (51/128) said their partners were IVDU's. Black men were more likely than whites to report that their partners were IVDU's (54% (57/106) vs. 32% (14/43) (p < .001). Blacks were also more likely than whites to report no enrollment in drug treatment programs during the previous 3 years. (ie. 49% (67/137) vs. 20% (14/70) (p < .01).

Conclusions: This study demonstrates that educational outreach programs in sexual risk reduction are important for both IVDU's and their sexual partners. The need for culturally sensitive programs is particularly important for black IVDU's and their sexual partners in San Francisco.

Th.D.0.16 IMPACT OF AIDS ON MORTALITY AND MORBIDITY AMONG INDIANIZED DRUG USERS (IVDU) IN A REHABILITATION TREATMENT PROGRAM (RMP)
 Richard M. Heron, J. W. Hennessey, M.D., and Robert C. Gardner, M.D., ¹Northwestern Medical Center/Albert Einstein College of Medicine, Evanston, Ill., USA

OBJECTIVE: To assess the impact of the AIDS epidemic on morbidity and mortality in a defined population of IVDU's in a long-term supervised RMP in New York City.

Methods: An unlinked sample in overall and cause-specific deaths (AIDS, liver disease, and medical hospitalizations among IVDU's in a Bronx RMP for 1984-1987). The underlying population each year was used to calculate crude incidence rates.

Results: The underlying population each year ranged from 828 to 8011 median age of the entire population was of 31.6/yr. Population demographics did not differ between study years. Total deaths increased from 13.3/1000 in 1984 to 24.2/1000 in 1987 (p<.001). Deaths from AIDS increased from 3.6 to 14.7/1000 (p<.003), and deaths from bacterial pneumonia/sepsis from 3.4/1000 to 12.6 (p<.001). Deaths from cirrhosis, osteomyelitis, trauma and other causes showed no significant increase or decrease over the five years. AIDS incidence rates from 6/1000 in 1984 to 20.4/1000 in 1987 (p<.001). Year-to-year analysis yielded similar results. Hospitalizations for AIDS, bacterial pneumonia, and endocarditis/sepsis increased from 84.9/1000 in 1986 to 144.9/1000 in 1987, with minimal or no increase in other diagnostic categories.

Conclusions: Results indicate that AIDS has had a profound impact on morbidity and mortality among IVDU's in our RMP, reflected not only in AIDS diagnoses but also in secondary bacterial infections. Data suggest that RMP's may be important sites for targeting clinical services for HIV-infected IVDU's, which will require expansion of existing resources to meet the growing need for AIDS-related care.

Th.D.0.18 AIDS PREVENTION THROUGH THE ORIGINAL JUSTICE SYSTEM (CJS): REFERRAL OF INTRAVENOUS DRUG ABUSERS (IVDA) TO DRUG ABUSE TREATMENT
 Lewald, Carl; Bellini, Robert; Picheno, R.
 National Institute on Drug Abuse, Rockville, MD, USA

OBJECTIVE: To explore the potential contribution of the CJS to AIDS prevention through referral of IVDA to drug abuse treatment.

Methods: Data from a recent study of IVDA admitted to methadone treatment were examined. Original justice and drug abuse treatment literature were reviewed, and relevant experts were contacted.

Results: Drug abuse treatment has proven effective in helping IVDA stop drug injection. In fact, there is an important AIDS prevention strategy. Yet, only 1 in 7 IVDA in the US is in treatment. The CJS provides access to approximately 80% of all arrestees but used illicit drugs at arrest. Rates of CJS involvement among IVDA are high. Yet, only about 20% of IVDA in treatment were CJS-referred. A study of treatment admissions in 5 cities found that 22.1% were CJS-involved, with rates of involvement ranging from 9.3% in New York City to 37.6% in San Antonio. HIV infection rates within each city were similar for CJS-involved and non-CJS-related individuals with no current CJS involvement, suggesting similar rates of HIV infection. Conclusions: The CJS provides an important AIDS prevention strategy. The treatment referral and other AIDS prevention programs. Yet, this resource is underutilized. Potential strategies to improve referral initiatives are high, especially in cities such as New York where HIV rates are high and CJS-involvement is low.

M.D.P.19 **ETHNOGRAPHIC AND RISK-REDUCTION PRACTICES OF MALE BAR WORKERS IN BANGLADESH**

DEBAPATI BHATTACHARYA, FRANKLIN P. BATTANARON, M. WEI
DAVID L. KONTZ, Ed. Center for Health Research and Education, Bangkok, Thailand, *Family Health International, North Carolina, USA.

Objective: To determine risk factors for directing intervention programs.
Method: We surveyed 141 male bar workers in 5 bars in Bangkok.
Results: 78% of the men were between 17 and 21 years old and 84% were born outside of Bangkok. 49% were living with friends who worked in similar bars. 31% had only primary school education. 68 were rarely or never exposed to the mass media. 55% had never worked in a bar before. 50% had worked in bars for 2 months or less. 82% had chosen bar work to solve their unemployment problem. 51% were introduced to this job by their friends and 34% by reading job advertisements. Only 50% stayed in the bar longer than 2 months. In the 2 week period prior to the survey, 100% had sex with male customers, 23% with female customers, 13% with non-customer males, and 50% with non-customer females. In the same period the men averaged 5.6 male partners. 53% of the men did not use a condom the last time they had insertive anal sex. The last time the bar worker had receptive anal sex, 43% of the bar workers' insertive partners did not use a condom. 72% had both insertive and receptive anal sex. 55% had used condoms for oral sex. 99% of the men had not used IV drugs in the last 5 months.
Conclusion: The sexual activities of these young men with little education and rural backgrounds place them at high risk for HIV infection. The potential for rapid HIV spread is high because they have sex with both men and women as customers and non-customers.

M.D.P.21

THE IMPACT OF COMMUNITY-BASED BEHAVIORAL GROUP INTERVENTION TO HELP PERSONS REDUCE HIGH-RISK SEXUAL BEHAVIORS
Ellis, Jeffrey A.*; St. Lawrence, J.S.*; Brawfield, T.L.*
Head, N.I.H.;* & Univ. of Mississippi Medical Center, **PL Dept. of Health & Rehab. Services, U.S.A.

Objective: Many individuals still have difficulty implementing and maintaining adequate change in sexual patterns. Behavioral skills training principles can be used to assist persons reduce high-risk behaviors.
Method: In Study 1, 106 men who engaged in risky behavior with multiple partners were randomly divided into experimental and control groups. Experimental subjects participated in 12 group sessions of risk education and self-management, assertion, and cognitive skills training specifically related to sexual risk reduction. In Study 2, a second cohort participated in a similar 6-session program. Behavior change was assessed using multiple self-report, self-monitoring, and sexual assertiveness skill measures. Follow-up data through 24-month postintervention were obtained.
Results: Multivariate analyses revealed significant reductions in occurrence of anal intercourse to near zero levels and greatly increased use of condoms, risk knowledge, and sexual assertiveness behavioral skills as a result of this training. Change was well-maintained even at long-term follow-up and was corroborated by change across the measures.
Conclusions: Behavioral principles derived from other areas of health promotion can be adapted for use in AIDS risk reduction. These findings identify a model to help persons acquire the skills to implement and maintain behavior change recommendations. This model is of practical importance for men clients seen in AIDS prevention programs, health and STD clinics, and schools.

M.D.P.23

PERSISTENCE OF HIGH-RISK SEXUAL BEHAVIOR IN HOMOSEXUAL/BISexual MEN: A MULTI-CENTER STUDY
Doll, Lawrence, Ph.D.; Rabin, G.M.; Douglas, J.M.***
Noon, P.*; Miller, Ph.D.***; Centers for Disease Control, Atlanta, GA; **San Francisco Public Health Dept., ***Denver Disease Control Service; **Newport Brown Clinic, USA**

Objective: To describe and predict high-risk sexual behavior in homosexual men attending 3 STD clinics.
Method: 463 men who engaged in unprotected anal or oral sex in the previous 6 months were interviewed from April-Dec, 1988. Risk was assessed by calculating: 1) absolute % of unprotected anal and total (anal and oral) exposure and 2) ratio of unsafe to total exposures for the 6-month period. Principal component and cluster analyses were used to arrive at groups of men; regression techniques were used to predict levels of risk.
Results: Preliminary cluster analyses identified subgroups: 1) a relatively-closed group (N=22) who self-identified as heterosexual/bisexual; 2) a somewhat-closed group (N=101) of older, self-defined bisexual/homosexuals; 3) a younger, openly-homosexual group (N=109) with male steady partners; 4) an older, openly-homosexual group (N=195) with higher incomes and nonsteady male partners; and 5) a small, openly-homosexual group (N=37) with large numbers of sex partners and higher cigarette and drug use. Regression analyses showed having sex with a steady partner, younger age at first sex, isolation from gay organizations, bisexuality, IV-drug use, and "hustling" were related to higher levels of unprotected exposures.
Conclusions: Relative exposure estimates to have unsafe sex; each subgroup will require targeted education to effect behavioral change.

M.D.P.20

Peer and Partner Influence and Self-confidence as Correlates of AIDS Preventive Behavior (APB) in a Low Prevalence State-
Landis, E.E., Kary JA, Univ North Carolina, Chapel Hill, NC

Objective: To examine the effects of social influence and self-efficacy on APB knowledge and by the self-reported practice for HIV-1 with a partner in a heterosexual sample in a low prevalence state.
Method: Over a 6-month period in a low prevalence state, 1000 men were conducted with 335 adults tested for HIV antibodies at 2 Counseling and Testing Sites in North Carolina. Emphasized were: perceptions of network behavior; respondents' own, as well as peers and partners', beliefs about practicing safer sex; and confidence in the ability to elicit negative social network influences.
Results: In this largely rural state, our sample was 64% black, 32% female, 67% homosexual, 12% IV drug users, 10% positive for HIV-1, with a median age of 26. Almost the entire sample (94%) knew that having only one steady sexual partner would reduce the risk of HIV infection. Over 80% of the men in the past month and believed "safe sex" was "turn off" over 80% (84%) believed their peers also had more than 1 partner while 60% felt "safe sex" was hard to practice "in the heat of passion". Over two-thirds (68%) believed their peers engaged in "unsafe sex" and 62% were not certain they could adopt safer sexual practices. Those who believed their peers and sex partners practiced or encouraged safe sex perceived fewer social barriers to change (10%), reported more preventive behaviors (16%) and were more confident they could change their behavior (33%).
Conclusions: In a heterogeneous but predominantly heterosexual, highly acute population in a low prevalence, rural state, imaginative counseling should try to reinforce perceptions of positive social influences, elicit network barriers, emphasize peer support and enhance self-confidence.

M.D.P.22

PSYCHOLOGICAL AND DEMOGRAPHIC CHARACTERISTICS OF GAY MEN WHO DO OR DO NOT ENGAGE IN UNSAFE SEX
Ellis, Jeffrey A.*; St. Lawrence, J.S.*; Brawfield, T.L.*
Smith, J.J.*; Head, N.I.H.*; Jones, A.L.*; Univ. of Mississippi Medical Center, **PL Dept. of Health & Rehab. Services, U.S.A.;*Newport, U.S.A.**

Objective: To determine differences between gay men who still engage in unprotected anal intercourse, a behavior of particular interest because it is strongly predictive of HIV seroconversion even at low rates of occurrence.
Method: 508 men who patronized 8 gay bars in 3 different American cities (Atlanta, Tampa, & Mobile) completed a survey measure eliciting information on sexual practices over the past 3 months and AIDS risk knowledge, beliefs, and perceived sexual norms. Over 75% of all men entering these bars on survey nights completed the measures.
Results: 17% of the entire sample reported engaging in receptive or insertive unprotected anal intercourse in the preceding 3 months; 87% did not. Multivariate analyses confirmed significant differences (p<.0001) between men who engaged or refrained from this activity. Men who engaged in anal intercourse were more likely to attribute AIDS risk to chlamydia and "powerful other" external factors. They scored lower in AIDS risk knowledge, were younger, and had less education than men who did not engage in the activity. Similar patterns were found regardless of whether subjects were insertive or receptive partners.
Conclusion: Some gay men still engage in high-risk sex. In addition, to continued education, there is a need to stress efficacy themes that one's own behavior (rather than chance or others) determines risk for AIDS. Efforts targeted toward young, less educated gay men are now especially needed.

M.D.P.24

CONDOM USE CAN OCCUR DESPITE USE OF ALCOHOL AND DRUGS
Harrison, Janet, Ph.D.;*Waller, P.*; Bartholow, B.***
Atkins, G.A.*; Jorg, L.***; Centers for Disease Control, Atlanta GA; **Denver Disease Control; ***San Francisco Health Dept.; **Newport Brown Clinic, Chicago IL, USA.**

Objective: To examine the use of alcohol and drugs during high and low risk sexual contacts of homosexual and bisexual men who had engaged in unprotected anal or oral sex during the previous year. Men who had engaged in unprotected anal sex were used to describe the circumstances under which they last engaged in unprotected anal/protected anal sex. Compared the alcohol/drug use of 180 men during their last instance of unprotected anal sex versus their last instance of protected anal sex.
Results: Preliminary analyses (using the McNemar Test for Significance of Change) indicated no significant differences (p>.05) in alcohol/drug use before or during unprotected protected anal sex. Percentage of men using were:

UNPROTECTED/PROTECTED	NO	1-2	3-5	6-10	11-15	16-20	21-30	31-40	41+
ALCOHOL	100	432	302	195	58	21	601		
DRUGS	100	432	302	195	58	21	601		

In response to a question on reasons for not using a condom during alcohol/drug use, only 9.1% listed alcohol/drugs as the major cause.
Conclusion: Among high risk homosexual/bisexual men, alcohol/drug use is associated with sexual behavior in general but not only with unprotected sex. Men can and do use condoms when they are drinking and using drugs. The risk of substance use in high educated gay men are now especially needed, rather than motivating factors.

Le SIDA et l'individu AIDS and the Individual

M.D.P.37 SEXUAL BEHAVIOUR AND HIV RELATED KNOWLEDGE AMONG A RANDOM SAMPLE OF YOUNG POPULATION OF ITALY.

Marina Giannini, D'Angelo R¹, De Cadedo D², Della Giotta G³, Lino B⁴, Paresi F⁵, et al.
¹ Istituto Superiore di Sanità, Rome, Italy, ² University of Rome, Rome, Italy, ³ Pragma-MRA, Rome, Italy.

Objective: To quantify sexual activity and behaviour and to determine HIV related knowledge.

Methods: A random sample of young population (age 16-30) was selected using a nested sampling procedure. Nine local authorities (Comuni), three each for Northern, Central and Southern Italy and, for each one, one for each of the following population size (10,000-50,000, 50,001-100,000, >100,000) were randomly selected in order to be representative of metropolitan, urban and rural areas. A random sample of individuals was then contacted by the selected local authorities. Each individual was interviewed by the population size of the individual, mentioning the broad scope of the research and the support given by the I.A. to the initiative was sent to the selected individuals. Each individual was then contacted by specially trained interviewers who handed him out a structured questionnaire for self completion. The key questions were asked at first sexual intercourse, number of sexual partners in different periods, use of condoms, knowledge about HIV transmission and use of IV drugs.

Results: 1,450 individuals were contacted. Valid questionnaires were obtained in 1,044, with an overall response rate of 72%. Analysis is not yet completed and will be presented at the Conference.

Conclusions: The good response rate suggests that the population in Italy is prepared to answer questions about their sexual lifestyle.

M.D.P.38 FEE WOMEN FOR SAFER SEX AS A PREDICTOR OF SEXUAL RISK BEHAVIORS IN A SORT OF GAY BAR

Scott, Barbara N., Meyer-Halpern, H.P.L., Green, R.S., Ehrhardt, A.A., and Gorman, J.M.
EIV Center for Clinical and Behavioral Studies, Columbia University, New York State Psychiatric Institute; Columbia University, New York, NY, USA.

Objective: Recent evidence suggests that positive peer norms for safer sex are associated with sexual risk reduction. This study looked at sexual risk behaviors as a function of perceptions of peer norms for safer sex in a sample of gay men. Subjects are primarily white and middle class; target ages: 19-60 years.

Methods: Subjects provided a detailed sexual history, and completed a self-report measure evaluating peer norms regarding safer sex, modeled after Finkelhor's theory of reasoned action.
Results: Preliminary analyses (N=70) indicate that approximately 74% of the cohort engaged in sex with multiple partners. Rates of at least one occasion of unprotected sex were: 56% (receptive anal); 41% (insertive anal); and 80% (vaginal). Subjects' perceptions of peer norms for safer sex were associated with having fewer sex partners (p<.025), with being monogamous (p<.005), with fewer sex occasions (p<.005), and with fewer occasions of unprotected sexual activity, but not with incidence of unprotected insertive or receptive anal activity.

Conclusions: Perceptions of peer norms for safer sex indicate at least some sexual activities, even in a sample of gay men from a highly organized community. Failure of peer norms to predict unprotected passive anal activity may be related to greater incidence of such activity among monogamous men (p<.025).

M.D.P.39 GAY IDENTIFICATION IMPROVES THE EFFECTS OF ALCOHOL USE ON AIDS RISK BEHAVIOR

Robert E. Page, D. Williams, D.J. University of Alabama at Birmingham, University of Illinois at Chicago, USA

Gay males' shift toward safe sex is often attributed to their identification with an active community which promotes safe sex, in contrast to IV drug users. Our data, however, show that many gay males slip from safe sex, and that this is often related to alcohol use. Given the importance of the gay bar, we reasoned that identification with the community, while providing safe sex norms, may also induce risk via exposure to alcohol settings. This process may differ by levels of gay identification.

Objective: To examine the complex relationships among gay identification, involvement in the gay community, alcohol settings, and AIDS risk behavior.

Methods: A structured interview among a sample of 87 gay men from a large urban area.
Results: For all respondents, alcohol use, both by the individual and their primary social network, increased risk for unsafe sex. However, for highly gay identified respondents, alcohol use increased risk behavior via alcohol use in multiple gay settings, and not primarily the bar. In contrast, for low identified respondents, AIDS risk behavior was strongly related to bar-going.
Conclusions: Alcohol continues to be an important risk factor for unsafe sex among gay men. Further, such risk factors operate differently for those with different levels of gay identity. Thus, understanding and/or preventing AIDS risk behavior requires that specific cultural features of the gay community be examined.

Travailleurs de la santé Health Care Workers

M.D.P.41 DECENTRALIZED SERVICES: GLOBAL NETWORK-TYPE APPROACH

POISSON, MARIE, WORMSTEIN, N.K.
AIDS AND TESTING TEAM, QUÉBEC CITY, QC, CANADA

Objective: To make accessible medical and psychosocial services in order to provide persons concerned by HIV infection and AIDS with quality services.

Methods: 1. Setting up of a general practitioner/physician network in the public and private sectors. 2. Selection according to interest, geographical distribution, accessibility and operation methods (confidentiality). 3. Self approach, pre and post-test counseling, coded on-site sampling, medical follow-up, psychological referral. 2. Setting up of a network of psychosocial professionals working in the public and private sectors. 3. Priority interventions: individual consultations, support groups for seropositive persons, case management. 4. Professional expertise: social workers, psychologists, sociologists. 5. Training of medical and psychosocial intervening parties. Information to target groups, interventions among media. Health education. Access to services through Info-Health (24 hr. hot line).

Results: After one year: 1. Staff: 33 physicians, 7 social workers, 2 sociologists, 2 psychologists, 1 nurse, distributed across 18 service points. 2. Achievements: 227 referrals to the medical network by Info-Health, 22 group meetings (seropositive persons), 85 interviews media, 33 presentations (lectures, conferences).
Conclusions: The "network" team is operational. Offered services aim at reaching target groups to help them to reduce their risk factors and to support them in what they are experiencing.

M.D.P.40 KNOWLEDGE, ATTITUDE AND PRACTICE RELATING TO AIDS AMONG A RANDOM SAMPLE OF STUDENTS AT A PARIS UNIVERSITY.

Jean-Marcus, P. Echeverry, V. Massat, F. Sureau, S. Lesieur, et al.
INSERM U263, Université Paris 7, 2, pl. Jussieu, 75251 PARIS, Cedex 05, FRANCE - INSERM Unit, Vigneul, FRANCE

Objective: To provide a database on perception and reaction of beginning university students concerning sexual practices in the AIDS epidemic in order to develop a continuously adapted program of information.

Methods: A 1st IV in the random sample including 471 male and female, 17-22 year old students answered a self-administered anonymous questionnaire, through 140 items, knowledge, attitudes and practice with regard to health in general, sexually transmitted diseases and AIDS.

Results: The response rate was 88%. Less than 5% of questions were unanswered. Questions concerning sexual practices have the same response rate as those concerning knowledge and attitudes. Students are concerned by the quality control of condoms. While 88 % say that they know that condoms, without reference to quality, reduce the risk of getting AIDS, this frequency rises to 82% when the condom proposed has the quality control seal. While 72% of the students actually plan to use condoms, only 49% of questions concerning the practical use of condoms were correctly answered by those students having sexual intercourse and only 40% of students say that they really use it (26% sporadically, 16% systematically). These latter figures do not differ between males and females nor between students with a single sexual partner and those with more than three sexual partners.

Conclusions: A proposed program of information should include a wholly explicit explanation about the practical use of condoms. A pilot program is to be proposed for adoption after discussion with students about specific sensitization and motivation.

M.D.P.42 OVERSTIMATION OF RISK FOR OCCUPATIONAL HIV TRANSMISSION AS A FACTOR IN THE DECISION TO USE CONDOMS

Scott, Barbara N., Meyer-Halpern, H.P., Green, R.S., Ehrhardt, A.A., and Gorman, J.M.
EIV Center for Clinical and Behavioral Studies, Columbia University, New York State Psychiatric Institute; Columbia University, New York, NY, USA.

Objective: To assess the prevalence of gross and exaggerated risk for HIV infection as they potentially function as a factor in the decision to use condoms. The study was conducted in a sample of gay men who were interviewed about their sexual practices and their use of condoms.

Methods: Having questioned by personal staff or apparent best of knowledge about HIV was frequently asked about overestimation because knowledge about occupational risk for HIV was frequently asked about and having studied at a major university. The study was conducted in a sample of gay men who were interviewed about their sexual practices and their use of condoms. The study was conducted in a sample of gay men who were interviewed about their sexual practices and their use of condoms.

Results: A total of 140 gay men were interviewed about their sexual practices and their use of condoms. The study was conducted in a sample of gay men who were interviewed about their sexual practices and their use of condoms.

Conclusions: A proposed program of information should include a wholly explicit explanation about the practical use of condoms. A pilot program is to be proposed for adoption after discussion with students about specific sensitization and motivation.

M.D.P.43

JOB-RELATED STRESS AMONG HIV-ANTIBODY TEST CONSULTORS
Buss, D. J., Spigel, Susan Liggett, Pagan, S. A., Rhodes, P., **
**California State University, Long Beach, CA, USA

Objective. To assess the stress and level of stress among counseling consultants in July 1987. A questionnaire designed to measure job-related demographic factors was self-administered by 781 (50) of all HIV, and in counseling and testing centers throughout California. Consultants included: respondents ranged to female (82%), white (82%), college educated (77%), and generally scored well on knowledge questions. Gender, education, training or degree, and volunteer versus paid status were not associated with either level of knowledge about HIV/AIDS. Psychosocial factors: 0.18) and stress index (Chronbach's $\alpha = 0.82$). Significant associations ($p < .05$) were observed for: age and knowledge questions (Chronbach's $\alpha = 0.82$); time pressure (Gittelman's $\alpha = 0.82$); and helplessness/optimism scale (Chronbach's $\alpha = 0.82$). Significant associations between levels of stress and counselor age, counselor gender, sexual orientation, and time pressure were observed. Significant associations between stress and stressor were reported by consultants who perceived less control in their work environment ($p < .05$). Age, sex, and education reported stress ($r = 0.22$, $p < .05$). Stress was measured by the S-OSSQ. Significant associations between perceived stress and counseling stressors were reported by consultants who were not target interventions.

M.D.P.44

PRIMARY CARE PHYSICIANS' KNOWLEDGE, ATTITUDES AND WILLINGNESS TO TREAT AIDS PATIENTS

George L. James*, Stoneburner, R., Gemson, D**, Columbus, J.A., and Elinson, J.

*New York City Dept. of Health, **Columbia University, New York, New York

Objective. To examine the relationship between physician knowledge, attitudes, personal characteristics and AIDS prevention and treatment practices. Data were collected from 472 primary care physicians in New York City were taken during 1988 about knowledge, attitudes and clinical practices toward AIDS prevention and treatment.

Methods. Telephone interviews of a representative sample of 472 primary care physicians in New York City were taken during 1988 about knowledge, attitudes and clinical practices toward AIDS prevention and treatment. Thirty-six percent of physicians would refer an HIV patient elsewhere rather than manage alone or in consultation. Stepwise logistic regression analysis estimated the adjusted odds ratios between physician characteristics and willingness to treat AIDS patients shown below.

Characteristic	Adjusted Odds Ratio
Age < 40 years	1.85-2.47
Practice Internal Medicine	2.56
High AIDS Knowledge	1.53-2.42
Liberal Political Orientation	3.22
	1.58-2.51
	1.5-2.65

Physicians' race and attitudes towards homosexuals were not retained in the final logistic model when controlling for variables shown above. Conclusions: Preliminary data suggest that physician age, specialty, level of knowledge and political orientation are associated with willingness to treat AIDS patients.

M.D.P.45

COLLABORATIVE EVALUATION STUDY OF AIDS TRAINING PROGRAMS FOR WOMEN'S HEALTH PROVIDERS

Doherty, M., Coughlin, E.,* Gillette, F.,** Sackel, J.,***
*NYC Dept. of Health, NYC, USA, **Montefiore Medical Center, Bronx, NY, USA, ***NYNY Health Science Center at Brooklyn, NY, USA, ****NY Sexual Health Center, NYC, NY, USA

Objective. To develop, implement and evaluate AIDS training programs for health care providers of inner-city women, so that AIDS education, prevention and counseling can be incorporated into routine women's health services.

Methods. Three NYC teaching hospitals have been selected to conduct training programs for a total of 750 women's health providers using three distinct models: (1) a competency-based, teaching symposia model; (2) a multi-modality model; and (3) a training-of-trainers model. Using a quasi-experimental study method to evaluate training effectiveness, pre- and post-training questionnaires were developed to measure changes in provider knowledge, attitudes and medical practices. As a further assessment of provider training, participants are being asked to report on the AIDS prevention services they receive.

Results. Changes in provider knowledge, attitudes and medical practices before and after the AIDS trainings will be described and analyzed across the three hospitals. Differences in outcome will be reported.

Conclusion. As a result of provider training in AIDS education, prevention and counseling, most women's health providers now incorporate these services into their routine health care. As a next step, it is important to ascertain whether provider training has an effect on the knowledge of AIDS and risk reduction practices among inner-city women who voluntarily seek health care.

M.D.P.46

THE NEEDS OF PERSONS LIVING WITH AIDS
Mena Herr, N.Sc.G.W., C.S.W., Social Services
Advisor, Federal Centre for AIDS, Health and Welfare Canada, Ottawa, Canada

A needs assessment study was conducted across Canada to identify and prioritize the major palliative care needs of persons living with AIDS. A two-part questionnaire was developed to gather both quantitative and qualitative information on eight core issues considered to be critical in the care of AIDS patients. A targeted sampling approach was used to ensure that within four categories of potential respondents, Canadians had with varying amounts of experience in caring for persons living with AIDS were included. The respondents were drawn from every region of the country which included 27 hospitals, 28 palliative care programs, 15 home care/visiting nurse services and 13 community AIDS groups. This presentation will present the results of this study and describe how Canadians who care for persons living with AIDS have spoken about the resources they require to provide an effective and a humane response to this devastating disease. This study has major implications in the development and expansion of Canada's present health care system.

M.D.P.47

THE KNOWLEDGE AND UNDERSTANDING OF HUMAN IMMUNODEFICIENCY VIRAL (HIV) INFECTION AMONG HEALTH CARE WORKERS (HCW) IN TEACHING AND NON-TEACHING HOSPITALS IN JAMAICA.

FRISBY A. OTHMAN, P. Franks

Department of Microbiology, University of the West Indies, Mona, Jamaica, W.I.
The Acquired Immune Deficiency Syndrome (AIDS) is now evolving into a global epidemic affecting a wide cross section of the world's population. Public education on AIDS in Jamaica began in April 1987. No known case of HIV infection in Health Care Workers (HCW) has been reported in Jamaica or in the Commonwealth Caribbean and neither has any study been undertaken to assess the understanding of HIV infections to Health Care Workers in Jamaica.

The aim of this study therefore, was to assess the knowledge and understanding of H.C.W. on HIV transmission and isolation and precision to be instituted for control of HIV infection and also, to ascertain whether any differences in knowledge existed between H.C.W. of teaching and non-teaching hospitals. A total of 650 questionnaires were sent to H.C.W. in four hospitals (2 non-teaching and two teaching), of which 509 were returned, a response rate of 79%. Questions on AIDS transmission via blood transfusion and sexual intercourse and proper disposal of sharps received highest scores (85-100), embracing all groups at both teaching and non-teaching hospitals. The greatest area of misunderstandings and misconceptions were reflected in responses obtained on sharps and needles which received low scores (4-100) for both teaching and non-teaching hospitals.

Our study demonstrated that there was no difference in the knowledge of HIV infection among HCW in teaching and non-teaching hospital, and an urgent need for a comprehensive approach to education of HCW on prevention and control of HIV infection in Jamaica.

M.D.P.48

IMPACT OF AIDS WORKSHOP ON KNOWLEDGE AND ATTITUDES IN HEALTH CARE WORKERS

Charles, Jennifer, Engstrom, M., Shaw, R., Metz, J.
AIDS Training and Information Centre, South Africa Institute for Medical Research, Johannesburg, South Africa

Objective. To determine the state of and change in health care workers (HCW) knowledge and attitude towards HIV infection and AIDS after attending a workshop in 1985. The workshop assessed the national history, transmission and prevention of infection, psycho-social aspects and counselling. The information was presented using a combination of didactic sessions, audio-visual material, role plays, group activities and discussion. 200 participants completed a pre and post-test questionnaire designed to elicit attitudes towards knowledge of the disease. The questionnaires were analysed comparing (1) knowledge before and after the workshop, and (2) the correlation between knowledge and attitude.

Results. Significant differences were found in knowledge and attitudes before and after the workshop. The majority of respondents lacked basic knowledge prior to the workshop. In addition, attitudes changed with more knowledge and anxiety decreased significantly.

Conclusion. The results of this study confirm that workshops promote knowledge, improve attitudes and thereby assist HCW in providing optimal care to patients and disseminating education for prevention of HIV infection and AIDS.

M.D.P. 49 EXPERIENCE WITH AIDS AMONG 3500 ZAIRIAN HEALTH WORKERS, 1987-1988

Moola, Ndinda, **, Hasiela, K. **, Luusuluira M. **, Bertrand DE **, Kambala TD **, Zaire School of Hygiene, Kinshasa, Zaire
** Tulane University, New Orleans, USA

Objective. To determine the current level of AIDS experience among health workers (HW) throughout Zaire.
Methods. We surveyed 3462 Zairian physicians, nurses, health facility workers, community HW and traditional healers.
Results. A total of 423 reported personally knowing someone with AIDS, and 183 had cared for an AIDS case. Cases were reported from urban and rural areas of all regions. Half of these persons had been informed of AIDS. One-third of persons caring for a patient of his HIV(+) or AIDS status, and 62% favor informing the family. However, only 81 of AIDS cases and 22% of their families were so far informed. These percentages increased greatly between 1987 and 1988, when national policy permitted informing cases of their AIDS status. One-third of respondents favor isolation of AIDS cases, and 3K recommend killing them.
Conclusions. 1) This is the first report suggesting that AIDS can be found throughout Zaire. 2) Patients and families are generally not informed of the AIDS diagnosis. 3) Negative attitudes of HW toward AIDS cases must be addressed to ensure a more positive role of HW in AIDS education activities.

M.D.P. 51 GENERAL PRACTITIONERS AND MANAGEMENT OF HIV INFECTION

Masard, Yvonna, Landman R. **, Fagnan F. **, A. J. Valeron **
INSERM U104, France, ** Services des Maladies Infectieuses, Hôpital Bichat, Paris, France, ** INSERM U240, Paris, France.

Objectives. To survey current practice and attitudes among GPs in relation to the presence of HIV and in relation to the management of HIV infection in asymptomatic, seropositive patients.
Methods. A questionnaire was mailed to all sentinel GPs (N=500) of the French Communicable Diseases Network (1% sample, representative of GPs in France). Questionnaire components included demographic data and attitudes towards HIV screening and follow-up of patients, personal methods for obtaining information about the disease, HIV antibody testing and their strategies for the management of HIV infection.
Results. The response rate was 70%. Within the context of their medical practice, 67% said that they were affected by the subject of HIV infection, while 29% were already caring for an infected individual. 47% of these GPs thought that it was useful for them to follow infected patients. 6% considered these patients to be a normal part of the practice of medicine for a GP. 38% complained that they did not have enough information to do this. 20% of these GPs had reservations about lack of an infected patient's 9% expressed fear of contagion. There was a positive relationship between having reservations about treatment and the perception of the lack of information ($p < 0.05$). 9% of GPs had no systematic routine toward HIV screening and always waited for patients to request the test. HIV testing was systematically proposed by 52% of the GPs in the case of prenatal screening, by 40% for prenatal patients, by 37% for IV drug users, by 30% for homosexual partners.
Conclusion: The better informed a GP is, the more likely he is to have a positive attitude towards prevention and care of HIV infection. HIV testing is more often proposed by GPs when the subject is not a 'prior' at risk (i.e. prenatal or prenatal screening).

M.D.P. 53 ACCESS TO DENTAL CARE IN THE SAN FRANCISCO AIDS BEHAVIORAL RESEARCH COHORT

Griffin, Richard, Maguire, R, Sumner, J, and Coates, T.
University of California, San Francisco, California, San Francisco, United States.

Objective. Press reports in recent years have reported cases of dentists refusing to provide care for HIV infected and HIV infected patients. These reports have raised doubts about whether such patients have full access to dental care. We wished to learn the extent to which a cohort of men with HIV disease or at high risk for HIV disease had used dental treatment.
Methods. The San Francisco AIDS Behavioral Research Cohort were surveyed in November 1988. This group of gay men has been surveyed annually since 1984 to track their reactions to the HIV epidemic. The response rate was approximately 70% (N=336).
Results. Only 5 respondents (1.5%) reported having been rejected from a dental practice in the past 3 years because of their HIV status. Only 16% said they would not inform their dentist if they were HIV positive. Over half (54%) indicated they would freely volunteer the information to their dentist. The remainder said they would disclose their status under certain conditions, e.g. if oral manifestations of the disease were present.
Conclusion. The low prevalence of denial of care suggests that dentists in this community have responded well to the needs of this population. The relative willingness of patients to disclose highly sensitive medical information may be a reflection of the positive response of dentists. It may also reflect stress state and local laws safeguarding confidentiality and prohibiting discrimination and the relatively positive response of San Francisco to the epidemic.
This study was supported by NIMH & NIDA Center grant #49814249.

Le SIDA et l'individu AIDS and the Individual

M.D.P. 50 A RAP SURVEY OF HEALTHCARE WORKERS IN BANGKOK ABOUT AIDS

Thongbun, Prachon, Sittivivat, T. **, and Visuvanond, S. **, Chulalongkorn University Hospital, **Center for AIDS Research, Bangkok, Thailand, Thai Red Cross Society, **National Statistical Office Bangkok

Objectives. To assess the knowledge, attitudes and opinions concerning AIDS among Thai healthcare workers (HCW) in order to find out the basis for their fears and the means to minimize such fears.
Methods. Questionnaire survey was conducted in 274 HCW in 3 hospitals in Bangkok during August-September 1988. Twenty-eight percent of the subjects thought that they have already had some exposure to HIV patients.
Results. Knowledge: Almost a quarter of the HCW admitted that they knew very little about AIDS. The misunderstanding was mainly the risk of HIV transmission with body fluids and the uncertainty about the efficacy of HIV inactivation procedures.
2. Attitudes: More than half of the HCW stated that they rather preferred staying away from HIV patients because of the fear of contracting the disease which they perceived lacked the adequate facility provided by the hospitals.
3. Practices: To make the HCW feel more comfortable in caring for HIV patients, they requested more frequent lectures and information distribution, particularly the measures to prevent nosocomial infection. They also requested free anti-HIV screening for themselves as well as better patient care among Thai healthcare workers (HCW) in order to find out the basis for their fears and the means to minimize such fears.

Conclusion: Results from this study can be used as the background information for every effort to improve the attitude and the quality of patient care in countries where HIV infection just emerges and resources are limited.

M.D.P. 52 WOULD PATIENTS SWITCH PHYSICIANS IF THEIR DOCTOR WERE HIV POSITIVE?

Griffin, Richard, Maguire, R, Hulley, S, and Coates T.
University of California at San Francisco, San Francisco, California, United States.

Objective. To assess patient perceptions of HIV in physicians' offices, including their reactions to physicians with HIV disease for their patients.

Methods. Telephone interviews were conducted in July and August 1988 with 2000 English-speaking, United States adults using a representative national sample generated by random digit dialing. A 73% response rate was achieved. The denominator for the data reported below is all those who received medical care from a physician in the past five years (N=1881; 94% of sample).

Results. Thirty-three percent of the respondents considered it likely that patients could get AIDS from an HIV infected physician. Forty-five percent believed that HIV positive physicians should not be allowed to continue to work (compared to 23% who believed HIV positive school teachers should not work). Fifty-six percent of respondents said they would find another physician if they believed their doctor were HIV positive. Twenty-five percent of the respondents said they would find another physician if they believed their doctor were treating people with HIV disease. Patients who said they would find another physician tended to believe that the virus could be transmitted from an infected physician to patients.
Conclusion: Patients are concerned about the presence of HIV in their doctors' offices but have misconceptions about the likelihood of transmission which should be addressed by public education program.

Supported by NIMH & NIDA #49814249 and the University-wide Task Force on AIDS.

M.D.P. 54 FEAR OF CONTAGION IN HOME HEALTH AIDS:

A COMMUNITY SURVEY

Melchior, Janine Bell, New England Deaconess Hospital, Boston, MA, U.S.A.

Objective: To determine the potential for severity of home health aides (HHA) willing to care for persons with AIDS (PWA) and seropositive persons for their clients.

Methods: A community telephone survey was conducted to the majority of proprietary agencies in our metropolitan area. A total of 21 agencies qualified for the survey. Fully answered the questions. The person in charge of assigning HHAs, usually a nursing supervisor, was asked three questions: 1) Are you having difficulty or do you anticipate having difficulty finding HHAs willing to care for PWA? 2) If yes, why are HHAs refusing to go into the homes of PWA? 3) Would a continuing education program for HHAs on HIV infection be useful to your agency?

Results: Difficulty finding HHAs willing to care is outlined below:

Agency	YES	NO	DON'T KNOW
Responding difficulty	9	2	
Anticipating difficulty	9	2	

Thematic analysis of answers to second question showed a high fear of contagion among HHAs. Contributing factors commonly identified included ethnic and cultural backgrounds of HHA, family pressure, and ignorance. Five of the supervisors felt strongly that education alone was not the answer. The interviews suggested a "kangaroo atmosphere" which either contributed to or ameliorated fear, which coincides with known fear by group anxiety.

Conclusion: Home health agencies may have difficulty meeting increasing needs of PWA's for personal home care due to the cultural, social, as well as educational factors which contribute to fear of contagion among home health aides.

M.D.P.67

40%-RELATED PROBLEMS FACING GENERAL PRACTITIONERS UPON RELEASE

Edil, Heston, Boston, F. N. and Swetlow, L. S.
F. Institute of Health Services, Belgium and St Scientific College of
General Practitioners in Brussels, Belgium.

In November 1983 a telephone survey was conducted among a representative sample of 175 GPs (12.6% of the total) working in Flanders (Belgium). The items studied were: 1) the proportion of GPs caring for seropositive or Aids patients, the indications for HIV-testing and the reasons later to avoid infection during medical practice. Eight percent of the GPs have at least one Aids seropositive patient and 1.5% the GPs without HIV-testing that for providing this medical care.

Number 12 of physicians asking HIV-test on different indications and number 13 of physicians

informing the patient about the meaning for seropositivity

	within for HIV-test		informing of the patient	
	Medical 12	13	Medical 12	13
physical follow-up	54/105 (51.4)	11/114 (9.7)	41/76 (53.9)	10/103 (9.7)
pregnancy	54/105 (51.4)	11/114 (9.7)	41/76 (53.9)	10/103 (9.7)
STI	54/105 (51.4)	11/114 (9.7)	41/76 (53.9)	10/103 (9.7)
"highly sensitive"	54/105 (51.4)	11/114 (9.7)	41/76 (53.9)	10/103 (9.7)
on the request of the patient	54/105 (51.4)	11/114 (9.7)	41/76 (53.9)	10/103 (9.7)

On the third of the physicians say to have changed their medical practice to avoid infection. Nearly seven percent of them allow either HIV-test or they refuse it. They refuse only a medicine for use during equipment, seven during hair visits 70% of the GPs learn the use of needles and syringes associated with the patient's advice.

Specific training for GPs is needed to be familiar with the needs of consulting seropositive and more informative education is desired to implement the HIV-test in a more appropriate way.

M.D.P.68

EVALUATION DE QUATRE DISPOSITIFS DE PROTECTION DES AIGUILLES USAGES POUR LA PREVENTION DE L'INFECTION HIV CHEZ LES FEMMELES DE SANTE ET PROPOSITION DE CRITERES DE CHOIX

Vismont-Ballemans, P., et al.
Centre Hospitalo-Universitaire, Angers, France ; * Centre Hospitalier,
Bellemeuse, St. Georges, France.

Objectif: Plusieurs dispositifs visant à éviter les piqûres accidentelles des personnels de santé sont aujourd'hui disponibles ; ceux-ci sont très hétérogènes dans leur conception et leur utilisation pratique. Nous avons testé quatre d'entre eux selon des critères rationnels et mesurables. Méthodes: 40 infirmières de 7 services différents de notre CHU ont testé 4 dispositifs couramment utilisés à savoir: Containeur (Sherwood), Sharpsafe (LBA), Acup-sécurité (Amdis) et Securoject (Astrim). Dix critères quantitatifs ou qualitatifs furent cotés: 1) facilité de désinfecter/éliminer l'aiguille et/ou le contenu du contenant; 2) risque de reflux; 3) résistance passive au cisaillement (distorsion, traction...); 4) risque de reflux; 5) résistance passive après usage; 6) acceptabilité sous différents usages (choix de soins, placement...); 7) présence ou non d'un désinfectant; 8) rapport qualité/prix. Résultats: Ils sont globalement satisfaisants pour les 4 dispositifs, mais 1) existe certaines disparités, en particulier pour les critères 3, 4, 5, 6. Discussion: Les critères retenus apparaissent une échelle de méthodologie pour une évaluation objective des différents dispositifs mis sur le marché; 2) ils sont compatibles avec les critères de choix établis dans des protocoles de soins et devraient permettre une acquisition raisonnée fondée sur un ensemble de critères objectifs et quantifiables; 3) convenirait-il d'appliquer ces critères à l'ensemble de l'équipement de soins pour une meilleure utilisation, d'affecter chacun de ces critères d'un coefficient qui tienne à leur importance.

M.D.P.69

MYTHS AND STIGMAS ABOUT AIDS IN HEALTH PERSONNEL IN A LATAMERICAN COUNTRY.

Bernal, M., de la Cruz, Valdeagüero, J.L., Alente, L.J., Granados, M.L., Ramirez, R., Sepúlveda, J.

Central Directorate of Epidemiology, Ministry of Health, Mexico

Objective: To obtain information about knowledge and attitudes of health personnel towards AIDS and the influence of communication media over them.

Methodology: A survey was done in a random sample of 808 health workers (61% (598 doctors and 598 nurses) working in care areas in institutional hospitals in 6 cities in Mexico.

Results: Although most do not identify the disease as produced by HIV (91%), 34% identify it as a disease caused by homosexual intercourse, 19% associate it to casual contact, and 17% to blood donation; more than 80% identify correctly sexual, blood and perinatal transmission and preventive measures. 20% consider that greatest population should be HIV tested. 57% are afraid of being infected, 51% would report an infected person, 80% would feel ashamed if a relative became infected, patient and only 20% would provide financial assistance. 51% would have sexual relations with an infected partner, 67% would refuse taking care of an infected patient and 57% would request another person to do it. 82% consider homosexuality a mental illness, 19% a sin, 60% a sexual aberration; 51% would not have homosexual friends. 40% consider prostitution immoral, 20% a sin and 51% socially condemned. No significant difference was found between attitudes in nurses and doctors. Their contact with information media is adequate, they consider that the messages are of good quality but incomplete.

Conclusions: Health care discordance between having received information and the level of knowledge and attitudes. This was consistent regardless of having received information about AIDS. Information is not enough to modify deeply ingrained attitudes. Educational campaigns must design specific educational strategies that influence social and psychological areas and not only cognitive aspects.

M.D.P.70

HIV-1 KNOWLEDGE, ATTITUDES AND RISK PERCEPTION IN BIOMEDICAL RESEARCH FACILITY EMPLOYEES

Stehman, Rubin, Vlahov, D., Currow, B.,

Johns Hopkins University School of Hygiene and Public Health, Baltimore, MD, USA

Objective: To identify and characterize HIV-1 knowledge, fear and risk perception among employees at a biomedical facility active in AIDS research.

Method: A questionnaire was self-administered by a random sample of 274 employees stratified into occupational groups: 1) custodial/maintenance, 2) clerical/administrative, 3) technical, 4) scientific. Information on potential occupational exposure to HIV-1 was available. The response rate was 64% (n=174). Results: Knowledge scores were high and not significantly different between groups except on a subset of questions dealing with casual

contact. On this section groups 1 and 2 scored significantly lower than groups 3 and 4 (p<0.05). Fear levels were similar across groups; 34% of custodial, 15% of clerical, 26% of technical and 10% of scientific staff reported moderate to high levels of fear. Surprisingly, despite high knowledge levels and wide differing levels of actual risk of exposure, approximately 40% of each occupational group felt themselves to be at occupational risk of HIV-1 infection; approximately 20% of workers assigned their role of infection to 1/10,000 or greater. Conclusion: Although potential actual risk of occupational exposure to HIV-1 varied greatly among a group of research facility workers, similar levels of fear, concern and risk perception were noted. The relatively high levels of fear in low exposure groups may be the result of misunderstandings regarding HIV-1 exposure in the workplace.

M.D.P.71

MEDICAL STUDENTS' KNOWLEDGE AND CONCERNS ABOUT HIV INFECTION

Sklar, J., Lee and Culbert, Arthur

School of Public Health, Harvard School of Medicine, Boston, Mass. U.S.A.

Objective: To examine the knowledge, concerns and attitudes of medical students about HIV, treatment of AIDS patients, and affect on careers.

Method: In May 1988 124 1st year and 103 2nd year medical students at Boston University were surveyed.

Results: All students were knowledgeable about casual, anal/vaginal and drug use transmission of HIV. Approximately 70% of 1st year students reported knowing a great deal about transmission of HIV, risk behaviors, and risk groups. Less than 25% of either year reported knowing a great deal about the legal or ethical obligation to treat AIDS patients, or the cost to patient and society; and less than 10% reported being taught about these issues. Over 50% of both years said you or did not know whether prostitutes, IV drug users, pregnant women, people getting married, and immigrants should be tested for HIV. 85% of 2nd year and 89% of 1st year worried about being infected as medical students, and 60% of 2nd year and 80% of 1st year wanted or were not sure if they should be allowed to refuse to treat AIDS patients. 45% of 2nd year and 27% of 1st year reported that the epidemic will influence their decision to practice clinical medicine.

Conclusions: Medical students' concerns about becoming HIV infected may influence their decision to practice clinical medicine. Their unwillingness to treat AIDS patients, 45% of 2nd year and 27% of 1st year, curricula should address HIV transmission, implications of testing and other AIDS-related policies, and legal, ethical and patient/societal issues.

M.D.P.72

RISK OF OCCUPATIONAL EXPOSURE TO HIV INFECTED BODY FLUIDS AND TRANSMISSION OF HIV-1 AMONG HEALTH CARE WORKERS: A MULTICENTRE STUDY

Ippolito, Giannini, Carrobbi, P., Carosi, G., Ripicco, P., Filini, G., Puro, V., Sanchez, M., Viscusi, D.

The Italian collaborative study group on HIV occupational risk, IRL

Objective: To evaluate the risk of occupational exposure to HIV and other

potentially infected body fluids and the risk of transmission of HIV infection

Method: In Italian hospitals (7840 beds) have been enrolled in a multicentric study on occupational risk of HIV infection. The study is supported, in part, by the Italian Ministry of Health (IDS Project).

All participating hospitals started in March 1985 and 1987. A prospective surveillance of occupational exposures, the risk of exposure, per person/month of work, has been calculated.

Results: In December, 1988, 255 occupational exposures to HIV infected blood or body fluids (parenteral 71.7%, mucous-membrane exposure 28.3%) have been observed on a total of 2220 exposures to potentially contaminated

materials. All HIV exposed to HIV, were prospectively followed and none of them seroconverted after a median follow-up of 13 months (range 2-34 months).

The risk of occupational exposure by occupational group were: nurses 52.1, physicians 28.7, housekeeping 19.8, laboratory technicians 7.3. The risk of seropositivity per person/month of work (on a total of 1465 person/month at risk) was: category was: physician .0066, Nurse .0095, Housekeeping .0004, Laboratory technicians .0011.

Conclusions: Despite massive information, the risk of occupational exposure to HIV contaminated materials continue to be high, but the risk of infection is low.

Session 4/1 Individual Poster Session

Le SIDA et l'individu AIDS and the Individual

M.D.P.73 ADVERSE EXPOSURES TO BLOOD AND BODY FLUIDS AMONG PRACTICING NURSES IN THE UNITED STATES
 Wylie, Mary E., D'Arcy, G., Lawson, N., Wesley, R.* and Janderson, D.K.*. *Clinical Center, N.I.H., Bethesda, MD., U.S.A. **Georgetown University School of Nursing, Washington, D.C., U.S.A.

Objectives: To 1) assess the frequency and intensity of adverse exposures to blood and body fluids and 2) assess the attitudes toward and practices of Universal Precautions (UP) among practicing nurses in the United States.

Methods: Detailed questionnaires requesting demographic data, knowledge and use of infection control procedures, and frequency and types of adverse exposures to blood and body fluids were distributed to certified nurse nurses in the U.S.

Results: 17642503 (60%) returned completed questionnaires. 1562 (88%) of the 1754 respondents provide patient care. Of those providing care, 85% have completed masters level training. With respect to knowledge and use of UP, 65% reported using UP in their practices. Of those not using UP, 40% reported occupational injury with UP, 30% had UP unnecessary, and 79% reported that UP interferes with the patient-nurse relationship. 45% perceive a high risk for occupational infection with hepatitis B virus and 45% perceive a high risk for occupational infection with HIV-1. 49% have received hepatitis B vaccine. Of the 1562, 375 (24%) reported 823 hazardous exposures and 762 (51%) reported 1154 hazardous exposures with blood or amniotic fluid in the past 6 months. **Conclusion:** This national sample of a small, but well-educated population of health-care workers demonstrates a high level of knowledge and use of UP. Although only a small percentage were unfamiliar with UP, almost half do not use UP in practice. These data emphasize the need for effective UP education, stressing both the presence of occupational risk as well as appropriate measures to minimize the risk.

M.D.P.74 THE IMPACT OF AIDS ON HEALTH CARE PROVIDERS: AN ANNOTATED BIBLIOGRAPHY AND SYNTHESIS
 Baskin, J.M., Palmer, Mergley, Taylor, K.M. Physician Behaviour Research Unit, Department of Behavioural Science, University of Toronto, Toronto, Ontario, Canada, M5S 1A8.

To understand further the impact of AIDS on health care providers, the International projects have been conducted by the Global Program on AIDS of the World Health Organization.

(1) Annotated International Bibliography. Drawing on health care and social science literature from around the world, the bibliography will focus on the psychosocial impact of AIDS for the providers of health care on factors associated with this impact, and on the implications of providers' response for the health care system and for quality of care. The bibliography will be based on a theoretical model of health care provider behaviour. Each citation will include a summary and an analytical commentary.

(2) International Survey. Approximately 160 countries will be surveyed to identify: (a) the nature of health care providers in each country who are currently caring for AIDS and seropositive individuals; (b) the major problems faced by these providers; and strategies to deal with them; (c) the settings in which care is being given; (d) the sources of funding; and the role of government in providing care; (e) ongoing research that focuses on the behavioural impact of AIDS on health care providers; (f) services and strategies that will be required in the future and (g) people who are interested in participating in future studies of health care providers and their response to AIDS.

M.D.P.75 THE ROLE OF HOMEMAKER/HOME SUPPORT SERVICES IN AIDS CARE IN CANADA
 Monahan, Kathleen*, Fiets, M.**

* Canadian Council on Homebased Services, Toronto, Ontario, Canada
 ** Family Services Unit, St. Catharines, Ontario, Canada

Objectives: To report the results of the Canadian Council on Homebased Services' AIDS training needs assessment study and describe service care delivery issues in the homebased industry in Canada and Europe.

Methods: Preliminary data from the 1989 C.C.H.S. Study on Homebased Services & Training Needs for AIDS care and from the 8th International Congress of the International Council on Homebased Services (May 7 - 12, 1989) will be presented to identify the issues affecting the delivery of homebased/home support services to persons with HIV/AIDS and their partners/families.

Results: Homebased services to persons with AIDS are now being provided in Europe and Canada through various home care models. Results will be available prior to June, 1989 indicating preferred models, training and support required, client-directed coordination methods, etc.

Conclusion: Participants will increase understanding of factors influencing effectiveness of home support/homebased service for persons with HIV/AIDS in Canada, with similarities to European care models noted.

M.D.P.76 THE DOCTOR-PATIENT RELATIONSHIP:
 IS IT WORKING FOR PEOPLE WITH HIV INFECTION?
 Boland, Michelle and Tomosak, L.

University of California School of Medicine, San Francisco, CA, U.S.A.

Objective: While many articles have been written from the physician's point of view about the doctor-patient relationship, there are few data-based studies from the patient's perspective. The aim of this study is to document the patient's perceptions of their experiences with their health care providers.

Methods: 100 seropositive homosexual men with at least one HIV-related structured interview inquiring about stressors and coping, at 3 time points about 6 months apart.

Results: Data are presented on the frequency and nature of stressful and supportive interactions with HCPs over time in the following areas: (a) communication/information regarding symptoms, treatment, test results, diagnosis, and medical procedures, (b) HCP attitudes about treatment, (c) diagnostic skill, (d) treatment efficacy, (e) hospital stays, (f) clinical trial trials, (g) financial concerns, and (h) appointments. Responses are also tabulated according to type of health care provider and health, as well as diagnostic status of the subject at the time of the interview. Most subjects BCP and/or staff at the clinic, office or hospital however, many also cited doctor-patient relationship stressors and coping changed over time.

Conclusion: A comprehensive understanding of patients' changing needs for information, support, and guidance in the context of the doctor-patient relationship over time and the course of disease will permit HCPs to respond more effectively to these needs or to make appropriate referrals.

M.D.P.77 AIDS/HIV INFECTION: KNOWLEDGE, ATTITUDES, AND BELIEFS OF HEALTH CARE PROVIDERS AND STUDENTS
 Shiu, Diana M.C. and Wong, A.Y.*

*Center for Infectious Diseases and Diseases (CIDDD) at University of California at Los Angeles (UCLA), USA **University of California at Los Angeles (UCLA) School of Dentistry, USA

Objective: To assess the current knowledge, attitudes, and beliefs of dental health faculty and students relative to AIDS/HIV infection as an new high prevalence infectious disease.

Methods: Knowledge of AIDS/HIV infection, attitudes, and beliefs relating to the care of those with AIDS, HIV infection, or at risk were assessed in 100 dental professionals at a school of dentistry in Los Angeles, L.A. 1988. Responses were received from 63 faculty members, 161 practitioners (year 1 and 2), and 175 dental (1 to 4) students were surveyed.

Results: Preliminary data demonstrated AIDS knowledge (measured by 20 items) was generally high, yielding a high mean correct score for all three groups (17.2, 17.5 and 16.9 for the faculty (F), dental students (S), and preclinical students (PC), respectively). However, there were a number of people who incorrectly answered questions related to HIV transmission, such as: from the water supply (25% F, 39% S, 39% PC), food handlers (19% F, 17% S, 21% PC), airborne transmission (29% F, 36% S, 28% PC), and donating blood (59% F, 20% S, 28% PC). Many dental faculty and students had a negative attitude regarding the dental professional's obligation to treat the AIDS/HIV infected individual; contributing to the reluctance by all three groups to treat was the fear of becoming infected and the potential loss of other patients. Although both dental faculty and students felt the AIDS patient had a right to quality dental care (94% F, 92% S, 92% PC), many felt dental professionals should be allowed to refuse care to AIDS patients (64% F, 46% S, 47% PC) and/or refer such individuals (58% F, 54% S, 47% PC). Among the three groups there were 65% F, 61% S, and 61% PC who believed that dental professionals should be 47% of the dental students, 78% of the preclinical, and 77% of the faculty believed their skills to be less than those of dental students. Both faculty and students were more about AIDS/HIV infection and infection control.

Conclusion: Preliminary data suggest that lack of knowledge regarding AIDS transmission, lack of skills, and concerns about the risk of infection may be deterrents to treating AIDS/HIV infected patients. Education in infectious diseases and AIDS/HIV infection, and the development of specific factors to enhance treatment of HIV infected patients by present and future dental health professionals.

M.D.P.78 PHYSICIANS' PERCEPTION OF PERSONAL RISK FROM AIDS (HIV) VIRUS
 Taylor, Kathryn M., Skinner, J.A., Ezdin, J.A., Bellner, W.H.,

Physician Behaviour Research Unit, Department of Behavioural Science, University of Toronto, Toronto, Ontario, Canada, M5S 1A8.

This research reports on physicians' perception of personal risk as a key element in their response to AIDS. In a questionnaire instrument we developed, the Physician AIDS Profile, we surveyed 440 physicians from a variety of specialties. A 1 month follow-up study of 100 physicians from the same specialties. We obtained a 10% (N=267) response rate from the mailed survey.

The concept of personal risk was differentiated into 1. physical risk of contagion and 2. social risk (such as professional burn-out) in caring for HIV positive patients. Separate indices were derived for each type of risk and statistical analyses were conducted. The significant findings included: (1) perceived physical risk was moderately but not highly correlated with perception of social risk (Pearson's $r = .49$, $p < .001$); (2) primary source of income (fee for service vs. salary), not medical specialty, was the most significant demographic variable in predicting physicians' perception of physical and social risk; and (3) perception of social risk tended to decrease as physicians were exposed to more seropositive patients in their practice, whereas there was no relationship between proportion of personal risk and number of seropositive patients. Physicians' perception of personal risk is a key factor in understanding their complex response to AIDS.

M.D.P.79

PRACTICES AND ATTITUDES OF HEALTH CARE WORKERS (HCW) TOWARDS HIV-INFECTED PATIENTS IN A LARGE ACUTE CARE HOSPITAL.
S. J. "BILLY" McDonald, M. J. Pansky, C. G. Lefort-Jost, J. A. *

* Dalhousie University Faculty of Medicine and Victoria General Hospital
** Victoria General, Nova Scotia Canada

Objective: To determine the attitudes and practices of HCW towards HIV-infected patients (HIV pts) in an 800-bed university hospital.
Methods: A 60-item anonymous questionnaire was distributed to 2,425 HCW Dec. 1988-Jan. 89. Standard demographic data, occupation, compliance with hospital guidelines, knowledge and attitudes about HIV, hepatitis B and serology were assessed.

Results: 1,137 responses (47%) have been analyzed to date. 44% of physicians and 55% of nurses had cared for HIV pts. 54% nurses vs 30% physicians were HCW for blood drawing and placement (p<.001). 77% nurses vs 42% physicians were gloves to move HIV patients from stretcher to bed (p<.001). Both groups thought it was more likely that they could acquire HIV from work-related activities than non-work-activities. Both groups took more inappropriate precautions for HIV pts vs Hep B pts (p<.001). 33% of physicians and 50% of nurses thought they should have the option to refuse care for HIV pts. 80% felt that they should be increased for HIV on admission; 40% felt that hospital staff should be notified; 80% felt HIV (+) staff should not be permitted to give direct patient care.

Conclusions: Despite intensive HIV education in our hospital, significant personal fears and misinformation still exist. Comparison of attitudes toward HepB and HIV suggest some fears are based on attitudes rather than risk.

M.D.P.80

AIDS AND DENTAL HEALTH PROFESSIONALS: KNOWLEDGE, ATTITUDES AND INFECTION CONTROL PRACTICES

S. J. "FRANCIS" Stepien, R. W. Kronenfeld, J. J. Daniel, J. M. * and Jackson, R. ** University of South Carolina School of Dentistry, 100 South Carolina Department of Health and Environmental Control, Columbia, S.C., USA

Objective: To determine the knowledge, attitudes and infection control practices related to AIDS among dental health professionals.

Methods: 584 dentists and dental hygienists responded to a survey. The questionnaire contained 54 multiple choice questions on knowledge, attitudes and infection control practices. Scores for knowledge, attitudes and infection control practices were calculated. Data were analyzed using chi-square tests, two sample t-tests, analysis of variance and Pearson correlation matrix.

Results: Respondents were quite knowledgeable about AIDS and HIV transmission. 75% knew the oral manifestations of AIDS. Dentists had a higher mean knowledge score than dental hygienists. Dental hygienists scored higher on infection control practices than dentists. 57% of the dentists felt safe in treating AIDS patients. Older dentists, dental hygienists had lower levels of knowledge about AIDS and infection control practices. There was no correlation between perceived risks and infection control practices.

Conclusion: Despite their high level of knowledge about AIDS, only 57% of the dentists were willing to treat AIDS patients and 43% perceived that they were at risk for HIV just the other health care workers. Only 64% of the dentists reported they were using gloves. More educational efforts should be aimed at dental professionals with emphasis on allaying their fear of AIDS and improving their infection control practices.

M.D.P.81

A METHOD FOR IMPLEMENTATION OF UNIVERSAL PRECAUTIONS
L. A. Chidister, M. S. F. Nottelbart, P. W. Soffen, J. Fiat, R. E. Hagan & W. H. Miller, Boston, Massachusetts USA

Objective: Develop a method for simple and objective determination of protection required by various blood and body fluid exposures which is recommended by the CDC. A form was designed that allows identification of representative procedures, the types of exposure to potentially infectious materials, and the classification of risk of exposure and type of fluid automatically indicates the barrier protections required.

Task	Exposure Body Fluid		Type	Contamination of Clothing		Risk	Barrier Protection
	Blood	Fluids		High	Low		
	High	Low	Direct	High	Low	High	Low
	High	Low	Indirect	High	Low	High	Low

Body Fluid: High - highly infectious; Low - potential transmission. **Contamination:** High - splash, spillage, contact; Low - contact with surface. **Risk:** High - splash, spillage, contact; Low - contact with surface.

Results: Supervisors used these forms to classify activities in their departments. Thirty-two managers identified an average of 50 tasks. After review, these forms formed the basis of detailed infection control guidelines. They were used for in-service education programs and are maintained at each work area for reference by hospital personnel.
Conclusion: This task worksheet simplified development of standardized barrier techniques. It improved understanding by hospital personnel of the requirements of blood and body fluid precautions, and facilitated compliance with required procedures.

M.D.P.82

A SURVEY OF KNOWLEDGE AND ATTITUDES CONCERNING HIV INFECTION AND AIDS AMONG FACULTY AND STUDENTS

THREE UNITED STATES DENTAL SCHOOLS
J. M. * Jones, S. R. * Robinson, J. W. * Holleran, J. A. ** and
University of Texas Dental School at San Antonio, **University of Texas at
San Antonio, **University of Detroit Mercy, Detroit, Michigan, U.S.A.

Objective: Compare knowledge and attitudes concerning HIV infection and AIDS among dental faculty and students in different U.S. cities. **Methods:** A questionnaire was distributed at 3 dental schools in 3 different cities (Detroit, Houston, and San Antonio). Frequency distribution was determined for all questions. General knowledge scores were obtained and classified.

Knowledge characteristics: personal infection concern, and professional self confidence were determined. **Results:** The 500 survey participants scored a 75% correct response rate although areas of weakness were noted. Faculty and student knowledge was comparable in all areas except for infection control (faculty 64%, students 54%). About half of respondents indicated anti-HIV test was diagnostic for AIDS. Faculty were twice as knowledgeable about agents which inactivate HIV. About 3/4 of respondents felt they should have the right to refuse treatment to a patient with AIDS/ARC and about 50% would refer such patients. All participants expressed a high index of personal infection concern, although the faculty expressed more professional self confidence. **Conclusion:** The majority of participants were reluctant to treat HIV positive and diagnosed AIDS patients as indicated by high response rates concerning referral, although they felt an obligation to treat these patients. The greatest knowledge deficit was use of virucidal chemical disinfectants and universal precautions for contaminated items.

M.D.P.83

HIV-RELATED RISK, WORRY AND BEHAVIOR CHANGES AMONG EMERGENCY MEDICAL WORKERS: PERSONAL AND JOB-RELATED FACTORS
Bolin, T. J. Zimmerman, N. M. Rodriguez, J. Patrono-Rosse, J. University of Miami, Miami, Florida, USA

Objective: To evaluate the relationship in job-related and socially transmitted risks for HIV infection to worry and behavior changes among emergency medical workers.

Methods: A voluntary, anonymous, self-administered questionnaire with 149 items related to HIV infection, job-related functions, sexual practices, and demographic variables was completed by 268 Emergency Medical Technicians, Paramedics, and Firefighters.

Results: 44% perceived themselves to be at high risk for contracting HIV infection through job-related activities and T related to sexual behaviors (paired t=13.60, p<.0001). Perceived job-related risks included needle sticks and negative attitudes toward AIDS patients (p<.01). 73% indicated worry about contracting HIV infection from patients; 51% from sexual activity (paired t=14.24, p<.0001). Predictors of job-related worry included marital status (B=.17, p<.01), worry related to sexual transmission of HIV (B=.28, p<.0001), and self-perceived high occupational risk (B=.24, p<.0001). 80% changed job-related behavior according to recommended CDC infection control guidelines. 6% used condoms regularly. Predictors of job-related behavior changes included a negative attitude toward AIDS patients (B=-.20, p<.01) and worry about contracting HIV infection from patients (B=.21, p<.01).

Conclusions: Among emergency medical workers, perceived job-related risks and HIV infection increased worry to motivate job-related behavior changes. In contrast, perceived sexual-related risks increased worry but minimally motivated sexual behavior changes.

M.D.P.84

ATTITUDES AND PRACTICES OF GENERAL INTERNISTS REGARDING CARE OF PEOPLE WITH HIV INFECTION
R. Haddad-Maxey, M. **, and Phillips B. **
*Beth Israel Hospital, Harvard Medical School, Boston, Massachusetts
**Boston University School of Medicine, Boston, MA, USA

Objective: To understand the attitudes and practices of primary care physicians concerning the care of people with HIV infection.

Methods: We surveyed the members of the Society of General Internal Medicine in 1987. Of 1753 surveys mailed, 75% were returned; 569 respondents indicated they had cared for a subjectively defined HIV patient.

Results: These general internists were asked about their care of people with HIV infection. 89% felt it most appropriate to counsel patients as AIDS risk reduction. 89% felt it most appropriate to evaluate and diagnose HIV infection and 52% felt they should follow people with HIV infection using subspecialty consultations when necessary. Only 6% felt it was most appropriate to refer AIDS patients to a specialist for primary care. They asked what would be effective ways to expand the role of primary care physicians in caring for those with HIV infection. 85% requested education on medical aspects of care. 83% wanted information about community services, and 38% sought help confronting fears and/or negative feeling about high risk individuals. **Conclusion:** Most general internists surveyed feel their role includes providing primary care for people with HIV infection. However, strategies must be developed to provide explicit education and emotional support in order to maximize the role played by these physicians.

Adolescents (Part 2)

T.D.P.1 MODIFICATIONS OF SEXUAL ACTIVITIES IN THE ERA OF AIDS: A TREND ANALYSIS

Yves-Jean LEBLANC
Gilles St. Laurent, Quebec, Canada; and
University of Calgary, Alberta, Canada.

Objectives: To assess whether sexual conduct of primarily heterosexual 17-21 year olds has changed since 1981 in a direction likely to reduce transmission of HIV.

Methods: Licit sexual history is used to identify trends and reversals of trends evident in responses of 1534 Montreal College students to questionnaires administered in 1981, 1983, 1985 and 1988.

Results: Trends showed decreasing age of first sexual intercourse, increased likelihood of males participating in same-sex sexual activities, likelihood of coital partners, increasing numbers of coital partners at least once use of condoms were identified for 1981 to 1985. In 1988 there is a reversal in the first two trends, and a continuation of the third.

Conclusions: Based on the students surveyed, initiation of risk-related sexual activity was more likely to be postponed and condoms more likely to be used in 1988 than in 1981-1985. There was no change in the incidence of casual sex or reduction in the number of sexual partners reported from 1981 to 1988.

T.D.P.3 SHORT-TERM IMPACT OF AN AIDS EDUCATION CURRICULUM FOR ADOLESCENTS

Blake, S., Timsone, L., and Mikhedon R.
University of Washington, U.S.A.

Objectives: To assess the short-term impact of an AIDS curriculum for adolescents on knowledge, attitudes, and behaviors related to AIDS, and to explore factors associated with change.

Methods: Two junior high schools in an ethnic, suburban community within the Boston metropolitan area participated in a 4-week AIDS education program. A treatment-delayed control group design was employed wherein 1/2 of the students received the educational program in health education classes, and the other 1/2 received no education. Measures of knowledge, attitudes, and behavior were obtained from all students before and after the program.

Results: Chi-square test statistics revealed relatively few baseline differences between students in the treatment and control groups (n=289) prior to the education program in HIV knowledge, attitudes, or behavior. Significant differences were observed following the curriculum with students receiving the program having improved scores on most measures of knowledge, attitudes, and behavior when compared to the control group. Results from further statistical analyses controlling for baseline differences between groups, and baseline scores will be presented.

Conclusions: The relative impact of an AIDS education curriculum on knowledge and attitudes can be demonstrated with junior high school students. Greater difficulty exists in documenting behavior change due to school system constraints, temporal factors, and the expected prevalence of risk behavior at lower ages.

T.D.P.5 CORRELATION BETWEEN 24, 26 AND 29 SERO-CD POSITIVENESS

Zelen, Mueli; Rice, J. and Reart, P.
National Institute of Public Health, Oslo, Norway.

Use of condoms is widely accepted as a "safe-sex" practice. The present study was undertaken to assess the level of understanding of condom behavior in Norwegian adolescents. The material comprised a representative sample of 860 persons in the age group 17 to 19, and a representative sample of 616 data were collected by self-administered questionnaires. The results showed that 68% of the boys, and 68% of the girls had used their sexual partners. For the 17 year-olds, 67% of the 18 year-olds, and 80% of the 19 year-olds. Median age at first intercourse for both sexes, and all age groups were 17. The proportions in the respective age groups who claimed they did not use condoms habitually were 33, 36, and 44%. However, 37% of the boys, and 36% of the girls used condoms at their last sexual intercourse. In order to provide a better understanding of condom behavior, the theory of reasoned action was applied, in which the intention to use condoms at the next intercourse was considered to be a function of attitudes towards use of condoms as well as personal use and subjective norms. Preliminary analysis of the model showed that behavioral beliefs related to the immediate consequences of condom use and the sexual context, and the normative expectations of significant others were the strongest determinants of intention (beta-coefficients 0.20-0.60). There was no relationship between neither intention to use condoms nor actual use of condoms and friends' intention. The theory of reasoned action was found to be a sufficient understanding of intention to use condoms, but further empirical analysis in terms of estimating the full model are forthcoming.

T.D.P.2 SEXUAL BEHAVIOR, CONTRACEPTIVE USE, AND STD HISTORY AMONG INTERCOLLEGE COLLEGE STUDENTS

Janet M. Ralston, S. A. Sanders, M. Zivich-Davis, and C. A. Hess
The Kinsey Institute for Research in Sex, Gender, and Reproduction, Indiana University, Bloomington, IN, U.S.A.

Objectives: To describe the prevalence and frequency of sexual behaviors of college-age university students that place them at increased risk for Human Immunodeficiency Virus (HIV) infection. A questionnaire developed by The Kinsey Institute asked respondents to indicate which of specific sexual behaviors they had engaged in and to report on a number of other factors relevant to HIV transmission.

Results: Data on the sexual histories of 810 self-selected college students, who based on their demographic characteristics appear to be representative of the targeted student population, were obtained. The typical respondent was 22 years old, white, Protestant, politically moderate, and from the Midwest. In reporting on sexual behavior, we consider only those respondents who labeled themselves as currently heterosexual (over 90%) and have experienced penile-vaginal or penile-oral intercourse. Over 80% of the respondents reported use of one or both of these behaviors, while over 20% of the females and 77% of the males reported engaging in heterosexual anal intercourse at least once. Of these self-labeled heterosexual males, 3,399 had engaged in anal intercourse with another male. The average number of one-night stands was 3.75, while the average number of male partners for females was 4.17 and the average number of female partners for males was 3.72. Less than a third of the respondents had used a condom the last time they engaged in male-vaginal or penile-oral intercourse, while close to a quarter had either used no contraception or used the rhythm or withdrawal methods. Approximately one in five respondents had experienced some form of sexually-transmissible disease (STD).

Conclusions: Although the young adults in this sample have been sexually active a relatively short time, they have both engaged in unprotected sexual activity and had multiple sexual partners. Based on 16 behaviors, these findings might be regarded as a conservative estimate of the proportion of young adults in the U.S.A. who engage in sexual activities which place them at risk for STD's, including HIV.

T.D.P.4

SEXUAL BEHAVIOR IN HIGH-RISK ADOLESCENTS
Meyer-Bahlburg, Helmut F.L., Netherem-Borus, M.J., Koopman, C., Emery, J.R., and Hirschman, S.B.
New York State Psychiatric Institute and Columbia University, New York, N.Y., U.S.A.

Objectives: To evaluate sexual behavior in high-risk adolescents and youths who are believed to be at high risk of unprotected sexual activities and HIV infection.

Methods: A detailed semi-structured sexual history interview, the Sexual Risk Behavior Assessment Schedule for Youths (SRBAS-Y): Meyer-Bahlburg et al., 1988) was developed in 3 iterations, extensively piloted, and then administered to 50 males and 50 females in 2 runaway shelters, and to 50 homosexual males in a special agency, all ranging in age from 12-18 years, with an overrepresentation of minorities.

Results: Preliminary analyses showed that 56% of the adolescents engaged in sexual intercourse during the past 3 months prior to evaluation, with significant differences between the 3 groups. Males reported significantly more partners and sexual occasions than females did. Only a small minority of adolescents in either group used condoms at all, and those who did so used condoms inconsistently and infrequently. Gay males were more likely to use condoms (r = .48) they experienced.

Conclusions: These results confirm that runaway adolescents are a high-risk sex group and in need of preventive intervention.

T.D.P.6 THE IMPACT OF FEMALE'S KNOWLEDGE AND CONCERN OF AIDS ON SEXUAL BEHAVIOR AND PREVENTION STRATEGIES

Samuel J. Hamrick, AIDS Prevention Center,
San Francisco, California, U.S.A.

Objectives: To assess the impact of teenager's delinquent behavior and attitudes on their sexual behavior, condom use, and prevention strategies. **Methods:** A survey of 419 high school students (15-19 years old) and representative of all ethnic groups was conducted. The survey included questions on: (1) whether they had ever had sex (181 females and 138 males); (2) whether they had ever used a condom (124 females and 112 males); (3) whether they had ever used a condom (124 females and 112 males); (4) whether they had ever used a condom (124 females and 112 males); (5) whether they had ever used a condom (124 females and 112 males); (6) whether they had ever used a condom (124 females and 112 males); (7) whether they had ever used a condom (124 females and 112 males); (8) whether they had ever used a condom (124 females and 112 males); (9) whether they had ever used a condom (124 females and 112 males); (10) whether they had ever used a condom (124 females and 112 males); (11) whether they had ever used a condom (124 females and 112 males); (12) whether they had ever used a condom (124 females and 112 males); (13) whether they had ever used a condom (124 females and 112 males); (14) whether they had ever used a condom (124 females and 112 males); (15) whether they had ever used a condom (124 females and 112 males); (16) whether they had ever used a condom (124 females and 112 males); (17) whether they had ever used a condom (124 females and 112 males); (18) whether they had ever used a condom (124 females and 112 males); (19) whether they had ever used a condom (124 females and 112 males); (20) whether they had ever used a condom (124 females and 112 males); (21) whether they had ever used a condom (124 females and 112 males); (22) whether they had ever used a condom (124 females and 112 males); (23) whether they had ever used a condom (124 females and 112 males); (24) whether they had ever used a condom (124 females and 112 males); (25) whether they had ever used a condom (124 females and 112 males); (26) whether they had ever used a condom (124 females and 112 males); (27) whether they had ever used a condom (124 females and 112 males); (28) whether they had ever used a condom (124 females and 112 males); (29) whether they had ever used a condom (124 females and 112 males); (30) whether they had ever used a condom (124 females and 112 males); (31) whether they had ever used a condom (124 females and 112 males); (32) whether they had ever used a condom (124 females and 112 males); (33) whether they had ever used a condom (124 females and 112 males); (34) whether they had ever used a condom (124 females and 112 males); (35) whether they had ever used a condom (124 females and 112 males); (36) whether they had ever used a condom (124 females and 112 males); (37) whether they had ever used a condom (124 females and 112 males); (38) whether they had ever used a condom (124 females and 112 males); (39) whether they had ever used a condom (124 females and 112 males); (40) whether they had ever used a condom (124 females and 112 males); (41) whether they had ever used a condom (124 females and 112 males); (42) whether they had ever used a condom (124 females and 112 males); (43) whether they had ever used a condom (124 females and 112 males); (44) whether they had ever used a condom (124 females and 112 males); (45) whether they had ever used a condom (124 females and 112 males); (46) whether they had ever used a condom (124 females and 112 males); (47) whether they had ever used a condom (124 females and 112 males); (48) whether they had ever used a condom (124 females and 112 males); (49) whether they had ever used a condom (124 females and 112 males); (50) whether they had ever used a condom (124 females and 112 males); (51) whether they had ever used a condom (124 females and 112 males); (52) whether they had ever used a condom (124 females and 112 males); (53) whether they had ever used a condom (124 females and 112 males); (54) whether they had ever used a condom (124 females and 112 males); (55) whether they had ever used a condom (124 females and 112 males); (56) whether they had ever used a condom (124 females and 112 males); (57) whether they had ever used a condom (124 females and 112 males); (58) whether they had ever used a condom (124 females and 112 males); (59) whether they had ever used a condom (124 females and 112 males); (60) whether they had ever used a condom (124 females and 112 males); (61) whether they had ever used a condom (124 females and 112 males); (62) whether they had ever used a condom (124 females and 112 males); (63) whether they had ever used a condom (124 females and 112 males); (64) whether they had ever used a condom (124 females and 112 males); (65) whether they had ever used a condom (124 females and 112 males); (66) whether they had ever used a condom (124 females and 112 males); (67) whether they had ever used a condom (124 females and 112 males); (68) whether they had ever used a condom (124 females and 112 males); (69) whether they had ever used a condom (124 females and 112 males); (70) whether they had ever used a condom (124 females and 112 males); (71) whether they had ever used a condom (124 females and 112 males); (72) whether they had ever used a condom (124 females and 112 males); (73) whether they had ever used a condom (124 females and 112 males); (74) whether they had ever used a condom (124 females and 112 males); (75) whether they had ever used a condom (124 females and 112 males); (76) whether they had ever used a condom (124 females and 112 males); (77) whether they had ever used a condom (124 females and 112 males); (78) whether they had ever used a condom (124 females and 112 males); (79) whether they had ever used a condom (124 females and 112 males); (80) whether they had ever used a condom (124 females and 112 males); (81) whether they had ever used a condom (124 females and 112 males); (82) whether they had ever used a condom (124 females and 112 males); (83) whether they had ever used a condom (124 females and 112 males); (84) whether they had ever used a condom (124 females and 112 males); (85) whether they had ever used a condom (124 females and 112 males); (86) whether they had ever used a condom (124 females and 112 males); (87) whether they had ever used a condom (124 females and 112 males); (88) whether they had ever used a condom (124 females and 112 males); (89) whether they had ever used a condom (124 females and 112 males); (90) whether they had ever used a condom (124 females and 112 males); (91) whether they had ever used a condom (124 females and 112 males); (92) whether they had ever used a condom (124 females and 112 males); (93) whether they had ever used a condom (124 females and 112 males); (94) whether they had ever used a condom (124 females and 112 males); (95) whether they had ever used a condom (124 females and 112 males); (96) whether they had ever used a condom (124 females and 112 males); (97) whether they had ever used a condom (124 females and 112 males); (98) whether they had ever used a condom (124 females and 112 males); (99) whether they had ever used a condom (124 females and 112 males); (100) whether they had ever used a condom (124 females and 112 males); (101) whether they had ever used a condom (124 females and 112 males); (102) whether they had ever used a condom (124 females and 112 males); (103) whether they had ever used a condom (124 females and 112 males); (104) whether they had ever used a condom (124 females and 112 males); (105) whether they had ever used a condom (124 females and 112 males); (106) whether they had ever used a condom (124 females and 112 males); (107) whether they had ever used a condom (124 females and 112 males); (108) whether they had ever used a condom (124 females and 112 males); (109) whether they had ever used a condom (124 females and 112 males); (110) whether they had ever used a condom (124 females and 112 males); (111) whether they had ever used a condom (124 females and 112 males); (112) whether they had ever used a condom (124 females and 112 males); (113) whether they had ever used a condom (124 females and 112 males); (114) whether they had ever used a condom (124 females and 112 males); (115) whether they had ever used a condom (124 females and 112 males); (116) whether they had ever used a condom (124 females and 112 males); (117) whether they had ever used a condom (124 females and 112 males); (118) whether they had ever used a condom (124 females and 112 males); (119) whether they had ever used a condom (124 females and 112 males); (120) whether they had ever used a condom (124 females and 112 males); (121) whether they had ever used a condom (124 females and 112 males); (122) whether they had ever used a condom (124 females and 112 males); (123) whether they had ever used a condom (124 females and 112 males); (124) whether they had ever used a condom (124 females and 112 males); (125) whether they had ever used a condom (124 females and 112 males); (126) whether they had ever used a condom (124 females and 112 males); (127) whether they had ever used a condom (124 females and 112 males); (128) whether they had ever used a condom (124 females and 112 males); (129) whether they had ever used a condom (124 females and 112 males); (130) whether they had ever used a condom (124 females and 112 males); (131) whether they had ever used a condom (124 females and 112 males); (132) whether they had ever used a condom (124 females and 112 males); (133) whether they had ever used a condom (124 females and 112 males); (134) whether they had ever used a condom (124 females and 112 males); (135) whether they had ever used a condom (124 females and 112 males); (136) whether they had ever used a condom (124 females and 112 males); (137) whether they had ever used a condom (124 females and 112 males); (138) whether they had ever used a condom (124 females and 112 males); (139) whether they had ever used a condom (124 females and 112 males); (140) whether they had ever used a condom (124 females and 112 males); (141) whether they had ever used a condom (124 females and 112 males); (142) whether they had ever used a condom (124 females and 112 males); (143) whether they had ever used a condom (124 females and 112 males); (144) whether they had ever used a condom (124 females and 112 males); (145) whether they had ever used a condom (124 females and 112 males); (146) whether they had ever used a condom (124 females and 112 males); (147) whether they had ever used a condom (124 females and 112 males); (148) whether they had ever used a condom (124 females and 112 males); (149) whether they had ever used a condom (124 females and 112 males); (150) whether they had ever used a condom (124 females and 112 males); (151) whether they had ever used a condom (124 females and 112 males); (152) whether they had ever used a condom (124 females and 112 males); (153) whether they had ever used a condom (124 females and 112 males); (154) whether they had ever used a condom (124 females and 112 males); (155) whether they had ever used a condom (124 females and 112 males); (156) whether they had ever used a condom (124 females and 112 males); (157) whether they had ever used a condom (124 females and 112 males); (158) whether they had ever used a condom (124 females and 112 males); (159) whether they had ever used a condom (124 females and 112 males); (160) whether they had ever used a condom (124 females and 112 males); (161) whether they had ever used a condom (124 females and 112 males); (162) whether they had ever used a condom (124 females and 112 males); (163) whether they had ever used a condom (124 females and 112 males); (164) whether they had ever used a condom (124 females and 112 males); (165) whether they had ever used a condom (124 females and 112 males); (166) whether they had ever used a condom (124 females and 112 males); (167) whether they had ever used a condom (124 females and 112 males); (168) whether they had ever used a condom (124 females and 112 males); (169) whether they had ever used a condom (124 females and 112 males); (170) whether they had ever used a condom (124 females and 112 males); (171) whether they had ever used a condom (124 females and 112 males); (172) whether they had ever used a condom (124 females and 112 males); (173) whether they had ever used a condom (124 females and 112 males); (174) whether they had ever used a condom (124 females and 112 males); (175) whether they had ever used a condom (124 females and 112 males); (176) whether they had ever used a condom (124 females and 112 males); (177) whether they had ever used a condom (124 females and 112 males); (178) whether they had ever used a condom (124 females and 112 males); (179) whether they had ever used a condom (124 females and 112 males); (180) whether they had ever used a condom (124 females and 112 males); (181) whether they had ever used a condom (124 females and 112 males); (182) whether they had ever used a condom (124 females and 112 males); (183) whether they had ever used a condom (124 females and 112 males); (184) whether they had ever used a condom (124 females and 112 males); (185) whether they had ever used a condom (124 females and 112 males); (186) whether they had ever used a condom (124 females and 112 males); (187) whether they had ever used a condom (124 females and 112 males); (188) whether they had ever used a condom (124 females and 112 males); (189) whether they had ever used a condom (124 females and 112 males); (190) whether they had ever used a condom (124 females and 112 males); (191) whether they had ever used a condom (124 females and 112 males); (192) whether they had ever used a condom (124 females and 112 males); (193) whether they had ever used a condom (124 females and 112 males); (194) whether they had ever used a condom (124 females and 112 males); (195) whether they had ever used a condom (124 females and 112 males); (196) whether they had ever used a condom (124 females and 112 males); (197) whether they had ever used a condom (124 females and 112 males); (198) whether they had ever used a condom (124 females and 112 males); (199) whether they had ever used a condom (124 females and 112 males); (200) whether they had ever used a condom (124 females and 112 males); (201) whether they had ever used a condom (124 females and 112 males); (202) whether they had ever used a condom (124 females and 112 males); (203) whether they had ever used a condom (124 females and 112 males); (204) whether they had ever used a condom (124 females and 112 males); (205) whether they had ever used a condom (124 females and 112 males); (206) whether they had ever used a condom (124 females and 112 males); (207) whether they had ever used a condom (124 females and 112 males); (208) whether they had ever used a condom (124 females and 112 males); (209) whether they had ever used a condom (124 females and 112 males); (210) whether they had ever used a condom (124 females and 112 males); (211) whether they had ever used a condom (124 females and 112 males); (212) whether they had ever used a condom (124 females and 112 males); (213) whether they had ever used a condom (124 females and 112 males); (214) whether they had ever used a condom (124 females and 112 males); (215) whether they had ever used a condom (124 females and 112 males); (216) whether they had ever used a condom (124 females and 112 males); (217) whether they had ever used a condom (124 females and 112 males); (218) whether they had ever used a condom (124 females and 112 males); (219) whether they had ever used a condom (124 females and 112 males); (220) whether they had ever used a condom (124 females and 112 males); (221) whether they had ever used a condom (124 females and 112 males); (222) whether they had ever used a condom (124 females and 112 males); (223) whether they had ever used a condom (124 females and 112 males); (224) whether they had ever used a condom (124 females and 112 males); (225) whether they had ever used a condom (124 females and 112 males); (226) whether they had ever used a condom (124 females and 112 males); (227) whether they had ever used a condom (124 females and 112 males); (228) whether they had ever used a condom (124 females and 112 males); (229) whether they had ever used a condom (124 females and 112 males); (230) whether they had ever used a condom (124 females and 112 males); (231) whether they had ever used a condom (124 females and 112 males); (232) whether they had ever used a condom (124 females and 112 males); (233) whether they had ever used a condom (124 females and 112 males); (234) whether they had ever used a condom (124 females and 112 males); (235) whether they had ever used a condom (124 females and 112 males); (236) whether they had ever used a condom (124 females and 112 males); (237) whether they had ever used a condom (124 females and 112 males); (238) whether they had ever used a condom (124 females and 112 males); (239) whether they had ever used a condom (124 females and 112 males); (240) whether they had ever used a condom (124 females and 112 males); (241) whether they had ever used a condom (124 females and 112 males); (242) whether they had ever used a condom (124 females and 112 males); (243) whether they had ever used a condom (124 females and 112 males); (244) whether they had ever used a condom (124 females and 112 males); (245) whether they had ever used a condom (124 females and 112 males); (246) whether they had ever used a condom (124 females and 112 males); (247) whether they had ever used a condom (124 females and 112 males); (248) whether they had ever used a condom (124 females and 112 males); (249) whether they had ever used a condom (124 females and 112 males); Le SIDA et l'individu AIDS and the Individual

T.D.P.7 **TITLE: DEMOGRAPHIC AND HIGH RISK BEHAVIOR STUDY OF INCREASINGLY ADOLESCENTS**

Authors: Morris, R., Hancock, S., Roseman, J., Wu, G., Baker, C.J., and Weikowski, K.A.
 *Juvenile Court Health Services, Los Angeles County, California, USA
 **UCLA Epidemiology Program, Los Angeles County Department of Health, California, USA

OBJECTIVE: To obtain demographic and AIDS high risk data to target and implement educational and research programs among increasingly adolescents.
DESIGN: Interviews to gather data were conducted following a randomized design. This information was computerized (data manager 3 BASE III Plus) and analyzed with the statistical software package PROLOG.

RESULTS: 262 minors, age 16 and 17 were interviewed. 83% were males and 17% were females. 28% were Black, 20% Hispanic and 52% White. Incidence of sexual activity was high. Alcohol consumption during sex was frequent (47%); drug use concomitant with sex activity was 13%. Heroin and cocaine were the most frequently used I.V. drugs. Incidence of IV was 17% with syringes the most common disease article. While awareness about contracting AIDS was high, correct and other precautionary resources were low.

CONCLUSION: Despite the fact that this population reported a 67% attendance to sex education classes, their degree of knowledge and concern about high risk behavior for AIDS was low. Educational programs with peer participation, surveillance studies and emphasis on HIV testing and counseling of high risk individuals will be pursued.

T.D.P.9 **HIV-RELATED KNOWLEDGE, BELIEFS, AND BEHAVIORS AMONG HIGH SCHOOL STUDENTS IN THE UNITED STATES**

Authors: Fagan, D., and School Health Center for Chronic Diseases (SHCCD), San Francisco, San Francisco, California, USA
 *University of California, San Francisco, San Francisco, California, USA
 and Chicago. To describe HIV-related knowledge, beliefs, and behaviors among high school students in cities and states in the United States with the highest cumulative incidence of AIDS and to describe the participation and strategies developed to enable departments of education to collect these data annually.
DESIGN: As part of a unique system of surveys involving participation and cities administered anonymous questionnaires to high school students in 1985. The response rate of schools from each state ranged from 52% to 100%. Results: Many students incorrectly thought HIV infection may be acquired from living blood (range: 27.8%-53.1%), using public toilets (range: 44.4%-64.4%), or having a blood test (range: 48.1%-64.4%). Most students knew IV drug use (range: 54.4%-84.4%), and needle sharing (range: 48.5%-84.4%) can result in HIV infection. High school students from 10% states reported variable rates of IV drug use and needle sharing. 44% of students reported sex partners at least once, and 19.4%-44.6% reported having had sex with sex partners. **CONCLUSIONS:** Implementation of education should implement programs to correct misperceptions about HIV transmission, to reduce behaviors resulting in HIV infection, and to assess periodically whether these misperceptions and behaviors change over time among high school students.

T.D.P.11 **ASSESSING KNOWLEDGE, INDIVIDUAL RISK FACTORS, BELIEFS ABOUT AIDS AND ATTITUDES ABOUT CURRENT CHANGES**

Authors: R.A., Petty, B.A., Frossen, A.C.; Baker, Charles E., and Kroegel, M., Dallas County Health Department, Dallas, Texas, USA

OBJECTIVE: Objectives of study were to 1) determine baseline risk factors and knowledge about AIDS, 2) determine attitudes about AIDS and prevention, and 3) determine attitudes about condom usage among runaway adolescents while at an alternative school. **DESIGN:** A questionnaire was administered to 213 runaways. Upon intake to the school, adolescents (213) were administered a questionnaire about AIDS knowledge, behavior risk factors and prevention information. While at the alternative school, adolescents received 3 to 4 instructional classes about AIDS and prevention information. After the classes the adolescents (102) were given the same questionnaire to determine if the group had improved its knowledge base about AIDS information, and changed attitudes about condom usage. **RESULTS:** Results indicate that of the 213 runaway adolescents (between the ages of 11 and 16), 76% are sexually active, 7% had used intravenous drugs and only 13% stated they always use condoms. Post data results on some knowledge questions indicated significantly larger proportions of correct responses. There are areas where misunderstandings persist, i.e., transmission through blood donation and transfusions. Attitudes about condom usage did not improve and adolescents felt uncomfortable talking about condoms with a partner. **CONCLUSIONS:** Runaway adolescents' behavior puts them at risk for HIV infection and AIDS. Alternative schools provide a setting for exposure to information about AIDS. A change in attitudes toward condom use and a change in condom use require more than classroom exposure to AIDS information.

T.D.P.8 **KNOWLEDGE, ATTITUDES AND BEHAVIOR OF STREET-INVOLVED PEOPLE IN VANCOUVER**

Authors: Michael J. Hanson, I. Loftus, P., STD Control, Ministry of Health, Vancouver, British Columbia, Canada

OBJECTIVE: To assess and describe the knowledge, attitudes and behaviors of street-involved people in Vancouver in relation to AIDS.
DESIGN: In January 1985, sixty-nine street-involved youth answered an anonymous, standardized questionnaire administered on the street by outreach nurses.

RESULTS: Of the 40 males and 29 females interviewed, 93% were 14-29 years old, 53% were Caucasian and 30% Native Indian, 44% lived with lovers or friends and 40% lived alone. The majority supported themselves by prostitution (70%) and/or welfare benefits (48%). Seventy-seven percent felt that AIDS was not as serious as the media said, 40% would use condoms with a new but not a steady partner, 45% felt their chances of catching an STD were low. With regard to drug-taking behavior, 50% had used intravenous drugs within the past year, 72% of these had shared tools and 76% cleaned their needles with bleach. The favorite drugs were cocaine and talwin and rituals. Findings with regard to sexual behavior included the following: 43% had had sex with a homosexual man and 43% with an IVUD; 6 women and 10 men said they were bisexual in their private lives; 85% always shared condoms with "dates" (i.e. customers) but only 28% always used condoms with "lovers" (i.e. steady partners). Their ability to use safe sex having sex or using intravenous drugs was often adversely affected by being drunk or high. **CONCLUSION:** Street involved people in Vancouver remain at highest risk for acquisition and transmission of HIV because of risk behavior in their personal lives.

T.D.P.10 **ETUDIANTS ET SIDA: INTERET D'UNE TYPOLOGIE POUR UNE PREVENTION SPECIFIQUE**

Authors: Failloux T., Larigault J., Lesarrieux A., L'Andrieu H., and Université Paris X à Rouen, Centre de Recherche de l'Enfant et de l'Adolescent (CREA), Paris, France, **Fondation des étudiants de France, Secours, France, CREA, Paris, France, ***Institut Français d'Etudes et d'Analyses (IFE), Paris, France.

OBJECTIF: 1) Décrire étudiants (18-22 ans) de région parisienne, 2) Mesurer les corrélations entre facteurs de risque SIDA et facteurs de risque "supposés", 3) Construire une typologie pour actions préventives spécifiques.

Méthode: 1) Échantillon: 963 étudiants représentatifs (méthode des quotas), 2) Intervention: strict anonyme, février/avril Juin 1985, 3) Auto-questionnaire: 176 items sur représentations, attitudes, comportements, sur sexualité, sida, SIDA, valeurs, informations SIDA, prévention, mesurer l'état des connaissances sur notre société SIDA, facteurs de risque SIDA, 4) Tri à plat, croisées, analyses en composantes principales et typologiques (logiciel SAS). **Résultats:** 1) Parmi tous les nombreux résultats: 50 % sans premier rapport ont utilisé préservatif, 15 % ont pratiqué coïtactus du V.D. 50 % pensent que le préservatif est le moyen le plus sûr pour éviter le V.D. 52 % s'estiment insuffisamment informés sur SIDA, 84 % pensent qu'un sérotest est mieux à faire de les informer, 52 % que l'information doit être faite en Faculté, 2) Cinq facteurs de risque supposés ont été retenus car tous bien corrélés aux facteurs de risque du SIDA, 3) Propose une typologie de dix types associés différemment aux facteurs de risque conduisant à approches préventives particulières d'out "tactis" groupées.

T.D.P.12 **THE RELATIONSHIP OF KNOWLEDGE AND ATTITUDES TOWARD AIDS TO SAFE SEX PRACTICES AMONG RUNAWAY AND SEX WORKERS**

Authors: Rosen, Mary Jane; Salfinger, C.; Koppman, C.; Halperin, C.; Meyer-Illand, R.; Bhatnagar, A.; and HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, NY, USA

OBJECTIVE: To evaluate the relationship between knowledge of and attitudes towards AIDS and safer sex practices among runaway and sex workers.
DESIGN: Questionnaire assessments of knowledge of transmission, high risk groups, outcomes, prevention strategies, definitions, and HIV testing were collected and separate interviews of sexual behavior during the last three months were conducted with 50 runaway and 30 sex youth in community agencies in New York City.
RESULTS: There was substantially high general knowledge of AIDS (74%) and positive attitudes towards safer sex (74%) across all groups as well as substantial unsafe sex. These high risk youth reported an average of 3 sexual partners and 12 sexual encounters over the last three months, most of which were unprotected by condoms used (89%). General knowledge of AIDS was more highly correlated with condom use ($r = .31$, $p < .05$) and positive attitudes ($r = .36$, $p < .01$) among sex youth than for runaway youth. In addition, general knowledge of AIDS was positively related to the number of partners among sex youth ($r = .31$, $p < .01$), indicating those most at risk knew the most about AIDS.

CONCLUSIONS: Although attitudes towards AIDS, not general knowledge, appears important and potentially effective among those at most risk, sex youth.

T.D.P.13

YOUTH IN DETENTION AT HIGH RISK FOR HIV KNOWLEDGE, ATTITUDES AND BEHAVIORS REGARDING CONDOM USAGE.
Thompson, Lizlin; Houston, J.M.; Risner, M.M.; Sweet, D.M.*
Baxter, M.**; Shalowitz, Giv. of California School of Medicine, San Francisco. **San Francisco Dept. of Public Health, San Francisco, CA, U.S.A.

Objective: Because youth who come into contact with the juvenile justice system are typically sexually active, prone to drug experimentation and have high levels of STDs, they are at particularly high risk for HIV infection and transmission. Our aim was to examine their knowledge of how HIV can be transmitted and prevented, and their attitudes and behaviors about condoms.
Methods: 184 juvenile offenders (mean age = 18) at the San Francisco Youth Guidance Center completed anonymous self-report questionnaires. The sample was 50% male and 50% Black, 16% Hispanic, 7% Asian, 0% White, 7% other. Results: Knowledge about HIV prevention was generally high, for example, 80% agreed that using condoms during sex reduces the chances of HIV infection. Further, ability to obtain condoms "very afraid of getting AIDS." On the other hand, 80% said that it would not be difficult at all. There was also evidence of motivation: 71% said they would use condoms more than a problem; 80% said that using condoms during sex reduces the chances of HIV infection. 80% said that using condoms would "really like to have a baby." **Conclusion:** The findings of low intention to use condoms and low usage are disturbing. In view of the high HIV infection rates among youth who have someone in exchange for money, drugs, etc. during the past year. Results here are culturally sensitive HIV education programs aimed at changing attitudes about using condoms are urgently needed for this high risk group.

T.D.P.15

HIV STATUS RELATED TO KNOWLEDGE AND BEHAVIORAL CHANGE
Miller, Kenneth and Patient, Margaret, University of California, San Francisco, U.S.A.

Objective: To assess whether knowledge about AIDS influenced behavior in anti-HIV(+) blood donors, blood recipients, hemophiliacs and their sexual partners as compared to controls.
Methods: A 16 item multiple choice questionnaire and an 11 item behavioral survey were distributed to 238 study participants and their sexual partners 6 to 12 months following standard verbal counseling regarding transmission and prevention of AIDS.
Results: 50/51 (98%) of anti-HIV(+) respondents and their sexual partners, who correctly identified preventive measures, indicated that they used condoms more than half the time; while only 30/313 (7%) of the anti-HIV(-) controls did so. 32/69 (46%) of anti-HIV(+) respondents and their sexual partners identified and practiced health promoting behaviors as compared to 17/405 (3%) of anti-HIV(-) controls. 66/69 (96%) of the anti-HIV(+) respondents avoided sharing unsafe items such as needles, razors, etc. with their partners while an equivalent number of anti-HIV(-) controls (39/115) (90%) evinced similar behavior.
Conclusion: In this sample, generally, knowledge about AIDS prevention was more likely to be translated into behavioral changes by anti-HIV(+) subjects than by those who were anti-HIV(-).

T.D.P.17

PREVALENCE OF GENITAL LESIONS IN A STD CLINIC: SEXUAL BEHAVIOR CHARACTERISTICS
Jacobs, R.; Roberts, T.**; Mosey, B.**; Whittington, N.P.; Whittington, Y.*
University School of Medicine. **Duke Health Department, and West Gate Hospital, Atlanta, GA, USA.

Objective: To determine the prevalence of genital lesions in individuals attending an STD clinic and to evaluate their sexual behaviors.
Methods: During a 15 week period, individuals (>200) making their first visit for a variety of reasons were studied. Those patients with genital lesions were referred to a single clinician for evaluation. The patterns of sexual behavior of these patients were compared to those without lesions.
Results: Patients with genital lesions accounted for 781 (7.5%) visits. Men were more likely than women to present with genital lesions (p<.01) and genital lesion patients were less likely to be referred as a sexual partner (p<.01). Women with genital lesions more often did not use chemical or mechanical barriers for contraception and also gave a history of sexual intercourse (p<.05). Men with genital lesions were less likely to use condoms than men without lesions (p<.01). After lesions were recognized, 24% of the men and 21% of the women continued to have sexual intercourse.
Conclusion: In view of previous findings that genital lesions are associated with an increased risk of HIV transmission, it is important to understand the pattern of sexual behavior of patients with genital lesions. The current evidence for poor use of preventive measures must be addressed.

T.D.P.14

THE NATIONAL STUDY OF HEALTH AND SEXUAL BEHAVIOR
Cain, Virginia B. and Baldwin, M.
National Institute of Child Health and Human Development, NIH, Bethesda, MD, U.S.A.

Objective: To describe the development of a national survey of health and sexual behavior, this is a major undertaking that will provide data to help understand sexual behavior patterns associated with varying degrees of risk with respect to HIV infection and the contexts in which the behaviors are occurring. It will also provide some of the data needed to model the spread of HIV infection, e.g. rates of partner change and sexual behaviors within relationships. Note, of the estimates of HIV infection depend upon estimates of risk behavior derived from the Kinsey studies of the 1940's. While these were landmark studies, the lack of a representative sample and the changes in sexual behavior that are known to have occurred in the past 40 years make them less than useful for current purposes. The present study involves the development of a national survey of sexual behavior that will obtain high quality data on sensitive questions from the general U.S. population and simultaneously being able to accommodate the less frequently occurring high risk behaviors. The development of the survey has included a number of methodological tests designed to determine the most effective means of eliciting accurate information. These include effects of: (1) matching interviewers and respondents on selected demographic characteristics, (2) the location of the interview (in situ or in the lab), (3) telephone vs. door-to-door interviewing including a mail-administered questionnaire and (4) a closed-ended questionnaire vs. an open-ended semi-structured interview.

T.D.P.16

SELF PERCEPTION OF THE RISK OF CONTRACTING AIDS AMONG UNIVERSITY STUDENTS
Dias, M.N.**; Agui, Francisco H.*; Goodson, P.**; Dias, J.*
Vera, E.* and Pinto e Silva, B. Brazil. ** The Population Council, New York, USA. *** CEMDOR, Campinas, SP, Brazil.

Objective: To assess how accurate is the self perception of the risk of contracting AIDS among University students.
Methods: A structured questionnaire on sexual behavior and knowledge about AIDS was mailed to 2009 students of the first two grades of the State University of Campinas, Brazil. Analysis was performed using SPSS PC.
Results: The percentage of students declaring not having risk of AIDS was 71.8%. But, 56.3% of them did not use condoms, 14.1% had anal intercourse and 12.2% of men had homosexual relations. Based on the whole questionnaire, each student was classified as having null, low or high risk. Seventy five per cent of those who classified themselves as having null risk, actually had low or high risk. On the other hand, 77.8% of those who classified themselves as high risk, were low, according to our classification.
Conclusion: Even though the level of knowledge about AIDS is relatively high among University students, there is still a high incidence of misconceptions or classifying which behaviors do actually constitute risk. Further educational activities appear as a high priority.

T.D.P.18

BEHAVIORAL PATTERNS OF BISEXUAL MALES IN THE U.S., 1982
Lever, Janet; Rogers, L.J.; Heron, R.*
Kenmore, D.R.*
*The RAND Corporation, Santa Monica, California, U.S.A.; **Wellesley College, Wellesley, Mass., U.S.A.

Objective: To analyze 1982 survey data on the sexual practices of 7,486 heterosexually bisexual males to better understand the behavioral and reported incidence of HIV infection in that population and their female partners.
Methods: Data from a national survey of 80,324 and female readers of Playboy magazine were examined using analysis of variance techniques. Demographic profiles and sexual behavior patterns were compared among men whose adult sexual behavior was exclusively heterosexual (N=4,082), exclusively homosexual (N=780), predominantly heterosexual (N=4,903), or predominantly homosexual (N=729).
Results: Of 7,486 heterosexually bisexual men, 2,111 described themselves as bisexual, 141 as homosexual, and 5,232 as heterosexual in orientation; 392 were currently married (vs. 44% of heterosexual men) and 391 were currently dating more than one partner. Bisexual men were less concentrated in cities than homosexual men (43% vs. 63%, 38% for heterosexual men). Behavioral bisexuality was associated with increased promiscuity (.43 SD on an index combining no. of partners and 3 other indicators) and increased risk of STIs (18% vs. 10% reporting one or more in past 5 yrs.) compared to exclusively heterosexual men, and with increased use of prostitutes in last five years (33% vs. 19% for exclusively heterosexual or homosexual men).
Conclusions: The behavior reported by this large sample of bisexual men would place them at intermediate risk of HIV infection. Sexual patterns of bisexual men are not representative of the general population.

Le SIDA et l'individu AIDS and the individual

T.D.P.19 PATTERNING IN THE SEQUENCES OF SEXUAL ACTIVITY BETWEEN MEN AND ITS IMPLICATIONS FOR HIV-1 TRANSMISSION

DETAILED, LONGER AND CONCISE, A.F.M.***, Project SIDA,
*South Bank Polytechnic, London and Univ. of Wales, Cardiff, U.K.

Objective: Until now, analysis has concentrated on individual sexual acts and their role in the transmission of HIV-1. This paper looks at sequences of sexual acts which take place between men in order to discover any **REGULARITY** which might be relevant to transmission.

Methods: Diaries of sexual activity were kept by 170 men who recorded, for each episode or session of sexual activity, where and when it took place; the other people involved (if any); the sequence of acts and other relevant details such as condom use. Diaries were encoded and analysed using a specially written computer programme.

Results: Analysis suggests the existence of 2 patterns or modes of sexual interaction: role-playing and reciprocal. Role-playing keeps the insertions/insertee distinction, while reciprocal action does not, typically involving an alternation of such roles. Role-playing sessions involve fewer individual acts than reciprocal ones ($p < .01$) and are more likely to include anal intercourse ($p < .05$). When anal intercourse does occur in reciprocal sessions, it is less likely to produce orgasm ($p < .001$).

Conclusions: Reciprocity seems to be likely to be safer. Further analysis of the patterns of sexual activity is urged as a means of understanding the context of transmission and as a resource for health education.

T.D.P.20 FACTORS ASSOCIATED WITH SEROPOSITIVITY TO HIV-1 AMONG A NON-CLINIC SAMPLE OF GAY AND BISEXUAL MEN IN LONDON

Busk, A.J.; Davies, J.G.; Conon, A.F.M.***, Kershaw, T.J.*** and Sutherland, S.***, Project SIDA, *South Bank Polytechnic, London; **University of Wales, Cardiff; ***King's College Hospital, London, U.K.; ****Dulwich PMS, London, U.K.

Objective: To describe the relevant characteristics of those found to be HIV antibody positive in a study of homosexually active men.

Methods: As part of a national study, 310 gay and bisexual men in London were recruited using a variety of sampling methods and interviewed in a non-clinic setting. 123 (71.9%) volunteered a sample of blood, which were tested for HIV-1 antibody using the Wellcome competitive assay, with positives confirmed using the Abbott recombinant assay. Interviewees could choose to know the result of the test. Data from the interview were analysed using SPSS 7.0.

Results: Individuals were classified as positive (30, 9.7%), negative (182, 61.3%) and not tested (88, 28.4%). Positives were found to be significantly younger ($p < .05$) and to have had more penetrative sexual partners - 'top's' partners with whom anal intercourse had taken place - ($p < .05$) in the course of their lives. There was no difference between the groups in having had a pop in the mouth prior to interview, but of those who had, positives had a higher proportion of partners who had a pop in the mouth than negatives ($p < .05$). Level of education, current relationship status and degree of disinclination were not significantly different.

Conclusions: The hypothesis that younger gay men are currently more at risk seems supported from these findings.

T.D.P.21 TRENDS IN AIDS KNOWLEDGE, ATTITUDES AND BEHAVIOURS (KAB) IN 18 COUNTRIES, HIGH-RISK SEX GROUPS, FLORIDA

Lieb, Spencer*; Zimmerman, R.S.***; Kuehler, M.***; Lengua, L.M.***; Sims, J.P.*** and Witte, J.J.**, Florida Department of Health and Rehabilitative Services, Tallahassee, Florida, USA, **University of Miami, Coral Gables, Florida, USA, ***Hunter College (CUNY), N.Y., N.Y., USA.

Objective: To compare levels of AIDS KABs in 1987 and 1988 in groups at high risk in a region having 4,000 reported AIDS cases as of 1/1/89.

Methods: A KAB survey was administered anonymously in 1987 (N=1,937) and 1988 (N=1,873) to those sampled non-randomly in 4 south Florida counties. Weights were assigned to each 1988 respondent by race, age, sex, education and distributing agency for comparability with 1987 values.

Results: Knowledge levels of HIV transmission modes were high in both years. A decline in anal intercourse was reported by gay/bisexual men [(1198)=2.7%, $p < .001$]. The percent tested for HIV antibody increased significantly ($p < .005$) for 6 of 7 hierarchical risk groups, 3 of which are shown below.

Condom use increased markedly among 2 of the 3 groups:

Group	1987	1988	1987	1988
	N	% tested for HIV	N	% tested
Gay/bisexual male	451	58%	514	75%
TV drug abuser	202	11%	30*	32
MSM alone	176	43*	118	31**
$p < .00001$				

Conclusion: To the extent that such groups may be 'sentinels' for larger, at-risk populations, these results favor a reduction in HIV transmission.

T.D.P.22 BEHAVIORAL AND PSYCHOSOCIAL PREDICTORS OF COMPLIANCE IN HIV ASYMPTOMATIC AND SEROPOSITIVE PATIENTS IN CLINICAL TRIALS

Condon, Jerome, Jiles, Malcolm, L.***, University of Miami, Miami, Florida, USA; Pringle, L. St. St. University of Miami, Miami, Florida, USA.

Objective: To evaluate and determine factors associated with study compliance among HIV infected patients in clinical drug trials.

Methods: A voluntary, anonymous, self-administered questionnaire consisting of demographic and risk factor information, recreational and non-IDA approved drug use, and sexual practices was completed by patients with asymptomatic or asymptomatic HIV infection participating in clinical drug trials.

Results: Of 150 distributed questionnaires, 120 were completed. The majority of patients not filling out questionnaires were Hispanic. Of the 150 participating patients, 86 had asymptomatic and 34 had asymptomatic HIV disease. A greater study compliance rate was noted among asymptomatic patients than asymptomatic patients as prescribed ($p < .02$).

Conclusions: Asymptomatic patients with HIV infection are generally more likely to be non-compliant with clinical drug trials. Factors associated with recreational drug use, alcohol use and sexual activity must be considered in developing strategies to improve compliance rates of asymptomatic patients in clinical drug trials.

T.D.P.23 MALE HOMOSEXUAL SEXUAL BEHAVIOR IN THE UK 1985-1988

Thomas, APRN Consultant
*Department of Contraceptive Methods, King's College Hospital, London SE5
*South Bank Polytechnic, London SE1
**University of Wales, Cardiff, UNITED KINGDOM

Objective: To monitor changes in male homosexual sexual behaviour in the United Kingdom using a non-clinic sample.

Method: A questionnaire was circulated via the gay press. It was self administered and asked about numbers of sexual partners, changes in sexual behaviour, drug, condom use, HIV antibody status and sexual attitude.

Results: 1292 replies from 1985 and 1200 from 1988 were analysed. The demographic details of both samples were comparable. 60% of men in 1988 had less than 3 sexual partners in the previous 12 months compared with 15% in 1985. The 1988 respondents reported a 50% decrease in both oral and anal sex with casual sexual partners but only 50% used condoms >50% of the time during anal sex. Very little illicit drug use was reported. 18% of the 1988 cohort had been sexually satisfied by another man.

Conclusion: This national survey of sexual behaviour in gay men in the UK is attempting to monitor changes in behaviour as the HIV epidemic of a change towards safer sex but a significant proportion of respondents still have unprotected anal sex. The number of men sexually satisfied is higher than previously reported in similar studies.

This investigation is part of Project SIDA and is funded by the Medical Research Council.

T.D.P.24 A REVIEW OF STUDIES OF BEHAVIORAL RESPONSE TO HIV-ANTIBODY TESTING AMONG GAY MEN

RR (Hempstead) AN Moss, School of Medicine, University of California, San Francisco, San Francisco, CA, USA

Objective: To review changes in annual behavior made by gay men receiving HIV-antibody test results.

Methods: We examined 22 studies of sexual behavior change by groups of gay men from the United States and Western Europe.

Results: A median of 41% of study subjects (range=23-84%) choose to know their HIV-antibody status when made available to them in the context of their research study. Most studies (16/22) have indicated that awareness of infection decreases risk behaviors (anal intercourse and multiple partners) with seropositives showing greater declines than seronegatives. A considerable number of studies (10/22), however, have shown no difference in the seronegativization behavior of subjects.

Conclusion: The behavioral consequences of HIV-antibody test results are not uniform. The reasons are unclear, but a reduction in behaviors which transmit HIV usually ensues. No clear pattern explaining these ambiguous findings is yet apparent. Inappropriate (change) behaviors following notification have not been reported in these groups.

T.D.P.31 FACTORS ASSOCIATED WITH RECURRING OF UNSAFE SEXUAL PRACTICES IN A COHORT OF GAY MEN PREVIOUSLY ENGAGING IN "SAFE" SEXUAL PRACTICES

William, Scott, S. Rodgers, A. Jaccard, J. J. Hayes, K. T. Frawley Community Health Center, Boston, Massachusetts, Anderson, W.

Objective: To analyze the behavior of gay men who had engaged in "safe" sexual behaviors (SB) for one or more years and assess the predictors of subsequent maintenance of SB.
Methods: Collection of the longitudinal behavioral, attitudinal, clinical and serological data was gathered as part of a natural history of HIV infection of a cohort of initially asymptomatic gay men (n=236) seen in a Boston health center. 254 condom usage if anal intercourse was practiced.

Results: Those maintaining SB were similar in age, smoking and drinking activities, duration of homosexual activity and AB status to those who did not. Those maintaining SB were more likely to have higher levels of "unsafe" sexual behavior on entry to the project as well feeling that behavior change was not beneficial. Non-maintainers increasingly perceived greater barriers to maintaining susceptibility and were less able to differentiate maintainers and non-maintainers.
Conclusions: Health education strategies designed around the Health Belief Model may need to be reassessed in relation to long term maintenance of sexual behavior change.

T.D.P.32 THE ROLE OF PENITENTIARY REFORM AND SOLIDARITY ENHANCEMENT ACTION JAIL DRUGS IN THE PREVENTION OF AIDS IN THE DOMINICAN REPUBLIC

De Moya, E. Antonio; Carías, S.; Rosario, G.; Guerrero, E.; Arrau-Larrocena, R.; García-Alvarez, E. PROCTIS, Ministry of Public Health, Santo Domingo, Dominican Republic.

Objective: To evaluate the approach to AIDS prevention in highly crowded Dominican jails through the inducement of penitentiary reform measures and the enhancement of solidarity networks among inmates.

Methods: AIDS GAP studies were carried out in Dominican jails in November 1987 and February 1989. Ongoing intervention includes attempts to create staff committees, training of health personnel, inmates' group discussion and lecture sessions, group formation and voluntary HIV testing and counseling.

Results: A lag of 14 months in AIDS awareness among inmates as contrasted to the general population has been overcome by the joint pro-professional intervention. Gang sex rates ("maniquis") of youngest prisoners have been reduced to a minimum by inmates' defense committees.

Conclusions: Empowering inmates for self-organized preventive action in prisons both enhances their self-esteem and decreases the transmission potential of HIV among inmates.

T.D.P.33 IMPLICATIONS OF HEALTH BELIEFS FOR AIDS PREVENTION PROGRAMS: THE SAN FRANCISCO MEN'S HEALTH STUDY

Edward, Margolin, J. C.; Coates, T. J.; Stone, G. W. Center for AIDS Prevention Studies, and "Health Psychology, U.C. San Francisco, CA, U.S.A. Fellow, for AIDS Research.

Objective: To examine the relationship between health beliefs and sexual behavior among gay and bisexual men in San Francisco.

Method: This analysis is based on 465 single sexually active gay and bisexual men participating in the San Francisco Men's Health Study (a population-based longitudinal study of single males in San Francisco). Health beliefs specific to HIV infection and AIDS prevention were assessed in 1987. Number of sexual partners and condom use were measured at six and twelve month follow-up. Low risk was defined as mutual monogamy or 100% condom use. High risk was defined as having multiple partners and less than 100% condom use. The longitudinal relationship between the respondent's beliefs and subsequent sexual behaviors was examined using univariate statistical tests.

Results: The longitudinal analysis showed that subjects who perceive safe sex as important in preventing the spread of AIDS and who do not perceive safe sex as pleasure reducing are significantly more likely to report low risk sex during the next twelve months than are those who hold the opposite beliefs. In addition, high risk subjects were significantly more likely to believe that safe sex is unnecessary when two partners have the same serostatus than are low risk subjects. Finally, high risk subjects perceived significantly fewer barriers as transmitting HIV than did low risk subjects.

Conclusions: These results support the hypothesis that health beliefs influence preventive behaviors among gay and bisexual men. AIDS prevention programs may thus benefit from including work on beliefs regarding HIV transmission and safe sex.

T.D.P.34 SEXUAL BEHAVIOR OF EXPATRIATES IN AFRICA

Roosendaal, Hans; de Groot, A.; Balis, S.F.; Lithebe, R.J.; Leentvaar, A.; Kok, J.M.; et al. National Institute of Public Health (RIVM), Bilthoven, The Netherlands.

Objective: To describe sexual behaviour of Dutch expatriates in Africa with respect to risk of HIV infection.

Methods: In the course of a routine medical check Dutch expatriates working in sub-Saharan African countries are asked to complete a self-administered questionnaire on sexual and other risk factors (since 1978) for HIV infection. **Results:** Between Sept. 1987-Dec. 1988 499 men and 531 women entered the study; 278 men and 429 women were married or cohabited; 179 men and 404 were accompanied by their partner during their stay in Africa. Participants were posted in cities and rural areas of all sub-Saharan countries, including those in which prevalence of HIV infection is high. Of participants 22% had heterosexual contact with African partners (NCA): 37% of men and 15% of women. The mean number of sex partners was 5, the median 2, range 1-50. 10% of men and 4% of women had been treated for S.T.D. NCA was associated with a history of S.T.D., being single, and not being accompanied by the partner ($p < 0.001$). Males more often had NCA, independently of the previously mentioned factors ($p < 0.001$). Condom use was infrequent and inconsistent.

Conclusion: Sexual contact with African partners is a frequent occurrence especially among single men; Dutch expatriates run a substantial risk of sexual exposure to HIV.

T.D.P.35 CHANGES IN SEXUAL PRACTICES IN THE SYDNEY AIDS PROJECT:

1985-1989
Tisdall, Brett*, Nicholas T. and Cooper DA*,
NSWRC Special Unit in AIDS Epidemiology and Clinical Research,
University of New South Wales, Sydney, Australia.

Objective: To describe the changes in sexual behaviour in a cohort of homosexual and bisexual men in Sydney, Australia.

Methods: The Sydney AIDS Project is a prospective cohort study of 1057 homosexual and bisexual men enrolled between February 1984 and January 1985. At each six-monthly review visit subjects complete a self-administered questionnaire that examines their sexual practices during the preceding six months.

Results: A decrease in the mean number of sexual partners during the preceding 6 months was reported by both seropositives (22 to 4) and seronegatives (16 to 2) over the first 3 years of observation.

Seropositives reported a reduction in receptive anal intercourse from a mean of 8 to 3 times per month and seronegatives from 4 to 1 per month. There was a similar reduction in all sexual practices. These changes were reflected in a decrease in the seroconversion rate from 4% to 1% which peaked at 4% during early 1985 but remained below 1% in 1988.

Conclusion: These data indicate significant changes in the sexual practices of a large group of homosexual men in Sydney since 1984. These changes are reflected in a decrease in the seroconversion rate for this cohort. An updated analysis of the data, incorporating data to early 1989, will be presented.

T.D.P.36 CHANGE IN SEXUAL BEHAVIOR IN HOMOSEXUALS AT RISK FOR AIDS

Subjunctive, Michael; Joseph, G. D., Jr. University of Michigan, Ann Arbor, Michigan, United States

Objective: To describe longitudinal prevalence and predictors of safe sex among homosexual men at risk for AIDS.

Methods: Detailed behavioral data describing condom usage during receptive and insertive anal sex were collected in the Ongoing sex Questionnaire (OSQ) cohort, beginning in February 1984. Change in behavior between 85 and 89, measured by a six month interval, was the dependent variable. Multivariate, logistic regression models with condom usage, and seronegative/seropositive status were used as predictors.

Results: OSQ data are shown in Table 1. Predictors of behavioral change during receptive vs. insertive anal sex were dissimilar. While HIV serologic status was related to behavioral change in receptive anal practices, seronegative and seropositive status predicted change in insertive anal practices.

	Safe (n=81)	Not Safe (n=141)	Total
	81%	84%	84%
INSERTIVE ANAL SEX:			
Safe (n=91)	149(84)	149(83)	298(73)
Not Safe (n=91)	131(62)	123(42)	254(52)
Total	280(80)	272(58)	552(50)
RECEPTIVE ANAL SEX:			
Safe (n=91)	243(64)	143(64)	386(64)
Not Safe (n=91)	124(44)	83(40)	207(36)
Total	367(64)	226(40)	593(50)

Conclusions: Individual condom usage is not constant over time. Previous reports of behavioral measures change longitudinal condom usage among gay men should be viewed with caution because of such individual fluctuations which are not yet fully understood. Our findings also suggest that serologic status is an important determinant of behavioral change and/or change of partner. Decreasing seroconversion rates might be attributed partly to these processes, rather than the utilization of anal sex or consistent use of condom.

TITRE : COMPORTEMENT SEXUEL ET RISQUE D'INFECTION
A. V. I. H. A. SÉNÉGAL

DIPIOT Ousmane*
CARRELLI M**; **WOITE Y**; **PEYRIBEAUD Anne****
*Ministère de la Santé Publique
** CFA/ONS - GENEVE

OBJECTIF : Identifier les comportements sexuels et ses déterminants dans une population de 15 - 49 ans.

METHODOLOGIE : Enquête par interview sur un échantillon national représentatif (sondage par groupes : 2.500 personnes) complétée par observation, interview ethnographiques, focus-group, Conception finale et Éducation faites par équipe pluridisciplinaire. Coordination par Centre National d'Éducation Pour la Santé.

RESULTATS : la recherche a permis d'établir les rapports entre comportements sexuels et données sur l'infection à VIH et les autres M.S.T. Les résultats permettent d'établir une échelle de risque en fonction des comportements et données démographiques (migration et fécondité sexuelle) et persistence de valeurs socio-culturelles (félicité, croyances religieuses) d'une part, estime de perception du risque et prédisposition à adopter un comportement sexual à risque.

CONCLUSION : Ces résultats indiquent les incidences pratiques pour l'orientation, la réflexion et l'évaluation des programmes d'intervention éducative facilitent leur intégration et efficacité.

T.D.P.38

"Pretesting AIDS Health Promotion Materials".

Ballal, Jai*, Kishorewani A**
*World Health Organization, Pacific Promotion Specialist, GPOW, Geneva; **World Health Organization, Health Educator, WHO/OS, Geneva, SWITZERLAND

This presentation will be supported by slides illustrating types of changes made to materials and pretesting sessions with target audience. A poster presentation will be available.

Objectives: 1) To introduce methods for pretesting prototype AIDS health promotion messages and materials designed for culturally diverse target audiences in Africa, Asia, the Pacific and the Caribbean. 2) To present the concepts of developing specific AIDS messages for primary, secondary and tertiary target audiences with the long range goal of behavioral change.

Method: 141 persons working in AIDS health promotion from 34 countries participated in a series of 5 self-reported workshops during 1985-1988. The health education and related variables among a semi-structured sample of gay men in the Richmond metropolitan area. Key variables to be discussed are: gay men's health, perceptions of themselves, self-esteem, and changes in risk-reduction and drug use behaviors.

Results: Initial data were collected in the spring of 1985; follow-up data were collected two years later. A questionnaire was prepared specifically for the study, with the help of focus groups of gay men in the city. The same process was used to modify the original questionnaire before follow-up. A two-stage method was used to distribute questionnaires to potential respondents. A list of distributors, both individuals and organizations, was recruited and trained in contacting gay men and explaining the study. The area distribution network was used for the follow-up, in order to make convenient feasible. Anonymity of respondents was carefully protected, in order to gain participation in this city, where homosexual behavior is a felony offense. The response rate was 45% in 1985 and 67% in 1987. Results: Very few had been tested for HIV infection in 1985, but 47% had been tested by 1987. Thirty-one percent of the 1987 cohort were inferring HIV/AIDS in 1985 and 20% reported "great fear" about their own vulnerability to infection; in 1987, this percentage was about the same (21%). However, more than half of gay men sampled in 1987 had experienced an increase in level of fear when they first heard about AIDS. Changes were noted in sources of information about HIV prevention, AIDS service organizations and the public health department being in attendance. Only a minority reported self-protective behavior in 1985; in 1987, almost everyone reported this behavior.

Conclusions: Gay men in this middle-sized southern city were 3 times as likely to have made sex changes in risk behaviors in 1987 as they were to have done so in 1985. Reported changes were probably sufficient to prevent transmission of the virus to increasing numbers of individuals in the population sampled.

T.D.P.39

BEHAVIORAL INTENTIONS AND OTHER FACTORS INFLUENCING BEHAVIOR CHANGE IN A COHORT OF GAY MEN: A PROSPECTIVE STUDY

Calcutt, Christine*, O'Malley, K.M.*, Higgins, D.L.*; Sheridan, J.S., Galloway, T.L.**, *Centers for Disease Control, Atlanta, Georgia, U.S.A.; **Professional Services, Rockville, MD, U.S.A. ***Denver Disease Control Service, Denver, Colorado U.S.A.

Objectives: To examine the influence of intentions to change unsafe sexual behavior on reported behavior change in a cohort of gay and bisexual men.

Methods: 217 gay and bisexual men completed baseline and six month follow-up questionnaires on their HIV risk behavior, beliefs, attitudes and intentions. A model to predict behavior change from Time 1 (T1) to Time 2 (T2) was developed using variables drawn from social cognitive theories of behavior change.

Results: Behavioral intentions at T1 predict behavior change at T2. Men who reported intentions to decrease the number of occasional partners with whom they had receptive anal intercourse at T1 reported significant decreases at T2 ($p=0.99$, $p<0.05$). Beliefs about normative behavior mediated this relationship. Among men who intended to decrease the number of meeting partners with whom they had anal intercourse, only those who perceived positive norms for this behavior had made significant reductions ($n=234$, $p<0.05$).

Conclusions: Cognitive models of behavior change may help identify predictors of change, and thus be useful in developing risk reduction interventions.

T.D.P.40

AIDS-RELATED BEHAVIOR CHANGE OF GAY MEN IN RICHMOND VA 1985-1988

Bradford, Judith B. and Johnson, D. Virginia Commonwealth University, Richmond, Virginia, USA.

Objectives: To present baseline and follow-up data on AIDS-related behavior change and related variables among a semi-structured sample of gay men in the Richmond metropolitan area. Key variables to be discussed are: gay men's health, perceptions of themselves, self-esteem, and changes in risk-reduction and drug use behaviors.

Method: Initial data were collected in the spring of 1985; follow-up data were collected two years later. A questionnaire was prepared specifically for the study, with the help of focus groups of gay men in the city. The same process was used to modify the original questionnaire before follow-up. A two-stage method was used to distribute questionnaires to potential respondents. A list of distributors, both individuals and organizations, was recruited and trained in contacting gay men and explaining the study. The area distribution network was used for the follow-up, in order to make convenient feasible. Anonymity of respondents was carefully protected, in order to gain participation in this city, where homosexual behavior is a felony offense. The response rate was 45% in 1985 and 67% in 1987. Results: Very few had been tested for HIV infection in 1985, but 47% had been tested by 1987. Thirty-one percent of the 1987 cohort were inferring HIV/AIDS in 1985 and 20% reported "great fear" about their own vulnerability to infection; in 1987, this percentage was about the same (21%). However, more than half of gay men sampled in 1987 had experienced an increase in level of fear when they first heard about AIDS. Changes were noted in sources of information about HIV prevention, AIDS service organizations and the public health department being in attendance. Only a minority reported self-protective behavior in 1985; in 1987, almost everyone reported this behavior.

Conclusions: Gay men in this middle-sized southern city were 3 times as likely to have made sex changes in risk behaviors in 1987 as they were to have done so in 1985. Reported changes were probably sufficient to prevent transmission of the virus to increasing numbers of individuals in the population sampled.

T.D.P.41

SEXUAL BEHAVIOUR CHANGES AMONG MALE SEXUAL CONTACTS OF MEN WITH HIV DISEASE: A 3 YEAR OVERVIEW

Calderazzo, Adriana*, Cohen, K. M., Reid, S. Johnson, G. C., Farwell, V., Fanning, M., Shephard, F., MacPáez, D. University of Toronto, Toronto, Ontario, Canada.

Objectives: To describe the behavior changes which have taken place (over a 3-year period) in a cohort of male sexual contacts of men with HIV disease.

Methods: 264 sexual partners of men with HIV disease were recruited into a retrospective study between July 1984 and July 1985. The cohort has been monitored every three months. Data on sexual activities have been collected through an interviewer-administered questionnaire and comparisons between the first and twelfth follow-up visit have been made.

Results: The cohort has experienced a reduction in the number of sexual contacts from a median of 3.7 (range=1) to a median of 1.1 (range=4). The percentage of men who did not have sex increased from 24% to 51%. The mean number of anonymous partners has dropped from 3.7 to 2.0. High risk sexual activities such as anal insertive and anal receptive have decreased (anal insertive from 68% to 43% and anal receptive 58% to 42%). Only a small number are being exposed to semen in the rectum (14/100) or orally (19/100). The frequency of lower risk activities such as oral insertive and receptive has also decreased; frequency of masturbation with a partner has remained unchanged. 70% of follow-up visits have been made. In anal intercourse, 80% more than 50% of the time.

Conclusions: Overall, the men have reduced both the numbers of sexual partners and the volume of sexual activity. The reduction in volume of sexual activity has been gradual and consistent in trend.

T.D.P.42

PSYCHOLOGICAL AND BEHAVIORAL COMPONENTS OF BELIEF IN ANTIVIRAL STATUS

Antoni, Ernest*, Anton, M. J., Johnson, G. C., Lapeere, A. T., Stribanowski, N. J., Fleisher, M. A. et al.
*University of Miami, FL, USA; **Miami University, Fair Hills, CA, USA

Objectives: This study investigated the relationships of perceived belief in HIV status to sexual and health behaviors, psychological and social variables in healthy gay men at risk for AIDS, prior to their anti-HIV-1 status.

Method: Healthy gay males at risk for AIDS ($n=45$) wishing to know their anti-HIV-1 status participated as part of a longitudinal investigation. At baseline, prior to being informed of their diagnosis, subjects provided behavioral and psychological data including measures of psychological distress, coping, gay history, internalized homophobia, and sexual behaviors. Immune function (serum and saliva) antibody status was also determined. Prior to diagnosis, subjects were classified as belief negative (BN) or belief positive (BP), based on their self-reported anti-HIV-1 status.

Results: Of 17 anti-HIV-1 subjects, 12 (69%) were BP of 25 anti-HIV-1 subjects, 22 (79%) were BN. Thus, 71% of all subjects predicted that anti-HIV-1 status correctly. Controlling for status, CD4+ (T-lymphocyte) cell counts, were significantly higher for BP than for BN subjects. Among all subjects, CD4+ numbers were positively correlated with distress measures of depressive and somatiform thoughts about AIDS. Significantly more intrusive thoughts about AIDS were reported by BP subjects. BP subjects also engaged in more anal insertive and female and reported more receptive anal intercourse partners in the last month, as well as, more female, active intercourse, and analque and greater number of partners for analque and female one year ago. BP subjects reported more gay history, more positive coping, more positive self-esteem, and more self-disclosure about their sexual orientation with family and friends. In BP subjects, internalized homophobia was negatively correlated with being gay and engaged in more self-disclosure about being gay in BP subjects was significantly correlated with decreased intrusive about anti-HIV-1 status.

Conclusions: Self-reported behavioral and psychological as well as actual immunological differences were related to belief in HIV-1 seropositivity. Supported by NIMH, P50MH42455-03.

T.D.P.43 SAFE AND UNSAFE SEXUAL PRACTICES BY HETEROSEXUAL AND HOMOBISexual MEN: PREDICTING INTENTIONS AND BEHAVIOR

M. C. Smith, M. H. Hirsch, G. G. Catania, Y. Kato, A. and Chavira, A.

University of Queensland

Objectives: To examine, in three groups, the influence of attitude, personal and peer norms, and past behavior on the intention to practice safe or unsafe sexual behavior and on actual behavior at the next sexual encounter.

Methods: Homosexual men and heterosexual men and women (N = 240) were recruited from the Brisbane community to participate in the study. They used (1) their intention to engage in several sexual behaviors and behaviors occurring during sexual encounters, (2) the pleasantness of these practices, and other stress and benefits, (3) their present norms about the behavior, (4) peer norms, (5) norms for significant others, and (6) their past sex role behavior. The behaviors had previously been classified as safe or safer with respect to HIV transmission. At their next sexual encounter, subjects completed a brief questionnaire indicating the behaviors they had engaged in, using the same list as on the initial questionnaire.

Results: On the basis of their intention, subjects were classified as positive, risky, or overly strict behavior. Homosexual men were significantly more likely to practice safe behavior than heterosexual men or women. Multiple regression analyses indicated that attitude was the strongest influence on both intentions and actual behavior for all three groups of subjects, but that attitude towards the behavior also played a significant role. Multivariate analysis of variance explored further differences among the three subject groups, and between subjects practicing safe and unsafe sex, on the influence of attitudes and norms, especially peer norms. These results indicated that peer norms are more influential for heterosexual men, while the best source of norms is the most important normative influence for homosexual men and women.

Conclusions: These results highlight the importance of individual psychological variables in the decision to practice safe or unsafe sex, and thus have strong implications for further education programmes. Much more research must be taken of the influence of past sexual behavior on present practice.

T.D.P.44 PSYCHONEUROIMMUNOLOGICAL RELATIONSHIPS IN MEN WITH AIC

T. M. Johnson, J. G. Solomon, G. P. Jenkins, F. W. Rutter, D. P. Sweet, D. H. Univ. of California San Francisco, Univ. of California Los Angeles, Univ. of California Berkeley, CA, U.S.A.

Objectives: To describe and understand the nature of relationships among psychological, neuropsychological, and immunologic variables in HIV disease. To our knowledge, the interactions of variables in these 3 domains have not been reported for men with HIV spectrum disorders.

Methods: Laboratory immunologic measures were obtained for 103 seropositive homosexual men with at least one HIV-related symptom who were recruited from the UCSF AIDS Clinic, and administered neuropsychological tests and psychological self-report measures. All the measures were obtained at 3 time points, approximately 6 months apart.

Results: Significant correlations were found between measures of anxiety, depression, contentment, fatigue and absolute numbers of T_{H1} cells, and natural killer (NK) cell activity. At Time 1, higher scores on emotional suppression were also significantly correlated with more T_{H1} and T_{H2} and T_{H2} cell numbers, as well as with more NK cell activity. At Time 2 (N = 56), higher scores on suppression of anxiety and unhappiness were significantly correlated with higher numbers of T_{H1} and T_{H2} cells, T_{H2} and T_{H2} and T_{H2} cell activity, and with more NK cell activity. Higher numbers of neuropsychological impairments from mild to marked.

Conclusions: While it is premature to draw conclusions about the implications of psychoneuroimmunologic relationships in HIV disease, our findings suggest that these relationships change with disease progression, and are perhaps best interpreted in the context of immunologic and psychological adaptation to ongoing disease and psychological events.

T.D.P.45 CHANGES IN CONDOM USE AMONG GAY MEN: PREDICTORS AND METHODOLOGICAL ISSUES

Calvin A. Jansz, Colette Y. Bell, R. E. Eys, L. J. Capel, F. J. Turner, H., et al. University of California, San Francisco, Center for AIDS Prevention Studies, California State Office of AIDS, U.S.A.

Objectives: Psychosocial predictors of changes in condom use over time were examined. Sample attrition and repeated measurement effects on changes in condom use in two studies were also examined.

Methods: Respondents were gay men in San Francisco. Study One: a longitudinal sample (N=300; 1984-1987) and cross-sectional samples (N=200 per year; 1985-1987) were randomly selected by random digit dial techniques; Study Two: a longitudinal sample (N=600; 1984-1987) was recruited from bars and bath houses and classified questionnaires. Identical behavioral measures were used across studies (Psychological measures will be described).

Results: Condom use increased significantly over time in all samples. The increase was unrelated to subject attrition or repeated measurement effects (Study 1 & 2). Higher levels of social support and enjoyment of condoms were associated with increased condom use over time (analysis of covariance; Study 2). Health beliefs, alcohol use, and antibody status did not predict changes in condom use.

Conclusions: Prevention programs with gay men should focus on building social support groups and enforcing safe sex practices. Changes in condom use observed in longitudinal studies of gay men are probably unrelated to design features.

T.D.P.40 COPING OF HIV-EXPOSED MEN AND AIDS-PATIENTS

Leiberman, P. J., Brooker, M. J., Newman, G. J., Harver, T. J., Oberlin, R. J., Kaldjian, R. J., University of Erlangen, Medical Clinic I, Medical Clinic III, Dept. of Psychology I, RWG AIDS-Center of Federal Health Administration, Berlin.

Objectives: To assess relationships between psychosocial stress caused by an HIV-infection and different reaction patterns as directly influenced or modified by coping processes.

Methods: Life Quality, Coping, and Social Support Questionnaire and semi-structured interviews, administered to 30 homosexual men and 30 HIV-IV, Walter Reed Stage IV, at least 3 months after diagnosis.

Results: Feelings of psychic (68% negatively affected) and job distress (45%) decreased from high levels after the HIV test to moderate degrees (20% resp. 10%). In order to minimize stress, individuals used differential patterns of coping. Passive cooperation, rationalization, problem-analysis, faculty, activity an diversion were used most frequently. Gay men further preferred perceptual defense and tried to preserve competence, while HIV-IV's were seeking social support. Gay men felt less threatened by HIV than HIV-IV's. Clustering over subjects, we found one group, aged 19 to 28, who at the start of their autonomous life were hit by the diagnosis, and developed a depression, showing high scores in perceptual defense, social withdrawal, self-esteem and psychosomatic reactions. A second group of professionally successful gay men focused on distraction by emphasizing job activity. Conclusions: Coping patterns of HIV-positives are similar to those of cancer patients (cf. Hein 1989). Effectiveness of coping will be discussed.

T.D.P.47 DE NOUVEAUX COMPORTEMENTS PARMIS LES HOMOSEXUELS EN EUROPE : LES CAS DE PARIS ET D'AMSTERDAM.

Algra, T., Berghe (Dr.) J., "prog. M.A.M.", (Ransome (Dr.) K.I.), Kaldjian, R.J.

*Amsterdam Jacks, Amsterdam, Jazzy-Bar, *Santé et Plaisir Gai, Paris, France, *Centre National de la Recherche Scientifique (CNRS), Paris, France.

Objectif: Étudier et de reconnaître l'existence de pratiques sexuelles à moindre risque, ainsi que de diffuser d'informations spécifiques ont une influence sur le changement en profondeur du comportement des homosexuels. Ces renseignements (Jack Off Parties-JOP) seront diffusés simultanément à Paris et Amsterdam et l'étude portera de mieux connaître les pratiques sexuelles des participants en dehors des Jack Off Parties.

Méthodes: Réalisation et diffusion de même questionnaire (60 questions) portant sur: prise de contact avec les JOP, évaluation des JOP, test de détection des anticorps du VIH et révélation, pratiques sexuelles habituelles en dehors des JOP, caractéristiques sociodémographiques des participants.... Questionnaires diffusés lors des JOP de janvier, février et mars 1989 (600 à 800 retours attendus pour les deux villes).

Résumé: La première enquête de ce type avait été réalisée à Paris début 88. Les conclusions, présentées à la Conférence de Stockholm (septembre 1988) 3, indiquent que le plus important des JOP pour diffuser et maintenir de nouveaux comportements sexuels à moindre risque. De même, cette enquête avait fait apparaître trois grands groupes de participants selon l'âge et le statut social. L'étude actuellement en cours devrait valider ces résultats, noter les évolutions, mettre en évidence les différences éventuelles entre deux pays ayant des traditions et des politiques de prévention différentes.

T.D.P.49 PSYCHOSOCIAL REACTIONS OF MEN WHO ARE CAREERS FOR HIV-INFECTED PEERS AND MEN WHO ARE HIV-ANTIBODY POSITIVE.

Wiley, Linda, L. Crooks, Leavitt, Walker, R.M.
Psychology Department, University of Waikato, NewSouth Wales, Australia.

Objectifs: (1) To describe and compare the psychosocial reactions of HIV-antibody positive gay men and gay men involved in providing care to their HIV-infected peers in three Australian cities. (2) To contrast these responses to those of two groups of men, one with non HIV-related illness and one with no major illness. (3) To examine the implications these findings have for the development and implementation of counselling and support services for carriers and HIV-infected men.

Méthode: Content analysis which was applied to transcripts of the men's interviews to secure measures of distress, anxiety, depression, anger and helplessness, together with their better experiences of competence and sociability as well as general positive emotion.

Résultats: (1) The psychosocial reactions of gay men showed considerable consistency across the three Australian cities. (2) HIV-antibody positive men and the carriers react differently from both the ill and well men, but their reactions are very similar to each other. (3) HIV-antibody positive men showed the most negative positive men, followed by the experience of anger. Depression is also common for carriers. However, perceived competence is also high for both the antibody positive and carrier groups.

Conclusions: Caring for people with HIV infection can be distressing and demanding. The psychosocial reactions of individual carriers need to be examined in order to develop adequate support structures for them. Methods of counselling and support and with HIV-antibody positive men should be examined when developing interventions for carriers. The perceived competencies resulting from carriers and HIV-infected men suggest these strengths should be fostered in developing counselling.

T.D.P.51 DEFENSE MECHANISMS AND HIV RISK RELATED BEHAVIORS IN SUBSTANCE ABUSERS

Blatt, Richard and Ottensmiller, Genevieve
SUNY Stony Brook Science Center, Brooklyn, N.Y., U.S.A.

Objectifs: The clinical importance of understanding a patient's defensive structure, little attention has been devoted to the role of defense mechanisms in the intrapsychic structure of substance abusers and the relationship of defenses to HIV-related risk behaviors. In this study, substance abusers were administered the Defense Mechanisms Inventory (DMI) and the Risk Behavior Inventory (RBI). The DMI measures five defense categories - Denial Against Object (DAO), Turning Against Self (TAS), Isolation (IS), Projection (PD) and Projection (PD). The RBI elicits demographic and HIV-related risk information such as sexual activities, needle sharing and drug-related risk activities. The sample consisted of 39 substance abusers hospitalized for detoxification from heroin and cocaine addiction. Results showed that despite an absence knowledge fund of AIDS prevention and risk reduction information, the patients reported substantial risk related behaviors on the RBI. Evaluation of the DMI data indicated that the patients scored highest on the RIV defense, followed by PD, DAO and TAS respectively. ISM and ISM, which represent intellectualization and denial defenses, may play a significant role in the interpersonal dynamics of continued involvement in substance abuse and continued HIV-related risk behaviors. Clinical and health education implications of providing treatment services and AIDS prevention information to substance abusers is discussed.

T.D.P.53 ENTENDEMENT PSYCHOLOGIQUE DE L'INFECTION A VIRUS SUR LA RELATION DE COUPLE.

Marijckx, Godefride*, S. Tisserand*, Y. Edelle*
* Département des Maladies Parasitaires et Infectieuses, Unité INSERM 313 (Dr. G. Gentilini), Cx. 75116-Bichat, Paris, France
** Service de Médecine Interne, Maladies Infectieuses et Tropicales (Dr. C. Lafatz), Centre Hospitalier de Villeneuve-St-Georges, France.

L'étude des facteurs psychologiques qui perturbent la relation d'un couple stable a été effectuée auprès de 40 couples séropositifs et SIDA, hospitalisés. A partir d'entrevues semi-directives et de questionnaires auprès du patient et de son partenaire habituel, les auteurs ont trouvé que les facteurs de risque psychologique sont corrélés avec la situation affective et sociale du couple séropositif à l'annonce de la séropositivité ou VIH.

Dans le majorité des couples homo-sexuels et hétérosexuels, la séropositivité est annoncée par le patient au partenaire, alors qu'elle est gardée secrète vis-à-vis des parents (tout au moins au début de l'infection et plus encore vis-à-vis des enfants. Le mode de contamination sexuelle est un réglé-on évoué ou tenu secret dans la relation de couple hétérosexuel (mécanisme de protection du couple, système de loyauté).

On observe une plus grande stabilité de lien dans le couple homo-sexuel. En cas de rupture, la cause de la séropositivité n'est pas le seul motif de rupture. On observe le lien affectif supplée à la réduction notable des pratiques sexuelles, à l'acceptation du sous-groupe des couples dont l'un des partenaires ou les deux sont touchés. Les particularités de ce sous-groupe sont analysées par rapport aux comportements du couple vis-à-vis de la prévention de l'infection par le VIH.

T.D.P.50 PSYCHOLOGICAL INTERVENTIONS IN THE TREATMENT OF PERSONS WITH AIDS, ARC & ASYMPTOMATIC HIV INFECTION.

Wiley, Linda L. Metastorming Inc., Montreal, Quebec, Canada

Objectifs: To report on the use of Neuro-linguistic Programming (NLP) in the treatment of HIV infected persons and the consequent beneficial effects on quality of life and clinical status.

Méthode: The approach is based on psychoneuroimmunology (PNI), the study of the complex bidirectional interactions of consciousness (psychic), brain and central nervous system (neuro), and the body's defense against disease (immunology). The NLP model of human behavior provides a characteristic lens between survivors of AIDS and other life threatening illness. The asymptomatic group participated in a 2 1/2 day workshop, persons with AIDS or ARC were seen individually (from 1 to 16 hours each).

Résultats: The preliminary results (follow-up period of 3 to 24 months) indicate substantial increase in self-perceived quality of life, changes in life style and living/working situations, weight gain, decrease in number and intensity of symptoms and infections, elimination and/or substantial decrease in number and intensity of side effects from drug treatments.

Conclusions: Because of lack of control with respect to other treatments it is not possible to isolate the effects of NLP. Nevertheless, the timing and extent of many changes was impressive and not merely coincidental. Given that it has no harmful side effects, NLP offers an effective strategy in the treatment of AIDS and ARC and in the maintenance of health in asymptomatic HIV-infected persons.

T.D.P.52

PROCESSUS D'ADAPTATION A LA MALADIE DE PERSONNES ATTENTES AU SIDA
Côté, José; Fortin, M.-F. Université de Montréal, Montréal, Québec, Canada.

En raison de l'absence de traitement efficace à ce jour, il paraît essentiel de promouvoir le bien-être des personnes atteintes de SIDA.

Objectif: Décrire le processus d'adaptation à la maladie des personnes atteintes du SIDA.

Méthode: Une étude descriptive de type transversal s'est déroulée dans un Centre hospitalier universitaire de Montréal auprès de 50 sujets, la moitié au stade préinfecté et les autres, au stade précoce d'avancé. Les variables étudiées ont été: les perceptions des sujets vis-à-vis la sévérité des pertes (questionnaire élaboré); leurs stratégies adaptatives (échelle de coping, Billings & Moos, 1984) et l'état psychologique (échelle de bien-être, Kovacs et al., 1985).

Résultats: Les pertes d'ordre physique sont celles perçues le plus sévèrement. I. Les stratégies adaptatives orientées vers la recherche d'information sont celles les plus utilisées. II. La sévérité des pertes détermine l'influence de façon statistiquement significative l'utilisation des stratégies d'évitement. IV. Les sujets qui ont les meilleurs scores de bien-être utilisent davantage des stratégies orientées vers la recherche d'information et ils ont moins recours à des stratégies d'évitement. V. Les sujets qui ont le stade précoce de la maladie perçoivent plus sévèrement les pertes d'ordre social que ceux au stade préinfecté.

Conclusion: Les efforts déployés par les sujets pour composer avec les pertes ont des répercussions profondes sur leur intégrité psychologique.

T.D.P.54

DIFFICULTES IN THE MANAGEMENT OF AIDS PATIENTS AND INFECTED PEOPLE IN BRAZIL
Instituto Lacta Evolucio Lacta, Vila Anália***
*** Divisão Nacional de Doenças Sexualmente Transmissíveis/AIDS - Ministério da Saúde - Brasília, Brazil

Objectifs: To identify the problems health professionals face in dealing with AIDS patients and infected individuals.

The management of AIDS patients and infected individuals in a hospital, out-patient clinics, home care facilities or work place have brought controversial responses from health professionals in Brazil. The main responses were the following: irrational fear, stigma, refusal to provide medical care, ignorance, lack of solidarity and discrimination. These responses brought a crisis on the management of patients on both in-patient and out-patient basis and led us to develop and implement a training course and counseling services. The methodology used in the training was role-play. From 400 health professionals evaluated, 90% (432/480) showed improvement on the level of knowledge, change in perceptions and attitudes towards infected individuals, AIDS patients, and themselves.

T.D.P.55 PSYCHOLOGICAL CORRELATES OF THE TRANSMISSION AND ACCEPTANCE OF RUMORS ABOUT AIDS

Kimmel, Allen J.
Fitchburg State College, Fitchburg, Massachusetts, U.S.A.

Objective. To identify the emotional and cognitive factors that underlie the transmission and acceptance of widely disseminated rumors about AIDS, and to determine the prevalence and degree of belief in the rumors. Rumors were expected to thrive in an atmosphere of anxiety and uncertainty.
Method. A questionnaire, which listed current rumors about AIDS, was completed by 229 college students. These were designed to explore the relationship between apprehension, doubt, AIDS-related changes in behavior, and rumor-specific anxiety, importance, and uncertainty as correlates of self-reported frequency of rumor transmission and degree of rumor belief.
Results. Stepwise regression analyses revealed that the best predictive variables of frequency of rumor transmission included rumor-specific anxiety and behavior change ($r=.56$, $p<.001$); rumor-specific anxiety, importance, and expectation of AIDS-related personal consequences best predicted belief in rumors ($r=.73$, $p<.001$). Rumor-specific credibility was related to AIDS uncertainty ($r=.30$, $p<.001$) and rumor transmission ($r=.17$, $p<.05$). Overall uncertainty about AIDS transmission was related ($r=.15$, $p<.05$).
Conclusion. Rumor-specific anxiety appears to be the strongest predictor of rumor transmission and credibility. Tendencies to transmit anxiety-provoking rumors are likely to increase AIDS-related behavior change, perhaps to justify the change or reduce post-decisional dissonance. Anxiety-provoking rumors perceived as important and personally consequential are most likely to be believed. Reduction of anxiety in AIDS education campaigns is advised.

T.D.P.57

HELP-SEEKING FOR AIDS-RELATED CONCERNS: A COMPARISON OF GAY MEN WITH VARIOUS HIV DIAGNOSES
Hass, Robert; Cunniff, Michael; Lusk, L. and Coates, T.
Center for AIDS Prevention Studies, University of California, San Francisco, San Francisco, USA

Objective. To examine psychological distress levels and help-seeking patterns among four groups of gay men (AIDS diagnosed, HIV seropositive, HIV seronegative, men unaware of their HIV status) and assess the helpfulness of different sources used (peers, family, professional helpers).
Methods. 574 gay men who participated in the 1987 wave of the AIDS Behavioral Research Project completed questionnaires regarding help-seeking, HIV status, AIDS-related worry, anxiety and depression.
Results. Respondents reported high anxiety and a high degree of help-seeking. Men diagnosed with AIDS and seropositive reported the most AIDS-related worry and were the most likely to seek help. Peers were the most widely sought help-source and perceived to be the most helpful. Help-seekers of peers was correlated with less anxiety and depression. Family members were least likely sought and perceived as least helpful.
Conclusions. Peers were seen as the primary and most effective help-source for gay men confronting the AIDS crisis. Community programs are needed to promote the helping abilities of peers, prevent burn-out among peer helpers and provide alternative help sources for men who lack supportive peer networks.

T.D.P.59 EVIDENCE OF FRANK COGNITIVE IMPAIRMENT AND DEPRESSION AMONGST INDIVIDUALS AWARENESS INDEPENDENTLY OF WALKER REED STAGE

Gibson, William C., Thomas, R.C.**, Carter, C.N.***
*Psychology Service, Walter Reed Medical Center and the Walter Reed Bioregulatory Research Group, Washington, D.C. United States of America
**Infectious Disease Service, Walter Reed Army Medical Center, United States of America.

Objective. To provide descriptive information on levels of depression and global cognitive functioning in HIV positive males at a military medical center.
Method. A retrospective review of psychological test data was conducted. Scores on a standard depression scale (Bard) and cognitive test (Shipley-Hartford) are presented, and these were examined in relation to the patient's stage of infection in the Walter Reed Classification system.
Results. Descriptive data are presented in tables. Of 254 patients, 278 scored in the clinically depressed range, and a frequency analysis of these showed no relation between Walter Reed stage and number of patients with a depressed score. Using a Shipley-Hartford IQ of less than 80 to indicate cognitive decline, 15% of 256 patients evidenced such a change. Frequency analysis revealed no relation between Walter Reed stage and IQ.
Conclusion. Patients in both early and late stage of HIV infection are subject to depression and cognitive impairment, and substantial numbers of patients in all stages had normal scores. Professionals should not assume either normality or dysfunction of a patient's psychological status on the basis of information on stage of infection alone.

T.D.P.56 THE STRESS OF CARING: DIMENSIONS OF STRAIN AMONG INFORMAL AIDS CAREGIVERS

Twiter, Heather University of California, San Francisco, USA

Objective. To identify the dimensions of stress experienced by gay men caring for friends or lovers with AIDS. Methods. Qualitative interviews were conducted with 20 informal caregivers. Interviews were taped, transcribed and analyzed for stress-related content. Structured questionnaires were administered to an additional 30 respondents. Results. Three broad dimensions of stress were identified: 1) Primary Caregiver strains that arise directly out of the demands and responsibilities of the caregiver's role; 2) Secondary Strains that develop in other areas of the caregiver's life because of the intrusion of caregiving demands; and 3) Intrapsychic strain resulting from the caregiver's own fear of contracting AIDS, the attenuation of his social network because of AIDS-related death, and the anticipated loss of an intimate relationship. Several sub-components within each of these general dimensions of stress have been identified. The importance of humanistic benefits for the patient and informal caregiver in often left to contend with a great number of intense stressors. The importance of incorporating the needs of informal caregivers into public health policy is evident.

T.D.P.58 SHORT-TERM MEMORY (STM) CAPACITY DECLINES AS A FUNCTION OF AIDS SEVERITY

Corfian, D; Kellip, JG; Sadler, AR; Wolf, J; Price, RW & Memorial Sloan-Kettering Cancer Center, NY, NY, USA

Objective. To assess STM capacity as a function of clinical severity of ADC. Although memory failure is a frequent complaint in ADC patients the bases for such complaints have yet to be determined.
Methods. STM on a free recall task was examined in a group of 80 patients at various stages of HIV-1 infection. Patients were rated according to cognitive impairment based on a standard neurological history and examination: 50 (unimpaired), 21 (mild) and 18 (moderate to severe). STM capacity was measured by determining the mean number of items recalled from STM in the Auditory Verbal Learning Test (Maugh, HC and Norman, DA. *Psych. Rev.* 85-104, 1965).
Results. STM declined as a function of cognitive impairment ($F(2,88) = 8.30$, $p<.001$). Memory decline was modest in patients with mild impairment (7%). It was more pronounced in patients with moderate or severe impairment (42%). The decrease in STM correlated with other neuropsychological measures of ADC: timed walk ($r=-.34$), grooved pegboard ($r=-.43$), and trail making A and B ($r=-.46$), but not with measures of psychiatric distress.
Conclusions. STM decreases as a function of increased severity of ADC. This decline reflects diminished cognitive capacity but because of the role of attention in STM, it is unclear whether the reported results represent a true memory deficit. The extent to which this decline affects cognitive functioning warrants further investigation.

T.D.P.60 ATYPICAL STYLE AND DEPRESSION IN HIV-RELATED ILLNESS

*Van Gorp, Wilfred**; Preams, D.***; George, L.****
*Department of Psychology, University of California, San Diego, CA, USA
**West Los Angeles VA Medical Center, Los Angeles, CA, USA
***Medical Center, Jackson, R.C., USA

Objective. To examine the influence of self-reported depressed mood in a group of AIC and AIDS patients and the relationship of attributional style to mood state.
Method. Thirty subjects (AIDS, $n=18$; AIC, $n=12$) were administered the following tests: BDI-16, Beck Depression Inventory (BDI), and Attributional Style Questionnaire (ASQ). The subjects were aged from 22-43 with a mean and median of 42 years and a mean education of 14 years.
Results. Internal depressed mood was found for the total sample on both the depression scales of the BDI-16 ($M=11.1$, $SD=4.4$) and the BDI ($M=10.8$, $SD=3.5$). Although both groups reported significant depression on the BDI-16 depression scale (AIDS, $M=9.8$, $SD=4.7$; AIC, $M=11.9$, $SD=4.4$) and ASQ to indicate depressed mood and the BEI (AIDS, $M=5.5$, $SD=4.7$; AIC, $M=5.7$), no significant differences were found between the groups on these measures. A significant positive correlation was found between the ASQ and BDI-16 depression scale ($r=.49$, $p<.05$) and the BEI ($r=.49$, $p<.05$).
Conclusions. Elevated depressed mood was observed in a sample of AIC and AIDS patients and a significant positive relationship was found between internal, stable and global explanations for negative events and self-reported depression. Attributional style may be an important factor in the manifestation of depression among patients presenting with HIV-related symptoms, and the implications of this will be discussed.

Le SIDA et l'individu AIDS and the Individual

T.D.P.61 HIV-1 PATIENTS' SELF-REPORTED COMPLAINTS OF MEMORY FAILURE AND THEIR RELATIONSHIP TO ACTUAL MEMORY PERFORMANCE
Kellip, John S.; Sadler, AE; Wolf, A; Brew, BJ; Dorfman, D; Price, NR; Stoltz, JJ. Memorial Sloan-Kettering Cancer Center, NY, NY, USA

Objective: To evaluate the relationship between HIV-1 patients self-reported memory complaints and their actual performance on formal tests of memory.
Methods: 123 untreated HIV-1 patients at varying AIDS Dementia Complex stages were evaluated with the Neuro-AIDS Study group neurological history, examination, and neuropsychological battery. Patients also completed a self-report scale of memory complaints (Memory Assessment Clinic, Inc.), which provides scores on two general factors: (1) ability (AM1) to perform a variety of everyday memory tasks and (2) frequency (FRQ) with which lapses in performing such tasks occur.
Results: AM1 and FRQ were strongly correlated with each other ($r = .54, p < .001$), and with the number of memory complaints elicited from neurological history (AM1: $r = .50, p < .001$; FRQ: $r = .50, p < .001$). AM1 score was lower ($t = 3.7, p < .001$) and FRQ score higher ($t = 3.2, p < .002$) in patients with mild to moderate symptoms of ADC. Only the AM1 score was significantly correlated with scores on formal tests of memory (with Verbal Learning, $r = .20, p < .009$; with Visual Retention, $r = .16, p < .08$) or tests with a memory component (with Digit Span, $r = .22, p < .01$). The FRQ factor was most strongly correlated with mood ($r = .51, p < .001$) and general psychiatric symptomatology ($r = .56, p < .001$).
Conclusions: Complaints of impaired memory ability are mildly related to actual decrements in performance. The frequency of reported lapses, however, is strongly related to the intensity of mood/psychiatric disturbance.

T.D.P.63 EMOTIONAL STATES IN RELATION TO IMMUNE FUNCTION IN A GROUP OF MALE SEXUAL CONTACTS OF MEN WITH HIV DISEASE

Authors: Rosenblatt, M.; Casser, R.***; Reed, S.***; MacPhaden, D.***; Johnson, M.***; Panning, M.***; Shephard, D.***
*Women's College Hospital, Toronto; **Department of Preventive Medicine and Biostatistics, University of Toronto; ***Hospital for Sick Children, Toronto; The Toronto Hospital, Toronto, Ontario, Canada.

Objective: To explore the relationship of emotional state and laboratory measures of immune function.
Methods: Men with prior homosexual contact with an individual with HIV-related illness were recruited without regard to emotional state for a study of HIV status, risk behaviour, clinical status, and immune function. 155/161 (96.3%) men without AIDS completed the Profile of Mood States (POMS) for at least one quarterly visit in one year. 6 POMS scales X 12 immune function measures = 72 possible significant (p < .05) correlations.

Results: POMS scale scores did not differ between HIV+ and HIV- men. For HIV+ men, 1 POMS/immune function pair was correlated at visit 1 ($N = 47$) and 2 different pairs were correlated at visit 2 ($N = 62$). For HIV- men, 5 POMS/immune function pairs were correlated at visit 1 ($N = 99$) and 19 pairs were correlated at visit 2 ($N = 72$); unexpectedly, greater emotional distress was associated with better immune function on all correlations.
Conclusion: In this long-term study of homosexual men, greater emotional distress was not associated with deterioration in immune function measures commonly used to monitor progress of HIV infection.

T.D.P.65 HIV INFECTION AND IMMUNOLOGICAL STATES IN ADOLESCENT GAY MEN
David GORSON, Bill LEE, Robert J. HANES
Division of Internal Medicine, Hospital "Thomas Traill" (TTH), Universitat Autonoma de Barcelona, Barcelona, Spain.

Objective: To analyze the role of viral-mediated immunity and viral load in HIV compared to CD4+ to determine if there is any relation between these immunological functions and HIV seropositivity.

Methods: 30 HIV seropositive individuals were tested from January II to December II. 10 seropositive tests were negative. The lower's memory progressive function for the area of visual-spatial reasoning (II spatial) and the III spatial area section for the sensitive memory area ("1" section) in age 10 and II after adjustment at the identification test, patients were tested with the digit span on the III spatial area.

Results: 14/20 (70.0%) of patients had HIV antibodies (HIV tests) and 16/20 (80.0%) had anti-HIV. The HIV test was 10.4% in 10 years and the time of infection was 10.2% in 10.7 months. 10.1% in 10.1% in HIV and 10.1% in 10.1% in HIV. 10.1% had only primary serological level and in 10.4% of such individuals was anti-HIV or anti-HIV. About of other drugs was high. We set significant in each group. 10.1% of the HIV test obtained in 10.1% permits in the area of visual-spatial reasoning. The digit span showed no differences, between the two days of testing, and finding the same conclusion in both seropositive individuals.

Conclusions: There was not significant differences in the visual-spatial reasoning and sensitive memory areas of both seropositive and seronegative individuals. It indicates a decreased visual-spatial reasoning in a 10% of the cases that does not seem related to HIV seropositivity. It seropositive. It is therefore, factors as low serological level, absence of other drug and longer seroconversion intervals could explain these findings.

T.D.P.62 QUALITY OF LIFE OF PERSONS WITH AIDS/ARC.

Donald Ellerman, Health Planning Consultant and Mark Smith, University of Pennsylvania, Philadelphia, PA, USA.

Objective: To document and quantify the effects a diagnosis of AIDS has on one's life.

Methods: All persons diagnosed with either AIDS or ARC (PWA) were surveyed in the metropolitan Philadelphia area. A mail-return survey method resulted in 90 completed surveys of a total documented population of 253 PWAs. The survey was distributed through health care and social service networks.

Results: The survey produced evidence for a cycle of impacts on PWA's of diagnosis leading to illness, to loss of employment, to loss of health insurance, to loss of financial security, and all these to mental stress. Average monthly income declined from \$180 before diagnosis to \$80 afterwards. Health care expenditures (PWA) lives; they spent a mean of 5.9 hours per day on their personal medical care, paperwork and extra hours attending and made an average of 6 visits per month to health care facilities. Overall quality of life is standardized on a scale from 0 to 10 using Spitzer's quality of life index. The mean for PWA is 6.8.

Conclusions: A diagnosis of AIDS leads to significant impacts on employment, finances, mental health, daily living and overall quality of life which can be documented and quantified.

T.D.P.64 IMMUNITY RESPONSE AND HIV INFECTION IN GAY MEN

Alan Corbin, Bill Lee, Robert J. Hanes, J. Hanes
Division of Internal Medicine, Hospital "Thomas Traill" (TTH), Universitat Autonoma de Barcelona, Barcelona, Spain.

Objective: To test the hypothesis that personality disorders are lower risk patients for HIV infection in comparison with other classes (BPD), based on the analysis of personality scales and factors. It is a typical characteristic of BPD.

Methods: 10 seropositive HIV test and 10 female seronegative tests (HIV-). HIV- test (HIV) and HIV- test (HIV) were administered to 10 gay men. HIV- test (HIV) and HIV- test (HIV) were administered to 10 gay men. HIV- test (HIV) and HIV- test (HIV) were administered to 10 gay men. HIV- test (HIV) and HIV- test (HIV) were administered to 10 gay men.

Results: 10/10 (100%) of HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV.

Conclusions: HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV. HIV- test (HIV) and HIV- test (HIV) had anti-HIV.

T.D.P.66 PSYCHOLOGICAL FACTORS PREDICTING DISTRESS AFTER HIV TESTING
Elizabeth, Barbara Perry, J. Hanes
Cornell University Medical College, New York, NY, USA.

Objective: To identify individuals at risk for distress after HIV testing.

Methods: When 264 physically asymptomatic subjects voluntarily sought HIV serology testing, three hypothesized predictors of distress were assessed: (1) perceived social support (Interpersonal Support Evaluation List, ISEL); (2) attributional style (Attributional Questionnaire, AQ); (3) attributional style (Health Attributional Style Questionnaire, HASQ). Distress was concurrently measured by the Beck Depression Inventory (BDI), State-Trait Anxiety Inventory (STAI, TAI), and Brief Symptom Inventory (BSI). The distress measures were re-administered 9 weeks later, after notification and one of three psychoeducational interventions.

Results: Seronegative correlations (initial) and partial correlations (follow-up) controlling for effects of serological status and intervention:

	Initial (N=264) 283 (N=14)	Follow-up (N=167) 283 (N=14)	
ISEL	-.55	-.44	-.52
AQ	-.59	-.58	-.57
HASQ	-.52	-.54	-.43

For all correlations, $p < .05$. For ISEL, $p < .01$. For AQ, $p < .01$. For HASQ, $p < .01$.

Conclusions: Perception of social support, pessimistic and attributional style were strongly associated with distress before HIV testing and predict distress 9 weeks later. They may be useful assessments to identify patients for preventive psychoeducational interventions.

PSYCHOLOGICAL ASSESSMENT IN AIDS RESEARCH: INTERVIEWER SELECTION, TRAINING, AND MONITORING

Spiegel, M. S.; Galanter, H. P.; Meyer-Bahlburg, H.F.L.*
Berkeley, A.A.*

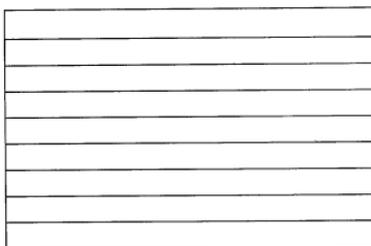

*MGI Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, NY, USA.

Objective. To describe a program designed to optimize rapport between interviewer and subject and to minimize specific biases in the value-laden and emotionally charged area of assessment.

Method. (1) Interviewer selection; criteria include both general educational requirements and level of comfort in dealing with diverse sexual histories. (2) Desensitization workshops, to familiarize the interviewer with sexual vernacular. (3) Item-by-item review of the sexual instrument. (4) Conducting of audiotaped interviews. (5) Supervised interview practice with staff members. (6) Supervised interview practice with subjects from the target population. (7) In the field: ongoing review of every interview. (8) Monitoring of interviewer style by audiotape-review of every 7th to 10th interview. (9) Weekly group supervision of interviews. (10) Results. Overall, selection of interviewers reduced overall training time. The training program facilitates rapport, self-disclosure, etc. Group sessions enhance interviewer awareness.

Conclusion. Overall quality of psychosocial data is enhanced by interviewer selection and training procedures.

T.D.P.74

T.D.P.76

SELF-LABELLED SEXUAL ORIENTATION AND SEXUAL BEHAVIOR AMONG WOMEN

Ryan, S. and Lerman, J.M. Raleigh and J. Zomba-Davis

The Kinsey Institute for Research in Sex, Gender, and Reproduction, Indiana University, Bloomington, IN, U.S.A.

Objective. To describe the relationship between women's self-labeled sexual orientation and actual sexual behavior both since 1981 and since 1980.

Method. A self-administered sample of 639 men completed a questionnaire specifically designed for this study. The instrument included questions concerning demographics, sexual behavior with both men and women, and both knowledge and opinion regarding AIDS.

Results. The data suggest the self-labeling of sexual orientation among women does not necessarily correlate with actual behavior since age 18 or since 1980. In our sample of 262 women who had themselves labeled as self-labeled of sexual orientation and actual sexual behavior patterns appear to be relatively independent - 75% of those women had had sex with men since age 18 and 49% had done so since 1980. Thirty percent of the Indian women reporting sex with men since 1980 had engaged in public-to-public intercourse. Our data also indicate that the likelihood of engaging in anal intercourse is significantly related to the sexual orientation of a woman's male partner. Among lesbian women in our sample, only 25% of those with heterosexual partners engaged in anal intercourse as compared to 67% of those with known behaviorally bisexual male partners.

Conclusion. The labels "heterosexual" and "homosexual" are often presumed to predict the sex of partners, the types of behavior engaged in and in some cases, the overall frequency of sexual activity. Moreover, once a label has been identified, it is accepted as characterizing an individual's lifetime sexual behavior. Like other non-risk-identified groups in our studies, lesbian women are assumed to be at minimal risk for infection with Human Immunodeficiency Virus (HIV). Although sexual behavior between women may act as a partially cover of transmission, the danger of assuming that lesbian women, for that matter men and women of any particular orientation group, are at minimal risk, lies in the erroneous notion that such group designations impose impermeable barriers to sexual intercourse.

T.D.P.76

SAFER SEX AMONG HOMOSEXUAL MEN: MEANING A MOTIVATION.

DeBruin, James* New, J.F.; Kallisher, J.

Christchurch School of Medicine, Christchurch, New Zealand.

Objective. To study the motivations and meanings of changing sexual practices amongst men who have sex with men. In response to AIDS.

Method. Fifty men were contacted at a gay sauna or through snowball sampling and were interviewed with an unstructured, in-depth approach.

Results. Sexual practices were variable over time and context dependent. Those generally practicing safer sex were characterized by one or more of the following: most strongly identifying themselves as gay; concerned to maintain a healthy life-style; close relationship with someone with HIV infection; concerned for health of others particularly their partners. Those men who tended to participate in "safer" sexual practices included those who were still in the process of "coming out"; saw themselves as sexually inexperienced; lacked social skills or self-confidence to assert their preference for safe sex; younger men who used sex as a means of gaining entry into gay society; older men who were willing to compromise health concerns for sexual availability; men who had broken off a stable relationship and were particularly vulnerable.

Changes to sexual behavior had usually been made at great cost. Often, safer sex represented a major disruption in social life. Some exchange was seen by men as "real sex" and therefore giving it up was a significant loss. It appeared that sex was the most important form of communication between these men. Other forms of fantasy were poorly developed. **CONCLUSIONS.** Consistency in the practice of safer sex depends upon circumstances, characteristics and context. The extent of the sacrifice required should not be underestimated.

T.D.P.77

VARIABLES INFLUENCING CONDOM USE AMONG INTRAVENOUS DRUG USERS

Marcus, Stephen, Shapiro, R.L., Siddons, C., Linton DS*

Nagano and Drug Research Inc., New York, New York, USA

Objective. To determine the knowledge, belief, attitudes, and behaviors related to the use of condoms among 110 IDUs at risk of contracting and/or transmitting HIV through unprotected sexual contact.

Method. 289 IDUs attending 3 methadone maintenance clinics in New York City completed confidential standardized questionnaires during 1987-1988.

Results. AIDS risk factors were: sexual activity in previous month (yes=79%); condom use among sexually active (no use=48%); sexual partner(s) injected drugs in past year (yes=53%); intravenous drug use in previous month (yes=41%); needle-sharing in previous month (yes=59%). Multiple logistic regression was conducted for the sexually active subjects to predict their condom use in the previous month (none vs. some). Condom users scored higher on Acceptability of Condoms, e.g. to believe that condoms did not "cut down" on enjoyment and to be willing to use condoms "if my partner asked me" (Odds Ratio=1.7, 95% CI=1.2, 1.4). Users also scored higher on Receptivity of Partners to Protection, e.g. to believe that their sexual partners would "not be insulted" by requests for condom use or other sexual protections (OR=1.6, 95% CI=1.1, 2.2). Condom users were also more likely to personally know a person with AIDS (OR=1.5, 95% CI=1.2, 2.3) and to be recent entrants to the study (OR=1.6, 95% CI=1.2, 2.0).

Conclusion. IDUs' willingness to use condoms is significantly determined by specific beliefs and attitudes that could be modified by appropriate health education and cognitive-behavioral interventions.

T.D.P.78

SEXUAL BEHAVIOR SURVEY OF BRAZILIAN MEN THAT ARE CLIENTS OF TRANSGESTIVE PROSTITUTES

Piquet, Arley*

*Centro de Referência e Treinamento-AIDS, São Paulo, Brazil

Objective. To elucidate the sexual behavior of men that engage in sexual contact with transvestite prostitutes.

Method. A 20-item questionnaire was applied to 162 men that regularly engaged in sex with transvestites. 150 men were included in the study.

Results. The mean age was 34.01 years, 60% were married or had stable female partners, 3.7% reported homosexual activity in adulthood. None had stable male partners. 97.3% of the subjects identified themselves as heterosexuals and 2.0% as bisexuals. 10% were engaged exclusively in active anal intercourse with the transvestite, 20.67% in passive anal intercourse, and 57.33% in both. 4% did not engage in anal intercourse. 61.3% reported some degree of alcohol or drug use before or during the encounter. 4.6% reported IDU with the transvestite. 94.67% acknowledged the risk for acquiring some form of STD. None thought that they were at risk for AIDS.

Conclusion. This study demonstrates that transvestite prostitution is an important risk factor for heterosexual transmission in Brazil, as well as, the need for developing specific educational programs for heterosexuals including these aspects.

T.D.P.79 CHILDHOOD GENDER NONCONFORMITY PREDICTS HIV-1 SEROPPOSITIVITY IN HOMOSEXUAL MEN

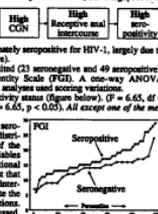

Richard James Grant, I. Adamson, J. Richman, D. Spence, S. University of California, San Diego, U.S.A.

Objective: To determine whether childhood gender nonconformity (CGN), an important variable in gender identity research) is of value in AIDS research. The central hypothesis is that homosexual men with high CGN become disproportionately seropositive for HIV-1, largely due to high levels of receptive anal intercourse (figures above).

Methods: N = 72 homosexual men have been recruited (23 seropositive and 49 seronegative), and completed the Childhood Gender Identity Scale (CGI). A one-way ANOVA compared seropositivity with CGI scores. Additional analyses used scoring variations.

Results: CGI scores differ significantly by seropositivity status (figures below) ($F = 6.65, df = 71, p < 0.012$). Fisher's LSD, $p < 0.05$, $p < 0.001$, all except one of the men with the higher CGI scores were seropositive.

Conclusions: The association between CGI and seropositivity is so strong at the high end of the CGI distribution that it might not arise merely by way of the hypothesized intermediate variable. Personality variables as well as behavioral ones may be required. Additional analyses are in progress that suggest that CGI may be a good surrogate for receptive anal intercourse experience, and might to some extent mitigate the underreporting of such experience in direct questions. Implications for medicine and sociology will be discussed.

T.D.P.81 CONDOM USE AMONG HETEROSEXUAL MALE IV DRUG USERS IS AFFECTED BY THE NATURE OF SOCIAL RELATIONSHIPS.

Richard James Grant, I. Adamson, J. Richman, D. Spence, S. University of California, San Diego, U.S.A.

Objective: To describe the extent to which male IV drug users in treatment know that condoms reduce HIV transmission risk, contrast knowledge to actual use, and determine whether characteristics of social relationships affect men's condom use with women.

Methods: One hundred fifty-one men recruited from a New York City methadone treatment program in 1986 and 1989 were interviewed with a structured questionnaire in 1987-88.

Results: Of the 150, 137 (91%) had sex with women in the period (mean 23 months) covered by the interview. Of these 137 sexually active men (of whom 2 also had sex with men), 57% (78/137) reported only one sexual partner. While 70% (125/144) knew that condom use can prevent sexual transmission of HIV, only 50% (76/153) of the sexually active men ever used condoms during the interval.

Conclusions: While men's sexual, educational, and number of women partners were not significantly associated with condom use, but the nature of social relationships was. Among the 64 men who lived with a sexual partner, 44% used a condom at some time during the period, compared to 68% of the 71 who did not live with a sexual partner ($p < 0.05$). The relationship remained significant after controlling for number of partners.

Conclusions: Education about condoms is not necessarily sufficient to promote condom use; the nature of social relationships also affects sexual risk reduction. Condom use among men is less frequent in relationships with more complex interdependencies.

T.D.P.83 EVALUATION OF SEXUALITY IN HIV INFECTED PATIENTS BY THE WARTING TEST.

Leopoldo Pineda, Gerardo Nieto, L.D. and Maria de S.C. Garcia & Duke University Medical Center - University of Rio de Janeiro (UFRJ) - Brazil

Objective: To observe possible changes in the sexuality of HIV infected patients by sexual transmission, compared to those infected by blood transfusion.

Methods: 20 HIV infected patients were assessed by a non-directive sociological method, this group including 18 (90%) infected by sexual transmission (heterosexuals and 2 female partners of bisexual men) and 2 (10%) by blood transfusion. The survey test was performed in all infected patients in a manner of a semi-structured interview. Through sociological stimulus the patients develop pictures and comments about the subject, eliciting adequate and non adequate responses in 8 different fields. The sexuality field was specifically evaluated and statistically assessed by Chi-Square Test.

Results: Data are presented in the following table:

SEXUALITY FIELD ALTERNATIVES	SEXUAL TRANSMISSION	BLOOD TRANSMISSION	T	O	A	Z
Observed	18	10	5	41,6	23	
Exp. Observed	6	6	7	38,3	7	

Alterations in the sexuality field observed ranged from difficulty in reacting to sociological stimuli to non adequate responses.

Conclusions: HIV positive individuals (who were) infected by sexual transmission may develop own changes in their conception of sexuality.

T.D.P.80 SEX AND DRUG PRACTICES IN THE ILLEGIT SEX INDUSTRY AS RELATED TO THE SPREAD OF AIDS

William J. Jones, I. Adamson, J. Richman, D. Spence, S. University of California, San Diego, U.S.A.

Objective: To assess the sexual practices of prostitutes and their clients with respect to AIDS transmission.

Methods: Information was collected from a total of 169 seropositive prostitutes contacted on the streets of New York City from 1983 to 1988. (22 in 1983, 43 in 1984, 65 in 1987, and 37 in 1988).

Results: Of 169 seropositive prostitutes, 14 (8.3%) were found by ELISA with confirmation by Western Blot to be positive for HIV-1. Of 22 (13%) of these women who admitted to former or present intravenous drug use, 25% were positive, while among the 147 (87%) women not admitting to intravenous drug use, only 5% were positive. Many of these women reported having lovers who used intravenous drugs.

Conclusions: Information was collected from a total of 169 seropositive prostitutes contacted on the streets of New York City from 1983 to 1988. (22 in 1983, 43 in 1984, 65 in 1987, and 37 in 1988).

Results: Of 169 seropositive prostitutes, 14 (8.3%) were found by ELISA with confirmation by Western Blot to be positive for HIV-1. Of 22 (13%) of these women who admitted to former or present intravenous drug use, 25% were positive, while among the 147 (87%) women not admitting to intravenous drug use, only 5% were positive. Many of these women reported having lovers who used intravenous drugs.

Conclusions: Information was collected from a total of 169 seropositive prostitutes contacted on the streets of New York City from 1983 to 1988. (22 in 1983, 43 in 1984, 65 in 1987, and 37 in 1988).

Results: Of 169 seropositive prostitutes, 14 (8.3%) were found by ELISA with confirmation by Western Blot to be positive for HIV-1. Of 22 (13%) of these women who admitted to former or present intravenous drug use, 25% were positive, while among the 147 (87%) women not admitting to intravenous drug use, only 5% were positive. MANAGEMENT OF PSYCHOLOGICAL DISTRESS: A HOSPITAL-BASED "MUTUAL AID" SUPPORT GROUP FOR HIV POSITIVE MEN

Johns, Jonathan, *Harvard Center for AIDS, New York Hospital-Cornell Medical Center, New York, N. Y., U.S.A.*

Objective: To decrease psychological distress and increase social support and the exchange of medical and treatment information, an inpatient "mutual aid" support group for HIV seropositive men was created.

Methods: A support group consisting of nine seropositive men led by a trained facilitator met for one and one-half hour weekly sessions for one month. In the "mutual aid" support group format two types of support occur: (1) a one-on-one, non-judgmental alliance structured by a facilitator (uses a group therapeutic technique and (2) a peer support model for group-generated topic preference, preparing the group to identify and process self-selected issues at their own pace.

Results: Two forms of self-report ratings were utilized in evaluating the intervention's efficacy. Inpatient, immediate reporting by group members on a weekly basis indicated a general decrease in emotional distress and an increase in social contact. A written assessment after two months of group involvement reported relief, increased adjustment to serostatus, decreased social support, increase in correct knowledge of medical and treatment information and a desire for continued group interaction.

Conclusions: This inpatient format of serostatus support, group therapy and crisis management encourages adjustment to a traumatic psychological event: HIV seropositivity. This group has proven so effective that group members have requested the need for continued sessions beyond the program two week period. This model is being used in the hospital outpatient care setting using trained staff resources while maintaining patient well-being.

W.D.P.8

THE NEED FOR COUNSELLING OF HIV TESTED INDIVIDUALS IN A RURAL POPULATION OF UGANDA

Uganda: Lumbago, A. J.; Kewer, M.*; Konde-Lule, J.***; Namara, N.***; Sanyal, S.***; Mupfema, S.*** AIDS Control Program, Entebbe, Uganda. Uganda: University, N. Y., USA**; Mukereye University, Kamula, Uganda.**

Objective: To determine the demand for HIV serological results among seropositive subjects in a rural Ugandan population.

Method: The Uganda AIDS Control Programme has implemented a longitudinal study of HIV related knowledge and behaviors, and of HIV serological trends in rural Rakai district. A baseline knowledge, attitudes and practices (KAP) and serological survey was conducted on consenting adults in 21 randomly selected rural and 5 trading center clusters. Plans call for repeated KAP and serological survey rounds.

Results: Preliminary results indicate 72% of adult study subjects stated they wished to know their serostatus. 81% knew there is no cure for AIDS, 82% knew of a period of latency between infection and illness, 83% knew of sexual transmission. Survey team members were approached by individuals asking to know their serostatus.

Conclusions: Demand for serological results in this population was high. Baseline knowledge of characteristics of the illness was also high. The information is being used to design a counselling program for survey clusters, which will encourage subjects to learn their results in a confidential and culturally appropriate manner. The special circumstances of seropositive subjects will also be considered in developing counselling in this non-clinical setting. The researchers consider a counselling program essential for program credibility and for the success of repeat visits for data and blood collection.

W.D.P.9

PSYCHOSOCIAL ISSUES PRESENTED BY SELF IDENTIFIED BISEXUAL MEN WITH HIV CONDITIONS

W. Gallo-Silver, S., McCabe, R., Mounthan, J., Rawels, G., Miller, J., & Y. M. Y.

Memorial Sloan-Kettering Cancer Center, New York City, U.S.A.

Objective: To examine the consequences and psychosocial issues confronting bisexual and gay men with HIV conditions.

Methods: A study of 35 HIV positive (30 with AIDS) bisexual men, aged 26-64, who were seen in individual counseling by a social worker as part of standard patient services and 36 gay men with AIDS, aged 24-61, who completed a structured interview with a social work researcher. Data collected from 8/86 to 12/88.

Results: Both groups were similar on educational, racial and religious background and occupational groupings. Groups differed on marital group (53% of bisexuals were currently or previously married compared to 13% of gay men) and parental status (41% of bisexuals had children vs. 3% of gay men). Prior to their learning their HIV status, only 11% of currently married bisexuals told their wives of their bisexuality and only 8% of bisexual fathers had told their children. However, 35% of bisexuals have told family members about their HIV status and 73% of those who have AIDS have told their family. Of the gay men 75% of their immediate family know about their status.

Conclusions: A major task confronting bisexual men is that of the disclosure of their condition and lifestyle. Mental health professionals need to develop specific strategies for assisting them in communication about these issues.

W.D.P.10

PSYCHOSOCIAL ISSUES PRESENTED BY TRANFUSION ASSOCIATED HIV INFECTED ADULTS AND THEIR FAMILIES

W. Gallo-Silver, S., Wise Campbell, R., Mounthan, J., Goldman, J., & Y. M. Y.

Memorial Sloan-Kettering Cancer Center, New York City, U.S.A.

Objective: To identify psychosocial issues of transfusion associated HIV infection in infected adults and their families.

Methods: 15 patients (5 with IDH/AIDS), ages 30-92, transfused for cancer-related treatments (3), cardiovascular surgery (5), trauma (3), other medical conditions (3), sexual contact with a transfused spouse (1). Information drawn from individual, family, and group counseling sessions and team meetings with physicians.

Results: Common themes reported by patients and their families: intense anger with medical community and blood banks; mistrust of health care providers; feelings of victimization, lack of identification with other HIV patient groups and need for control of their medical care. Male patients reported concerns of being labeled homosexual. Fourteen patients and families expressed anger at the gay community and reluctance to utilize community AIDS organizations. Of 8 married couples, 7 have since abstained from sexual relations.

Conclusions: Special circumstances of transfusion associated HIV infection require psychosocial interventions that are specifically designed to diminish feelings of isolation, enhance communication with family, health care professionals and physicians; and provide a way to manage anger and mistrust.

W.D.P.11

A REVIEW OF HIV COUNSELLING IN AN INNER CITY UNIVERSITY HOSPITAL

Harbach, Margaret, *Wilcox, W., Chalmers, R., Johns Hopkins University, Baltimore, MD, USA.*

Objective: To review HIV counselling procedures in an inner city university hospital.

Methods: Review of HIV counselling policy in effect 8/77-1/88 at Johns Hopkins University Hospital. Pre-test counselling and informed consent was the responsibility of the medical staff treating the HIV test. Patients with positive or indeterminate Western blot results were to be referred to the hospital HIV counselor for post-test counselling. No policy is in effect for counselling patients with negative HIV results.

Results: Between September 1987 and January 1988, 4300 HIV tests were performed. Of these, 190(12%) were ELISA and Western blot positive; 47(1%) were ELISA positive and Western blot indeterminate. HIV infection risk factors: 50% intravenous drug use (IVDU), 7% gay/bisexual men, 4% sexual partner of a person at risk, 2% transfusion.

No risk factor was identified in 48% of patients testing positive/indeterminate. Of 157 patients with positive/indeterminate tests, 329 (59%) were referred for post-test counselling. Counseling sessions include basic education re HIV infection, safer sex practices, cleaning IV drug needles, ending with the counselor making a determination what psychologic and/or medical follow-up is necessary. The remaining patients testing HIV+, being followed by either an inpatient service or an outpatient clinic, will likely receive some form of informal counseling from their care provider.

Although most patients testing HIV positive/indeterminate received some post-test counselling, this represents only 30 (29/103%) of patients undergoing HIV testing. **Conclusions:** This HIV test counselling program was effective at reaching most HIV positive/indeterminate patients. Since there was no policy for counselling HIV patients, those at continued risk of infection may not get adequate counselling. HIV counselling should not only be based on test results, but on the patients risk factor as well.

W.D.P.12

COUNSELLING TRAINING - CURRENT NEEDS: AN EVALUATION OF AIDS COUNSELLING TRAINING COURSES LOOKING AT CHANGE AND CONTENT

L. Sherry, A. MacCreaner, J. Green / St Mary's Hospital, National AIDS Counseling Training Unit, London, UNITED KINGDOM

OBJECTIVE: To examine the change/needs for training over time and to assess current course content, demand and efficacy.

METHOD: - Training of health care workers - carried out since 1985. All participants are questioned before and after course. A random sample followed up for 12-18 months after course. This study examines change over time and current course needs.

RESULTS: - AIDS and HIV Counselling training has changed in focus, content and style over time. This is in response to new information, needs, demands and essentially different audiences who require training. A shift has been noted over three years. Initially front line workers were involved. Their needs were informational and they required a validation of counselling need, approach and technique. Counselling has now become accepted and attendees tend to be more entrenched role staff. Training has moved towards skills based training, early anxieties about contact with AIDS and HIV individuals has now been replaced with worries about basic counselling skills. Skills training is more lengthy and the requires active participation. Role play, contracts, group work and the use of video techniques are discussed.

CONCLUSION: - Training demand is high and needs constantly change.

W.D.P.26 **REPRESENTATIVITY, RETENTION AND COMPLIANCE OF MINORITY PATIENTS AND USER AGREEMENT IN A VA COOPERATIVE STUDY**

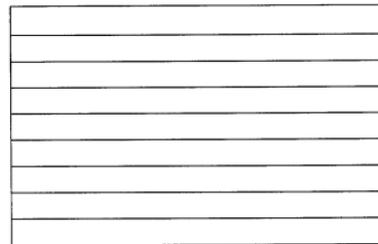

Shiboski, M., Hamilton, J., Harrison, P., Brusano, G., and the Cooperative Studies Group on Treatment of AIDS-related Complexes, New York, N.Y., USA

Objective: Minorities and drug abusers (TVA) have under-represented in some HIV treatment studies. We evaluated their recruitment, retention and compliance in a multi-center VA Cooperative Studies trial of AZT vs. placebo for patients with AIDS-related Complexes.
Methods: Demographic characteristics, risk behavior activities and follow-up (F/U) for scheduled visits of the patients were reviewed. Blood samples were analyzed for study drug by HPLC and classified as compliant, non-compliant or indeterminate.
Results: Results are tabulated below: (*p<.01)

RACE OR RISK	PATIENTS	RECRUITED F/U	FURTHER DRUG COMPLIANCE		
			COMP	NON-COMP	INDETERMINATE
White	131	80-2	92	2	6
Non-White	58	75*	93	3	4
MS (nonsexual)	115	83	92	2	7
TVA	32	64*	92	4	5
Blk & TVA	28	78*	91	2	7
MS	5	75	97	3	0
Intersexual	6	85	94	3	3
Unknown	10	78	0	0	8

Conclusion: Minority patients and TVA were significantly less likely to return for scheduled F/U. However, they were compliant with taking study medication. These data should be taken into account in considering them for HIV clinical trials.

W.D.P.26

W.D.P.27 **CLOSE ENCOUNTERS OF AN UNSAFE KNID: RISKY SEXUAL BEHAVIORS AND PREDICTORS AMONG BLACK GAY AND BISEXUAL MEN**

***John L. Pearson,* Robert Phillips,**Joseph Catania,** Thomas Coates,* Center for AIDS Prevention Studies, University of California, San Francisco and Multicultural Institute, Bayview-Hunter's Point Foundation**

***Center for AIDS Prevention Studies, University of California, San Francisco, U.S.A.**

Objective: To determine the current high risk sexual behaviors and predictors of those behaviors in a cross-sectional study of Black gay and bisexual men.
Method: The sample consisted of 50 gay and 50 bisexual Black men recruited in 1988 through gay organizations, gay bath houses, parties, personal referrals and unsolicited volunteers in San Francisco, Oakland and Berkeley, California. All respondents were questioned about their unsafe sexual behaviors (e.g. all and oral unprotected sexual activity within the last month), AIDS knowledge, attitudes and beliefs.

Results: Compared to gay men, Black bisexual men had a higher total number of sexual partners (M= 3.9 vs. 5.7, p<.01), a higher percentage of unsafe sex (50 % vs. 78 %, p<.01), and unsafe sex with other partners (50 % vs. 88 %, p<.05), in using for correlates of unsafe sex for the combined sample, discriminant analysis revealed the following predictor variables significantly discriminated (p<.01) between the respondents who practiced unsafe compared to those who practiced safe sex: self efficacy, enjoyment of sexual activity with partners, close association with persons with AIDS, and media awareness of AIDS.
Conclusion: This study, one of the first to examine sexual behavior and self-reported unsafe sex, reveals high levels of risk behaviors in bisexual men. Preventive studies and culturally appropriate interventions are drastically needed among these minority men at high risk for HIV infection.

W.D.P.28 **DEMOGRAPHIC PROFILES OF SAN FRANCISCO BAY AREA BLACK AND LATIN AIDS DEATHS, 1985 - 1986**

Blumen, R.*, Chin, G., Kiserles, N.**, Toliver, D.**, Fuller, J.**, *Multicultural Institute and Research on AIDS components of the UCSF Center for AIDS Prevention Studies and Bayview-Hunter's Point Foundation. ** UCSF Center for AIDS Prevention Studies, ** Kaiser Foundation Hospital, San Francisco, U.S.A.**

Objective: To obtain demographic data not currently available from AIDS surveillance statistics for planning intervention strategies for Blacks and Latins in five San Francisco Bay Area counties.
Methods: Vital statistics data were used to identify all Black and Latin deaths in 1985 and 1986 with ICD codes consistent with AIDS-related illnesses. Death certificates were then reviewed to confirm AIDS as the cause of death and abstract demographic data. Addresses of decedents were converted to census tracts.

Results: 223 Black and Latin AIDS deaths were identified, 97.7% were male, living primarily in middle-class neighborhoods. 27.8% died in private residences, 33.2% in public housing, and 38.0% in private hospitals. Overall, 31.5% were employed as skilled workers. Blacks in professional and clerical/creative positions were more likely to die in private residences (62.5%) while Latins in those occupations were more likely to die in private hospitals (61.5%). Occupations of most Latins suggest proficiency in English.
Conclusion: In contrast to the underclass profile of minorities with AIDS nationally, data show that, prior to 1985, AIDS was not a disease of disadvantaged Blacks and Latins in the San Francisco Bay Area. These findings are consistent with the nature of the epidemic in San Francisco where, gay men are disproportionately represented among people with AIDS. Active surveillance, incorporating socioeconomic data, such as that available from death certificates, is necessary for planning targeted regional interventions and tracking the epidemic in minority communities.

W.D.P.29 **COMPARISON OF THE KNOWLEDGE, ATTITUDES, AND AIDS-RISK BEHAVIOR OF BLACK AND WHITE COLLEGE STUDENTS IN THE SOUTHEASTERN UNITED STATES**

St. Lawrence, Jesse S., Jr., Jarvis, S.A. *Jackson State University, Jackson, MS, USA

Objective: To compare the knowledge, attitudes, and risk behaviors of black and white college students in a currently low-AIDS prevalence area.
Method: 393 undergraduate students attending 3 state-supported universities in Mississippi completed measures evaluating AIDS-risk knowledge, prejudice toward persons with AIDS, willingness to interact with PMA, and self-reported sexual behavior and substance use for the preceding month. The sample included 211 black and 182 white college and engaging in practices which pose potential HIV-exposure risk. There were no significant racial differences in the frequency and range of sexual activities. Black and white college students were significantly different in substance use patterns with white students reporting use of both legal and illegal substances significantly more often (p<.001), although white students were better informed about practical aspects of AIDS risk (p<.003). Black students reported less prejudicial attitudes toward persons with AIDS (p<.05). There were no significant differences between black and white students' willingness to interact with a person with AIDS or willingness to interact with PMA, and self-reported findings no relationship between students cognitive knowledge of AIDS-risk and the frequency with which they personally engaged in potentially risky practices.
Conclusion: The results confirm the need for prevention efforts targeting college students to reduce their present and future vulnerability to HIV infection.

W.D.P.30 **AIDS: KNOWLEDGE, ATTITUDES AND SEXUAL PRACTICES AMONG HISPANIC IN CHICAGO-RESULTS OF A 1988 CITIZEN SURVEY**

Aldas, L. C., Glicklich, A., Aguilon, O., and Probat, J. *University of Illinois at Chicago, Chicago, Illinois U.S.A.

In 1980 Hispanics represented 6 percent of the U.S. population and currently they account for 15 percent of all U.S. AIDS reported cases.

Objective: To obtain baseline information on Chicago Hispanic AIDS knowledge, attitudes about AIDS transmission, sexual practice and prevention of HIV infection useful for program planning and implementation and for policy formulation.

Method: During the Spring of 1988 400 Hispanic persons 16 years of age and over were interviewed using Random Digit Dialing (RDD) telephone survey.

Results: Most Hispanics have general awareness and basic knowledge about AIDS. However, they have high levels of misinformation about modes of transmission. Many believe that they can contract AIDS through kissing, shared towels or through toilet seats. Younger people and those with high education know more about AIDS. Youth and single people were found to be more at risk for AIDS due to their sexual practices.
Conclusion: There is a gap between what Hispanics know and what they do. They know that AIDS can be prevented with the use of condoms, but most Hispanics do not use them as a mean of protection.

W.D.P.49 COMPARISON OF BLACK AND WHITE WOMEN TESTED FOR
HUMAN IMMUNODEFICIENCY VIRUS
Cats, Bonita¹; Simpson, Sharon L.²
¹University of Florida, Gainesville, Florida, U.S.A.

Objective: The primary goal was to develop a profile of women in a low incidence area by examining characteristics of 360 white and 53 black women, self-selected as at risk for HIV infection.

Methods: The women were anonymously recruited and tested at a public health facility in a university town in north central Florida. Differences in risk behaviors, STD history, educational level, safer sexual practices, sources of information regarding AIDS, and level of fear were examined.

Results: The mean educational level for white women was 12 years, for black women 13 years. Using Spearman correlation coefficients, history of hepatitis, IV drug use, sexual partner with HIV infection, and presence of tattoos were significantly associated with seropositivity in the group as a whole. Seropositivity in black women were more likely to have had transfusion, tattoos, and an HIV seropositive partner. Seropositivity in white women was negatively correlated with education. They were also more likely to have had a history of hepatitis, IV drug use or a partner who was a hepatitis C.

Conclusions: Women who come for voluntary testing represent an educated group which may imply that this type testing only reaches a select population, and that women at risk may not be represented. Identified risk factors for women who are seropositive match those found in high risk areas.

W.D.P.51 UNSAFE SEXUAL BEHAVIOR AND HIGHER RISK PARTNERS: CHANGE OVER
TIME IN A PROSPECTIVE STUDY OF WOMEN AT RISK FOR AIDS
Cohen, Judith B., Dorfman, L.E., Kelly, T.A., Rik, M., Garcia, D.A., Wofsy, C.A.
University of California San Francisco, San Francisco, California, USA

Objective: To assess sex and drug use behavior changes in a prospective study of women at risk for HIV infection.

Methods: 270 sexually active women with increased, high risk, or multiple partners were interviewed and tested between 1985 and 1987, and followed up to 18 to 24 months later.

Findings: At entry, 64% reported sexually or possibly unsafe behavior with VDRL, syphilis, or HIV-infected partners. At follow-up, 70% fit the same definition; one had seroconverted. Significantly more women reported changing to lower risk partners than reported changing to lower-risk behaviors.

Partner at Risk and High Risk Behavior	Entry	Follow-up
Partner at Risk and Low Risk Behavior	54%	70%
Low Risk Partner and High Risk Behavior	1%	4%
Low Risk Partner and Low Risk Behavior	14%	20%

Conclusions: Women followed over time have significantly reduced unsafe partnerships but only moderately reduced unsafe behaviors. To the extent that they continue to engage in risky behavior and do not always know their partners' risk, they remain at some risk for HIV infection. Prevention programs for women need to emphasize reduction of risky behavior as the only certain prevention strategy.

W.D.P.53 BEHAVIOR CHANGES TO REDUCE HIV TRANSMISSION RISK IN A
PROSPECTIVE STUDY OF SEROPOSITIVE WOMEN

Frank, Lanning E.; Cohen, J.B.; Lyons, C.A.; Kelly, T.A.; and Wofsy, C.A.
University of California San Francisco, California, USA

Project AWARE has evaluated 1047 women at risk for HIV infection 66 (6%) of whom are seropositive. Of the 40 seropositive who have been followed for at least 12 months, 118 (40%) are VDRL (16.40%) had an HIV infected sexual partner, (4) 12% had a partner at increased risk for HIV infection (3) 5% had no identified sexual partners. Behavior changes include:

Behavior	Entry	6 Mo.	12 Mo.
Number of Women	40	40	24
Avg. No. Sex Partners	5.2	5.1	4.0
% With Fewer Partners	n/a	40	60
% Abstinent	9	22	29
% Tongue Kissing	93	60	67
% Contraception, No Barrier	85	45	54
% Any vaginal Sex, No Condom	75	37	37
% Using Males	42	11	8
% Sharing Needles	40	23	19
% IV Drug Use	40	15	15

Of the 11 women who are still reporting uninfected partners to vaginal secretions, 6 engage only in consensual, 3 have partners who relate to use condoms, and 2 have been unable to disclose their antibody status.

Although many HIV+ women experienced a period of abstinence, most resumed sexual activity but discontinuously reduced sexual and needle-sharing behavior known to transmit HIV to others.

W.D.P.50 COMPARING ESTIMATES OF HIV SEROPREVALENCE IN U.S. WOMEN:
CHILDREARING WOMEN AND MILITARY RECRUIT APPLICANTS.

Massey, Shari¹; Quinn M²; Papapanagos M¹; Novelli Ave¹; Willoughby A¹; AIDS Program, CID, CDC, Washington, DC, USA; ²Wesley, Bethesda, MD, USA.

Objective: To assess bias in estimated HIV seroprevalence rates for U.S. women by comparing rates in female military recruit applicants with those from the Survey in Childbearing Women.

Methods: Since October 1985, female civilian applicants for U.S. military service have been tested for HIV-1 infection. Beginning in October 1987, ongoing, blinded statewide HIV seroprevalence surveys have been conducted in U.S. women delivering live infants.

Results: Statewide prevalence rates among childbearing women were higher than corresponding rates among female military applicants in each of four regions of the U.S. among childbearing women, state-specific rates ranged from 0.025 to 0.045, with corresponding rates from 0.002 to 0.025 in female military applicants. State-specific rates from both surveys were highest in the Northeast, followed by the South, West Central, and West regions. Women who participate in high-risk behaviors such as IV drug use may be less likely to apply for military service. This introduces bias in the population tested and likely produces underestimates of the prevalence of HIV infection among U.S. women. In contrast, the population of women delivering live infants includes women from all risk groups.

Conclusions: Women who participate in high-risk behaviors such as IV drug use may be less likely to apply for military service. This introduces bias in the population tested and likely produces underestimates of the prevalence of HIV infection among U.S. women. In contrast, the population of women delivering live infants includes women from all risk groups. Seroprevalence among childbearing women, however, may be different from that in women who choose not to or are unable to become pregnant or who experience adverse pregnancy outcomes. Data from both surveys, however, though subject to these biases, provide useful information on the prevalence and trends of HIV infection in U.S. women of reproductive age.

W.D.P.52 EMERGING PATTERNS OF DRUG USE, SEXUAL BEHAVIOR, HIV
INFECTIONS AND STDs IN HIGH RISK SAN FRANCISCO AREAS
FROM 1980-1989

Cohen, Judith B., Lyons, C.A., Lusk, G.J.^{1,2}, McConnell, P.A.^{1,2}, Senneker, L.R.^{1,2}, Wofsy, C.A.
¹University of California San Francisco, ²California Prostitution Education Project, San Francisco, California, USA

Objective: To evaluate changes in drug use, sexual behavior and STDs among high risk women and their partners participating in a street-based peer provided prevention research and education program.

Methods: In a three phase ongoing program, 100 women in 1980-87 (T1) and 153 women and 34 male partners (MP) that in 1988-89 (T2) received interviews, counseling, and testing for HIV Ab, HepB, and syphilis infection in San Francisco Bay Area districts known for drug use and prostitution.

Findings: From T1 to T2, HIV infection was unchanged at 8% in women but was 12% among MP. HepB rates were unchanged among women (60%, 60%) but rose 60% for MP. HIV infection was associated with IV drug use among women and MP. Probable acute syphilis (PPH and RPR-TP) was significantly associated with crack cocaine use, younger age, and less condom use, but not with IV drug use or HIV infection.

Conclusions: Ongoing assessment of AIDS risk in these areas indicates two patterns of HIV infection associated with IV drug use, and an ominous new pattern of crack use. Existing prevention programs do not address the problems and needs of people in the latter group.

W.D.P.54 EPIDEMIOLOGICAL, INFECTIOLOGICAL AND IMMUNOLOGICAL
RESULTS FROM THE HIV-AMBULANCE OF THE DEPARTMENT
OF OBSTETRICS AND GYNECOLOGY

Fricks K, Rosael S, Voth H, Hearn G, Meyer am Buchenfeld, H, Knappstein PG, University of Mainz/FEDERAL REPUBLIC OF GERMANY

OBJECTIVE: To examine gynecological problems in HIV infected women in relation to immunological parameters.

METHODS: From 40 HIV-infected female patients, who were tested 25 women were seen every three months. Six months most of them are living outside the cities of the state Rheinland-Pfalz. 12% of them are or have been infected by sexual transmission. Only one third use condoms for cohabitation, another third denies this form of protection. The rest has no sexual intercourse in the moment.

23 pregnancies are known in this group and in 20% of the cases HIV-infection has been discovered during prenatal care. Results: 80 % of the patients had have a recurrent candida infection of the vagina which was detected in culture. Immunologically 75% of the women belong to the stage III (in order to the CDC-classification). Out of this group more than 50% show less than 400 CD 4 cells/ml. A positive result for HIV-1g, anti-p-18 and negative anti-p-24 could be detected in five cases. One of the four women with AIDS died of a rapid growing cervix cancer although treated with radiotherapy.

CONCLUSIONS: Our data provide evidence for the increasing incidence of gynecologic problems in HIV-infected women. From our experience gynecological examination has to be routinely integrated into medical care of HIV-infected women.

**CRACK USE AND RISK FOR AIDS AMONG BLACK
ADOLESCENTS**

Bullimore Robert, Ph.D., Fullilove M.T., Bowser B.M., Gross S.A.
*Multinational Inquiry and the University of California, San Francisco & California State and the Bayview-Hunter Point Foundation, San Francisco, CA; S.A.
**California State University at Hayward

Objective: To describe the characteristics of black adolescent crack cocaine users and assess their risk for sexually-transmitted HIV.
Methods: 204 black adolescent crack users in Oakland and San Francisco, California, were surveyed about their use of crack and other drugs, their social partners, their sexually transmitted disease (STD) history, their attitudes toward condoms, their use of condoms, and their use of crack during sexual activity.

Results: 100 respondents (49%) were using crack in combination with sexual activity. Of those mixing crack with sex, 50% reported a history of one or more STDs, as compared with 29% (significant at p<0.05) of those who did not combine sexual activity with crack. A history of gonorrhea was more prevalent among those combining sex with crack (42%) than among those who did not (15%, significant at p<0.01). The prevalence of STD history among those who reported both having sold crack and having combined sexual activity with crack was 92% for females, 48% for males) was much higher than for those who did not combine sex with crack. **Conclusions:** Given the prevalence of a history of STD reported by respondents, particularly among those who have sold crack and among those who combine crack use with sexual activity, the risks for contracting and transmitting HIV in this population appear to be great. Further studies to assess HIV prevalence among crack users and dealers and expanded efforts to develop and test interventions to prevent HIV spread within this population are urgently needed.

W.D.P.63

**THE EFFECT OF A NEEDLE AND SYRINGE EXCHANGE ON A HEROIN-DEPENDENT
RESIDENTIAL UNIT**

Wolk, J.L., Haddad, A., Oleson, J.J.,***
*University of New South Wales, Sydney, Australia. ** St. Vincent's Hospital, Sydney, Australia. ***Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia.

Objective: To determine if the location of a needle and syringe exchange adjacent to the methadone maintenance unit was associated with an increase in the use of heroin. **Methods:** A needle and syringe exchange scheme was opened in November 1986 adjacent to an inner city NSW maintenance unit. **Results:** 128 MSU clients who were on the programme continuously 3 months before and 3 months after the introduction of a needle and syringe programme were analysed for heroin use. **Results:** There was no significant increase in the overall proportion of clients who had contaminated urines before and during exchange opening (14.6% established urines before 1986 and 14.9% had clean urines prior to the opening). A proportion of clients (28%) who had clean urines prior to the establishment of the exchange were found to have contaminated urines after it began. However, a comparable proportion of clients (19%) with dirty urines prior to the exchange opening were found to have contaminated urines prior to the exchange opening were found to have clean urines after it opened. **Conclusion:** The increase in availability of sterile needles and syringes adjacent to a drug treatment unit did not appear to adversely affect the proportion of drug free clients in this study. While some clients started using heroin during exchange, others who were using heroin exchange ceased, indicating that factors other than the exchange were influencing heroin use.

W.D.P.65

**A HIV-PREVENTION SYRINGE EXCHANGE PROGRAM IN LUND,
SWEDEN. TWO YEARS OF OBSERVATIONS OF THE ATTENDERS**

Tunving, Kerstin; Andersson, B.; Ljungberg, B**;
Christensson, B*.
*Dept of Paediatrics and Neurochemistry. **Dept of Infectious Disease. University of Lund, Sweden.

In November 1986, a syringe exchange program at the Clinic for Infectious Diseases (General Hospital) in Lund, Sweden, was started. The program gets active support from the local drug treatment facilities. So far no HIV-epidemic has broken out in our region. No negative side-effects have been observed. 804 patients have visited the program. 75 % use centralinums, the rest use heroin. Drug abusers with a small limited abuse, attend the program. 75 % of the visitors are males. The program attracts even those with a hidden abuse, since only half of the attenders have been in contact with local drug treatment facilities. There were no significant differences between these two groups except the fact that a greater proportion of those who used amphetamines were without treatment experiences. In spite of this, we have observed that more drug abusers come to the out-patient clinic and detoxification unit. Most of the clients are below 20. The program does not reach the very young and probably not the most chaotic.

W.D.P.62

**RELATIONSHIP BETWEEN HIV RISK BEHAVIOURS, KNOWLEDGE AND
SENSITIVITY OF SYRINGE INTRAVENOUS DRUG USERS (IVDU)***

Wolk, J.L., Haddad, A., Oleson, J.J., Bullimore R., Gross S.A.,
*Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia. **St. Vincent's Hospital, Darlinghurst, Sydney Australia

Objective: To investigate the HIV risk taking behaviours, knowledge, attitudes and HIV serostatus of Sydney intravenous drug users (IVDU)*. **Methods:** On hundred and eighty-one Sydney intravenous drug users both in and out of drug treatment were recruited. An interviewer-administered questionnaire was used to collect information on demographic characteristics, drug-using and sexual behaviour, AIDS knowledge and prison experience. HIV test results were obtained from subjects. **Results:** The mean age was 27 +/-, the HIV ratio 12%, and 77% of the males were heterosexual. The majority injected daily (91%) and shared needles and 91% cleaned their equipment. Condoms were used only by 12% with regular partners but by 12% with casual partners. 77% of the males were prostitutes with their clients. Thirty percent (54/181) had been in prison since 1981 of whom 50% (27/54) had engaged in risk taking behaviours while in custody. Knowledge was satisfactory and perception of risk of HIV infection for IVDU* was high. However perception of personal risk was low. Twelve percent (14/119) subjects had HIV antibodies of whom 7 were homosexual. **Conclusion:** The 9% HIV seroprevalence found in this study can be explained to increase due to the frequency of HIV risk-taking behaviours. The high proportion of HIV positive homosexual IVDU* suggests the need for targeted campaigns for this subgroup.

W.D.P.64

**HIV RISK BEHAVIOURS OF INTRAVENOUS DRUG USERS PRESENTING TO
THE ALBION STREET (AIDS) CENTRE, SYDNEY, AUSTRALIA.**

Wolk, J.L., Oleson, J.J., Bullimore R., Gross S.A.,
*Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia.

Objective: To investigate needle sharing behaviour and sexual practices of intravenous drug users (IVDU) presenting to the Albion Street (AIDS) Centre. **Methods:** Detailed medical history, physical examination, intravenous drug use history and sexual behaviour information were collected and computer coded for all clients presenting for HIV diagnosis. Those reporting IV drug use, between March 1985 and March 1988, were included in this analysis. **Results:** 1047 clients presenting during this period reported IV drug use as a risk factor. The mean age was 27 (sd 5.6) years, 747 (71.3%) were male, 292 (27.9%) female and 6 (0.6%) transsexual. 59% of males and 77% of females claimed exclusive heterosexual. 39% reported current intravenous drug use and 87% of the total reported having shared needles and syringes. 10% had worked as prostitutes and the mean monthly number of sexual partners in this sample was 12.45, with 15.4% of males and 4.7% of females being infected. 42.0% of homosexual men were infected compared to 3.8% of male and female heterosexuals. There was a small but significant quarterly increase in the proportion of HIV seropositive heterosexual IVDU during this period. **Conclusions:** The HIV seropositive prevalence of IVDU tested was substantially lower than reported amongst European and 8th American samples and is consistent with the low incidence of IVU AIDS cases reported to Australia (1%, MV 1988). However, evidence of continued risk behaviour indicates the possibility of rapid spread of HIV within this subgroup.

W.D.P.66

**Need Taking and Risk Reduction
Among IV Drug users in A U States**

Wilhelm, Wayne; Altman M. Chasn, D.; Prits R.
University of Illinois at Chicago, Chicago, Illinois, USA

Objective: To examine the AIDS risk behaviors and risk-reduction activities of active IV drug users in Baltimore, Maryland, and El Paso, Texas. **Methods:** This is a multi-site study using quantitative and qualitative methods. Face to face interviews were conducted with intravenous drug users not in treatment. Study participants were recruited using street-based indigenous outreach workers who are also involved in community and educational activities. In addition, telephone interviews were conducted to aid the interpretation of results. **Results:** A total of 110 active IV drug users were interviewed in Baltimore, 619 in Chicago, 139 in Denver, and 92 in El Paso. Different patterns of needle sharing and needle cleaning emerged in each city. Intercity comparisons reveal a complex but identifiable set of associations between various social, demographic, and drug-related variables on the one hand and needle sharing and cleaning behaviors on the other. **Conclusions:** It is concluded that AIDS/IVU education programs must understand and take into account (1) racial/ethnic and regional subcultural differences and (2) the local IV drug practices (i.e. in terms of types drugs used and frequency of injection).

W.D.P.67 CESSATION OF ALCOHOL AND DRUG USE DISORDERS IN AN HIV SAMPLE
Reisin, Robert B.; Hankin, J.; Williams, J.; Gorman, J.; Ehrhardt, A.

HIV Center for Clinical and Behavioral Studies, NY State Psychiatric Institute and Columbia University, New York, N.Y., U.S.A.

Objective: To assess longitudinal patterns of cessation of abuse of alcohol and other drugs in an HIV community sample.
Methods: 167 gay and bisexual men were assessed at part of a longitudinal study examining predictors of HIV 11-month progression. Structured clinical interviews were conducted to evaluate past and current psychiatric disorders, as well as current levels of depression and anxiety. Self-report measures of personality attributes and life outlook were also collected.

Results: A significant number of our sample reported successful termination of past alcohol and drug abuse and dependence with maintenance of that change (see table below). Many of the men attribute this behavioral change at least in part to their concern about AIDS. They appear to be different on current measures of psychological distress when compared to those men who never had an alcohol or drug use disorder.

	Past Dependence/Abuse*		Current Dependence/Abuse*	
	Alcohol	Drug	Alcohol	Drug
Group (N=118)	24	35	35	35
HIV (N=42)	24	40	75	50
Total (N=167)	48	62	80	85

* percentages refer to cessation of alcohol and drug diagnoses in our subjects.
Application: In a group of men at risk for AIDS we find successful cessation of an addictive substance use that is rarely reported in the alcohol and drug literature.

W.D.P.68 DEMOGRAPHIC, BEHAVIORAL, AND CLINICAL FEATURES OF HIV INFECTION IN NEW YORK CITY AND INTERVIEWING DRUG USERS (IVDU)

Bravo, Lawrence B.; Chu, A.; Menzies, T. and Frawley, B.J.
Behavioral and Treatment Corporation, New York, USA

Objective: To determine the demographic, behavioral, and clinical features of HIV infection.
Methods: Subjects were recruited from patients scheduled for physical examination in drug treatment clinics in NYC. A questionnaire was administered and serum was collected for HIV serology, using ELISA and Western blot techniques. Subjects were categorized using the CDC HIV classification criteria. Data was analyzed using univariate and multivariate analyses.

Results: 167 subjects were interviewed. 61% were HIV infected and anti-HIV was detected in 58% and 43%, respectively, of the population. HIV infection rates for HIV seropositive and HIV seronegative of the CDC classification criteria for HIV-associated conditions. Only behavioral factors (p<.001) and clinical indicators (p<.001) were found to distinguish the HIV infected from the non-infected. Frequent use of IV drugs (p<.016), duration of drug use (p<.005), daily methadone dose (p<.018), and duration of drug treatment enrollment (p<.038) were significantly associated with HIV seropositivity status and CDC HIV stage. **Conclusions:** These findings strongly support aggressive efforts to reduce parenteral drug use and enroll IVUDs into effective drug treatment.

W.D.P.69 NEEDLE SHARING AMONG IVDU'S WHERE NEEDLES ARE AVAILABLE WITHOUT PRESCRIPTION

Sibthorn, Beverly**; Egan**; McClain**R.; Klockner, J.; Gossel**, Oregon Health Division, Portland, Oregon, USA** *Multnomah County Health Division, Portland, Oregon, USA.

Objective: To assess needle sharing among intravenous drug users (IVDU's) in a region where needles are more readily available without prescription.

Methods: Current IVDU's in Portland, Oregon, were questioned about AIDS, drug-use history, and needle-sharing practices using a standardized questionnaire that included both structured and open-ended questions. Sources of recruitment included a correction facility, county health clinic, private welfare organizations and street outreach. Participation was voluntary and confidentiality was assured. Preliminary results are presented below.

Results: Between 12/88 and 2/89, 150 IVDU's were interviewed. Mean age was 28 years; 56% were male. Mean years of IV drug use was 7.5 years. Heroin was the principal drug injected; 23% cocaine for 31%, methamphetamine for 27% and heroin plus cocaine or amphetamines for 17%. Most (85%) had never been in drug treatment. Needles were purchased from pharmacies or other stores by 79% of users. Over half (54%) stated they currently shared needles while shooting drugs. Of those sharing needles, 13% shared only with their sex partners, 39% also shared with other friends, and 46% shared with total strangers. The main reason given for sharing needles was convenience (50%); less than 7% said they shared because of difficulty obtaining needles. Needles were never cleaned by 27%. Needles were cleaned by 2% with bleach and 50% with water. Over 50% of all these IVDU's, including those who shared of needles, knew that sharing could transmit AIDS. Sixty five percent of IVDU's who shared needles assessed their level of AIDS as moderate or high compared with 18% of those who did not share (p<.001 by chi square). **Conclusions:** The ready availability of needles, knowledge of AIDS transmission, and perception of personal risk are not sufficient to prevent needle-sharing among many IVDU's. Education regarding safe needle cleaning may be the most effective intervention among IVDU's who continue to shoot up.

W.D.P.70 SEXUAL RISK FOR HIV TRANSMISSION IN A GAY MALE SUBSTANCE-ABUSING POPULATION

Stall, Ronald** and D'Augelli, University of California San Francisco Center for AIDS Prevention Studies; **HIV St. Services) U.S.A.

Objective: Combining alcohol and/or drugs with sex is associated with sexual behavior that is high-risk for HIV transmission. Gay substance abusers were compared to the general gay population to further test the reasonable hypothesis that high-risk sex and drug use are related.

Methods: Substance abusers entering treatment at 16th St. Services in San Francisco were asked to fill out a self-administered questionnaire on sexual activity, substance use, and AIDS knowledge (n = 108). The comparison sample of gay/bisexual men were recruited in a random digit dial telephone study in San Francisco (Community Oriented Epidemiology Study, 1987, n = 207).

Results: Sexual risk was calculated with a version of the Chicago Multi-Center AIDS Cohort Study (MACS) group's scale. 28.8% of the substance abusers were rated "high-risk" (i.e. anal sex without condoms outside of monogamous relationships), compared to 6.9% in the sex and without injecting AIDS prevention. This was true although the clinical sample was well-informed regarding AIDS prevention, had high levels of educational achievement, and was as likely to be sober as high-risk sex. **Conclusions:** The association between drug/alcohol use and unsafe sex is not a simple one. The proportion of high-risk sex not associated with drug or alcohol abuse in this clinical population suggests that we may be dealing with more than a "demonstration effect". Programs are needed to intervene with substance abusers, and further research on the psychosocial factors contributing to these levels of unsafe sex is needed.

W.D.P.71 ABSENCE OF ANTIBODY TO HIV IN LONG-TERM, SOCIALLY REHABILITATED METHADONE MAINTENANCE PATIENTS

E.A.; Wang, G.; Dreyfus, David R.; Joseph, H.; Crosson, T.S.; Salatis, Beth Lateral Medical Center, New York, NY, USA; ** New York State Division of Hospital Care, New York, NY, USA; *** St. Luke's - Roosevelt Hospital Center, New York, NY, USA

Objective: To determine the prevalence of antibody to HIV in long-term, socially rehabilitated methadone-maintained former heroin addicts in New York City, where 35-60% of active IV heroin addicts are HIV-infected.

Methods: Of the 68 former parenteral heroin addicts in "medical maintenance", 18 (26%) agreed to participate in this study. In medical maintenance, and socially rehabilitated methadone maintenance patients are treated in the offices of primary care physicians, who provide methadone treatment and general medical care (AMA 1988:129:2393). Antibody to HIV (anti-HIV) was determined in all patients by both ELISA (Dupont) and indirect immunofluorescence (Fluoroguard). Hepatitis B surface antigen, antibody and core antibody were determined by ELISA (Abbott).

Results: None of the 58 socially rehabilitated methadone maintenance patients had anti-HIV. One of seven markers of HIV infection were seen in 53 (91%). The duration of methadone maintenance was 16.9 ± 0.3 yr, and the median daily dose was 40mg. 25% of the 58 patients had been on parenteral heroin maintenance for 10.1 ± 1.7 yr, and they had engaged in additional high-risk practices for HIV infection. **Conclusions:** Effective HIV infection. Methadone maintenance treatment can protect parenteral drug abusers from HIV infection.

W.D.P.72 HIV STATUS & RISK BEHAVIOR IN PARTICIPATING AND NON-PARTICIPATING I.V. DRUG PATIENTS IN A COMMUNITY

Schaefer, Heidi R.;**; Melnick, R.;**; Dorus, W.;**; Puchucki, C.;**; Lettino, J.;**; Schaefer, D.;**; Hines Johnson, Illinois, IL, USA; ** Loyola University, Maywood IL, USA.

Objective: To describe differences in rates of HIV infection and risk behaviors between I.V. drug patients who volunteer (n=224) and those who decline (n=25) to participate in a HIV seroprevalence and risk reduction program.

Methods: I.V. drug users seeking drug treatment were screened for willingness to participate. Post-test results revealed significant differences in age (higher in non-participants, p<.020), and number of needle-sharing partners (higher in participants, p<.014). There were no significant differences related to drug choice, length of drug treatment, number of sexually active, number of sexual partners, frequency of sexual activity, or demographic variables. Reasons given for not participating included: not interested in the program (13%); didn't think they were at high risk (12%); didn't want to spend the time (12%); didn't think they were at high risk (12%); previously tested (7%).

Conclusions: Although participants reported more needle-sharing partners, non-participants appear to have a higher frequency of HIV infection. Patients who refused to participate may under-report high-risk behaviors or engage in other high risk behaviors. Voluntary serotyping and education programs may miss some I.V. drug users at high risk for HIV infection.

Th.D.P.7 THE WOMEN'S CHOICES: A MODEL PEER SUPPORT PROGRAM FOR HIGH RISK HIV INFECTION AND CRACK DRUG USE IN WOMEN.
Mello, A.; DeBruin, Ernest; Welch, B.; Chabon, B.; Finkel, A.; Chalmers, J. The University Medical Center/Albert Einstein College of Medicine, Bronx, N.Y., USA.

Objective: To provide women with a safe and confidential group setting in which to share feelings, thoughts, and information about sexual behavior, drugs and AIDS, and to support behavior change and risk reduction activities.

Method: Groups meet weekly in a methadone clinic or in a Community Health Center. Focus groups, educational lectures, videos and support groups are used to facilitate discussion. Peer leadership is encouraged and participants do outreach work in the community to recruit other women.

Results: The groups have been functioning for one year in which there have been 625 visits from over 100 women. Each weekly group session is attended by an average of 20 women.

Conclusions: The relationship of crack use and sex (especially crack) to high risk sexual behavior is apparent and has led to a "strong peer" ethos in the groups. The group process has contributed to the development of peer counseling, group leaders, and outreach workers from many participating women. In one group with 25 regular participants, 13 (52%) women have entered hospital or detoxity from crack use, four have enrolled in a local community college.

Conclusions: Group based counseling in risk reduction is possible among high risk drug using women through peer support models focusing on reducing drug use.

Th.D.P.9 DIFFERENCES BETWEEN SYMPTOMATIC HIV+ FEMALE & MALE PATIENTS
Bellet, J.; Graham, V.; Hall, L.; Hines, A.; Baselin, J.; and Delavilla, J.; Kings County Hospital Center, Brooklyn, NY, USA

Objective: To compare clinical presentation of female & male patients.
Methods: All 84 female patients seen in the year 1988 (N=86) at the HIV Clinic of a NYC municipal hospital were compared to male controls selected for similar initial visit dates.

Results: Ethnic origins of female patients (Black=8, Italian=16, Hispanic=19, Other=5) were similar to those of males (53,11,21,3). TDM was the largest risk factor for both females & males (41,54), but heterosexual transmission was a larger second risk factor for women (33) than men (4) in this clinic. Both sexes were similar in age (33=3.0 for women, range 19-54; 31=3.7 for men, range 19-55.8), in the average month of time spent in the clinic for men (8 and 8.8 months), in receiving ART (62/52) and in numbers blood dead (13 each). Significantly fewer women than men had a CDC-defined AIDS at their first visit (7/11) or in receiving ART (62/52) and in numbers blood dead (13 each).

Conclusions: Significantly fewer women than men in this clinic had a CDC-defined AIDS diagnosis, suggesting that they seek medical care earlier in the HIV disease process. However, this early intervention on their part results in an inability to receive CDC-AIDS defining economic and social benefits. Alternatively, the natural history of HIV infection may be different in women, with fewer severely immunosuppressed HIV infected women fulfilling CDC-AIDS criteria than men.

Th.D.P.11 COLLEGE WOMEN'S SEXUAL BEHAVIORAL INTENT AND PERCEPTION OF RISK OF HIV INFECTION FOR SELF AND PEERS
Blighter, Donna L.; Sp, J.; Theobald, T.; Summers, D.; and Hauser, J. University of South Carolina School of Public Health, Columbia, South Carolina, USA

Objective: To determine women college students' perceived risk of sexual behavior and their intent to engage in such behaviors with males in long-term and recently-initiated relationships.

Method: 334 randomly-selected female undergraduate students responded to a questionnaire in October 1988 at a major southeastern U.S. university. The questionnaire presented two hypothetical situations, one involving a long-term relationship with a male student and the other involving a recently-initiated relationship. Respondents identified for each situation the sexual behavior in which they and their peers would engage, and rated the level of risk of each behavior. Data were analyzed using paired T-tests.

Results: Preliminary analyses indicate the following significant differences: self and peer perception of risk in the newly-initiated relationship; self perception of risk in both hypothetical situations; self and peer behavioral intent in both hypothetical situations.

Conclusions: It appears that women college students perceived greater risk to themselves than to their peers in both hypothetical situations, even though they predicted lower sexual behavioral intent scores for themselves than for their peers.

Th.D.P.8 THE EXTENT AND IMPACT OF HIV-RELATED DISCRIMINATION IN NEW YORK CITY-A SURVEY OF PWAS AND SERVICE PROVIDERS

Reed, Mitchell, New York City Commission on Human Rights, AIDS Discrimination Unit, New York, N.Y., USA.

Objective: To document the full extent of HIV-related discrimination in New York City.

Methods: A diverse sample of 60 PWAs and 60 AIDS service providers interviewed in standardized format concerning discrimination.

Results: Survey revealed that the scope of actual discrimination experienced by people affected by AIDS extends far beyond areas anti-discrimination laws are designed to remedy.

Conclusions: Local, state and federal anti-discrimination laws must be amended if they are to provide meaningful protections to those who suffer HIV-related discrimination. Further, the social impact of HIV-related discrimination--e.g., of access to public health, social services, education and prevention--is far greater than is generally recognized and must be incorporated into all programs and policy planning.

Th.D.P.10 SELECTED GYNECOLOGIC ISSUES IN WOMEN WITH HIV INFECTION

Anderson, Jean, W.; King, K.; Felder, J.; Hancock, S.; Babcock, K. et al. The Johns Hopkins University School of Medicine, Baltimore, Maryland, USA. Supported by the Freeman Foundation.

Objective: Describe gynecologic (GYN) variables in women attending an inner-city HIV clinic.

Methods: Retrospective review of available GYN information obtained from 83 HIV-infected women seen between 1987 and 1989.

Results: The mean age was 31.9 years (range 19-58). The racial distribution was: Black=60; Caucasian=18; Other=5. HIV infection risk factors included: IV drug use (10/81) alone=19; heterosexual contact with a high-risk partner only=14; blood transfusion; unknown on denied=17; IVPI and heterosexual contact with a high-risk partner=19. Of 67 patients, 418 had ever been pregnant and 574 of these had 7 living children. Furthermore, 718(19/51) continued to be sexually active; of these 4, 713(51) used no form of contraception and only 39(11/74) used condoms. Abuse history of these women, 181(19/51) became pregnant and 8/10 delivered term infants. History of GYN problems was elicited in 34(11/74). Of 50 women reporting a history of sexually transmitted disease 56 had gonorrhea; 18 syphilis; 10 genital herpes; 14 genital warts.

Active GYN problems of great visit were uncovered in 34%. During the time of review, 37(11/51) women had abnormal GYN exams including a pelvic mass and 10 cases of genital herpes; 19(4/71) Pap smears were abnormal.

Conclusions: Heterosexual activity is a frequent mode of HIV transmission in this population. Unsafe sexual practices and inadequate contraception are prevalent and likely to perpetuate spread of infection. The GYN history and exam were often overlooked, but GYN problems accounted for substantial past and current morbidity in this predominantly inner-city population.

Th.D.P.12 FEMALE SEX PARTNERS OF IV DRUG USERS: A STUDY OF SOCIO-PSYCHOLOGICAL CHARACTERISTICS AND NEEDS

Agapiou, L., Rivers, A.M., Henshaw, C.L., and Corey, A.L. AIDS Research and Education Project, California State University, Long Beach, CA, USA

**School of Social Welfare, University of California, Los Angeles, CA, USA

***Department of Public Health, Long Beach, CA, USA

Objective: To identify and examine the socio-psychological characteristics, needs, and service requirements of non-using female sex partners of IV drug users in Los Angeles County. The data will provide information bases for effective HIV infection prevention education programs and strategies.

Method: Eighty six informants including service providers, law enforcement officers, IV drug users, and sex partners from various ethnic groups were interviewed in-depth. Purposive sampling guided the approach to selecting the key informants. The interview protocols were semi-structured, with both open-ended and objective questions.

Results: The sex partner population is made up of different subpopulations with different characteristics correlated to ethnicity, non-IV substance use, and income and education levels. Commonalities across subpopulations are: low self-esteem, powerlessness, history of abuse, isolation, and low perception of HIV infection risk.

Conclusions: HIV prevention education and intervention programs should be based upon an empowerment model which addresses the psychologies of powerlessness, and is sensitive to cultural and class differences.

Th.D.P.13 GENDER DIFFERENCE IN "MATURING OUT" OF INTRAVENOUS DRUG USE Birnbaum, Patrick, Maslow, J., Aldrich, M. Youth Environment Study, Inc., San Francisco, CA, USA

Objective: To specify the proportion of women among different categories of IVDU's, in order to better describe and predict the spread of AIDS.
Methods: Secondary analysis of 3 data sets of IVDU's (reported AIDS cases, drug treatment agency roster, and hospital emergency room admissions) in 3 cities (San Francisco, the Bronx and Chicago), compares the gender ratios at different ages.
Results: In each urban area the proportion of women among IVDU's declines with age. About 1/3rd of IVDU's in their 20's, and 1/4th of those 40 and older are women. On treatment dates, at least half the clients in their early 20's are female, though for older clients the proportion of women IVDU's in treatment increasingly resembles the proportion on other indicators. The declining proportion of women holds for all racial and ethnic groups, though at all ages there are few Hispanic, and especially Mexican American, women.

Conclusions: "Maturing out" cessation of IV drug use for people as they age "occurs" for men and women at different rates. IV drug use is neither permanent nor demands a total commitment overriding all other aspects of life such as raising a family or a desire not to be a criminal. These countervailing forces weigh differently for men than women, so their IV drug careers are markedly different. In the early years, women especially seek out drug treatment to get away from "the life," and by their early 30's, and especially 40's, all indicators show far more women than men have abandoned IV drug use. Substantial ethnic differences in gender roles are evident, though in all groups the risk of AIDS among IVDU's diminishes with age at a faster rate for women than men.

Th.D.P.15 FEMALE FAMILY MEMBERS AS MEDIATORS OF UTILIZATION OF HEALTH AND SOCIAL SERVICES Cristal, Stueha, Schiller, B., Dejewski, E., Hassell, S.; Moran, C.; Beck, P. Rutgers University, New Jersey, United States

Objective: To analyze the degree to which the availability of family members, particularly women, as sources of informal support is related to the utilization of health and social services by the elderly.
Methods: Data from a survey of a population based random sample of living PWAS in New Jersey is analyzed. The sample includes a high number of intravenous drug users, male homosexuals, racial and ethnic minorities and women. An analysis is made of the differential access of these population groupings to informal family support and the reasons and extent of utilization of formal services.
Results: Family members, especially women, are found to be the major source of informal support of PWAS among both IV drug users, homosexuals and women who acquired AIDS through heterosexual transmission. This finding holds true, for Black, American, Hispanic, and white. Support from women family members is demonstrated to be both instrumental and emotional. A significant relationship is demonstrated between high level of support from female family members and a high degree of utilization of health and social services.
Conclusions: There is a relationship between access to informal and formal supports among PWAS.

Th.D.P.17 DETERMINANTS OF SEXUAL RISK REDUCTION IN FEMALE IV DRUG USERS FROM DIVERSE ETHNIC GROUPS Trang, Sahn*, Abadi-Quader, A*, Des Jarlais, DC**, Kouzi, A*, Friedman, SK*

*Narcotic and Drug Research, Inc., N.Y., U.S.A. **New York State Div. of Substance Abuse Services, N.Y., N.Y., U.S.A.

Objective: Female IVDU's are the primary link to perinatal HIV transmission. Their motivation for HIV sexual risk reduction is multifaceted. We examined the reasons and determinants of such efforts in a street sample of active female IVDU's in the lower east side of Manhattan.

Methods: 116 female IVDU's were recruited through street outreach contacts by neighborhood outreach workers. Paid face-to-face structured interviews were conducted to assess HIV-related risk behaviors, beliefs, personal or network experience, and network norms.
Results: 61% of the sample reported initiating any sexual risk reduction behavior (i.e., condom use, abstinence, reduction in number of partners, avoidance of "high risk" partners) since they heard of AIDS. In multiple logistic regression, significant positive predictors included having more than 1 partner during the average month of the past year (p<0.05); having friends who practiced sexual risk reduction (p<0.05); and perceived current (p<0.05) and future (p<0.05) risk of HIV infection. Ethnicity, relationship status, knowing someone with HIV disease, and perceived self-efficacy about being able to carry out risk reduction were not significantly associated with risk reduction behavior.

Conclusions: Elements of both Health Belief and Social Influence theory predict sexual risk reduction behavior in female IVDU's. These results are consistent with the findings of prior studies of drug risk reduction in IVDU's in treatment - which demonstrate that both fear of AIDS and positive social norms (Friedman, et al, 1987) are associated with drug risk reduction behavior. Since both health beliefs and perceived norms are modifiable, these findings have immediate relevance for designing sexual risk reduction interventions.

Th.D.P.14

Th.D.P.16 HIV INFECTION AMONG FEMALES ENTERING NEW YORK STATE PRISONS Smith, Barry*, Hall, L.J., Trumbo, D.P., Landi, L.M., Broadwin, R.M., Noree, D.A.*

*New York State Department of Health, Albany, New York, USA.
**New York State Department of Correctional Services, Albany, New York, USA.

Objective: To determine the prevalence and risk factors for HIV infection among females entering New York State prisons.

Methods: From September 1988 to January 1989, information was extracted from the medical records of 314 consecutive females entering New York State prisons, and their sera were tested in a blinded fashion by ELISA and Western blot for antibodies against HIV.

Results: Of 450 females tested to date, 85 (18.9%) were HIV seropositive. Seropositivity was highest among 30-39 year olds (24.5%) and varied by ethnicity (Black=14.3%, Hispanic=28.9%, White=8.2%) and residence (New York City=23.9%, Upstate=4.1%). Nearly half (46.9%) of the 126 intravenous drug users and one-third (24.8%) of the 69 women with serologic evidence of syphilis were HIV seropositive. Two of 19 pregnant women were seropositive. By logistic regression, seropositivity was associated with intravenous drug use (adj. OR=0.0, p<0.05), Hispanic ethnicity (adj. OR=3.8, p<0.05), black race (adj. OR=2.9, p<0.10), and residence in New York City (adj. OR=7.3, p<0.05).

Conclusion: In New York, nearly one of every five female prison entrants is infected with HIV, primarily due to IV drug use. The association between seropositivity and ethnicity may have resulted from unreported confounding risk factors, such as sex with an unrecognized high-risk partner. Female prisoners are an important group for educational efforts to reduce the risk of transmission to their sexual partners and offspring.

Th.D.P.18 DIFFERENCES IN HIV/AIDS COUNSELLING FOR WOMEN AND FOR MEN

Hutterer, Judith; Blas, P., Oberauer, C.; Opris, M.; Pec, G.; Siggler, F.; Zeman, A.
Österreichische AIDS-Hilfe (Austrian AIDS Foundation) - GdM, Vienna, Austria.

Objective: 1) To find out the differences in the motives of why women and men VISIT HIV/AIDS counselling centre and take an HIV test and 2) to present the varied role of female counsellors when counselling men and women.
Methods: Evaluation of reports of experiences given by the female counsellors of the seven HIV/AIDS counselling centres of the Austrian AIDS Foundation (GdM).

Results: Many women visit the counselling centres to get advice for others. They want to take an HIV test to make sure that they are not dangerous for others. Protection against AIDS is considered - like contraception - as in the first place a matter of women. The wish for an HIV test often has the following functions: to confirm the closeness to the male partner (especially when he is infected), to "liberate" ("permissit") to engage in new relations), to draw a line underneath the past (test result as a proof of purity), to repress the topic AIDS (after a negative result, the topic AIDS is definitely terminated), to lay down a criteria for continuing a relationship (infection through the sexual evaluation of the partner or not). Male clients often try to force a female counsellor to take the role of the "excuse-making woman" and of a "Wailing Wall". Discussion of the effects of these circumstances in the course of the counselling.
Conclusion: The differences between men and women require different concepts for women which take into account their special concerns and desires.

Th.D.P.25 AIDS AND WOMEN: CHANGE IN SEXUAL BEHAVIOR
By Francisco Richter, D'Theocharis, J. Theusey, J. and Summers, D.
University of South Carolina School of Public Health, Columbia, South Carolina, USA

Objective: To determine the change in sexual behavior of college women with emphasis on their use of effective AIDS risk reduction behavior.
Methods: 334 randomly selected, female undergraduate students in a major university in southeast U.S. responded to an AIDS questionnaire survey for women. Data collected included demographic information, level of sexual activity, change in sexual behavior, knowledge and frequency of use of effective AIDS risk reduction behavior.

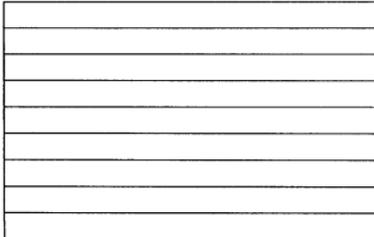

Results: The majority of the respondents had high level of knowledge regarding effective AIDS risk reduction behavior. 49.4% reported changes in sexual behavior. Those who claimed to have changed their sexual behavior tend to have been more sexually active. They are more likely to discuss their partners' past sexual experience, and insist their use of condoms. They are also more likely to report using condoms frequently.
Conclusions: Despite the high level of knowledge regarding effective AIDS risk reduction behavior, only half of the respondents reported to have changed their sexual behavior and of whom only 15% claimed to always use condoms.

Th.D.P.27 UPDATE TO THE COMMUNITY RESPONSE ON WOMEN AND AIDS
Saint Cyr-Deje, Women and AIDS Resource Network, Brooklyn, N.Y., U.S.A.

AIDS is the leading cause of death among women aged 25 - 34 years in New York City. Black and Hispanic women account for 85% of all cases. Nationwide AIDS surveillance data indicate that the proportion of women who acquired AIDS through heterosexual contact is increasing (from 12% in 1982 to 30% in 1987). Despite this increase and the projected need for services geared towards women with HIV infection and their families, there has been minimal planning and little systematic response by the public and private sectors or by service providers.

The Women and AIDS Resource Network (WARN) is a not-for-profit agency that has been working to enhance and facilitate access to resources for women and children affected by HIV infection and AIDS. WARN provides information and referral, counseling including crisis intervention, technical assistance to agencies developing services for women, group training and educational presentations is also provided in hopes of empowering women so we can help curve the rising trend of mortality and morbidity statistics among women.

Th.D.P.29

Th.D.P.26 EPIDEMIOLOGY OF WOMEN OF CHILD-BEARING AGE IN TEXAS, USA
Thompson, E. L., Sauer, L. A., Bess, C.M., L. Robinson, R. E. and Harwell, W. L., Jr.
Texas Dept. of Health, Austin, Texas, USA

Objective: To survey women of child-bearing age in Texas for the presence of HIV antibodies.

Methods: 67,816 white blood specimens of women infants received at the Texas Department of Health (TDH) Laboratory for Venereal Disease Screening were tested in a blind test fashion for HIV antibodies. Results: Eighty-three (83) HIV positive women were found among all women tested for an overall prevalence rate of 0.12% (95% confidence interval, .08%-0.17%). When only latex resistant (44,188 women and 81 HIV positive) were considered, the prevalence rate remained essentially the same at 0.18% (95% confidence interval, .07%-0.17%). The HIV positive women were widely dispersed across the state's 124 counties generally consistent with the distribution of the state population. The 2 counties were: (1) Harris County, which has approximately 17.5% of the 1987 estimated Texas population and submitted 20,173 of the samples tested in this survey, and accounted for 47.75% of the HIV positive women for a prevalence rate of 1.04% (95% confidence interval, .64%-1.70%); (2) East Texas which has 7.5% of the state population and accounted for 4.4% of the specimens tested, but only had 1.23% of the HIV positive women for a prevalence rate of 0.20% (95% confidence interval, .05%-0.48%); and (3) For most Texas, which has 8.75% of the state population and accounted for 1.8% of the specimens tested, but had no HIV positive. Ninety percent of 17,148 of the state population and 21.76% of the specimens tested had had at least one of the positive HIV results. When asked about sex of the state population and accounted for 30.4% of the specimens tested, only accounted for 21.0% of the specimens. Statistics were reported for 72,138 of the specimens tested, but only had 14.8% of the HIV positive.

Conclusions: Prevalence of HIV antibodies is generally distributed across Texas women of child-bearing age in a manner similar to the overall population of the state, with the noted exception. However, black women were more likely to be HIV positive in 1988 than either whites or persons of Hispanic origin. Women of Hispanic origin were the least likely to be HIV positive.

Th.D.P.28 MEDICAL-PSYCHOLOGICAL COUNSELLING FOR WOMEN
Friedrich, Monika; Dorn, B.; Rutenzer, G.
Breslau, Poland, G.D.R.

Dermatological Department of Ludwig-Maximilians-University, Munich, FRG

Objective: To determine problems of medical-psychological counselling for women. **Methods:** In our outpatient clinic for sexually transmissible diseases (STD), we have attempted to realize a medical-psychological care system. **Results:** 12.4% (53/429) of medical patients were female. They are younger than men (24.4 vs 35.1 years) and come with special problems in particular with questions concerning contraception and childbirth. Since January 1987 psychosocial counselling was carried out in 3200 cases, 86% of whom were female. 68.6% required information about HIV-infection or antibody tests. 57 women made use of the phone counselling service and 105 wanted to have personal counselling. 33% of women coming to personal counselling were partners or relatives of HIV-infected men. 14.8% of female clients were HIV-infected. **Conclusions:** To the present most of the women require information about HIV-infection. The close cooperation between physician, psychologist and social worker as an integrated team has proved a great benefit for patients and seems to be especially useful for counselling women.

Th.D.P.30 RISK-TAKING BEHAVIORS OF INTRAVENOUS DRUG ABUSERS
NOVA Research Company, Bethesda, Maryland, USA 20814

Objective: To describe the needle use and sexual risk behaviors of intravenous drug abusers (IVDA) interviewed in nine large U.S. cities.

Methods: Persons included in this study are 1,669 IVDA who responded to an interviewer-administered questionnaire developed by participants in the National Commission on Drug Abuse.

Results: High-risk practices identified as risk factors included: number of persons sharing needles/borings; using/borrowing used needles, and cleaning needles (with other than bleach). Seventy percent of males and 56% of females reported sharing needles with two or more persons in the past six months. Furthermore, fifty 8% of those male IVDA and 14% of female IVDA had engaged in all three of the identified risk behaviors. Forty-one percent of the total sample reported having visited a "shooting gallery".

Conclusions: Several practices identified as risk-behaviors included type of sex practice (e.g., anal and receptive), number of IVDA sex partners, and condom use. As a group, 16% reported sex having had sex in the past six months and an additional 47% reported having had sex but not with an IVDA. This latter figure represents a potential vector for the transmission of HIV infection outside the IVDA population. Additionally, 49% of the males and 56% of the females reported having engaged in the exchange of sex for money and/or drugs. Twenty-nine percent of both male and female IVDA engaged in sexual activity with one or more IVDA and did not always use a condom, thus increasing their own risk for HIV infection.

Conclusions: Despite efforts to reduce the IVDA population, the danger of continued risk-taking drug behaviors, a large proportion of IVDA continues to put themselves and others at high risk of HIV infection. The NIDA's project should identify interventions that are effective in bringing about risk reducing behavioral change.

Th.D.P.37 AN AIDS INTERVENTION PROGRAM FOR THE BLACK OUT-OF-TREATMENT INTRAVENOUS DRUG USER

Valente, A., Thomas, A.,* Krupcho, M.,* Johnson, D.,* Freeman, A.,* Bailey, Charles, P.,* Dallas County Health Department, *Dallas Urban League, Dallas, Texas, U.S.A.

Objective: To reach the black out-of-treatment intravenous drug users, develop relationships to promote risk reduction behaviors, promote drug treatment, and improve their access to health care. **Methods:** The intervention in the targeted community is conducted in 4 steps, and includes: 1) involving former and current black IVU's in the outreach effort, 2) establishing a local counseling/testing site, 3) mobilizing assistance from local merchants to distribute intervention materials, and 4) making contact with the black IVU's, offering information regarding AIDS, antibody testing, drug treatment, and providing condoms and bleach kits. Outreach educators visit the target areas regularly, becoming recognizable to the target population. The program has been ongoing for 7 months on a weekly basis in 4 specific sections of the targeted community. Of the 1,500 persons reached, most were black, young adult males, 3,200 condoms, 800 bleach kits, and 420 brochures have been distributed. No merchant has refused to distribute the brochures. Three merchants are distributing bleach kits. Reasons from the community use the local counseling/testing site, and initiates requests to the "AIDS Ladies" for condoms and bleach kits. **Conclusions:** Although black IVU's experience multiple barriers to health care and information, they are receptive to AIDS risk reduction information when educators come to "the streets" and develop relationships with the black IVU's in their own communities.

Th.D.P.39 RISK OF AIDS IN SEROCONVERTER DRUG INJECTORS: A COMPARISON WITH OTHER RISK GROUPS

Deza, Giovanni, Menotti-Ippolito, F., Lazzarini, A.; Zerbini, R.; Agrasano, G.; Prioresi, R.; Sincico, A.; Barbarelli, M.; Dromas, A.; Costantini, R. and Tiscoll, E. (DIRECZ, Italian Multiple Cohort Study on AIDS), AIDS Unit, Dept. Social Medicine (Ministry of Health) and National Institute of Health, Rome, Italy.

Objective: To estimate the risk of developing AIDS from HIV seroconversion in drug injectors and in a group of subjects with sexually acquired HIV infection.

Methods: A multiple cohort study has been conducted to follow subjects for whom the seroconversion period was identified (availability of a negative test preceding the positive confirmed one). Clinical evaluation was performed each 6 months. A modified CDC clinical definition was utilized to classify the clinical stage of patients. The disease progression was analyzed according to actuarial based on Kaplan-Meier survival curves, and differences between groups were assessed by Wilcoxon test. **Results:** 255 subjects who acquired the infection by drug injecting and 122 by sexual contact (46 heterosexual males and 36 heterosexual contacts) were enrolled until October 30, 1988. The estimate of AIDS progression rate by 4 years from seroconversion was respectively 14% in drug injectors and 18% subjects who acquired the infection by sex. **Conclusion:** No statistically significant difference in the risk of developing AIDS was found between drug injectors and the other group.

Th.D.P.41 HIV INFECTION IN INTRAVENOUS DRUG ADDICTS.

Stepniński A., Mazurkiewicz Walentyna, Ochalska B., Cholewa M. Medical Academy Warsaw, Poland

Objective: In the Institute of Venerology, 2075 patients/71.5% of 17,161, 50.5% of 14,674, who were seropositive to narcotic drugs injected intravenously, have been tested for the presence of HIV antibodies in the period from Jan 1986 to Jan 1989. They were patients of detoxification wards and/or patients of drug treatment centers. **Methods:** HIV antibodies were determined by the EIA method, and positive results were confirmed by the Western-blot technique. **Results:** HIV antibodies were found in 21 patients/54 males and 7 females, which accounts for 0.7% of cases. In 1986-1987, all tests were negative. The first positive HIV test was detected in Aug 1988 after testing of 2254 drug addicts. Since Aug 1988 to Jan 1989, 21 cases were positive to HIV antibodies /2.5% of 817 patients studied. This indicates that HIV infection is spreading fast in this population. Infections of drug addicts with HIV represent 7% of total cases of HIV antibody-positive individuals in Poland. **Conclusion:** Intravenous narcotic drug use program should be performed among drug addicts, accompanied with the distribution of free disposable syringes and needles, as well as condoms. Further more, problems related to drug should be covered by special training program for staff of drug treatment centers in Poland.

Th.D.P.38 THE NEEDLE AND SYRINGE EXCHANGE PILOT PROGRAM IN NEW YORK CITY

Edelman, J., Robinson, Gordon, Peck, M., Eaton, C.J. and Joseph, S. New York City Department of Health, New York City, New York, U.S.A.

Objective: To evaluate the first government sponsored needle and syringe exchange pilot program in the United States so as to assess its potential for the control of HIV infection among intravenous drug users. **Methods:** The Needle Exchange Pilot Program of the New York City Department of Health began operation on November 7, 1988. As New York State is one of 11 states which requires prescriptions for the sale of needles and syringes the New York State Commissioner of Health has authorized this pilot study for the purpose of scientific research. In the absence of treatment on demand, the needle exchange program was considered as part of a multiphase approach towards the issue of intravenous drug abuse and AIDS. Current IV drug use by 16 years of age or older consisting of 200,000 persons, rehabilitation program throughout the city are available. A questionnaire is administered periodically for information on needle sharing behavior, in addition to other risk behaviors. Drug treatment referrals and intensive risk-reduction education is provided. Those who take part must return their used injection equipment before they can receive a sterile needle and syringe. One needle and syringe is distributed per encounter. **Results:** Within the first 2 months of operation, 56 persons have enrolled; 19 are men, 37 are women; 24 are black, 28 are Hispanic, 13 are white, and 1 is Native American. The number of participants entered into treatment is 26. **Conclusions:** It has been possible to initiate and continue a pilot needle exchange program in New York City in the context of a "Bridges to Treatment" service program, despite misunderstanding of the program's objectives.

Th.D.P.40 AIDS INCIDENCE AND RISK FACTORS FOR DISEASE PROGRESSION IN A COHORT OF SEROCONVERTER DRUG INJECTORS.

Deza, Giovanni, Menotti-Ippolito, F., Lazzarini, A.; Anagnano, G.; Sincico, A.; Tirrelli, P. et al. (DIRECZ Italian Multiple Cohort Study on AIDS), AIDS Unit, Dept. Social Medicine (Ministry of Health) and National Institute of Health, Rome, Italy.

Objective: To describe the natural history of HIV infection in drug injectors since seroconversion, and to evaluate risk factors associated to disease progression.

Methods: The enrollment criteria were represented by the identification of the seroconversion period (availability of a negative serological test followed by the positive one). Clinical and laboratory evaluation was performed each 6 months. Data collection on demographic and behavioral features was made by means of individual case reports. The disease progression was analyzed according to actuarial based on Kaplan-Meier survival curves. **Results:** 255 subjects fulfilling criteria entered the cohort. Males/females ratio was 41%; mean age was 28 years. The mean period of follow-up until October 30, 1988 was 79 month-period; 13 cases of AIDS occurred up to that date. The actuarial incidence of AIDS was 2.1% by years and 14.5 by four years after seroconversion. The risk of developing increased significantly after two years since seroconversion (Mantel-Cox test).

Conclusions: The duration of exposure to the virus seems to be the main factor in determining the disease progression in seropositive drug injectors.

Th.D.P.42 RISK BEHAVIOR AND ATTITUDES AMONG SEROCONVERTER IV DRUG

Deza, Giovanni, Menotti-Ippolito, F., Lazzarini, A.; Anagnano, G.; Sincico, A.; Tirrelli, P. et al. (DIRECZ Italian Multiple Cohort Study on AIDS), AIDS Unit, Dept. Social Medicine (Ministry of Health) and National Institute of Health, Rome, Italy.

Objective: To describe a study of how knowing IV drug users appraise risks associated with AIDS. **Methods:** The presenters describe findings from structured interviews with 348 seroconverters IV drug users, who were seropositive to narcotic drugs injected intravenously, drug use, and sexual behavior. Structured interview data on Risk, Heroin, and White Anger, and other risk factors were collected in one clinic in New York and Northern New Jersey. **Results:** More than two thirds (68%) admitted to sharing needles in the past and almost a third indicated that they had used needles at least once within the past six months. One in five subjects reported having had sex with an IV drug user on at least six occasions during the past six months. Those who used IV drug in the past six months reported significantly more IV using sexual partners, using sex with heroin, cocaine, crack, speedballing, and greater frequency of crack use. Among 149 males, 68% indicated that they had sex with a woman in treatment more likely to have changed their needle cleaning habits. Current users who reported changing their needle hygiene, were less likely to be sharing needles with women in treatment more likely to have changed their needle after sex than others. About half of respondents claimed to have altered their sexual behavior over the past six months. Persons who had one or more friends die of AIDS were significantly more likely than others to have changed their needle cleaning and sexual behaviors. **Discussion:** Consistent with other findings, these data suggest that past drug use, social attitudes that include sharing, and knowing persons who have died of AIDS, predict favorable behavior changes. Also corroborated with other investigators' data, the descriptive study found that sexual behavior is more difficult to change than many drug related risks.

Th.D.P.43 AIDS BELIEFS AND BEHAVIOR CHANGE IN MINORITY IV DRUG USERS
Adele Green, M. Greenberg, G. A. Branganstein, Mildred Personalized Nursing Corporation, P.C., Detroit, Michigan, USA

Objective. To identify the IV drug users' (IVDU's) beliefs regarding AIDS and related behaviors.
Methods. Nonprobability sample of IVDU's seen thru the emergency rooms and in the hospitals of 3 inner cities reporting a high incidence of IV drug use and AIDS. Structured interview -- fixed response and open-ended questions.

Results. Interviewed 721 IVDU's: 73.9% male, 26.1% female, 70.1% Black; 19.8% Hispanic, 7.7% White, 2.2% other, 86.9% unemployed. Multiple partners: 92.3% use barbit, 79.4% cocaine, 69.1% speedballs. General knowledge regarding AIDS transmission: 76.6% report drug use, 82.9% report sexual activities, 61.4% report getting information about AIDS from radio or TV, 52.8% report getting from printed media, 75.7% report changing to reduce risk; 71.9% avoid pregnancy, 43.6% stopped or decreased needle sharing, 41.3% use safer sex, 41.8% use needles.
Conclusion. IVDU's report making efforts to change their behaviors to decrease their risk of getting/transmitting AIDS.

Th.D.P.45 THE EPIDEMIOLOGY OF AIDS AMONG NEW YORK STATE PRISON INMATES

Morris Dale*, Thomas, S.*, Nisi, J.*, Smith, P.*, Broadwin, R.**, Maguire, R.***
*New York State Department of Health, Albany, New York, USA
**New York State Department of Correctional Services, Albany, New York, USA

Objective. To describe the epidemiologic characteristics of AIDS among New York State (NYS) prison inmates.
Methods. We analyzed demographic, risk factor, disease and mortality data obtained from medical record reviews of all inmates developing AIDS within the NYS Correctional System from 1981-1988.

Results. Through December 31, 1988, 838 cases of AIDS had been confirmed among inmates in NYS correctional facilities, accounting for 1% of the U.S. and 4% of NYS AIDS cases. Cases increased from 2 in 1981 to 205 in 1987, with an incidence of >450 cases per 100,000 inmates per year since 1983. While most cases (98%) have occurred in males, females have the same high incidence rates (compared to the general population where female rates are 1/8 those of males). Hispanics had the highest incidence rates (2 times other groups) and significantly higher rates of narcotic use and drug related sentences. Intravenous drug use (IVU) was the major risk factor. Six percent of cases have had concurrent tuberculosis and 63% of TB cases since 1985 have had AIDS or HIV infection. HIV seroprevalence has been 17% and 17% among 4000 male and female inmates, respectively. To date, 49% of inmate AIDS cases have died and AIDS now accounts for 70% of inmate deaths.
Conclusion. AIDS is the preeminent health problem among New York State inmates and is primarily related to IV drug use.

Th.D.P.47 SERIAL ACTIVITIES OF IV DRUG USERS WITH MULTIPLE SEX PARTNERS
Michele E. Virginia*, Trapido, S.J.**, Incardini, J.A.***, McBride, D.C.*** and McKay, C.T.***
*Florida International University, Miami, FL, USA; **University of Miami School of Medicine, Miami FL, USA; ***University of Delaware, Newark, DE, USA; ****University of Virginia, Berlin Springs, VA, USA.

Objective. To describe the types of sexual activities of IV drug users who have multiple sex partners and their association with serostatus.
Method. As part of a study which tests two interventions to reduce AIDS among IVUDs, 346 subjects were recruited from drug networks, interviewed and tested for HIV serostatus. Bivariate analyses, using Gamma and Chi-Square values, were conducted to determine the associations.
Results. While about 90% of IV drug users in this sample had multiple sex partners, less than one-fourth admitted to having sex for money and one-sixth had sex to obtain drugs. The type of sex (except for vaginal sex) engaged in with their multiple partners was significantly associated with the number of sex partners and with serostatus, but only when condoms were not used.

Conclusion. The type of sexual activity is an added dimension to be considered for educational prevention information for IV drug users on HIV risk factors.

Th.D.P.44 COCAINE USE AND SEXUALLY TRANSMITTED DISEASES INCLUDING HIV IN BLACK, HISPANIC, AND WHITE COCAINE USERS
Michael R. Hanson*, Rebecca S. DeBruin, M. P. Williams, J. P. Stowers, J. L. Williams, M.D., Health Services Center at Brooklyn, New York, NY, NY, Department of Health, Albany, New York, U.S.A.

Objective: To study the association between cocaine use and sexually transmitted diseases (STD), particularly HIV, in a community with a high prevalence of both cocaine use and HIV disease.
Methods and Results: Between 10/88 and 1/90, 1,170 women birthing at an inner city hospital in New York had otherwise discarded urine coded and stored. Demographic, syphilis serology and HIV risk data was collected from 1028 of these patients. Identifiers removed and codes reassigned corresponding to urines applied. In the latter part of the study 299 patients had blood (remaining after syphilis studies) stored and coded. After all identifiers were removed the urine was analyzed for cocaine, and other drugs. The blood was analyzed for HIV antibody by ELISA and Western blot.
Results: 13.1% of urine had cocaine, cocaine (use) 1.8% seropositive and 1.4% syphilis. 49% of cases denied drug use during pregnancy. 92.3% of patients without cocaine denied intravenous use. 17% of cases had positive syphilis serologies compared to 2.84 (p.R.=7, 1.699C, 1.1-8-12-91) seropositive without cocaine (controls). Among controls 0.784 (1/250) had HIV antibody compared to 9.094 (4%) of cases (p.R.=11, 6.994 C12, 2-3-41). No patient with HIV antibody had other drugs in their urine. One HIV infected case acknowledged intravenous drug use and one HIV infected control was from an endemic country.
Conclusions: 1) Cocaine use among participants in the inner city is epidemic. 2) Preliminary results suggest a link between cocaine use and HIV.

Th.D.P.46 HIV-INFECTION AMONG IV DRUG ABUSERS IN BUENOS AIRES, ARGENTINA
Cahn-Indaco*, Perez JP, Castro A*, Vallejo JM, Hella D*, Marchitelli*, Ramos Aires, Argentina

Objective. To evaluate HIV-infection prevalence and related factors in an IV drug abusers (IVDA) population.

Method. The sera of 538 contemporaneously attending IVDA were studied thru ELISA HIV-1 (Abbott) and reconfirmed thru immunofluorescence. Presence of symptoms, time of addiction and sexual behavior were assessed.

Results. There were 253 men (47.01) and 87.15 women (25.11); 87.15 (294) was under 30 years of age, the average being 23 years old. The time of addiction average was 3.4 years. Seropositivity was found in 204 patients (37.92); 52% of Pt showed 1 or more symptoms (fever >38°C > 1 month, diarrhea > 1 month, weight loss >10% > 1 month, adenopathy, skin lesions, epinoma/gall); 28% of the latter, 771 was HIV+ vs. 211 asymptomatic ones. Positive correlation was found between time of addiction and presence of symptoms (1 year = 121; 3 years = 453), and between the former and seropositivity (60% HIV+ after 3 years; 50% after 4 years). Mono- or bisexual behavior was admitted by 231 of the Pt, which percentage did not significantly alter seropositivity level.

Conclusion. A high proportion of IVDA is HIV+. Time of addiction and presence of symptoms were separately associated to seropositivity while homosexual/bisexual activity didn't involve additional risk for this young group. Greater educational efforts should be made in order to limit the epidemics growth within heterosexual population.

Th.D.P.48 MOBILITY, SEX CITIES, SEX RISK BEHAVIOR, AND HIV STATUS OF IV DRUG USERS

McCoy, Clyde A.*; Chiswood, D.S.*; Page, J.B.*
*University of Miami School of Medicine, Miami, FL, USA.

Objective. To determine the mobility of IVUDs and its relationship to risk behavior and HIV status of more than 400 IVUDs recruited from the streets of the Miami metropolitan area.

Methods. IVUDs have been actively recruited by outreach workers into a centralized assessment center at the medical school at the University of Miami where blood samples and extensive assessments were provided to IVUDs in conjunction with pre and post case counseling. Assessments of sexual, drug taking and other social histories were taken by trained, specialized interviewers. Blood was drawn by a trained phlebotomist, specialized in working with IVUDs.

Results. Of the 541 of IVUDs who traveled outside of their local area, a large majority reported having had sex and a lesser majority indicated that they had shot up with drugs during this mobility. Those having sex, and having said they shot up during this period have a higher rate of seropositivity than those who had less mobility and/or had engaged in fewer risk practices.

Conclusion. There is a potential risk of transmitting the HIV virus from the primary risk heterosexual contacts to other areas as potentially high risk IVUDs travel to other cities.

Th.D.P.49 GENERATIONAL DIFFERENCES IN HIV RISK BEHAVIOR AND SEROCONVERSION RATES AMONG IVDS

Michelle D.C.,* Inceffari, J.A.,** McCoy, C.B.,***
Chitwood, D.D.,** and McCoy, M.V.,***. *Andrew University, Berry Springs, MS, USA, **University of Delaware, Newark, DE, USA, ***University of Miami School of Medicine, Miami, FL, USA; **Florida International University, Miami, FL, USA.

Objective. To examine generational differences in AIDS risk behavior and seroprevalence rates among IVDS.
