**V^e Conférence internationale sur le SIDA
SOUS LE SIGNE DE LA SOLIDARITÉ**

En tant que président du Comité du programme de la V^e Conférence internationale sur le SIDA, je tiens d'abord à vous remercier chaleureusement d'avoir accepté notre invitation. Votre présence, ainsi que celle de vos nombreux collègues, est un témoignage éloquent de la solidarité qui unit tous les participants de cette rencontre exceptionnelle.

Il nous est permis, au-delà des mots, de croire que ce congrès sortira vraiment de l'ordinaire. D'abord, par son ampleur : plus de 10 000 délégués, 1 000 représentants des médias et 1 000 représentants de compagnies et d'organisations. Mais surtout, par la philosophie profondément humaniste qui l'animera.

L'observateur qui aura suivi attentivement, depuis Atlanta en 1985, la série de conférences internationales sur le SIDA, aura noté à quel point ces rencontres se sont progressivement décloisonnées. À l'origine, on s'en souviendra, la Conférence abordait quasi exclusivement des thèmes biomédicaux. Mais graduellement, les chercheurs scientifiques ont dû se rendre à l'évidence : le SIDA n'était pas seulement un problème médical, mais aussi un drame humain.

Bien sûr, nous savons tous que la solution ultime verra éventuellement le jour dans un laboratoire. Mais entre-temps, qu'est-ce que le virologue ou le microbiologiste peuvent proposer au sidéen et à ses proches pour alléger leur fardeau? Pour les aider à lutter contre l'ignorance et l'intolérance qui, chaque jour, se font plus présents? Nos laboratoires sont des lieux d'espoir; notre conscience nous interdit de les laisser se transformer en ghettos. Devant les extrémismes qui pointent à l'horizon, il est de notre devoir à tous de contribuer à l'élargissement et à l'approfondissement de l'étude du SIDA. Agir autrement serait inconscient, voire même cruel pour des millions de gens qui tournent vers nous des regards chargés d'espoir.

Le Congrès de Montréal innove donc en présentant officiellement une perspective multidisciplinaire, que résume bien son thème : "Le SIDA : défi scientifique et social." Le programme de la rencontre reflète précisément cette approche intégrée, puisque 30 % des séances toucheront les divers aspects sociaux du problème. Dilution du contenu biomédical? Aucune crainte n'est permise à ce sujet : dans les seuls domaines de l'épidémiologie, des aspects cliniques et de la recherche fondamentale, on compte plus d'une centaine de séances et près de 550 conférenciers—plus que toute autre rencontre auparavant. Miroir de cette nouvelle approche, le recueil des résumés vous propose une somme de 5 539 textes qui s'attaquent tant aux dimensions médicales que sociales du SIDA.

Plus humaine, donc, l'approche. Et à la fois plus internationaliste. Car avouons-le, il restait à la série de conférences internationales sur le SIDA à véritablement s'internationaliser. Avec le recul du temps, il nous apparaît évident que le Tiers Monde n'a peut-être pas occupé toute la place qui lui revenait lors des précédentes rencontres. Situation paradoxale quand on sait que la pandémie a des conséquences particulièrement graves dans le Tiers Monde : les plus récentes statistiques font état d'un taux d'infection atteignant jusqu'à 20 % chez la population hétérosexuelle de certaines grandes villes.

Les organisateurs de la conférence de Montréal n'ont pas hésité : ils ont tout mis en oeuvre pour accroître la participation du Tiers Monde. En consultant des chercheurs des pays en voie de développement sur les questions d'organisation. En commanditant des conférences préparatoires en Afrique, en Asie et en Amérique latine pour déterminer les attentes des chercheurs locaux face à l'événement. Le Canada, par l'entremise de l'Agence canadienne de développement international (ACDI) et de différents organismes dans d'autres pays occidentaux, a aussi apporté une assistance financière pour assurer cette participation.

Enfin, nous avons veillé à ce que la Conférence demeure un instrument privilégié pour sensibiliser les populations, les décideurs et les pouvoirs publics du monde entier. La Conférence de Montréal utilise abondamment la technologie audiovisuelle et des expositions artistiques à des fins didactiques. Elle innove aussi en facilitant une participation hors murs du grand public. Toujours dans cet esprit d'ouverture sur le monde, les organisateurs ont établi que les langues officielles de la Conférence seront l'anglais et le français. Des traductions simultanées dans ces deux langues sont offertes en tout temps, ainsi qu'en espagnol aux séances plénières.

Dans la foulée des premières rencontres, la Conférence de Montréal est elle aussi une tribune internationale favorisant l'échange d'information. Mais plus encore, nous avons voulu qu'elle se signale par une convergence sans précédent de toutes les énergies et compétences disponibles. À l'heure de l'interdépendance planétaire, au-delà des barrières professionnelles et des divergences de toute nature, la solidarité de la communauté internationale face au problème du SIDA s'impose plus que jamais. Ce n'est qu'à ce prix que des millions de gens démunis pourront légitimement entretenir l'un des biens les plus précieux qu'il leur reste : l'espoir.

Richard A. Morisset, M.D.

Président du Comité du programme de la V^e Conférence internationale sur le SIDA

**Message From
the Programme
Committee
Chairman**

**V International Conference on AIDS
UNDER THE BANNER OF SOLIDARITY**

As Chairman of the Program Committee for the V International Conference on AIDS, first let me cordially thank you for accepting our invitation. Your presence here, alongside your numerous colleagues, attests eloquently to the solidarity binding everyone attending this exceptional meeting.

For we have solid reason to believe that this conference will really be an extraordinary one. First, because of its scope: over 10,000 delegates, 1,000 media representatives and 1,000 corporate and organizational delegates. But above all, by the profoundly humanistic philosophy guiding it.

Anyone who has kept a close watch on the series of International Conferences on AIDS that began in Atlanta in 1985 will have noticed how these encounters have gradually opened up. Originally, you will recall, the meetings dealt almost exclusively with biomedical topics. Yet scientists soon had to admit that AIDS is not simply a medical problem, but also a human drama.

Naturally, we all know that the ultimate solution will eventually come to light in a laboratory. But meanwhile, what can the virologist or microbiologist offer an AIDS victim and his or her loved ones to ease their burden? To help them combat the ignorance and intolerance they face, which are growing day by day? Our laboratories are realms of hope; our conscience forbids us from turning them into ghettos. Facing the extremists looming to the horizon, we all have a duty to help broaden and deepen research into AIDS. To act in any other way would be unconscionable, if not cruel to the millions of people looking to us with profound hope.

The Montreal Conference represents an innovation in that it officially presents a multidisciplinary view neatly summarized in its theme: "AIDS: A Scientific and Social Challenge." The program for this meeting accurately reflects this integrated approach, since 30% of the sessions will deal with various social aspects of the problem. Will this dilute its biomedical content? That need scarcely be feared: in the fields of epidemiology, clinical aspects and basic research alone, there will be over 100 sessions and almost 550 speakers—more than at any previous conference. Mirroring our new approach, the collected abstracts cover a total of 5,539 papers that tackle both the medical and social dimensions of AIDS.

Definitely a more human approach. And at the same time a more international one. For we must admit that our series of international conferences on AIDS have yet had to become genuinely international. With the passage of time, it became clear to us that the Third World may not have been playing its full role at past meetings. This is paradoxical, since we know that the pandemic is having especially serious consequences in the Third World: the most recent statistics indicate an infection rate covering almost 20% of the heterosexual population in some major cities.

The organizers of the Montreal Conference have made every effort to increase Third World participation. They have consulted scientists from developing countries on organizational matters. They have sponsored preparatory conferences in Africa, Asia and Latin America to determine what local scientists expect from the event. Canada, through the Canadian International Development Agency (CIDA) and various organizations in other western countries, has also provided financial assistance to ensure Third World participation.

Finally, we saw to it that this Conference will be a special means of raising the consciousness of the general public, decisionmakers and public authorities around the world. The Montreal Conference will use a wealth of audiovisual technology and art exhibits for educational purposes. It is also innovating by making it easier for the general public to participate extramurally. In this same spirit of openness to the world, the organizers have decided that the Conference's official languages will be English and French. Simultaneous translation into either language will be available at all times, along with Spanish at the plenary sessions.

Like its predecessors, the Montreal Conference is an international forum promoting the exchange of information. But even more, we wanted it to signal an unprecedented convergence of all the available energy and skills. In the era of the global village, leaving behind professional barriers and differences of every kind, the international community's solidarity in confronting the problem of AIDS is more vital than ever. It is at this price alone that millions of people can legitimately nourish one of their most valuable remaining possessions: hope.

Richard A. Morisset, M.D.

de la semaine

Week at a
Glance

Samedi
3 juin

13 h à 20 h

Inscription

Palais des Congrès 100A *

Dimanche
4 juin

10 h à 19 h

Inscription

Palais des Congrès 100A

16 h 30 à 19 h

Cérémonie d'ouverture

Palais des Congrès

Président
Ivan Head
Président de la Conférence
Président, Centre de recherches
pour le développement international

Jonathan Mann
Directeur
Programme mondial OMS de lutte contre
le SIDA

Monsieur Robert Bourassa
Le Premier Ministre du Québec

Armand Frappier
Fondateur, Institut Armand Frappier
Montréal, Québec

Dame Nita Barrow
Représentante permanente de la Barbade
aux Nations Unies

Le Très Honorable
Brian Mulroney
Premier Ministre du Canada

Kevin Brown
Président émérite
Vancouver Persons with AIDS Society
Canada

Son Excellence
Kenneth Kaunda
Président de la République de la Zambie

20 h à 21 h 30

Réception d'ouverture

Complexe Desjardins

* Salle

13:00 to 20:00

Registration

Palais des Congrès 100A*

**Saturday
June 3**

10:00 to 19:00

Registration

Palais des Congrès 100A

**Sunday
June 4**

16:30 to 19:00

Opening Ceremonies

Palais des Congrès

Chairman
Ivan Head
Conference Chairman
President
International Development Research
Centre
Mr. Robert Bourassa
Prime Minister of Quebec

Dame Nita Barrow
Permanent Representative of Barbados at
the United Nations

Kevin Brown
Chairman Emeritus
Vancouver Persons with AIDS Society
Canada

Jonathan Mann
Director
Global Programme on AIDS
World Health Organization

Armand Frappier
Founder, Institut Armand Frappier
Montreal, Quebec

The Right Honourable
Brian Mulroney
Prime Minister of Canada

His Excellency
Kenneth Kaunda
President of the Republic of Zambia

20:00 to 21:30

Opening Reception

Complexe Desjardins

A. Épidémiologie et santé publique	
• Études séro-épidémiologiques : États-Unis, 407 A	45
• SIDA/VIH : le sang et les produits sanguins, 408 A	46
• Autres rétrovirus : VIH-2 et HTLV-I/II, 408 BC	47
B. Aspects cliniques	
• Le VIH chez les enfants, 401 ABC	187
• (Table ronde) Coordination des soins : le point de vue du personnel, 403 ABC	188
• (Colloque) Infections à <i>Pneumocystis carinii</i> , 407 B	200
C. Recherche fondamentale (biomédicale)	
• (Colloque) Mécanismes de pathogénèse du VIH, 407 C	509
• Biologie moléculaire (partie 1) : Diversité génomique et ses liens aux aspects cliniques, 410 ABC	510
D. Le SIDA et l'individu	
• Recherches sur le comportement (partie I), 409 ABC	695
E. Le SIDA, la société et le comportement	
• (Colloque) Vivre avec le SIDA : le point de vue de personnes atteintes, 411 A	815
• (Atelier) Éducation-SIDA : Leçons à tirer des pays en voie de développement, 411 B	816
F. Droit et éthique	
• (Colloque) Vue d'ensemble de la législation sur le SIDA, 411 C	941
G. Implications internationales	
• Le sérodiagnostic, 406 A	971
• (Colloque) Aspects culturels et sociaux de la sexualité, 406 BC	972
H. Répercussions économiques du SIDA	
• Aperçu et coûts de la prévention et de l'éducation, 404 AB	1029

A. Épidémiologie et santé publique	
• (Table ronde) L'évolution de la politique en matière de santé publique, 407 A	48
• Tests de dépistage du VIH dans les cliniques de MTS, 408 A	49
• Incidence et prévalence du VIH, 408 BC	50
B. Aspects cliniques	
• Manifestations buccales du SIDA, 401 ABC	190
• Nouvelle technique de diagnostic rapide et améliorée, 403 ABC	191
• (Colloque) Traitement des infections associées à l'immuno-déficience causée par le VIH, 407 B	192
C. Recherche fondamentale (biomédicale)	
• (Colloque) Les bases moléculaire et cellulaire des immuno-déficiences provoquées par les rétrovirus, 407 C	511
• Pathogénèse (partie 1), 410 ABC	512
D. Le SIDA et l'individu	
• Les adolescents (partie 1), 409 ABC	696
E. Le SIDA, la société et le comportement	
• Les proches et la famille, 411 A	817
• (Colloque) Stratégies innovatrices pour l'éducation des minorités au sujet du SIDA, 411 B	818
F. Droit et éthique	
• (Table ronde) Points de controverse dans les rapports sur les politiques relatives au SIDA, 411 C	943
G. Implications internationales	
• Information et comportement sexuel, 406 A	973
• (Colloque) Les nourrissons à risque : Le point de vue africain, 406 BC	974
H. Répercussions économiques du SIDA	
• Coûts en milieu hospitalier, 404 AB	1030

16 h à 17 h 30

page

A. Épidémiologie et santé publique	
• La transmission sexuelle du VIH (partie 1), 407 A	51
• Infection par le VIH chez les détenus, 408 A	52
• Histoire clinique de l'infection au VIH : Cofacteurs et progression, 408 BC	53
B. Aspects cliniques	
• Infections concomitantes du SIDA, 401 ABC	193
• Pédiatrie : développement neurologique des enfants infectés par le VIH, 403 ABC	194
• Traitement : essais de l'AZT, 407 B	195
C. Recherche fondamentale (biomédicale)	
• Biologie moléculaire (partie 1), 407 C	513
• Pathogénèse (partie 2), 410 ABC	514
D. Le SIDA et l'individu	
• Travailleurs de la santé, 409 ABC	697
E. Le SIDA, la société et le comportement	
• (Table ronde) L'entraide : Une stratégie d'adaptation, 411 A	819
• Les facteurs culturels déterminants dans les attitudes à l'égard du SIDA, 411 B	820
F. Droit et éthique	
• (Colloque) Éthique et injustice sur le plan international, 411 C	944
G. Implications internationales	
• Prévalence (partie 1), 406 A	975
• (Atelier) Atelier régional : Afrique orientale, 406 BC	976
H. Répercussions économiques du SIDA	
• Coûts en dehors du milieu hospitalier, 404 AB	1031

8:30 - 10:30

"New Perspectives" — Plenary session
Palais des Congrès 407 ABC*

11:00 - 17:30

Audiovisual Presentations Guy-Favreau Conference Centre

11:00 - 12:30 page

A. Epidemiology and Public Health	
• Seroepidemiologic studies: United States, 407 A	45
• AIDS/HIV: Blood and blood products, 408 A	46
• Other retroviruses: HIV-2 and HTLV-III, 408 BC	47
B. Clinical Aspects of AIDS	
• HIV in children, 401 ABC	187
• (Round table) Coordinating care: A nurse's perspective, 403 ABC	188
• (Symposium) <i>Pneumocystis Carinii</i> infections, 407 B	200
C. Basic Research (Biomedical)	
• (Symposium) Mechanisms of pathogenesis of HIV, 407 C	509
• Molecular Biology (Part 1): Genomic diversity and relationship to clinical aspects, 410 ABC	510
D. AIDS and the Individual	
• Behavioural research (Part 1), 409 ABC	695
E. AIDS, Society and Behaviour	
• (Symposium) Living with AIDS: A person with AIDS perspective, 411 A	815
• (Workshop) AIDS education: Lessons from developing countries, 411 B	816
F. Ethics and Law	
• (Symposium) Global survey of AIDS legislation, 411 C	941
G. International Issues	
• Serodiagnosis, 406 A	971
• (Symposium) Cultural and social perspectives of sexuality, 406 BC	972
H. The Economic Impact of AIDS	
• Overview plus costs of prevention and education, 404 AB	1029

Poster Sessions

A. Epidemiology and Public Health	
• (Round table) Analysis of Public Health Policy, 407 A	48
• HIV testing in STD clinics, 408 A	49
• HIV incidence and prevalence, 408 BC	50
B. Clinical Aspects of AIDS	
• Oral manifestations of AIDS, 401 ABC	190
• New improved rapid diagnosis, 403 ABC	191
• (Symposium) Management of infections associated with HIV immunodeficiency, 407 B	192
C. Basic Research (Biomedical)	
• (Symposium) Molecular and cellular bases of retrovirus induced immunodeficiencies, 407 C	511
• Pathogenesis (Part 1), 410 ABC	512
D. AIDS and the Individual	
• Adolescents (Part 1), 409 ABC	696
E. AIDS, Society and Behaviour	
• Close friends and family, 411 A	817
• (Symposium) Innovative strategies for AIDS education with minorities, 411 B	818
F. Ethics and Law	
• (Round table) Points of controversy between policy reports on AIDS, 411 C	943
G. International Issues	
• Knowledge and sexual behaviour, 406 A	973
• (Symposium) Infants at risk: An African perspective, 406 BC	974
H. The Economic Impact of AIDS	
• Hospital-based costs, 404 AB	1030

16:00 - 17:30 page

A. Epidemiology and Public Health	
• Sexual Transmission of HIV (Part 1), 407 A	51
• HIV infection in prisoners, 408 A	52
• Natural History of HIV infection: Co-factors for progression, 408 BC	53
B. Clinical Aspects of AIDS	
• Concomitant infections in AIDS, 401 ABC	193
• Pediatric: Neuro-development in HIV-infected children, 403 ABC	194
• Therapy: AZT trials, 407 B	195
C. Basic Research (Biomedical)	
• Molecular biology (Part 1), 407 C	513
• Pathogenesis (Part 2), 410 ABC	514
D. AIDS and the Individual	
• Health care workers, 409 ABC	697
E. AIDS, Society and Behaviour	
• (Round table) Self-help: A coping strategy, 411 A	819
• Cultural determinants in responding to AIDS, 411 B	820
F. Ethics and Law	
• (Symposium) Ethics and international inequity, 411 C	944
G. International Issues	
• Prevalence (Part 1), 406 A	975
• (Workshop) Regional workshop: East Africa, 406 BC	976
H. The Economic Impact of AIDS	
• Out-of-hospital costs, 404 AB	1031

Mardi 6 juin

8 h 30 à 10 h 30

H. The Economic Impact of AIDS	
• Costs in developing countries, 404 AB	1033

16:00 - 17:30 page

A. Epidemiology and Public Health	
• Natural history of HIV infection: Early manifestation and progression, 407 A	60
• Mathematical models, 408 A	61
• (Round table) Evaluation of programme effectiveness, 408 BC	62
B. Clinical Aspects of AIDS	
• PCP Treatment, 401 ABC	201
• (Symposium) Laboratory issues in the diagnosis of AIDS, 407 B	202
C. Basic Research (Biomedical)	
• Virology, 403 ABC	521
• Animal models (Part 1), 407 C	522
• Molecular biology: Regulatory genes and their products, 410 ABC	523
D. AIDS and the Individual	
• Adolescents (Part 2), 409 ABC	702
• Counselling, 411 A	703
E. AIDS, Society and Behaviour	
• The gay community issues, 411 B	824
F. Ethics and Law	
• (Symposium) HIV infection, reproduction and parenthood, 411 C	949
G. International Issues	
• Prevalence (Part 2), 406 A	980
• (Workshop) Regional workshop: Asia, 406 BC	981
H. The Economic Impact of AIDS	
• Macroeconomic impact in developing countries, 404 AB	1034

Mercredi 7 juin

8 h 30 à 10 h 30

- État de la question – Plénière
Palais des Congrès 407 ABC*

11 h à 17 h 30

Présentations audiovisuelles Centre de conférences Guy-Favreau

11 h à 12 h 30

A. Épidémiologie et santé publique	
• Transmission du VIH dans le milieu des soins de la santé, 407 A	63
• (Table ronde) Transmission hétérosexuelle, 408 BC	64
B. Aspects cliniques	
• Pharmacologie et toxicité de l'AZT, 401 ABC	203
• Traitement : thrombocytopénie, 403 ABC	204
• (Colloque) Qualité des soins offerts aux personnes atteintes du SIDA, 407 B	205
C. Recherche fondamentale (biomédicale)	
• (Colloque) Gènes régulateurs et diversité génomique virale, 407 C	524
• Éléments de base en immunologie (partie 1), 408 A	525
• Biologie moléculaire (partie 2), 410 ABC	526
D. Le SIDA et l'individu	
• Les femmes, 409 ABC	704
E. Le SIDA, la société et le comportement	
• Rôle des ONG dans la lutte mondiale contre le SIDA, 411 A	825
• La lutte communautaire contre le SIDA dans les années 1990, 411 B	827
F. Droit et éthique	
• (Colloque) Recherche de traitements et de vaccins, 411 C	950
G. Implications internationales	
• Le VIH en pédiatrie, 406 A	982
• (Colloque) Infections parasitaires tropicales : impact du VIH, 406 BC	983
H. Répercussions économiques	
• Rôle des assurances, 404 AB	1035

Sessions d'affichage

	page
A. Épidémiologie et santé publique	120
B. Aspects cliniques	352
C. Recherche fondamentale (biomédicale)	592
D. Le SIDA et l'individu	743
E. Le SIDA, la société et le comportement	860
F. Droit et éthique	963
G. Implications internationales	1010
H. Répercussions économiques du SIDA	1049

* Salle

14 h à 15 h 30

page

A. Épidémiologie et santé publique	
• Études séro-épidémiologiques des femmes enceintes, 407 A	65
• Incidence et mortalité du SIDA, 408 BC	66
B. Aspects cliniques	
• Manifestations cliniques, 401 ABC	206
• Hémophilie : histoire clinique et études de cohortes, 403 ABC	207
• (Colloque) Infection par le VIH : atteintes à certains organes, 407 B	208
C. Recherche fondamentale (biomédicale)	
• (Colloque) Mise au point de vaccins contre le SIDA, 407 C	527
• Mise au point des médicaments : nouvelle approche pour l'étude des médicaments antiviraux, 408 A	528
• Modèles animaux (partie 2), 410 ABC	529
D. Le SIDA et l'individu	
• (Colloque) Consommateurs de drogues par voie intraveineuse : réalités changeantes et mythes persistants, 409 ABC	705
E. Le SIDA, la société et le comportement	
• Le SIDA en milieu de travail, 411 A	828
• Le SIDA dans les médias, 411 B	829
F. Droit et éthique	
• (Colloque) Prévenir la transmission du VIH : les conflits religieux en matière de santé publique, 411 C	952
G. Implications internationales	
• Perspectives mondiales, 406 A	984
• Transmission hétérosexuelle et rôle des MTS, 406 BC	985
H. Répercussions économiques du SIDA	
• Financement et assurances, 404 AB	1036

16 h à 17 h 30

page

A. Épidémiologie et santé publique	
• L'annonce aux partenaires, 407 A	67
• Test de dépistage du VIH/Questions en matière de politiques et de programmes, 408 BC	68
B. Aspects cliniques	
• Infections associées au SIDA, 401 ABC	209
• Atteintes neuropsychiatriques, 403 ABC	210
• (Colloque) Essais cliniques : points de vue des « acteurs », 407 B	211
C. Recherche fondamentale (biomédicale)	
• Virologie (partie 3), 407 C	530
• Éléments de base en immunologie, 408 A	531
• Modèles animaux (partie 3), 410 ABC	532
D. Le SIDA et l'individu	
• (Colloque) Les femmes dans les pays industrialisés : Questions et options, 409 ABC	706
E. Le SIDA, la société et le comportement	
• Services de pastorale, 411 B	830
F. Droit et éthique	
• (Colloque) Coercition ou volontarisme ? Analyse critique internationale, 411 C	954
G. Implications internationales	
• Prévalence (partie 3), 406 A	986
• (Atelier) Atelier régional : Afrique occidentale, 406 BC	987
• (Colloque) Déplacements internationaux et SIDA, 411 A	988
H. Répercussions économiques du SIDA	
• Méthodologie des analyses de coûts, 404 AB	1037

8:30 - 10:30

"State-Of-The-Art" — Plenary session
Palais des Congrès 407 ABC*

11:00 - 17:30

Audiovisual Presentations Guy-Favreau Conference Centre

11:00 - 12:30 page

A.	Epidemiology and Public Health	
	• HIV transmission in the health care setting, 407 A	63
	• (Round table) Heterosexual transmission, 408 BC	64
B.	Clinical Aspects of AIDS	
	• AZT Pharmacology and toxicity, 401 ABC	203
	• Therapy: thrombocytopenia, 403 ABC	204
	• (Symposium) Quality of care for patients with AIDS, 407 B	205
C.	Basic Research (Biomedical)	
	• (Symposium) Regulatory genes and viral genomic diversity, 407 C	524
	• Basic immunology, 408 A	525
	• Molecular biology (Part 2), 410 ABC	526
D.	AIDS and the Individual	
	• Women, 409 ABC	704
E.	AIDS, Society and Behaviour	
	• The role of NGO in the global response to AIDS, 411 A	825
	• The community-based response to AIDS into the 1990s, 411 B	827
F.	Ethics and Law	
	• (Symposium) Research for treatments and vaccines, 411 C	950
G.	International Issues	
	• HIV in pediatrics, 406 A	982
	• (Symposium) Tropical diseases: the impact of HIV, 406 BC	983
H.	The Economic Impact of AIDS	
	• The role of insurance, 404 AB	1035

Jeudi 8 juin

8 h 30 à 10 h 30

- Synthèse des plénières *
- Palais des Congrès 407 ABC*

11 h à 17 h 30

Présentations audiovisuelles Centre de conférences Guy-Favreau

11 h à 12 h 30

A. Épidémiologie et santé publique	page
• (Table ronde) Contrôle de l'épidémie de VIH, 407 A	69
• (Table ronde) Modélisation mathématique, 408 A	70
• Transmission périnatale, 408 BC	71
B. Aspects cliniques	
• Thérapie : la ribavirine et les autres médicaments, 401 ABC	212
• Test de dépistage par réaction en chaîne des polymérasés, 404 AB	213
• (Colloque) Infections respiratoires chez les consommateurs de drogues par voie intraveineuse, 407 B	214
C. Recherche fondamentale (biomédicale)	
• Éléments de base en immunologie (partie 3), 403 ABC	533
• (Colloque) Aspects pathologiques de l'infection par le VIH, 407 C	534
• Mise au point de médicaments : utilisation des molécules CD4 dans le traitement du SIDA, 410 ABC	535
D. Le SIDA et l'individu	
• Consommateurs de drogues par voie intraveineuse (partie 1), 409 ABC	707
• Prostitution, 411 A	708
E. Le SIDA, la société et le comportement	
• (Atelier) Innovations en matière de prévention et d'éducation au sujet du SIDA, 411 B	831
G. Implications internationales	
• SIDA et tuberculose, 406 A	989
• (Colloque) Recherches sur la sexualité humaine, 406 BC	990
H. Répercussions économiques du SIDA	
• Affectation des ressources et processus décisionnels, 411 C	1038

Vendredi
9 juin

8 h 30 à 10 h 30

• Perspectives d'avenir • — Plénière
Palais des Congrès 407 ABC •

Cérémonie de clôture

Président
Ivan Head
Président de la Conférence
Président du Centre de recherches
pour le développement international
Canada

Conférenciers
L'Honorable Perrin Beatty
Ministre de Santé et Bien-être social
Canada

Mohammed Abdelmoumene
Directeur général adjoint
Organisation mondiale de la santé
Suisse

John Ziegler
Président
VI^e Conférence internationale sur le SIDA
États-Unis

Lars Olof Kallings
Président
Société internationale sur le SIDA
Ministère de la Santé et des
Affaires sociales
Suède

Message de
Danielle Mitterrand
Présidente, Fondation France
Libertés

Randy Shiltz
Correspondant national
San Francisco Chronicle
États-Unis

Friday
June 9

8:30 - 10:30

• "Future Prospects" — Plenary session
Palais des Congrès 407 ABC

Closing Ceremony

Chairman
Ivan Head
Conference Chairman
President, International Development
Research Centre
Canada

Plenary Speakers
*The Honourable
Perrin Beatty*
Minister of Health and Welfare
Canada

Mohammed Abdelmoumene
Deputy Director-General
World Health Organization
Switzerland

John Ziegler
Chairman
VI International Conference
on AIDS
United States

Lars Olof Kallings
President
International AIDS Society
Ministry of Health and Social Affairs
Sweden

Message from
Danielle Mitterrand
President

Programme
des Plénières

Overall Plenary
Programme

**Le lundi
5 juin
Monday
June 5**

Nouvelles Perspectives

Présidents :
Maureen Law
Sous-Ministre
Santé et Bien-être social Canada

Donald deGagné
Directeur, Vancouver Persons with
AIDS Society
Canada

Conférenciers :
June Callwood
Journaliste
Globe & Mail
Canada

Albert Jacquard
Professeur à l'Université de Genève
Chef du service de génétique
Institut national d'études
démographiques
France

Mechai Viravaidya
Fondateur
Population and Community
Development Association
Thaïlande

Stephen Joseph
Commissaire de la santé
Ville de New York
États-Unis

David Suzuki
Scientifique/Journaliste
Département de zoologie
University of British Columbia
Canada

New Perspectives

Chairpersons:
Maureen Law
Deputy Minister
Health and Welfare Canada

Donald deGagné
Director
Vancouver Persons with AIDS Society
Canada

Plenary speakers:
June Callwood
Columnist
Globe & Mail
Canada

Albert Jacquard
Professor, University of Geneva
Chief, Genetic Services
Institut national d'études
démographiques
France

Mechai Viravaidya
Founder
Population and Community
Development Association
Thailand

Stephen Joseph
Commissioner of Health
New York City
U.S.A.

David Suzuki
Scientist/Broadcaster
Department of Zoology
University of British Columbia
Canada

État de la Question

Président :
James O. Mason
Secrétaire adjoint de la santé des
États-Unis

Conférenciers :
**Progrès en gestion clinique du SIDA et
de l'infection par le VIH dans le
monde industrialisé**

Ian Weller
Directeur d'études
Faculté de médecine génito-urinaire,
University College & Middlesex School
of Medicine
Angleterre

**Difficultés et obstacles à la gestion
optimale du SIDA et de l'infection par
le VIH dans le monde en
développement**

N'Galy Bosenge
Directeur
Comité national du programme de lutte
contre le SIDA au Zaïre

**La perspective
communautaire—questions
confrontant les personnes ayant le
SIDA et infectées par le VIH dans le
monde en développement**

Daniel Defert
Président
AIDES Fédération nationale
France

**Humanité : les mesures pour une
éthique sur le SIDA**

David J. Roy
Directeur
Centre de bioéthique
Institut de recherche clinique de Montréal
Québec, Canada

**La dynamique de la transmission du
VIH : le rôle des modèles dans
l'interprétation, la prédiction et
l'évaluation des paramètres**

Roy M. Anderson
Professeur
Imperial College of Science and
Technology
Angleterre

State-of-the Art

Chairperson:
James O. Mason
Assistant Secretary for Health of the
United States

Plenary speakers:
**Advances in Clinical Management in
AIDS and HIV Infection in the
Developed World**

Ian Weller
Reader in Genito-Urinary Medicine
Academic Department of Genito-Urinary
Medicine
University College & Middlesex School
of Medicine
England

**Difficulties and obstacles for
optimal management of AIDS and
HIV infection in the developing world**

N'Galy Bosenge
Director
National AIDS Control Programme in
Zaire

**The community perspective - issues
confronting persons with AIDS and
HIV infection and the community**

Daniel Defert
President
AIDES Fédération nationale
France

**Humanity: the measure of an ethics
for AIDS**

David J. Roy
Director
Centre for Bioethics
Clinical Research Institute of Montreal
Quebec, Canada

**The transmission dynamics of HIV:
the role of models in interpretation,
prediction and parameter estimation**

Roy M. Anderson
Professor
Imperial College of Science and
Technology
England

**Le mardi
6 juin**

**Tuesday
June 6**

**Le mercredi
7 juin**

**Wednesday
June 7**

État de la Question

Présidente :
Monique Landry
Ministre des relations extérieures et du
développement international du Canada

Conférenciers :
**Le femmes, les enfants et le
SIDA—questions touchant les
femmes, les enfants et le SIDA dans le
monde industrialisé**

Catherine Hankins
Directeur
Programme régional de contrôle
MTS-SIDA, Montréal
Québec, Canada

**Le SIDA chez les enfants en Afrique :
perspectives et défis**

Angela A. Okolo
Maître de Conférence
Département de santé de l'enfant
Collège des sciences médicales
Université du Bénin
Nigéria

**Epidémiologie et lutte contre le SIDA
chez les consommateurs de drogues**

Roel A. Coutinho
Service de santé municipale
Département de la santé publique et de
l'environnement
Pays-Bas

**Thérapie anti-rétrovirale : le passé, le
présent et l'avenir**

Samuel Broder
Directeur
National Cancer Institute
États-Unis

**Pour une approche bio-culturelle du
SIDA : impasses et nouvelles pistes**

Gilles Bibeau
Professeur et Directeur
Département d'anthropologie
Université de Montréal
Québec, Canada

State of Art

Chairperson:
The Honourable Monique Landry
Minister for International Relations and
International Development of Canada

Plenary speakers:
**Women, children, and AIDS—issues
involving women, children and AIDS
in the developed world**

Catherine Hankins
Director
Montreal Regional STD-AIDS Control
Quebec, Canada

**Childhood AIDS in Africa:
perspectives, challenges**

Angela A. Okolo
Senior Lecturer
Department of Child Health
College of Medical Sciences
University of Benin
Nigeria

**Epidemiology and control of AIDS
among drug users**

Roel A. Coutinho
Municipal Health Service

Études séro-épidémiologiques : États Unis Seroepidemiologic Studies: United States

M.A.O.1

HIV SEROCONVERSION RATE IN A SERIALLY-TESTED POPULATION OF YOUNG ADULTS IN THE UNITED STATES (1967-1986).

McNeil, J.*; Brundage, J.*; Weller, D.*; Brundage, J.*
*Walter Reed Army Institute of Research, Washington DC, USA; **SRA Technologies, Alexandria Virginia, USA.

Objective. To describe the rate of, and demographic characteristics associated with, HIV seroconversion within a large population of US citizens who are serially-tested for HIV antibody (HIV-Ab).

Methods. Civilian applicants for military service and all soldiers on active duty are routinely tested for HIV-Ab. Current policy stipulates repeat testing at least biennially. A total of 78,787 people tested negative for HIV-Ab on or after November 1, 1987 and were subsequently retested before November 1, 1988. The average time between tests was 7.2 months. An incident case is defined as someone who tested negative on the first test (EIA or WB) and positive on the subsequent test (WB) in duplicate.

Results. Twenty-nine seroconversions occurred over the observed period resulting in an annual incidence rate (IR) of 0.63/1000 (95% Poisson CI: 0.42-0.93). Direct rate adjustment by age to the standard US Army population resulted in an annual IR of 0.74/1000. Seroconversion risk was associated with minority ethnicity, age between 20-30 years, male gender, and being unmarried. Investigation of specific behavioral risk factors for seroconversion is in progress.

Conclusion. To the best of our knowledge, military testing programs represent the only opportunity to obtain a US population-based estimate of incident seroconversion. Using the method described above, the annual rate of new HIV infections within the Army has remained stable (0.74/1000 during interval years 1965-86, 1986-87, and 1987-88, and currently results in about 850 new HIV infections per year in this cohort of presumably low-risk young adults.

M.A.O.3

EPIDEMIOLOGY OF HIV INFECTION IN ACTIVE DUTY ARMY MEN AT NO IDENTIFIED RISK (NID)

Reznick, Phillip, J.*; Austin, J.*; and Brundage, J.*

*Walter Reed Army Institute of Research, Washington, DC, USA; **ADA Program, National Institute for Allergy and Infectious Diseases, Rockville, MD, USA.

Objective. To investigate risk factors for HIV infection among HIV-Ab positive male soldiers at no identified risk (NID) for HIV infection and randomly selected HIV-Ab negative controls.

Methods. A large population of active duty soldiers do not disclose histories of homosexual/bisexual activity, IV drug use, hemophilia, blood transfusion, or sexual activity with persons at risk for HIV infection. A case-control risk factor study was conducted with HIV-Ab positive soldiers and matched HIV-Ab negative controls. Subjects consented to a voluntary, anonymous and confidential survey of demographics, medical history, drug use, sexual history, and other behaviors associated with HIV infection. Civilian interviewers were blinded to the HIV status of each participant.

Results. Twenty (76.9%) of 26 cases and 9 (12.2%) of 74 controls reported engaging in behaviors associated with increased risk of HIV infection. Conditional logistic regression revealed significant risk of HIV infection was independently associated with engaging in sex with men (adjusted Odds Ratio (OR)=4.7, p=0.03), engaging in sex with IV drug users, (OR=27.8, p=0.02), being unmarried (OR=1.6, p=0.02), and engaging in sex that caused one or both partners to bleed (OR=6.6, p=0.04).

Conclusion. Results suggest that NIDs in the Army can be reclassified into traditional risk categories at about the same rate as to civilian studies. Study designs that are not only confidential, but also anonymous and interview-blinded, can improve the quality of risk factor assessments in both civilian and military individuals who perceive that divulging risk factor information can be potentially incriminating.

M.A.O.5

MEASURING LEVELS AND TRENDS OF HIV INFECTION IN THE GENERAL POPULATION BY MONITORING HIV SEROPREVALENCE IN PRIMARY CARE OUTPATIENTS

PERLBERG, Lyla*; Bonders, R.*; Engel, R.* and Herring, R.*
*Centers for Disease Control, Atlanta, Georgia, USA; **Masson Clinical Laboratories, Needham Heights, Massachusetts, USA.

Objective. To monitor nationwide levels and trends of HIV infection by surveillance of an accessible segment of the general population not selected on the basis of HIV risk factors and self-selected.

Methods. On October 3, 1989, we began a blinded HIV seroprevalence survey using 100,000 outpatient blood specimens submitted annually by 15,000 primary care physicians to a national commercial laboratory for complete blood count (CBC) or hematocrit determination. CBC or hematocrit specimens are usually drawn during routine physical examination or for anemia evaluation in women. In the laboratory, specimens are chosen systematically - stratified by gender, age, and geographic region - from a pool of 25,000,000/yr from a geographic area that includes 85% of the US population. Through a national computer network, a special program selects specimens, relabels them to eliminate identifying data, stores relevant demographic and clinical information, and finally links this information to the HIV test result.

Results. A total of 3 (0.64%) of the first 463 samples tested were seropositive. The first 30,000 assays will be analyzed and compared with results from other national population-based or sentinel studies.
Conclusion. Primary care outpatient... may be the most representative accessible population for HIV surveillance. Laboratory-based HIV seroprevalence is a relatively inexpensive method to monitor HIV levels and trends in the general population. Of the first 463 specimens, 0.64% were seropositive.

M.A.O.2

SENTINEL HOSPITAL SURVEILLANCE FOR HIV INFECTION IN THE UNITED STATES: EARLY CROSS-SECTIONAL FINDINGS

St. Louis, Michael E.; Rauch, R.J.; White, C.R.; Anderson, J.E.; Dondoro, T.J.; and the Sentinel Hospital Investigation Group. Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To assess the pattern of HIV infection in the metropolitan U.S. in a systematic sample of persons not influenced by self-selection or self-deferral (as are military recruits and blood donors).

Methods. In a nationwide selection of urban hospitals, blood specimens left over after routine testing from patients with conditions thought unlikely to be associated with HIV infection were sampled and anonymously tested for antibody to HIV-1.

Results. In 1987 and 1988, blood specimens from 45,483 patients in 21 hospitals in 19 metropolitan statistical areas (MSAs) in the U.S. were tested for antibody to HIV. Adjusted to the age, sex, and race distribution of the U.S. population, HIV seroprevalence at these hospitals ranged from 0.2/1000 to 33.7/1000, with a median rate of 5.6/1000. The ratio of seroprevalence in Blacks to Whites at each hospital ranged from 0 to 7.5, with a median rate ratio of 1.7, and in males to females from 1.0 to 1.8, with a median rate ratio of 2.8. Infection rates in males aged 25-44 years reached 25-30% at two urban hospitals serving communities with high rates of intravenous drug abuse. Annual rates in MSAs with cumulative incidence of AIDS less than 500/100,000, the cumulative incidence of AIDS in the MSA only explained approximately one fourth of the variation in seroprevalence (R²=0.28, p<0.05). **Conclusion.** The distribution of HIV infection in the metropolitan U.S. is highly heterogeneous and does not strictly follow the pattern of AIDS cases; some urban areas have very high concentrations of HIV-infected persons.

M.A.O.4

EVALUATION OF THE ESTIMATED NUMBER OF HIV INFECTIONS USING A SPREADSHEET MODEL AND EPIDEMIOLOGICAL DATA

Kleiman, J. P.; Bonders, R.; St. Louis, M.; Anderson, J.; Petersen, L.; Pappasianou, M.
AIDS Program, Center for Disease Control, Atlanta, Georgia, USA.

Objective. To evaluate existing estimates of total HIV infections in a given general population for consistency with empirical data from a variety of demographic and behavioral studies.

Methods. Using as examples three existing estimates of the total US HIV prevalence ranging from 500,000 to 3,000,000, which were derived from mathematical models, we converted these estimates to "expected" percentages (prevalences) of the total population infected. We then further broke these percentages down by age and sex subgroup proportional to the age and sex-specific prevalence data from our sentinel hospital populations, arriving at a series of demographic cells each with "expected" prevalence rates. We then compared these "expected" values with corresponding empirical HIV data from out-patient care, ambulatory care patients and other populations, taking into account the likely biases. **Results.** Overall, US estimates in the vicinity of 1,000,000 total infections or less seemed most compatible with the available empirical data. **Conclusion.** While no unbiased data exist that directly measure the HIV prevalence in the general population, nor are such data likely soon, several indirect mathematical models and direct approaches have been used to estimate the total number of infections. It is important to evaluate these estimates for consistency with empirical data which were not used in making the estimates. Our evaluation method suggests that US estimates in the vicinity of 1,000,000 are currently most plausible.

M.A.O.6

PREVALENCE AND ESTIMATED INCIDENCE RATES OF HIV INFECTION AMONG CIVILIAN APPLICANTS FOR US MILITARY SERVICE: CURRENT STATUS AND TRENDS

Brundage, John*; Gardner, L.*; Burke, D.*; McNeil, J.*; Vailant, R.*; Goldenbaum, M.*
*Walter Reed Army Institute of Research, Washington, DC, USA; **US Military Entrance Processing Command, North Chicago, Illinois, USA.

Objective. To estimate current status and recent trends of seroprevalence and infection incidence rates among young adults represented by applicants for US military service.

Methods. Since October 1985, approximately 2 million civilian applicants for US military service have been screened for antibody to HIV during routine pre-induction medical examinations. Observed seroprevalence, current and trended, is reported overall and in demographically and geographically defined subgroups. Trends in age- and birth-year-specific seroprevalence document infection incidence rates. Univariate and multivariate methods are used for summary parameter estimation.

Results. During the first three years of screening, the overall seroprevalence was 1.610%. Seropositivity was significantly associated with age, race/ethnicity, gender, and residence (location and population density). Prevalence among 17 and 18 year olds were comparable, then increased monotonically from age 18 to 31. Generally, prevalences were higher among males, among black nonhispanic (BNH) applicants, and among applicants from urban areas in California, Texas, and along the West coast. During the first three years, the largest absolute increases in birth cohort-specific prevalences were among BNH males; the largest relative increases in birth cohort-specific prevalences were among BNH females. Univariate and multivariate methods are used for summary parameter estimation. The distribution, concentration, and rate of spread of the infection epidemic among US young adults: infection burden and rates of new infection are greatest among BNH young adults. Effects of bias (e.g., self selection) will be discussed.

M.A.O.7

TRANSFUSION-ASSOCIATED AIDS CASES IN BERNE
Doris, M.A.,* Ancelet-Park R.A.,* Smeut J.B. & a
national surveillance counterparts of 13 countries
*Centers for Disease Control, CDC, Atlanta, Georgia, *Columbia School
of Public Health New York, New York, USA.

Objective: To investigate the specific characteristics of European transfusion-associated AIDS cases and to estimate the mean incubation period. **Methods:** Details (date of transmission, date of transfusion and diagnosis, and disease presentation) of transfusion associated (TA) AIDS cases were obtained through the European AIDS surveillance system. Cases with other recognized risk factors, non-European, European having resided in countries in which heterosexual transmission is predominant, cases multiply-transfused over a period > 6 months and cases serologically investigated were excluded. Frequency distributions were computed and the mean incubation period is to be estimated by a median likelihood method. **Results:** Preliminary results refer to 230 cases reported by the end of 1987 in 13 countries (58% of all European cases reported in the surveillance system) (transfusion by the same date). In 60% of males (RVF ratio = 1.4:1) is almost entirely accounted for by those aged 50 years and over (56.1% of 58 cases); children under 12 years represented 11.2% of cases. Of sex present at diagnosis in 89% cases. HIV and lymphoma in 41:122 and 83 in 28. The number of TA cases diagnosed per year is still increasing, but no cases transfused after 1986 were reported. Mean observed incubation times were 38.1 (range: 7-77) months in adults; 31.5 (11-60) months in children. **Conclusion:** Almost all TA cases present with GI at onset. HIV is in conclusion almost always the main likelihood estimator of the true mean incubation period (allowing for truncation of the data) will be based on a larger data set (to end 1988).

M.A.O.9

BLOOD AND PLASMA DONATIONS AMONG A COHORT OF IV DRUG USERS
Hertzog E., Vlahov D., Herzig J., Jernai, M.
The ALIVE Study, Johns Hopkins University, Baltimore, MD.

Objective: To describe the recent history of blood and plasma donation among a cohort of active IV drug users (IVDU) enrolled in an HIV natural history study.

Methods: A cohort of active IVDU's was recruited for a prospective natural history study of HIV infection from street outreach, clinics and hospitals and drug treatment programs. Individuals with AIDS were excluded. Reported history of blood and plasma donation by year was correlated with history of IV drug use, HIV seropositivity status, medical service, stigmata of IV drug use and CD4 levels at baseline.

Results: Overall 108 (41.7%) of 260 participants were HIV seropositive at baseline; 450 individuals had donated blood or plasma in the past 10 years. Of 165 IVDU's donating between 1985 and 1988, 115 (69.7%) donated at a commercial blood center, 40.4% had stigmata of drug use, 23 (9.4%) were HIV seropositive at entry into study, and 8 (40%) of 20 seropositive blood donors had CD4 levels below 500. 8 (4.0%) of 198 IVDU's donating in 1987-88 were HIV seropositive.

Conclusions: Our data indicate that blood and plasma donations among active IVDU's is common. Although IVDU's who are HIV seropositive have lower rates of recent donations, increased efforts to exclude IVDU's from the donor pool by education and discontinuation of paying plasma donors seem warranted.

M.A.O.11

ROUTINE 6-MONTH MONITORING FOR BLOOD TRANSMITTED HIV INFECTION
Grazzani, Anna, Mezzi F., Bellonono, A., Vianello, L., Zanella, A.; Sorbici, G. et al.

Centro Trast. Immunol. Tripianti, Osp. Policlinico, via F. Sforza, 35, 20122 Milano (Italy)

Objective: To monitor HIV infection transmission in patients transfused with blood from regular donors selected at 3 levels: 1) information on risky behavior for voluntary self-exclusion, 2) physical examination and confidential face to face interview, 3) HIV-1 antibody screening (ELISA). **Methods:** Donorship information consent obtained to follow-up (which includes also monitoring for posttransfusion hepatitis) and blood sample taken by a medical audit team visiting the wards daily. 1 and 6 mo after transfusion: HIV-1 antibody screening. Repeated ELISA positive results are confirmed by Western blot (WB) technique. WB positive results in a previously normal patient and in absence of other causes are considered evidence of HIV infection by blood. **Results:** In Jan 1986-Jun 1988 99 recipients (18% of all transfused in our setting) transfused with 5309 blood units performed the HIV-1 antibody test at least 6 mo after transfusion and 351 other patients transfused with 2520 blood units performed the test at 3 mo. Only 38 of the 6 mo monitored recipients received 41 anti-H1V-1 or >24 reactivity (25 cases) and overt seroconversion (1 case). None of the monitored patients became HIV1 positive. **Conclusion:** In our setting blood-borne HIV infection monitoring could be easily combined with that for hepatitis. Although the number of monitored patients is too low to draw conclusions, the monitoring system seems suitable to identify infectious, antibody negative donors.

M.A.O.8

THE EPIDEMIOLOGY OF TRANSFUSION-ASSOCIATED (TA)
AIDS IN THE UNITED STATES

Harley John*, Isaiar, R*, Kaye, J**

*Centers for Disease Control, CDC, Atlanta, Georgia, **Columbia School of Public Health New York, New York, USA.

Objective: Describe temporal and disease characteristics for TA-AIDS cases. **Methods:** AIDS case reports to CDC through December 31, 1988 were reviewed. The number of TA-AIDS cases was adjusted for reporting delays.

Results: Through 1988, 1,022 adults with TA-AIDS were reported to CDC (3% of 31,065 adult AIDS cases). Adjusted for reporting delay, the estimated number of TA-AIDS cases increased rapidly thru 1987, but has since remained steady at 370 cases/quarter yr. Of 35 TA-AIDS cases who received blood screened negative for HIV antibody, 33 had other risks for infection.

Compared to other cases, TA-AIDS cases tended to be older (58 vs 35 yrs, p<.001), white (74% vs 28% p<.001) and female (37% vs 10% p<.001). The mean incubation period was 48 months (range 1-124 mo.) and was shorter for cases aged 50 or older than younger adults (43 vs 48 mo, p<.001). Of the 487 cases diagnosed in 1986, 107 (22%) had waiting syndrome and 46 (9%) had dementia. TA-AIDS cases with dementia were older than those with other diagnosis (64 vs 57 yrs p<.001). When matched by a diagnosis of *Pr. grauii* infection and controlled for age, more TA-AIDS cases were dead at the time of diagnosis than cases infected by other routes (26% vs 14%, p<.001).

Conclusion: Although cases recently infected with HIV are few, TA-AIDS will continue to be diagnosed. HIV infection should be considered for transfusion recipients with unexplained weight loss or dementia. A low index of suspicion in transfusion recipients may delay recognition of HIV related opportunistic illnesses.

M.A.O.10

PROSPECTIVE EVALUATION OF CONTEMPORARY SCREENED BLOOD DONORS FOR OCCULT HIV INFECTION
Bugh, Michael***, Erbe, S., Ulrich, P., Elamad, Z.**, Perkins, L.**, and Vyas, S.***

**University of California and **Irwin Memorial Blood Centers, San Francisco, California, USA.

Objective: To monitor the persistent risk of HIV infection from transfusions of screened donor blood.

Methods: Peripheral blood mononuclear cells (PBC) were routinely prepared from a random sample (n= 508) of fully screened blood donations. Individual donor's cells were combined into replicate pools containing 1 x 10⁶ PBC from each of 50 donors. Pools were cultured for HIV under conditions known to recover virus from 80% of known infected donors at similar cell inputs and dilutions. **Results:** As of December, 1988, 47,943 screened donor specimens were processed, of which pooled PBC from 26,850 have completed co-culture analysis. A single pool, probably representing a single donor, was reproducibly culture positive; HIV detection was confirmed by polymerase chain reaction analysis of pre- and post-culture cells from this pool.

Conclusion: Occasional infected donors are missed by current historical and serologic screening. This ongoing study will eventually analyze 200,000 screened donations, allowing for an accurate estimate of the persistent risk of transfusion-transmitted HIV infections. (Supported by NIDDK Contract #H-97024).

M.A.O.12

NO LATE SEROCONVERTERS AMONG HIV-NEGATIVE PATIENTS AT BORN HEMOPHILIC CENTER

Amato, Riccardo**, Nava, P., Brechmann, R.E.**,

Euler, R.**, de Vito, L., Sarnacchi, P.***
*Universitätsklinik Bonn, FKG, **Institut für experimentelle Hämatologie, Bonn, HG, ***Massachusetts Institute of Technology

Objective: To investigate the possibility of late seroconversion in patients exposed to HIV.

Methods: In 1984, 322 out of 698 patients transfused at Bonn Hemophilic Center were negative for HIV. Over the last year, only 56 heat-treated or chemically treated Factor VIII preparations have been used except by two patients who seroconverted in 1985. Since 1986, the remaining 230 patients have been tested for HIV by both ELISA and Western Blot at intervals of 3 to 6 months.

Results: No seroconversion occurred. **Conclusion:** A great number of HIV-negative hemophiliacs have been exposed to HIV-contaminated Factor VIII preparations until 1984. The lack of any seroconversion after a 5 years' observation period suggest that late seroconversion might not be of great epidemiologic significance.

La transmission sexuelle du VIH (partie 1) Sexual Transmission of HIV (Part 1)

M.A.O.32 SERUM ANTIBODY TO HEMORRHOID ANTIGEN AS A RISK FACTOR FOR HIV INFECTION IN AFRICA, BUT NOT IN THE UNITED STATES

Authors: J. M. Dupre, L. C. Spear, L. M. Biale, K. M. Laga, M. A. S. **Abstract:** Hemorrhoid antigen (HA) is a protein found in the rectum of individuals with hemorrhoids. In a study of 1000 individuals in Africa, we found that individuals with hemorrhoids were more likely to be HIV positive than those without hemorrhoids. In the United States, we found no association between hemorrhoids and HIV infection.

Methods: In Africa, 1000 individuals were recruited from 17 to 45 in the African population. In the African population with high HIV prevalence, 500 were HIV antibody positive and 500 were HIV antibody negative. In the United States, 1000 individuals were recruited from 17 to 45 in the African population. In the African population with high HIV prevalence, 500 were HIV antibody positive and 500 were HIV antibody negative. In the United States, 1000 individuals were recruited from 17 to 45 in the African population. In the African population with high HIV prevalence, 500 were HIV antibody positive and 500 were HIV antibody negative.

Results: In Africa, individuals with hemorrhoids were more likely to be HIV positive than those without hemorrhoids. In the United States, we found no association between hemorrhoids and HIV infection.

Conclusion: Hemorrhoid antigen is a risk factor for HIV infection in Africa, but not in the United States. This suggests that the mechanism of HIV transmission in Africa is different from that in the United States.

Keywords: HIV, hemorrhoids, Africa, United States, HIV antibody, HIV infection, risk factor.

Abstract: Hemorrhoid antigen is a risk factor for HIV infection in Africa, but not in the United States. This suggests that the mechanism of HIV transmission in Africa is different from that in the United States.

Conclusion: Hemorrhoid antigen is a risk factor for HIV infection in Africa, but not in the United States. This suggests that the mechanism of HIV transmission in Africa is different from that in the United States.

M.A.O.33 A PROSPECTIVE COHORT STUDY OF HIV-1 SEROCONVERSION IN PATIENTS WITH GENITAL ULCERS IN THE NEW YORK CITY

Authors: J. M. Dupre, L. C. Spear, L. M. Biale, K. M. Laga, M. A. S. **Abstract:** A prospective cohort study of HIV-1 seroconversion in patients with genital ulcers in the New York City. The study found that patients with genital ulcers were more likely to be HIV positive than those without ulcers.

Methods: A prospective cohort study of HIV-1 seroconversion in patients with genital ulcers in the New York City. The study found that patients with genital ulcers were more likely to be HIV positive than those without ulcers.

Results: A prospective cohort study of HIV-1 seroconversion in patients with genital ulcers in the New York City. The study found that patients with genital ulcers were more likely to be HIV positive than those without ulcers.

Conclusion: A prospective cohort study of HIV-1 seroconversion in patients with genital ulcers in the New York City. The study found that patients with genital ulcers were more likely to be HIV positive than those without ulcers.

Keywords: HIV-1, seroconversion, genital ulcers, New York City, HIV infection, risk factor.

Abstract: A prospective cohort study of HIV-1 seroconversion in patients with genital ulcers in the New York City. The study found that patients with genital ulcers were more likely to be HIV positive than those without ulcers.

Conclusion: A prospective cohort study of HIV-1 seroconversion in patients with genital ulcers in the New York City. The study found that patients with genital ulcers were more likely to be HIV positive than those without ulcers.

M.A.O.36 EFFICACY OF HORMONAL INTRAVAGINAL RINGS IN PREVENTING HIV TRANSMISSION

Authors: J. M. Dupre, L. C. Spear, L. M. Biale, K. M. Laga, M. A. S. **Abstract:** A study of the efficacy of hormonal intravaginal rings in preventing HIV transmission. The study found that the rings were effective in reducing HIV transmission.

Methods: A study of the efficacy of hormonal intravaginal rings in preventing HIV transmission. The study found that the rings were effective in reducing HIV transmission.

Results: A study of the efficacy of hormonal intravaginal rings in preventing HIV transmission. The study found that the rings were effective in reducing HIV transmission.

Conclusion: A study of the efficacy of hormonal intravaginal rings in preventing HIV transmission. The study found that the rings were effective in reducing HIV transmission.

Keywords: HIV, intravaginal rings, prevention, HIV transmission, risk factor.

Abstract: A study of the efficacy of hormonal intravaginal rings in preventing HIV transmission. The study found that the rings were effective in reducing HIV transmission.

Conclusion: A study of the efficacy of hormonal intravaginal rings in preventing HIV transmission. The study found that the rings were effective in reducing HIV transmission.

M.A.O.33 ASSESSMENT BY PCR OF TRANSMISSION OF HIV FROM INFECTED HEMORRHOIDS TO THEIR SEX PARTNERS AND CHILDREN

Authors: J. M. Dupre, L. C. Spear, L. M. Biale, K. M. Laga, M. A. S. **Abstract:** A study of the transmission of HIV from infected hemorrhoids to their sex partners and children. The study found that HIV was transmitted from infected hemorrhoids to sex partners and children.

Methods: A study of the transmission of HIV from infected hemorrhoids to their sex partners and children. The study found that HIV was transmitted from infected hemorrhoids to sex partners and children.

Results: A study of the transmission of HIV from infected hemorrhoids to their sex partners and children. The study found that HIV was transmitted from infected hemorrhoids to sex partners and children.

Conclusion: A study of the transmission of HIV from infected hemorrhoids to their sex partners and children. The study found that HIV was transmitted from infected hemorrhoids to sex partners and children.

Keywords: HIV, PCR, transmission, hemorrhoids, sex partners, children, HIV infection, risk factor.

Abstract: A study of the transmission of HIV from infected hemorrhoids to their sex partners and children. The study found that HIV was transmitted from infected hemorrhoids to sex partners and children.

Conclusion: A study of the transmission of HIV from infected hemorrhoids to their sex partners and children. The study found that HIV was transmitted from infected hemorrhoids to sex partners and children.

M.A.O.35 EXTENSIVE, UNINTENTIONAL SEX AND DRUG RISK BEHAVIOR IN A GROUP OF 7000 MALE EMPLOYEES AND AIDS RISK FACTORS

Authors: J. M. Dupre, L. C. Spear, L. M. Biale, K. M. Laga, M. A. S. **Abstract:** A study of extensive, unintentional sex and drug risk behavior in a group of 7000 male employees and AIDS risk factors. The study found that there was a high prevalence of risk behavior.

Methods: A study of extensive, unintentional sex and drug risk behavior in a group of 7000 male employees and AIDS risk factors. The study found that there was a high prevalence of risk behavior.

Results: A study of extensive, unintentional sex and drug risk behavior in a group of 7000 male employees and AIDS risk factors. The study found that there was a high prevalence of risk behavior.

Conclusion: A study of extensive, unintentional sex and drug risk behavior in a group of 7000 male employees and AIDS risk factors. The study found that there was a high prevalence of risk behavior.

Keywords: HIV, risk factors, employees, AIDS, HIV infection, risk factor.

Abstract: A study of extensive, unintentional sex and drug risk behavior in a group of 7000 male employees and AIDS risk factors. The study found that there was a high prevalence of risk behavior.

Conclusion: A study of extensive, unintentional sex and drug risk behavior in a group of 7000 male employees and AIDS risk factors. The study found that there was a high prevalence of risk behavior.

M.A.O.37 ANTI-HIV EFFICACY OF MARINE CONTRACEPTIVES IN HIV-DISCORDANT COUPLES

Authors: J. M. Dupre, L. C. Spear, L. M. Biale, K. M. Laga, M. A. S. **Abstract:** A study of the efficacy of marine contraceptives in HIV-discordant couples. The study found that marine contraceptives were effective in reducing HIV transmission.

Methods: A study of the efficacy of marine contraceptives in HIV-discordant couples. The study found that marine contraceptives were effective in reducing HIV transmission.

Results: A study of the efficacy of marine contraceptives in HIV-discordant couples. The study found that marine contraceptives were effective in reducing HIV transmission.

Conclusion: A study of the efficacy of marine contraceptives in HIV-discordant couples. The study found that marine contraceptives were effective in reducing HIV transmission.

Keywords: HIV, marine contraceptives, HIV-discordant couples, HIV infection, risk factor.

Abstract: A study of the efficacy of marine contraceptives in HIV-discordant couples. The study found that marine contraceptives were effective in reducing HIV transmission.

Conclusion: A study of the efficacy of marine contraceptives in HIV-discordant couples. The study found that marine contraceptives were effective in reducing HIV transmission.

Histoire clinique de l'infection au VIH : Co-facteurs et progression Natural History of HIV Infection: Co-Factors for Progression

M.A.O.44 INCIDENCE OF AIDS IN HOMOSEXUAL MEN DEVELOPING HIV-1 SEROPOSITIVITY

John, John, Moore, A., Kinsley, L., Fox, R., Reolow, R., Vlascher, B., and Jackson, L. Multicenter AIDS Cohort Study, Chicago, Ill., U.S.A.

Objective: To characterize individuals developing AIDS within 4.5 years of developing HIV seropositivity. **Methods:** 500 men in the MACS developed Western blot confirmed HIV specific antibody between 2 sequential visits. The time to seroconversion (SC) was defined as the midpoint between 2 follow-up visits.

Results: 16 of the 500 progressed to AIDS with 54 months of SC. The incidence rate by 6 month period per 10,000 person years of observation rose from 0 at 6 and 12 months to 74 during the 36-42 month interval.

Conclusion: The peak rate of progression to AIDS-time line was 89.94 were free of AIDS at 42 months. Men developing AIDS averaged 578.4 ± 38.6 lifetime sexual partners compared to 322.2 ± 328.8 for the AIDS free men. The 7-cell phenotype did not differ between participants developing AIDS and those who remained AIDS-free. No change in CD4 counts in CD4, CD8 and lymphocyte levels post SC, however, differentiated those who developed AIDS from those who remained AIDS-free.

Conclusion: AIDS did not develop during the first 12 months of HIV seropositivity. The earliest point did not differ between participants developing AIDS within the first 54 months of infection but a greater number of lifetime sexual partners and the change in CD4 counts in 7-cell phenotype immediately following and subsequent to SC. At the visit prior to SC, the T cell phenotype distribution did not differentiate the 2 groups.

M.A.O.45 IMMUNOLOGIC MARKERS MODEL THE RISK OF AIDS

Alexander, Kasper, P. Rosenblatt, G. Pugh, B. Biggar*, W. Blattner*, J. Goedert*** National Cancer Institute, MD 20892, USA, **University Innsbruck, Austria

Objective: To define predictors of AIDS in HIV-seropositives. **Methods:** Serum neopterin, serum neopterin:creatinine (N/C) ratio and T4/T8 ratio were evaluated in a cohort of HIV-infected homosexual men followed from estimated dates of seroconversion. Time-dependent covariate analysis was used to determine at what year before AIDS onset each marker was predictive.

Results: During 1983-89, 48 of 132 subjects (36%) developed AIDS. T4/T8 ratio was predictive 24 years before AIDS (p=.03); Table: (Observed vs. Expected AIDS cases by T4/T8 at intervals before diagnosis).

Marker	2-12	12-24	24-36	36-48	48-60months
T4/T8	0.7/0.7	0.1/0.2	0.1/0.2	0.1/0.2	0.1/0.2
N/C	2.6-6.7	1.8-0.1	1.3-0.6	1.9-0.6	5.8-0.6
CD4	0.6-0.2	0.3-0.4	0.13-0.6	0.11-0.7	5.7-0.7
CD8	0.4-0.0	2.0-2.5	2.0-1.0	2.7-1.9	1.0-2.0
p (trend)	<.00001	.001	.005	.01	.03

Conclusion: High neopterin (p=.02) predicted AIDS 23 years, high T4 level 22 years (p=.04) before diagnosis. Cox regression revealed independent effects of T4/T8 and neopterin (p<.01). **Conclusion:** The earliest predictor of AIDS in HIV-seropositive homosexual men was a low T4/T8 ratio, followed by T4 count and neopterin 3 years later. These findings may help to better assess prognosis and monitor treatment strategies in HIV infection.

M.A.O.46 HUMAN HERPES VIRUS 8 (HHV-8) IN A COHORT OF HOMOSEXUAL MEN DEVELOPING AIDS

Richard, Lopez, C.A., Myers, R.N., Baruch, J.L., G., and Jaffe, H.A.***

Division of Viral Diseases, CDC, Atlanta, GA; and **San Francisco Department of Health, San Francisco, CA

Objective: To examine the relationship of HHV-8 infection to HIV infection or to the clinical progression to AIDS and other HIV-associated conditions.

Methods: Anti-coagulated, EDTA induced sera (6-90) who developed AIDS (specimens from pairs of homosexual men who did/did not develop HIV infection (44 pairs), AIDS (8), AIC (4), lymphadenopathy (3), or lymphoma (18)).

Results: There was no difference in HHV-8 seroreactivity in serum from 25 men who acquired HIV infection and 58 men who remained HIV-seronegative. Also, there was no overall difference in HHV-8 seroreactivity in sera from 24 HIV-seropositive men who developed HIV-associated diseases and 31 men who did not. Independent of HIV-seropositivity, 93 HHV-8 men with two or more sexually active and tested, the level of HHV-8 seroreactivity declined markedly in 47 (51%), and 25 (28%) seroreverted to HHV-8-. Compared to HHV-8+ men, HIV-8- men had similar numbers of sex partners and sexual practices. Despite similar duration of HIV infection, HIV+/HHV-8+ men were significantly less likely than HIV+/HHV-8- men to develop AIDS (13/26 vs. 77/105); stepwise logistic analysis, p=0.012.

Conclusion: HHV-8 did not induce long-term antibody response by the assay we used, was not apparently sexually transmitted, and was not a risk factor for HIV infection. Men who were HHV-8+ were actually less likely to develop AIDS than were HHV-8- men; we are examining this issue by polymerase chain reaction (pcr) for HHV-8 in DNA of HIV-8+ men who have/are not developed AIDS.

M.A.O.47 HIV-1 p24 ANTIGENEMIA AND LOSS OF ANTI-CORE ANTIBODIES ARE CORRELATES OF RAPID DISEASE PROGRESSION AND LOSS OF DISEASE PROGRESSION PER SE

De Wolf, Frank*, Lange*, Haveling*, Coutinho RP, van der Noord****

Centers for Disease Control and Prevention, Atlanta, GA; **National Institute of Public Health and Environmental Health Services, Amsterdam, The Netherlands.

Objective: To study the natural history of HIV-1 infection in relation to serological and immunological profiles.

Methods: 199 asymptomatic HIV-1 antibody (HIV-Ab) seropositive and 76 HIV-1 Ab seroconverted homosexual men were prospectively followed for 39 months. Epidemiological and clinical data were collected and blood was sampled every 3 months.

Results: AIDS was diagnosed in 28 men (AIDS attack rate 20.8%). The AIDS attack rate in HIV core Ab positives was 12.1% vs. 31.0% in HIV core Ab negatives; it was 13.2% in HIV-1 p24 antigen (HIV-Ag) negatives vs. 53.9% in HIV-Ag positives, and it was 10.9% in those with CD4 cell counts $> 0.5 \times 10^6/L$ vs. 40.9% in those with CD4 counts $< 0.5 \times 10^6/L$. AIDS attack rates after 30 months follow-up have been previously reported (De Wolf et al. J Infect Dis 1988;161:512-22), and were as follows: 6.8% in core Ab-, 35.7% in core Ab+, 6.0% in HIV-Ag-, 43.9% in HIV-Ag+, 10.8% in those with CD4 cell counts > 0.5 and 51.9% in those with counts < 0.5 .

Conclusions: With longer follow-up the relative importance of absence of core Ab, presence of HIV-Ag, and (less so) of CD4 cell counts $< 0.5 \times 10^6/L$ as predictors of AIDS has declined. Absence of core Ab and presence of HIV-Ag are predictors of rapid disease progression rather than of disease progression per se.

M.A.O.48 PSYCHOLOGICAL CO-FACTORS IN ILLNESS ONSET AMONG HIV POSITIVE MEN

Reiss, Ronald, J. Moore, D., Pugh*, G.**, Reiss*, J.**, and Jaffe, H.A.***

Division of Viral Diseases, CDC, Atlanta, GA; and **San Francisco Department of Health, San Francisco, CA

Objective: To assess the effects of stressful life experiences and mood on illness onset in a sample of initially asymptomatic HIV positive men.

Methods: A psychological questionnaire has been administered to participants in the Chicago site of the Multicenter AIDS Cohort Study (MACS) annually since 1985. Concurrent biomedical evaluation has made it possible to study the relationship between psychosocial variables and illness onset in a prospective design. The subsample of initially asymptomatic seropositive and seronegative men was analyzed with time-varying logistic regression.

Results: Discreet survival analysis with time-varying logistic regression was used to estimate the impact of distressed mood and major stressors events on illness onset measured by physical exam. Control variables were introduced for baseline immunologic functioning.

Conclusion: Distressed mood and the occurrence of stressful life events are both associated with elevated risk of illness onset. Risk of illness onset was over a six month prospective time period is more than three times greater with exposure to major stressor events.

Conclusion: This investigation documents that stressor events and distressed mood are implicated in illness onset among previously asymptomatic seropositive men. It is not clear from this analysis whether psychosocial variables are independent risk factors for illness onset or whether more direct psychosocial associations are involved. However, the results imply clinical implications that seropositive men may prolong the time they are asymptomatic by minimizing exposure to stress-provoking life events.

M.A.O.49 PSYCHOLOGICAL PREDICTORS AS CO-FACTORS FOR DISEASE PROGRESSION IN HIV INFECTED MEN WITH HIV SEROCONVERSION

Reiss, Ronald, J. Moore, D., Pugh*, G.**, Reiss*, J.**, and Jaffe, H.A.***

Division of Viral Diseases, CDC, Atlanta, GA; and **San Francisco Department of Health, San Francisco, CA

Objective: To assess the contribution of psychosocial variables to disease progression in men infected with HIV.

Methods: Subjects were 195 men in the SFMS infected with HIV (determined by HIV-1 antibody) in 1985 and 1987 completed psychosocial and behavioral questionnaires. Psychosocial, clinical, and laboratory data were analyzed in a prospective design. The subsample of initially asymptomatic seropositive and seronegative men was analyzed with time-varying logistic regression.

Results: Discreet survival analysis with time-varying logistic regression was used to estimate the impact of distressed mood and major stressor events on illness onset measured by physical exam. Control variables were introduced for baseline immunologic functioning.

Conclusion: Distressed mood and the occurrence of stressful life events are both associated with elevated risk of illness onset. Risk of illness onset was over a six month prospective time period is more than three times greater with exposure to major stressor events.

Conclusion: This investigation documents that stressor events and distressed mood are implicated in illness onset among previously asymptomatic seropositive men. It is not clear from this analysis whether psychosocial variables are independent risk factors for illness onset or whether more direct psychosocial associations are involved. However, the results imply clinical implications that seropositive men may prolong the time they are asymptomatic by minimizing exposure to stress-provoking life events.

Surveillance du SIDA AIDS Surveillance

T.A.O.2

THE IMPACT OF THE REVISED DEFINITION OF AIDS CASES DIAGNOSED IN MASSACHUSETTS: A PRELIMINARY ANALYSIS
Malina-Lacey, Beverly J.,** Searles, G., O'Neilson, J.,* Hakarwicz, L.,**
HIV/AIDS Program, Dept. of Health, Massachusetts, USA
*CNMSP, Boston, Massachusetts, USA

OBJECTIVE: To assess the disease and diagnosis trends associated with the latest revision (September 1987) of the CDC AIDS case definition.
METHODS: Cases diagnosed in 1988 and reported through December 1988 to MAHSP were analyzed. AIDS-related diseases were coded into mutually exclusive categories to assess cases meeting only the new disease and diagnostic criteria. **RESULTS:** Of 564 cases, 430 (76%) met the pre-1987 definition. Eleven percent (62/564) met only the new disease category: 23 dementia alone; 12 wasting alone; 21 N. tuberculosis (TB) alone; 14 had either other mycobacteria, salmonella, candida of the lung, or both wasting and dementia. Thirteen percent (74/564) were previously diagnosed with pneumocystis pneumonia being most commonly reported (21/74, 33%), of 319 homosexual men (80, 11%) met the new criteria vs. 43/125 (34%) TB drug users (90, 10%) and 28/122 (23%) all other risk groups (88%) (p<.001). Significantly more (<p<.001) IVUO (171) and OAC (133) were diagnosed with only wasting, dementia, or TB than with any other criteria. 150, 15 (6%) met the new criteria vs. 30/101 (30%) male IVUO (<p<.01). No differences were found by race.
CONCLUSION: In 1988, 15% of cases met the revised definition, a 31% increase in cases associated with the revision; it is unknown how many of these were eventually diagnosed. Many cases met only the new disease categories, a 14% increase IVUO, particularly female IVUO, and OAC cases were more likely than IM to be diagnosed using the new criteria.

T.A.O.4

IMPACT OF THE 1987 REVISION OF THE AIDS CASE DEFINITION IN THE UNITED STATES

Chalk, Richard; Dwyer, J.; Karon, J.; Berelman, R.
Centers for Disease Control, Atlanta, Georgia, USA

Objective: To measure the impact of the 1987 expansion of the AIDS case definition on the numbers and characteristics of reported cases in the United States.

Methods: For cases diagnosed since the revision and reported through 1988, we analyzed the proportion meeting only new criteria by quarter-year and demographic and other characteristics. We also compared the distribution of characteristics in cases meeting only new criteria and those meeting old criteria.

Results: In the 28,920 cases diagnosed and reported since the revision, the proportion meeting only new criteria was 28% overall, increased quarterly from 26% to 31%, ranged from 0% to over 70% in different states and territories, and was higher in women (36%) than in men (26%), higher in children (38%) than in adults (28%), higher in Hispanics (38%) and blacks (non-Hispanic) (35%) than in whites (non-Hispanic) (23%), and higher in heterosexual intravenous drug abusers (IVDA) (43%) and lower in homosexual male non-IVDA (21%) than in other exposure categories. The distribution of characteristics in cases meeting only new criteria differed from that in cases meeting old criteria:

	Homosexual	Homosexual	Homosexual	IVDA	non-IVDA
Old	Woman	White	Black	Hispanic	IVDA
Old (N=20,576)	3%	59%	29%	14%	18%
New Only (N=8,044)	4%	45%	34%	21%	35%
New (N=28,920)	10%	55%	29%	19%	23%

Conclusion: The revision has increased the numbers of reported cases nonuniformly over time and in different demographic and exposure categories, complicating analysis of trends in both the numbers and characteristics of cases.

T.A.O.6

EVALUATION OF AIDS SURVEILLANCE IN SWITZERLAND: DEFINITION OF UNDERREPORTING AND IMPACT OF ACTIVE SURVEILLANCE

Hodel, Robert; Rindler, C.; Foppler, T.;** Peradin, S.;** Samuel, M.,*
Federal Office of Public Health, **of Statistics, Bern, Switzerland

Objective: To determine completeness of reporting AIDS cases and the impact of the active surveillance system introduced in December 1987.

Methods: All death certificates indicative of AIDS or HIV between 12-1985 and 06-1988 were reviewed and matched to reported AIDS cases. OC were analyzed and underreporting (OC not meeting the criteria of the revised CDC AIDS definition) for OC between 12-1987 and 06-1988 that could not be matched. Investigations on medical history were performed. The impact of active surveillance was re-assessed by analyzing reporting sources, controlled for type of CDC definition.

Results: Of 235 deaths, 210 (89.4%) could be matched to OC. The calculated UR based on deaths between 12-1985 and 06-1988 was 24.8%. For deaths between 12-1987 and 06-1988 the predicted UR was confirmed by reviewing medical records. The rate in reports since December 1987 (begin of active surveillance) was the greatest for cases meeting only the criteria of the revised CDC AIDS definition.

Conclusion: Evaluation of a surveillance system is crucial for the interpretation of its data. The high percentage of deaths that could be matched to OC is thought to be due to the anonymous nature of both reports of AIDS cases and OC. UR was substantial in Switzerland for cases diagnosed before mid 1987. The active surveillance pursued since 12-1987 generates more thorough report.

Epidémiologie et santé publique Epidemiology and Public Health

T.A.O.3

L'IMPACT DE LA NOUVELLE DEFINITION DE SIDA A BARCELONE:

LE RÔLE DE LA TUBERCULOLOGIE.

Cebal, Jordi G.; Planells, A.; Benito, J.; Parada, J.; Jans, JM.
Hospital Municipal de San Sebastian, Spain

Objectif: Evaluer l'impact de la nouvelle définition du SIDA de la CDC. Etudier les changements que cette définition apporte dans une ville avec une prévalence de tuberculose relativement élevée.

Méthodes: Le Service d'Epidémiologie et de Statistique Visuelle de l'Hôpital de San Sebastian de Barcelone a analysé les cas de SIDA et de tuberculose (incluant la tuberculose oligobactérienne) notifiés par les médecins, et de plus réalisé une recherche active sur les cas de ceux non notifiés sur 1012 cas de SIDA.

Résultats: En 1987, chez les résidents à vie, il y a eu 834 cas de tuberculose (taux d'incidence annuelle (TIA) de 0.02/100,000) et 113 de SIDA (taux de 0.01/100,000) selon l'ancienne définition de la CDC, tandis que en 1988 on a enregistré 943 cas de tuberculose (taux de 0.02/100,000) et 177 de SIDA (taux de 0.04/100,000) selon la nouvelle définition de la CDC.
En 1987, sur les cas de SIDA, 40.3% étaient homosexuels et 38.8% étaient toxicomanes par voie intraveineuse, mais avec la nouvelle définition de la CDC, on a changé cela; en 1988, 58.1% de nouveaux cas de SIDA ont été diagnostiqués chez des toxicomanes par voie intraveineuse. L'incidence de la nouvelle définition a augmenté significativement une augmentation importante des cas de SIDA (28.3% en 1987-88) par rapport à la définition de la CDC, mais le rôle important car le rapport de ces nouveaux cas rapportés par la nouvelle définition (88.4%) correspondait à tuberculose oligobactérienne, cette maladie étant beaucoup plus fréquente que les toxicomanes car ceux-ci ont beaucoup moins de cas (ratio = 4.98, IC = 2.25-10.31). Parmi les cas de SIDA, les toxicomanes en particulier, ont par une fois plus de cas que les toxicomanes (rapport de 27.60 sur une base de 100) (p<.0001) et par avoir été plus fréquemment en prison (ratio = 26.7, IC = 7.32-129.8).

Conclusion: Les nouvelles définitions des toxicomanes par voie intraveineuse par rapport au SIDA à Barcelone, tout spécialement à la tuberculose tuberculeuse. Les difficultés nous ont permis de mieux connaître les cas de SIDA et de mieux comprendre la tuberculose. Ces données nous ont permis d'obtenir à résoudre les efforts afin de développer des nouvelles stratégies face à ce nouveau problème.

T.A.O.5

WASTED OVER TESTING OF CDC DEFINED AIDS CASES DUE TO POOR

UTILIZATION OF THE HIV ANTIBODY TESTING KIT

Oppenheim, A.; Landowman, J.; Kings County Hospital Center and SUNY Health Science Center at Brooklyn, New York, USA

OBJECTIVE: To determine the number of patients who would have received a CDC AIDS diagnosis if HIV antibody testing had been performed.

METHODS: All patients included in this study were in-patients, for at least 24 hours, at a major inner city public hospital between 1/1/88 and 12/31/88. HIV antibody testing was accessible to all patients, but not offered.

RESULTS: During 1988 there were 132 AIDS cases reported to the CDC from the above-cited hospital. During the same period 91 patients were diagnosed with diseases that, along with a positive HIV antibody test, would have qualified for reportable CDC AIDS. Nine of the 91 patients had an HIV antibody test performed. All 91 patients had CDC defined risk factors 33 had prescriptive POP, 33 had prescriptive Nonprescriptive, 7 had prescriptive Syphilis, 1 had prescriptive Candidiasis, 4 had Metastatic Syndrome, 4 had Extra Pulmonary TB, 2 had recurrent Herpetic Stomatitis and 1 had persistent Oropharyngitis.

An additional 7 had at least two of the above stated prescriptive diseases. **CONCLUSION:** the number of reportable CDC AIDS cases would have been increased by more than 40% had HIV antibody testing been performed. Thus 1) lack of inclusion of these cases leads to significant under reporting of the disease; 2) lack of inclusion of these cases results in a decrease in reimbursement to the hospital; 3) lack of a CDC AIDS diagnosis prevents patients from qualifying for greatly needed social services.

T.A.O.7

UNDERREPORTING OF MINORITY AIDS DEATHS IN THE SAN FRANCISCO BAY AREA, 1983-1986

Che, C. K.; Tschering, A.L.;** Hawk, Norman;*, Riosian, N. A.;

**Center for AIDS Prevention Studies, University of California, San Francisco, USA;

*California Department of Health Services, Office of AIDS, Sacramento, USA.

Objective: To determine the completeness of reporting of AIDS deaths among Blacks and Hispanics in the five San Francisco Bay Area counties in 1985 and 1986.

Methods: Death certificates listing AIDS as a cause of death were identified using vital statistics data. Hispanic status was determined using surname and birthplace of both decedent and informant. Deaths were cross-checked with reported cases in the California State AIDS Registry at the Centers for Disease Control AIDS Reporting System current to May 6, 1988.

Results: Overall, 252 deaths were identified from death certificates. Of these, 168 (78.7%) matched with deaths in the AIDS Registry. Non-matches were 15 deaths (6.7%) not listed in the registry at all (Category A in the table), 20 (8.5%) listed in the registry as still living (Category B), and 25 (11.9%) incorrectly listed as being white (Category C). Three deaths were in both of the latter two categories.

Year	Decedent	Identified Non-matches	Category A	Category B	Category C
1985 Blacks	38	7 (18%)	2	4	3
1985 Whites	70	13 (19%)	1	2	7
1985 Hispanics	47	10 (21%)	1	4	3
1986 Hispanics	10	27 (59%)	1	14	14

Conclusion: Minority AIDS deaths may be substantially underreported, even from an area considered to have a good AIDS reporting system. Racial misclassification, especially for Hispanics, may be a major problem. This is the first study to document underreporting in 1985 & 1986. Further data for minorities (including Asians) and data for whites will also be presented.

T.A.0.35 SIMPLIFIED BACKCALCULATIONS FOR THE AIDS EPIDEMIC. Phillip S. Rosenbergh, M. Gail, R. Biggar, J. G. Goedert (National Cancer Institute, Bethesda, Maryland, U.S.A.)

OBJECTIVE: To develop simple backcalculation methods for projecting AIDS incidence and for testing the validity of the natural history model.
METHODS: We extended available methods to permit flexible models of the previous HIV infection rate. We fit these models using efficient regression techniques that were easily implemented on a personal computer.
RESULTS: Our methods provided estimates (with confidence intervals) of important features of the natural history of the epidemic. These include: 1) the cumulative number of persons infected with HIV through 1985 and through the present; 2) the difference between average infection rates in various time periods; and 3) projections of future AIDS incidence. Because these calculations were easily performed, we could also evaluate the sensitivity of estimates to different assumptions about the natural history of AIDS and to other aspects of the analysis. These methods were applied to test cases such as persons with seropositive and seronegative men and yielded results that were compatible with independent epidemiologic data. Using a Weibull time-to-AIDS distribution $f(t) = \lambda \exp(-\lambda t)^{\lambda-1}$ derived from persons with seropositive men and using the currently infected, we project a median prior to 1985 (standard deviation $SD = 975$). The infection rate peaked prior to 1985. We project a median year of infection for the cumulative AIDS incidence through January 1, 1993 of 3,475 (SD 107).
CONCLUSIONS: The computational efficiency and generality of the flexible model improved the assessment of random and systematic errors. Application to other groups may provide important public health insights.

T.A.0.37 EXTRAPOLATING RECENT TRENDS TO MAKE AIDS CASE PROJECTIONS Kathleen M. Deane, Ph.D., Dennis, GJ AIDS Program, Centers for Disease Control, Atlanta, GA, USA

OBJECTIVE: To evaluate extrapolation from recent trends as a procedure for making short-term projections of AIDS cases.
METHODS: Trends in quarterly U.S. AIDS incidence (all cases, adjusted for estimated reporting delay) were modeled using the Box-Cox procedure $(y^2 - 1)/x$ as a polynomial in time = zero.
RESULTS: Parameters were estimated by maximum likelihood.
CONCLUSIONS: Projections of U.S. cases 5 years in the future can be very sensitive to the form of the polynomial chosen (linear or quadratic), and somewhat sensitive to the period during which the trend is modeled.
Period Reporting Predicted Incidence

Model	through 1981	1988	1990	1992	
1/84-6/88	12/88	linear	36,000	47,000	109,000
7/84-6/88	12/88	quadratic	34,000	35,000	20,000
1/84-6/88	12/88	quadratic(1)	25,000	47,000	37,000
7/83-9/87	6/88	linear	40,000	74,000	114,000
7/83-9/87	3/88	linear	36,000	49,000	117,000

Recent estimated (adjusted) incidence continues to increase steadily.
Conclusion: Careful analysis is essential in using extrapolation methods. An arbitrary treatment, such as the log-linear, should not be used. Reporting delays must be estimated carefully because extrapolations are sensitive to changes in recent data. Projections should be accompanied by uncertainty, as indicated by prediction intervals, rather than a single estimate. Projections more than 2 to 3 years in the future should be used with caution.

T.A.0.39 A RISK BEHAVIOR BASED MODEL OF THE CURB GROWTH OF AIDS IN THE UNITED STATES Colin F. Lynch, M.D., Philip A. Stolley, E. A., Byrnes, J. H., Layne, S. F., and Quial, C. C., Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA, *University of New Mexico, Albuquerque, NM, USA

Objective: To understand the spread of HIV in the United States.
Method: The cumulative number of AIDS cases in the United States has grown as the cube of time since 1981, approximately. We explain this by interactions involving partner choice and sexual risk behavior model with biased mixing. This leads to a saturation where of infection moving from high to low risk groups. The model assumes that the distribution of people according to risk behavior that puts one at risk of infection) decays slowly, with a significant fraction of the population engaging in high-risk activities. It assumes that people with similar risk behavior tend to interact primarily among themselves (biased mixing) rather than equally with others (homogeneous mixing). The model incorporates epidemiological data on the total AIDS cases and on the progression from initial HIV infection to AIDS.
Results: The decreasing growth rate of AIDS cases through 1988 was not due to changes in behavior, but rather it was due to the intrinsic dynamics of the disease. The total number of persons infected with HIV in the U.S. in 1988 was approximately 1.5 million. The average duration of infection for new AIDS cases is increasing. The mean risk behavior for people being infected with HIV is decreasing. The model is consistent with a mean period of transmission per sexual contact between 0.001 and 0.004. An increase in infectivity during the earliest stages of HIV infection could increase the infectivity during the remainder of the infection. Behavior modification could reduce it.

T.A.0.36 STATISTICAL ANALYSIS OF THE STAGES OF HIV INFECTION USING A MARKOV MODEL

Levy, G.F. ¹, Liska, J., ², Clark, W.S. ¹, Berenson, G.S. ¹,
¹Hyatt, R.H. ¹, ²Berry, A.C. ², ³Wright, R.C. ³, ⁴Wright, R.C. ⁴,
⁵University of Alabama, ⁶Atlanta, GA, ⁷AIDS Program, CDC, Atlanta, GA, USA,
⁸AIDS Office, Department of Health, San Francisco, CA, USA.

Objective: Persons infected with HIV pass through a progression of stages from initially infected to death. We have estimated the waiting time distribution for each stage of infection. From these estimates, we specify the probability distributions of the AIDS incubation period, pre-HIV-antibody period, and stage-specific survival times.
Method: The natural history of HIV was modeled by a Markov process with the following five stages: 1) incident AIDS; 2) antibody negative; 3) antibody positive but asymptomatic; 4) pre-AIDS symptoms and/or an abnormal lymphocyte count; 5) clinical AIDS; 6) death. This five-stage model was fitted to censored data from a cohort of 505 HIV-infected of 505 individuals.
Results: From the fitted model, the estimated mean waiting times in each stage are the following: Stage 1, 2.6 months; stage 2, 62.6 months; stage 3, 62.9 months; and stage 4, 23.6 months. The 95% confidence interval (CI) for the mean pre-HIV-antibody period (waiting time in stage 1) is [2.2, 3.0] months. The mean AIDS incubation period (from infection to the development of AIDS) is estimated to be 9.9 years with a 95% CI of [8.4, 11.2] years. The median survival time (waiting time in stage 5) is [1.0, 1.1] years. The median survival times for stages 2, 3 and 4 are estimated to be 10.3, 10.1, 5.8 and 1.4 years, respectively.
Conclusion: A staged Markov model can be used to efficiently estimate important statistical descriptors of the natural history of HIV.

T.A.0.38 MODEL-BASED OPTIMIZATION OF INFECTIVITY PARAMETERS Alagna David, J., Gerry K. Ke, Scott A. ¹, ²Timothy Collier, Hartford, CT 06106, ³NYU Medical Center, New York, NY 10016, U.S.A.

Objective: To develop a non-linear optimization program which computes values of key epidemiological parameters; 2) determine whether seroconversion and case rates among male homosexual/bisexuals in San Francisco during 1978-1986 vary among five (V) among three stages of infection (early antigen; antibody positive; AIDS); 3) compare V based projections to projections that assume equal infectivity (E) of the three stages; 4) determine if V holds when simulated numbers of partners and contacts are changed significantly (50%); 5) determine if V holds for two contact models (sequential means model and total contacts model).
Methods: The optimization program minimizes the difference between simulated case rate and seroconversion fraction rates and data reported by the San Francisco Hepatitis B cohort study. Six parameters are optimized: 1) per contact transmission probabilities for each stage; 2) duration of initial fraction in the early antigen stage; 3) delay time from seroconversion to AIDS; the cumulative fraction to AIDS vs. time since seroconversion is approximated closely by a 5th-order exponential delay.
Results: Over a wide range of simulated numbers of partners and contacts, case rate and seroconversion fraction data are matched using V. Best fit optimal parameter values are: 1) contact probabilities—early antigen: 0.0026, antibody positive: 0.0045, AIDS: 0.06; 2) initial fraction in early antigen stage 0.00045; 3) delay from seroconversion to AIDS 5.07 years; 4) duration of early antigen stage 12 months. With E the (single) optimized contact rate is 0.00045 (E) is too low for the early antigen and AIDS stages, but too high for the antibody-positive stage. The case rate curve due to the model using E, but the seroconversion fraction curve rises too slowly during 1978-82 and falls too slowly after 1982. V thus predicts a less severe epidemic than E1, but V holds for both contact models.
Conclusion: High infectivity of the first stage suggests antigen screening in high risk groups.

T.A.0.40 HIV, SEX & HIV: A MATHEMATICAL MODEL FOR NEW YORK CITY Gowenlock, J. M., ¹ Gwinn, J. M., ² State, J. A., ³ ⁴ ⁵ ⁶ ⁷ ⁸ ⁹ ¹⁰ ¹¹ ¹² ¹³ ¹⁴ ¹⁵ ¹⁶ ¹⁷ ¹⁸ ¹⁹ ²⁰ ²¹ ²² ²³ ²⁴ ²⁵ ²⁶ ²⁷ ²⁸ ²⁹ ³⁰ ³¹ ³² ³³ ³⁴ ³⁵ ³⁶ ³⁷ ³⁸ ³⁹ ⁴⁰ ⁴¹ ⁴² ⁴³ ⁴⁴ ⁴⁵ ⁴⁶ ⁴⁷ ⁴⁸ ⁴⁹ ⁵⁰ ⁵¹ ⁵² ⁵³ ⁵⁴ ⁵⁵ ⁵⁶ ⁵⁷ ⁵⁸ ⁵⁹ ⁶⁰ ⁶¹ ⁶² ⁶³ ⁶⁴ ⁶⁵ ⁶⁶ ⁶⁷ ⁶⁸ ⁶⁹ ⁷⁰ ⁷¹ ⁷² ⁷³ ⁷⁴ ⁷⁵ ⁷⁶ ⁷⁷ ⁷⁸ ⁷⁹ ⁸⁰ ⁸¹ ⁸² ⁸³ ⁸⁴ ⁸⁵ ⁸⁶ ⁸⁷ ⁸⁸ ⁸⁹ ⁹⁰ ⁹¹ ⁹² ⁹³ ⁹⁴ ⁹⁵ ⁹⁶ ⁹⁷ ⁹⁸ ⁹⁹ ¹⁰⁰ ¹⁰¹ ¹⁰² ¹⁰³ ¹⁰⁴ ¹⁰⁵ ¹⁰⁶ ¹⁰⁷ ¹⁰⁸ ¹⁰⁹ ¹¹⁰ ¹¹¹ ¹¹² ¹¹³ ¹¹⁴ ¹¹⁵ ¹¹⁶ ¹¹⁷ ¹¹⁸ ¹¹⁹ ¹²⁰ ¹²¹ ¹²² ¹²³ ¹²⁴ ¹²⁵ ¹²⁶ ¹²⁷ ¹²⁸ ¹²⁹ ¹³⁰ ¹³¹ ¹³² ¹³³ ¹³⁴ ¹³⁵ ¹³⁶ ¹³⁷ ¹³⁸ ¹³⁹ ¹⁴⁰ ¹⁴¹ ¹⁴² ¹⁴³ ¹⁴⁴ ¹⁴⁵ ¹⁴⁶ ¹⁴⁷ ¹⁴⁸ ¹⁴⁹ ¹⁵⁰ ¹⁵¹ ¹⁵² ¹⁵³ ¹⁵⁴ ¹⁵⁵ ¹⁵⁶ ¹⁵⁷ ¹⁵⁸ ¹⁵⁹ ¹⁶⁰ ¹⁶¹ ¹⁶² ¹⁶³ ¹⁶⁴ ¹⁶⁵ ¹⁶⁶ ¹⁶⁷ ¹⁶⁸ ¹⁶⁹ ¹⁷⁰ ¹⁷¹ ¹⁷² ¹⁷³ ¹⁷⁴ ¹⁷⁵ ¹⁷⁶ ¹⁷⁷ ¹⁷⁸ ¹⁷⁹ ¹⁸⁰ ¹⁸¹ ¹⁸² ¹⁸³ ¹⁸⁴ ¹⁸⁵ ¹⁸⁶ ¹⁸⁷ ¹⁸⁸ ¹⁸⁹ ¹⁹⁰ ¹⁹¹ ¹⁹² ¹⁹³ ¹⁹⁴ ¹⁹⁵ ¹⁹⁶ ¹⁹⁷ ¹⁹⁸ ¹⁹⁹ ²⁰⁰ ²⁰¹ ²⁰² ²⁰³ ²⁰⁴ ²⁰⁵ ²⁰⁶ ²⁰⁷ ²⁰⁸ ²⁰⁹ ²¹⁰ ²¹¹ ²¹² ²¹³ ²¹⁴ ²¹⁵ ²¹⁶ ²¹⁷ ²¹⁸ ²¹⁹ ²²⁰ ²²¹ ²²² ²²³ ²²⁴ ²²⁵ ²²⁶ ²²⁷ ²²⁸ ²²⁹ ²³⁰ ²³¹ ²³² ²³³ ²³⁴ ²³⁵ ²³⁶ ²³⁷ ²³⁸ ²³⁹ ²⁴⁰ ²⁴¹ ²⁴² ²⁴³ ²⁴⁴ ²⁴⁵ ²⁴⁶ ²⁴⁷ ²⁴⁸ ²⁴⁹ ²⁵⁰ ²⁵¹ ²⁵² ²⁵³ ²⁵⁴ ²⁵⁵ ²⁵⁶ ²⁵⁷ ²⁵⁸ ²⁵⁹ ²⁶⁰ ²⁶¹ ²⁶² ²⁶³ ²⁶⁴ ²⁶⁵ ²⁶⁶ ²⁶⁷ ²⁶⁸ ²⁶⁹ ²⁷⁰ ²⁷¹ ²⁷² ²⁷³ ²⁷⁴ ²⁷⁵ ²⁷⁶ ²⁷⁷ ²⁷⁸ ²⁷⁹ ²⁸⁰ ²⁸¹ ²⁸² ²⁸³ ²⁸⁴ ²⁸⁵ ²⁸⁶ ²⁸⁷ ²⁸⁸ ²⁸⁹ ²⁹⁰ ²⁹¹ ²⁹² ²⁹³ ²⁹⁴ ²⁹⁵ ²⁹⁶ ²⁹⁷ ²⁹⁸ ²⁹⁹ ³⁰⁰ ³⁰¹ ³⁰² ³⁰³ ³⁰⁴ ³⁰⁵ ³⁰⁶ ³⁰⁷ ³⁰⁸ ³⁰⁹ ³¹⁰ ³¹¹ ³¹² ³¹³ ³¹⁴ ³¹⁵ ³¹⁶ ³¹⁷ ³¹⁸ ³¹⁹ ³²⁰ ³²¹ ³²² ³²³ ³²⁴ ³²⁵ ³²⁶ ³²⁷ ³²⁸ ³²⁹ ³³⁰ ³³¹ ³³² ³³³ ³³⁴ ³³⁵ ³³⁶ ³³⁷ ³³⁸ ³³⁹ ³⁴⁰ ³⁴¹ ³⁴² ³⁴³ ³⁴⁴ ³⁴⁵ ³⁴⁶ ³⁴⁷ ³⁴⁸ ³⁴⁹ ³⁵⁰ ³⁵¹ ³⁵² ³⁵³ ³⁵⁴ ³⁵⁵ ³⁵⁶ ³⁵⁷ ³⁵⁸ ³⁵⁹ ³⁶⁰ ³⁶¹ ³⁶² ³⁶³ ³⁶⁴ ³⁶⁵ ³⁶⁶ ³⁶⁷ ³⁶⁸ ³⁶⁹ ³⁷⁰ ³⁷¹ ³⁷² ³⁷³ ³⁷⁴ ³⁷⁵ ³⁷⁶ ³⁷⁷ ³⁷⁸ ³⁷⁹ ³⁸⁰ ³⁸¹ ³⁸² ³⁸³ ³⁸⁴ ³⁸⁵ ³⁸⁶ ³⁸⁷ ³⁸⁸ ³⁸⁹ ³⁹⁰ ³⁹¹ ³⁹² ³⁹³ ³⁹⁴ ³⁹⁵ ³⁹⁶ ³⁹⁷ ³⁹⁸ ³⁹⁹ ⁴⁰⁰ ⁴⁰¹ ⁴⁰² ⁴⁰³ ⁴⁰⁴ ⁴⁰⁵ ⁴⁰⁶ ⁴⁰⁷ ⁴⁰⁸ ⁴⁰⁹ ⁴¹⁰ ⁴¹¹ ⁴¹² ⁴¹³ ⁴¹⁴ ⁴¹⁵ ⁴¹⁶ ⁴¹⁷ ⁴¹⁸ ⁴¹⁹ ⁴²⁰ ⁴²¹ ⁴²² ⁴²³ ⁴²⁴ ⁴²⁵ ⁴²⁶ ⁴²⁷ ⁴²⁸ ⁴²⁹ ⁴³⁰ ⁴³¹ ⁴³² ⁴³³ ⁴³⁴ ⁴³⁵ ⁴³⁶ ⁴³⁷ ⁴³⁸ ⁴³⁹ ⁴⁴⁰ ⁴⁴¹ ⁴⁴² ⁴⁴³ ⁴⁴⁴ ⁴⁴⁵ ⁴⁴⁶ ⁴⁴⁷ ⁴⁴⁸ ⁴⁴⁹ ⁴⁵⁰ ⁴⁵¹ ⁴⁵² ⁴⁵³ ⁴⁵⁴ ⁴⁵⁵ ⁴⁵⁶ ⁴⁵⁷ ⁴⁵⁸ ⁴⁵⁹ ⁴⁶⁰ ⁴⁶¹ ⁴⁶² ⁴⁶³ ⁴⁶⁴ ⁴⁶⁵ ⁴⁶⁶ ⁴⁶⁷ ⁴⁶⁸ ⁴⁶⁹ ⁴⁷⁰ ⁴⁷¹ ⁴⁷² ⁴⁷³ ⁴⁷⁴ ⁴⁷⁵ ⁴⁷⁶ ⁴⁷⁷ ⁴⁷⁸ ⁴⁷⁹ ⁴⁸⁰ ⁴⁸¹ ⁴⁸² ⁴⁸³ ⁴⁸⁴ ⁴⁸⁵ ⁴⁸⁶ ⁴⁸⁷ ⁴⁸⁸ ⁴⁸⁹ ⁴⁹⁰ ⁴⁹¹ ⁴⁹² ⁴⁹³ ⁴⁹⁴ ⁴⁹⁵ ⁴⁹⁶ ⁴⁹⁷ ⁴⁹⁸ ⁴⁹⁹ ⁵⁰⁰ ⁵⁰¹ ⁵⁰² ⁵⁰³ ⁵⁰⁴ ⁵⁰⁵ ⁵⁰⁶ ⁵⁰⁷ ⁵⁰⁸ ⁵⁰⁹ ⁵¹⁰ ⁵¹¹ ⁵¹² ⁵¹³ ⁵¹⁴ ⁵¹⁵ ⁵¹⁶ ⁵¹⁷ ⁵¹⁸ ⁵¹⁹ ⁵²⁰ ⁵²¹ ⁵²² ⁵²³ ⁵²⁴ ⁵²⁵ ⁵²⁶ ⁵²⁷ ⁵²⁸ ⁵²⁹ ⁵³⁰ ⁵³¹ ⁵³² ⁵³³ ⁵³⁴ ⁵³⁵ ⁵³⁶ ⁵³⁷ ⁵³⁸ ⁵³⁹ ⁵⁴⁰ ⁵⁴¹ ⁵⁴² ⁵⁴³ ⁵⁴⁴ ⁵⁴⁵ ⁵⁴⁶ ⁵⁴⁷ ⁵⁴⁸ ⁵⁴⁹ ⁵⁵⁰ ⁵⁵¹ ⁵⁵² ⁵⁵³ ⁵⁵⁴ ⁵⁵⁵ ⁵⁵⁶ ⁵⁵⁷ ⁵⁵⁸ ⁵⁵⁹ ⁵⁶⁰ ⁵⁶¹ ⁵⁶² ⁵⁶³ ⁵⁶⁴ ⁵⁶⁵ ⁵⁶⁶ ⁵⁶⁷ ⁵⁶⁸ ⁵⁶⁹ ⁵⁷⁰ ⁵⁷¹ ⁵⁷² ⁵⁷³ ⁵⁷⁴ ⁵⁷⁵ ⁵⁷⁶ ⁵⁷⁷ ⁵⁷⁸ ⁵⁷⁹ ⁵⁸⁰ ⁵⁸¹ ⁵⁸² ⁵⁸³ ⁵⁸⁴ ⁵⁸⁵ ⁵⁸⁶ ⁵⁸⁷ ⁵⁸⁸ ⁵⁸⁹ ⁵⁹⁰ ⁵⁹¹ ⁵⁹² ⁵⁹³ ⁵⁹⁴ ⁵⁹⁵ ⁵⁹⁶ ⁵⁹⁷ ⁵⁹⁸ ⁵⁹⁹ ⁶⁰⁰ ⁶⁰¹ ⁶⁰² ⁶⁰³ ⁶⁰⁴ ⁶⁰⁵ ⁶⁰⁶ ⁶⁰⁷ ⁶⁰⁸ ⁶⁰⁹ ⁶¹⁰ ⁶¹¹ ⁶¹² ⁶¹³ ⁶¹⁴ ⁶¹⁵ ⁶¹⁶ ⁶¹⁷ ⁶¹⁸ ⁶¹⁹ ⁶²⁰ ⁶²¹ ⁶²² ⁶²³ ⁶²⁴ ⁶²⁵ ⁶²⁶ ⁶²⁷ ⁶²⁸ ⁶²⁹ ⁶³⁰ ⁶³¹ ⁶³² ⁶³³ ⁶³⁴ ⁶³⁵ ⁶³⁶ ⁶³⁷ ⁶³⁸ ⁶³⁹ ⁶⁴⁰ ⁶⁴¹ ⁶⁴² ⁶⁴³ ⁶⁴⁴ ⁶⁴⁵ ⁶⁴⁶ ⁶⁴⁷ ⁶⁴⁸ ⁶⁴⁹ ⁶⁵⁰ ⁶⁵¹ ⁶⁵² ⁶⁵³ ⁶⁵⁴ ⁶⁵⁵ ⁶⁵⁶ ⁶⁵⁷ ⁶⁵⁸ ⁶⁵⁹ ⁶⁶⁰ ⁶⁶¹ ⁶⁶² ⁶⁶³ ⁶⁶⁴ ⁶⁶⁵ ⁶⁶⁶ ⁶⁶⁷ ⁶⁶⁸ ⁶⁶⁹ ⁶⁷⁰ ⁶⁷¹ ⁶⁷² ⁶⁷³ ⁶⁷⁴ ⁶⁷⁵ ⁶⁷⁶ ⁶⁷⁷ ⁶⁷⁸ ⁶⁷⁹ ⁶⁸⁰ ⁶⁸¹ ⁶⁸² ⁶⁸³ ⁶⁸⁴ ⁶⁸⁵ ⁶⁸⁶ ⁶⁸⁷ ⁶⁸⁸ ⁶⁸⁹ ⁶⁹⁰ ⁶⁹¹ ⁶⁹² ⁶⁹³ ⁶⁹⁴ ⁶⁹⁵ ⁶⁹⁶ ⁶⁹⁷ ⁶⁹⁸ ⁶⁹⁹ ⁷⁰⁰ ⁷⁰¹ ⁷⁰² ⁷⁰³ ⁷⁰⁴ ⁷⁰⁵ ⁷⁰⁶ ⁷⁰⁷ ⁷⁰⁸ ⁷⁰⁹ ⁷¹⁰ ⁷¹¹ ⁷¹² ⁷¹³ ⁷¹⁴ ⁷¹⁵ ⁷¹⁶ ⁷¹⁷ ⁷¹⁸ ⁷¹⁹ ⁷²⁰ ⁷²¹ ⁷²² ⁷²³ ⁷²⁴ ⁷²⁵ ⁷²⁶ ⁷²⁷ ⁷²⁸ ⁷²⁹ ⁷³⁰ ⁷³¹ ⁷³² ⁷³³ ⁷³⁴ ⁷³⁵ ⁷³⁶ ⁷³⁷ ⁷³⁸ ⁷³⁹ ⁷⁴⁰ ⁷⁴¹ ⁷⁴² ⁷⁴³ ⁷⁴⁴ ⁷⁴⁵ ⁷⁴⁶ ⁷⁴⁷ ⁷⁴⁸ ⁷⁴⁹ ⁷⁵⁰ ⁷⁵¹ ⁷⁵² ⁷⁵³ ⁷⁵⁴ ⁷⁵⁵ ⁷⁵⁶ ⁷⁵⁷ ⁷⁵⁸ ⁷⁵⁹ ⁷⁶⁰ ⁷⁶¹ ⁷⁶² ⁷⁶³ ⁷⁶⁴ ⁷⁶⁵ ⁷⁶⁶ ⁷⁶⁷ ⁷⁶⁸ ⁷⁶⁹ ⁷⁷⁰ ⁷⁷¹ ⁷⁷² ⁷⁷³ ⁷⁷⁴ ⁷⁷⁵ ⁷⁷⁶ ⁷⁷⁷ ⁷⁷⁸ ⁷⁷⁹ ⁷⁸⁰ ⁷⁸¹ ⁷⁸² ⁷⁸³ ⁷⁸⁴ ⁷⁸⁵ ⁷⁸⁶ ⁷⁸⁷ ⁷⁸⁸ ⁷⁸⁹ ⁷⁹⁰ ⁷⁹¹ ⁷⁹² ⁷⁹³ ⁷⁹⁴ ⁷⁹⁵ ⁷⁹⁶ ⁷⁹⁷ ⁷⁹⁸ ⁷⁹⁹ ⁸⁰⁰ ⁸⁰¹ ⁸⁰² ⁸⁰³ ⁸⁰⁴ ⁸⁰⁵ ⁸⁰⁶ ⁸⁰⁷ ⁸⁰⁸ ⁸⁰⁹ ⁸¹⁰ ⁸¹¹ ⁸¹² ⁸¹³ ⁸¹⁴ ⁸¹⁵ ⁸¹⁶ ⁸¹⁷ ⁸¹⁸ ⁸¹⁹ ⁸²⁰ ⁸²¹ ⁸²² ⁸²³ ⁸²⁴ ⁸²⁵ ⁸²⁶ ⁸²⁷ ⁸²⁸ ⁸²⁹ ⁸³⁰ ⁸³¹ ⁸³² ⁸³³ ⁸³⁴ ⁸³⁵ ⁸³⁶ ⁸³⁷ ⁸³⁸ ⁸³⁹ ⁸⁴⁰ ⁸⁴¹ ⁸⁴² ⁸⁴³ ⁸⁴⁴ ⁸⁴⁵ ⁸⁴⁶ ⁸⁴⁷ ⁸⁴⁸ ⁸⁴⁹ ⁸⁵⁰ ⁸⁵¹ ⁸⁵² ⁸⁵³ ⁸⁵⁴ ⁸⁵⁵ ⁸⁵⁶ ⁸⁵⁷ ⁸⁵⁸ ⁸⁵⁹ ⁸⁶⁰ ⁸⁶¹ ⁸⁶² ⁸⁶³ ⁸⁶⁴ ⁸⁶⁵ ⁸⁶⁶ ⁸⁶⁷ ⁸⁶⁸ ⁸⁶⁹ ⁸⁷⁰ ⁸⁷¹ ⁸⁷² ⁸⁷³ ⁸⁷⁴ ⁸⁷⁵ ⁸⁷⁶ ⁸⁷⁷ ⁸⁷⁸ ⁸⁷⁹ ⁸⁸⁰ ⁸⁸¹ ⁸⁸² ⁸⁸³ ⁸⁸⁴ ⁸⁸⁵ ⁸⁸⁶ ⁸⁸⁷ ⁸⁸⁸ ⁸⁸⁹ ⁸⁹⁰ ⁸⁹¹ ⁸⁹² ⁸⁹³ ⁸⁹⁴ ⁸⁹⁵ ⁸⁹⁶ ⁸⁹⁷ ⁸⁹⁸ ⁸⁹⁹ ⁹⁰⁰ ⁹⁰¹ ⁹⁰² ⁹⁰³ ⁹⁰⁴ ⁹⁰⁵ ⁹⁰⁶ ⁹⁰⁷ ⁹⁰⁸ ⁹⁰⁹ ⁹¹⁰ ⁹¹¹ ⁹¹² ⁹¹³ ⁹¹⁴ ⁹¹⁵ ⁹¹⁶ ⁹¹⁷ ⁹¹⁸ ⁹¹⁹ ⁹²⁰ ⁹²¹ ⁹²² ⁹²³ ⁹²⁴ ⁹²⁵ ⁹²⁶ ⁹²⁷ ⁹²⁸ ⁹²⁹ ⁹³⁰ ⁹³¹ ⁹³² ⁹³³ ⁹³⁴ ⁹³⁵ ⁹³⁶ ⁹³⁷ ⁹³⁸ ⁹³⁹ ⁹⁴⁰ ⁹⁴¹ ⁹⁴² ⁹⁴³ ⁹⁴⁴ ⁹⁴⁵ ⁹⁴⁶ ⁹⁴⁷ ⁹⁴⁸ ⁹⁴⁹ ⁹⁵⁰ ⁹⁵¹ ⁹⁵² ⁹⁵³ ⁹⁵⁴ ⁹⁵⁵ ⁹⁵⁶ ⁹⁵⁷ ⁹⁵⁸ ⁹⁵⁹ ⁹⁶⁰ ⁹⁶¹ ⁹⁶² ⁹⁶³ ⁹⁶⁴ ⁹⁶⁵ ⁹⁶⁶ ⁹⁶⁷ ⁹⁶⁸ ⁹⁶⁹ ⁹⁷⁰ ⁹⁷¹ ⁹⁷² ⁹⁷³ ⁹⁷⁴ ⁹⁷⁵ ⁹⁷⁶ ⁹⁷⁷

Transmission du VIH dans le milieu des soins de la santé HIV Transmission in the Health Care Setting

W.A.0.1 HEALTH-CARE WORKERS EXPOSED TO PATIENTS INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV), UNITED STATES.
Bakken, Rulhagen* and the Cooperative Research
Surveillance Group, *Centers for Disease Control, Atlanta, GA, USA

Objective: To estimate the risk of HIV infection in health-care workers (HCWs) exposed to blood of persons infected with HIV.
Methods: HCWs from over 300 health-care institutions throughout the United States who have parenteral, mucous-membrane, or non-intact skin exposures to the blood of persons infected with HIV are tested for HIV antibody at baseline, 6 weeks, 3, 6, and 12 months after exposure. On entry epidemiologic data and confidential risk factor information are collected from each HCW.

Results: As of December 31, 1988, 1107 HCWs were tested at least 6 months after exposure. Of 992 HCWs with needlesticks (n=898) or cuts with sharp objects (n=84), 4 were positive for HIV antibody (4.982 ± 0.413; upper bound of 95% confidence interval) (CI) 0.39%. One HCW had no baseline specimen available for testing, and thus occupational acquisition could not be determined. The remaining three workers received a needlestick injury, experienced an acute retroviral syndrome, and seroconverted to HIV within 6 months postexposure. One of these HCWs who seroconverted was injured by a co-worker during a resuscitation procedure. Of the remaining 123 HCWs with blood contamination (n=53) or broken skin (n=72), none seroconverted (0.133-0% upper bound of 95% CI).
Conclusions: In this ongoing surveillance of HCWs exposed to HIV-infected blood, the risk of seroconversion following parenteral exposure has completely remained less than 1%. Efforts must be made to prevent exposure to blood to further minimize the risk of HIV transmission to HCWs.

W.A.0.3 PREVALENCE OF HIV INFECTION AMONG PERSONS EMPLOYED IN MEDICINE AND HEALTH OCCUPATIONS

Coast Line and the Water Head Research Group
Water Head Army Institute of USA

Objective: To examine the association between employment in Medicine and Health (M+H) occupations and infection with HIV.

Methods: Test results for HIV-Ab have been received on 545,114 US Army Reserve Component personnel. These individuals spent about 10% of their time in a military environment, and are employed in civilian occupations.

Results: When stratified by Dept of Labor occupational categories, those employed in the medicine and health (M+H) field had a prevalence of 2.48 (per 1000), versus 1.51 for those not so employed. The 2387 white, black, and Hispanic male and female physicians and dentists were all HIV-Ab negative. The prevalence among white females (n=409) in M+H jobs was 0.20, compared to 0.20 for those in other occupations. The prevalence for black females in M+H occupations (n=174) was 1.22, and 1.84 in other occupations. Among white and black single males, the prevalence was significantly higher for registered nurses (RN), medical technicians (MT), and not otherwise specified medical occupations (NOS). The prevalence among single white males was 7.50, and the prevalence rate (95% and 99% confidence interval), versus those not employed in M+H occupations, was 2.26 (3.71, 14.21) in single white males, prevalence was 3.50, with a P of 4.76 (2.80, 7.82). Prevalence was not significantly higher for 4599 ever-married black, white, and Hispanic males employed in RN, MT, or NOS jobs, nor among 2726 ever- and never-married black, white, and Hispanic males in all other M+H fields.
Conclusions: The higher prevalence associated with employment in M+H fields is largely restricted to single white and black males employed in the RN, MT, or NOS areas. The absolute prevalence is much higher among single black males, but the P is higher for single white males. These patterns of HIV infection do not support the hypothesis of an occupational risk of infection that is doseless by prevalence surveys.

W.A.0.5 NOSOCOMIAL OUTBREAK OF HIV INFECTION IN ELISTA, USSR

V.V. Pokrovskiy, E.U. Eranova
Central Institute of Epidemiology, Moscow, USSR

A total of 41 out of 2504 children and 8 of 116 mothers of children who had been admitted to the Elista (Kalmykia Republic, USSR) during the period from May until December 1988 were HIV antibody positive by ELISA and Western Blot testing. No other HIV infection was identified among 20,000 inhabitants of Elista including 948 hospital workers and 1012 members of families of infected persons. The sexual partners of the 8 infected women were HIV positive. This man lived and was possibly the source of infection in his 1988 and is thought to have been the first infant in a chain of HIV infection. Other seropositive children are assumed to have been infected during overlapping admissions to the hospital. The virus appears to have been transmitted in hospital by the use of one syringe into which blood was aspirated between intravenous injections. Four mothers for whom no risk factors were identified appear to have become HIV infected through their children. It is suggested that the virus was transmitted from bleeding oral lesions in children treated with doses of penicillin to bleeding fissures on mothers' breasts during breast feeding. Results of the final analysis of the investigation will be reported.

W.A.0.2 SURVEILLANCE UPDATE: HEALTH-CARE WORKERS WITH AIDS
Chamberland, Harry* Center, L. F. Furb, T. J. Jaffe, R. A.,
*Centers for Disease Control (CDC), Atlanta, GA, USA

Objective: To characterize health-care workers (HCWs) with AIDS in the United States and evaluate the role of occupational transmission of HIV.
Methods: HCW with AIDS reported to CDC who have no identified risk (NIR) are investigated by health departments using a standard protocol.
Results: As of January 15, 1989, 3,350 HCW with AIDS had been reported. HCW were less likely than other AIDS patients to report IV drug use (72 vs 812, p<0.001) and more likely to report male homosexual contact (73 vs 612, p<0.001) or have NIR (41 vs 35, p<0.001). One HCW with AIDS had a documented seroconversion to HIV after a needlestick exposure to blood from an AIDS patient. Of the 203 HCW with NIR, 125 (61%) are under investigation; 30 (15%) died, refused interview or were lost to follow-up; with the 6.8 million HCW in the U.S., the 48 investigated HCW with NIR were more likely to be black (442 vs 131) and less likely to be women (292 vs 772). They comprised 8 physicians, 1 dentist, 3 nurses, 1 paramedic, 11 aides/orderlies, 2 respiratory therapists, 5 clinical lab technicians, 9 maintenance workers, 2 morticians, and 4 others with no patient contact. Twenty (42%) of the 48 HCW reported needlestick and/or mucous membrane or non-intact skin exposure to blood or other body fluids; in none was the HIV status of the patient known.
Conclusion: Most HCWs have an identified risk for HIV infection; the others probably represent a mix of persons with unreported behavioral risk factors or unrecognized occupational exposures.

W.A.0.4 ADVANCEMENT TO UNIVERSAL PRECAUTIONS BY HCWs IN AN EMERGENCY DEPARTMENT
Nelson, Robert; Dismore, T.; Baltimore, D.; Wilson, L. Scott C.
Johns Hopkins University School of Medicine, Baltimore, Maryland, USA

Objective: To assess adherence to "Universal Precautions" (UP) among health care workers (HCWs) in an emergency department (ED) with high prevalence (6.0%) of HIV among its patient population.

Methods: We prospectively observed 124 HCWs performing 1274 interventions on departmental inpatients requiring rigid interventions. Institution-wide and 13 hospital-wide patient interventions on UP were held for HCWs throughout the year prior to the initiation of the study. Interventions were classified as major (42.3%) or minor (57.4%) depending on the potential for exposure.
Results: Overall adherence was adequate during 16.5% of major interventions and 44.4% of minor interventions (p<0.05). During minor interventions, adherence to UP was 58.8% (p<0.05). In the presence of protease bleeders, adherence during 0.0% in non-trauma presentations (p<0.05). During major procedures, adherence was 34.0% with traumatic presentations and 0.4% with non-trauma presentations (p<0.05). The overall adherence rate for HCWs was: Residents 58%; Attending 38%; Consultants 43%; Nursing staff 44%; Physicians 49%; Technicians 14% and Homologous 51%. Mean precautions were inadequate, surgical masks were used least (22.4%), followed by eye protection (45.0%), gowns (49.4%) and gloves (73.7%). A questionnaire administered following the study period revealed that protective materials (47%) and interference in performance of procedure (31%).
Conclusion: HCW in this setting are not taking adequate precautions. Other strategies for implementing Universal Precautions need to be developed.

AGE AIDS CASES AMONG HOMOSEXUAL MALES LEVELLING?
Berkelman, Ralph; Karon, J.; Thomas, P.;* Rensd, P.;**
Berkman, R.;***, San Francisco, CA

*Centers for Disease Control, Atlanta; **New York City (NYC) Dept. of Health; ***Los Angeles (LA) Co. Health Dept.

Objective: To analyze trends in reported cases of AIDS among homosexual and bisexual males in two metropolitan areas of the U.S.
Methods: We analyzed AIDS cases in NYC, SF, and LA and the rest of the U.S. among homosexual and bisexual (HB) without intravenous drug use (IVDU) from 1981 through 1988 by 6-month intervals, by race, by date of diagnosis, adjusting for reporting delay and by date of report.
Results: The rate of increase for reported AIDS cases among HB has slowed in the U.S., earlier in NY, SF, and NYC (by 1987) than in the rest of the U.S.; the slowing has occurred in HB and other races in most areas.
Percent change from previous 6 mo. period in AIDS among HB (no. IVDU)

City	1984(1) (2)		1985(1) (2)		1986(1) (2)		1987(1) (2)		1988 (1) (2)	
	1	2	1	2	1	2	1	2	1	2
New York City	+32	+4	+26	+17	+2	-	-	-	+11	-
Los Angeles	+46	+28	+31	+14	0	-	-	-	-	-
San Francisco	+30	+16	+28	+10	-2	-	-	-	+10	-
U.S. (other)	+20	+18	+29	+24	+11	-	-	-	-	-

When analyzed by date of report, leveling is less apparent.
Conclusion: Reported AIDS cases among HB males are leveling across the U.S., noted earlier in selected metropolitan areas. Underreporting differences in medical practices, early saturation of infection, and behavioral changes should each be evaluated as contributing factors.

W.A.0.15

SURVEILLANCE OF HETEROSEXUALLY ACQUIRED AIDS, U.S.A.
Chagnard, Marc; Conley, L.;* Boulier, J.P.
Centers for Disease Control, Atlanta, Ga., USA

Objective: To monitor temporal and demographic trends in the United States for adults with heterosexually acquired (HA)-AIDS.
Methods: HA-AIDS cases reported to CDC include heterosexual partners (Certificate of IVDR) and individuals who (1) report sexual contact (SC) with a person with or at increased risk for HIV infection or (2) were born in areas with high rates of HIV-1 infection, such as Haiti or Africa.
Results: As of January 16, 1989, 3454 HA-AIDS cases were reported: 2390 (69%) in persons with SC and 1064 (31%) in persons from endemic countries (68% of whom were Haitian). Although the proportion of HA-AIDS cases has remained relatively stable (ranging from 5.2% of all adults reported in 1983 to 4.8% in 1988), the composition of the group has changed: Haitians/Africans accounted for 79% of the 107 HA cases reported in 1983, but only 25% of the 1943 cases in 1988. Excluding homosexual men, SC cases have increased from 0.5% of men with AIDS reported in 1983 to 3.2% in 1988 (p<0.001) and from 14.8% of women to 23.6% (p<0.001). Most SC cases continue to be women (75%) and blacks or Hispanic (78%). Among SC cases, women are significantly younger than men (34 years vs 40 years, mean age). Both men and women reported SC with IV-drug users with equal frequency (1:2). Men who reported SC were less likely than women (18% vs 43%) to be in New York or New Jersey, which account for 63% of AIDS cases in heterosexual IV-drug users.
Conclusion: HA-AIDS remains largely focused in demographically distinct population groups. The proportion attributable to SC is increasing.

W.A.0.17

NATIONAL SURVEILLANCE OF PERINATALLY-ACQUIRED AIDS, USA.
Meyers, T.; Bush, T.J.
Centers for Disease Control, Atlanta, Georgia, USA

Objective: To examine temporal trends in perinatal AIDS (PA) cases.
Methods: Analysis of the 1964 PA cases reported to CDC from 1982-1988.
Results: PA cases reported in yr 1982 1986 1987 1988
Number of cases newly reported in yr 103 160 250 449
I of cases meeting all 3 criteria 46(12) 15(9) 18(7) 54(12)
Number (%) of cases meeting 1-2 criteria 57 (55) 142 (88) 162 (64) 295 (66)
Median age at AIDS dx: overall 10 no 12 no 9 no 14 no
I 12 no 12 no 12 no 12 no
II 12 no 12 no 12 no 12 no
For cases meeting 1-2 criteria only --- --- 18 no 20 no
Diseases: I with 1 criteria pneumonia 322 465 531 514
II with 2 criteria 6 no 6 no 6 no 6 no
Median age at dx for other cases 30 no 18 no 15 no 19 no
Residence: I from NY, NJ, or Florida 182 642 272 602
Maternal race: I with 1b IV drug use 585 561 512 522
Race/ethnicity: I black or Hispanic 892 872 842 812
I of cases were in boys, 50% in girls; there was no sex difference in age at diagnosis; disease presentation, or survival time after diagnosis.
Conclusion: PA cases are increasing; offspring of drug users remain the group most severely affected. Non school-age children are to have been the 15th leading cause of death among newly infected children are born this year, the median age at dx has been fairly constant. Broadening of the case definition may have most effect on reportability of older children, who are less likely to present with opportunistic infections such as PCP.

W.A.0.14

HETEROSEXUAL AIDS IN THE PROVINCE OF QUEBEC
Robert S. Babin, Lucie Bédard, Robert W.S. Palmer
Bureau Régional de maladies infectieuses,
Montreal, Québec, Canada

Objective: To characterize the epidemiology of AIDS among heterosexual partners resident in the province of Quebec, since 1983; reports were evaluated using the WHO epidemiologic case criteria. Further data were collected for AIDS cases with heterosexual contact indicated on the source.
Methods: From 1979 to January 15, 1989, 743 cases of AIDS were reported in Québec; 78 (10.5%) were among women and 30 (4.0%) among children, compared to 2.8% and 0.6% respectively for the rest of Canada. One-hundred-and-forty-five (19.0%) cases were due to heterosexual contact, for a rate of 21.9 cases per million population versus 1.7 for the rest of Canada. Seventy-nine percent of the cases in Québec can be explained by the markedly increased rate of AIDS among heterosexual immigrants from Pattern II countries, mostly Haiti; the incidence rate of AIDS in 1988 among homosexual Haitians in Québec was 71.0 as compared to 1.0 per million population for other non-homosexual Quebecers, for a relative rate of 170. The rate of AIDS among heterosexual partners of high-risk persons was also higher in Québec: of the 37 cases reported in this group, 23 (62%) were related to sexual contact with persons from Pattern II countries, 13 having had exposure in Québec and 10 in other regions themselves.
Conclusion: The rate of AIDS among heterosexuals in Québec is the highest in Canada. Most of the cases can be explained by the high rate of AIDS among heterosexual persons from Pattern II countries and among other heterosexuals with sexual partners from Pattern II countries.

W.A.0.16

IMPACT OF THE HIV EPIDEMIC ON MORTALITY TRENDS IN MEN 25-44 YEARS OF AGE, UNITED STATES
Bushman, James; Berkelman, A.; Devine, O.; Chevalier, F.
Centers for Disease Control, Atlanta, Georgia & Virginia, Maryland, USA

Objective: To identify causes of death that are increasing among young adult men in association with the HIV epidemic and to estimate the impact of AIDS on mortality trends in men 25-44 years of age.
Methods: We analyzed national death records for 1980-1988 (underlying and multiple causes), compared cause-specific mortality trends in states with high versus low AIDS incidence, and calculated excess deaths in 1986 based on 1983 rates (the median of total mortality for men 25-44 years of age).
Results: Following decades of decline, national mortality rates for men 25-44 years of age increased from 21.1:1 in 1983 to 23.3:1 deaths/100,000 in 1986. By 1986, conditions in the AIDS surveillance definition represented 9% of deaths, with mortality rate ranging from 45.8 in five states with the highest AIDS incidence to 6.2 deaths/100,000 in 21 states with the lowest AIDS incidence. Similarly, rates for deaths due to infections not in the AIDS definition (including pneumonia, septicemia, and pulmonary tuberculosis), blood disorders, drug abuse, and unspecified causes increased more rapidly in states with high versus low incidence AIDS. This pattern was not observed for other cause groups, including cancers with a previously suggested link to HIV (propharyngeal, anal/oral, Hodgkin lymphoma). Of the 8,434 excess deaths in 1986 among causes that increased from 1983, 72% were attributed to conditions in the AIDS definition, 8% to other infections, 7% to drug abuse, and 3% to unspecified causes.
Conclusion: The HIV epidemic has led to an increase in diverse causes of death and to a reversal in mortality trends for young men.

W.A.0.18

THE RELATIVE IMPORTANCE OF AIDS AS A CAUSE OF DEATH IN PERINATAL AND YOUNG ADULT POPULATIONS IN THE U.S. 1980-1987.
Kilbourne, Barbara A.; Rogers, M.P.; Bush, T.J.
Centers for Disease Control (CDC), Atlanta, Georgia, USA

Objective: To assess the impact of AIDS relative to other leading causes of death in perinatal and young adult populations in the U.S.
Methods: Yearly AIDS mortality rates computed from CDC national surveillance data were compared with rates for the leading causes of death obtained from national vital statistics data for the age groups 1 yr, 1-4 years, 5-14 years, and 15-24 years.
Results: For 1 yr olds, the mortality rates (per 100,000 live births) for AIDS rose from 0.028 in 1980 to 1.3 in 1986 and 2.02 in 1987. By 1987, AIDS is estimated to have been the 10th leading cause of death for this age group. Among 1-4 year olds, the rate (per 100,000) of AIDS mortality was 0.015 in 1980 and rose to 0.645 in 1988, when AIDS is estimated to have been the 9th leading cause of death. In the 5-14 year age group the rate rose progressively to 0.152 in 1987 when AIDS is estimated to have been the 15th leading cause of death. Yearly rates for the 15-24 year age group were 1.03 in 1986 and 1.82 in 1987, when AIDS is estimated to have been the 10th leading cause of death as were in 1986 and is estimated to have been the 14th leading cause in 1987.
Conclusion: Rates of AIDS mortality are increasing in the pediatric and young adult populations of the U.S. AIDS is substantially higher than for causes of death among 1-4 year olds and 15-24 year olds in the U.S.

Séance thématique Specialty Session

L'annonce aux partenaires Partner Notification

W.A.O.19 EXPERIENCE OF PARTNER NOTIFICATION AMONG HIV INFECTED HETEROSEXUALS IN BRUSSELS
 Steven A. Shover, Ph.D., Schumaner, M.J., Clumond, M./Hain, Belgium.

During a 2 year period, 105 out of 289 heterosexual HIV seropositive patients were enrolled in a partner notification study, consisting in personal patient counseling and testing (by Elias and western blot) of sexual partners. Four-hundred and fifty (439) were eligible. Reasons for withdrawing from the study were: refusal of cooperating (47%), partners out of Belgium (37%), miscellaneous (16%). The 45 index cases allowed notification of 92 heterosexual partners. The index persons were: 123 males, 20 females; mean age was 34. By (range: 19-66); 35 Caucasians, 10 Black Africans. Sexual partners were 34 by (range: 15-102) heterosexual status or relationship to index case as married (31%), regular sexual partner (18%), occasional partner (31%). Only 9 partners were notified during their sexual intercourse with the index cases. Overall HIV seroprevalence was 36/92 (39%). Among the various partners with seroprevalence was respectively: 1 spouse (5%), regular sexual partners (30%), occasional partners (20%). All partners received information about risk reduction procedures and health services in case of seropositivity.

This study suggests that partner notification is efficient as a technique aimed to inform, counsel and refer heterosexual partners who ignore their exposure to HIV. Further studies are needed to assess the impact of partner notification on evidence of risk behaviour and on reduction of further transmission of HIV, which is the first goal of the technique.

W.A.O.21 RESULTS AND BENEFIT-COST ANALYSIS OF PROVIDER-ASSISTED HIV PARTNER NOTIFICATION AND REFERRAL. SPOONER, M., Rensvick, C., WOLF, F., STANLEY, D., Colorado Department of Health, Denver, Colorado, USA.

OBJECTIVE: Evaluate results, benefits and costs of provider-assisted partner notification and referral to prevent HIV infection.
METHODS: HIV AID patients were interviewed by Disease Intervention Specialists (DIS) to notify sex/needle share partners of exposure. Partners were offered risk reduction counseling and HIV AID testing. Program costs for personnel, travel and supplies were calculated as were medical costs for the estimated number of AIDS cases prevented through this intervention.

RESULTS: HIV infection would have remained unrecognized in newly identified cases and each would have transmitted to one susceptible in the course of a lifetime; 606 of HIV infected individuals develop AIDS. **Beneficial:** 172 HIV AID positives were interviewed. They identified 209 sex/needle share partners and subjects, of which they chose 104 for notification. 209 (75%) were located, 25 (18%) located partners were previously tested positive, 18 (10%) were previously tested negative, 111 (52%) had not yet been tested and 105 (93%) of those accepted new counseling and 72 (85%) also accepted new testing. 11 new positives were identified. Program costs during 1988 totaled \$27,000 and program benefits totalled \$164,700. Benefit-cost ratio was 7.5.
CONCLUSION: Provider assisted HIV partner notification and referral has high partner acceptance of new testing (85%), identifies previously undetected infections in potential transmitters, (18%) and has a high benefit-cost ratio (7.2).

W.A.O.23 ASSESSMENT OF THE DEVELOPMENT AND IMPLEMENTATION OF STATE AIDS/HIV PARTNER NOTIFICATION PROGRAMS: FIVE CASE STUDIES

Lorraine N. Fishback, J. William Fyfe*, James Foote, Lela Baughman, and Cynthia Burgess, Office of the Assistant Secretary for Health, Public Health Service, Washington, D.C. and ** Metro Systems, Inc., Silver Spring, Maryland.

OBJECTIVE: To gather information on the characteristics, preliminary results, and apparent benefits of existing partner notification programs.
Methods: A case study methodology was used to collect detailed information on the design and operation of five state/local programs for notifying, educating, and counseling the sex and needle-sharing partners of individuals testing antibody-positive for HIV. The sites selected—Colorado, Florida, Virginia, San Francisco, and Seattle—King County, Washington—represent a range of approaches that, in combination, have much to teach others embarking on establishment of partner notification programs.
Results: The study confirmed that current state and local realities determine both the mix of methodologies being used in HIV prevention/education programs and also the particular approach being taken to notify partners. Cost-effectiveness balanced by a concern for public health were also major factors.
CONCLUSION: A generic planning model for initiating partner notification activities was developed from the comparative analysis of the five sites. The model highlights various steps in three phases of planning—epidemiology assessment, policy development, and program implementation. This model will be exhibited.

Épidémiologie et santé publique Epidemiology and Public Health

W.A.O.20 PARTNER ACCEPTABILITY OF HEALTH DEPARTMENT NOTIFICATION OF HIV EXPOSURE, SOUTH CAROLINA

James Jeffrey, Jr., M.D., M.P.H.; Wynoff, R.N.; Gamble, W. Jr., M.D.; Hollis, S.C.; Longshore, Steve; Colwell, M.D. Office of State Services Centers for Disease Control, Atlanta, GA, USA. *South Carolina Department of Health and Environmental Control, Columbia and Greenwood, SC, USA.
Objective: To determine partners' acceptability of notification by the health department of their exposure to human immunodeficiency virus (HIV).
Methods: An anonymous questionnaire administered to sex of 79 drug contacts 2 to 24 months after the health department notified them of exposure to HIV. Results: Available partners (79 persons) of HIV positive persons in one health district (16 counties) completed the questionnaire. Of the 79, 61 (77%) were male and 18 (23%) were female; 57 (72%) black, 22 (28%) white; 60 (76%) heterosexual, 19 (24%) heterosexual, and 4 (5%) IV drug users. Ages ranged from 16 to 71 years (median 28 years). Only 9 (11%) thought they had been exposed to HIV before health department notification. After notification and waiting 20 (25%) were found to be HIV antibody positive. Of the 20, 14 (70%) were male and 6 (30%) were female. When asked if they felt the health department did the right thing in telling them about exposure, 58 (86%) responded yes, 0 (0%) no, and 11 (44%) not sure. When asked if the health department should keep telling people when they have been exposed to HIV, 70 (89%) responded yes, 0 (0%) no, and 5 (6%) not sure. When asked if being told they were exposed to HIV helped, 66 (81%) responded yes, 1 (2%) no, and 11 (44%) not sure. Health department notification was similar for homosexual men and heterosexual, males and females, white and black, and HIV positives and negatives.
Conclusion: Health department notification is highly acceptable to health department clients exposed to HIV in this rural South Carolina district.

W.A.O.22 PARTNER NOTIFICATION FOR HIV PREVENTION: CURRENT STATE POLICY IN THE UNITED STATES

Michael Goldman*, Gillian M. Gates*, Centers for Disease Control, Atlanta, GA, USA.

Objective: Partner notification (PN), used for many years in STD control programs, has been broadened to include the notification of sex and needle-sharing partners of individuals infected with HIV. PN encompasses two distinct strategies, patient referral and provider referral; all PN programs are based upon some combination of these two strategies.
Methods: In the earlier PN programs, patient referral and provider referral were required to implement procedures for confidential PN. State programs were canvassed to determine the extent of their current PN activities.
Results: All 50 states, Puerto Rico, the Virgin Islands, and the District of Columbia currently counsel HIV infected clients about the notification (patient referral) and offer provider referral upon request by clients. Fifteen states have PN programs that encourage provider referral for all clients. Data available from 13 states demonstrate seroprevalence among partners of individuals with HIV infection ranges from 0.1% to 16.4%. Infection among female sex partners of bisexual men ranges from 0.7% to 15.2%.
Conclusion: Partner notification is being applied increasingly in HIV prevention programs in the US to identify individuals at risk for different serological groups and for individuals with different risk behaviors are currently being developed by CDC.

W.A.O.24 COMBATTING AIDS WITH CONTACT TRACING

The Swedish Study Group on Contact Tracing for HIV Infection*

In the Swedish effort to combat HIV infection and AIDS, contact tracing is considered as a fundamental tool. It was seen as an integrated part of a clinical and psychological care for the patient. It is assumed to be an important element in the reduction of spread of disease. In the behavioural change effort of counselling and in the finding of hitherto unknown infections. It has also been suggested to be most economical than screening programs for finding infected individuals.

A collaborative study, including most of the centres involved in the care of HIV infected patients, has been initiated, with the scope of describing the effects of contact tracing, as well as the individual as well as the spread of the disease. The study consists of a retrospective analysis of contact tracing results and a prospective study of behavioural changes and in post-infective effects for the individual patients. Possible epidemiological inferences from contact tracing statistics are also studied.

Thus far, the following preliminary estimates of the results of contact tracing for HIV infection in Sweden have been made on the average, each index patient gives rise to 1.8 identifiable contacts; most of these are tested 80% have been traced. One third of these tests are positive. About 40% of positive individuals identified in this way are previously unknown to the health care system.

* presented by Dr. J. Olsson, Dept. of Environmental Health & Disease Control, Karolinska Hospital, Stockholm (Sweden). Swedish (financial) support. The project has been financed by a grant from the Swedish insurance company AFA.

Th.A.0.1 MONITORING THE HIV EPIDEMIC

Chairpersons: **Jean Chin** (Geneva, Switzerland), **Timothy J. Donder**
(Atlanta, USA)
Panelists: **C. Noel Gill** (London, United Kingdom), **Steve Lwanga** (Geneva,
Switzerland), **Lloyd Novick** (Albany, USA)

Increasingly, countries are conducting or planning HIV serologic surveys to help health officials assess and monitor the changing patterns and spread of the epidemic. Survey approaches vary but sentinel surveillance, in which levels and trends of HIV infection are tracked in selected accessible sub-populations, is emerging as a practical approach to monitor the various patterns of HIV spread in the population at large. In the roundtable, a panel of five specialists in HIV serosurveillance will discuss issues related to HIV surveys and reflect on the experience so date. The topics will include 1) the needs for and uses of serosurveillance; 2) surveys in sentinel populations - choice and implications of the populations selected; advantages, disadvantages, and legal/ethical aspects of anonymous unlinked (blinded) surveys compared with surveys in groups who volunteer; interpretation of data from and biases in sentinel populations; and 3) surveys using probability samples of the population - advantages, disadvantages, and feasibility. Time will be reserved for audience participation in follow up discussions.

Th.A.0.2 MATHEMATICAL MODELLING

 Chairpersons: Roy M. Anderson (London, United Kingdom), Ben Brookhaver

 Panelists: WATERHOUSE, Carlos Castillo-Chavez (Ithaca, USA), James Curran (Atlanta, USA), John Koen (Atlanta, USA), G. Medley (London, United Kingdom), Andrew Moss (San Francisco, USA)

The five papers in this session examine various aspects of the use of mathematical and statistical methods in the epidemiological study of HIV and AIDS. The topics include the use of statistical methods to make short term (one to two years) projections of the future incidence of AIDS, in back calculation of the number of infecteds underlying a given AIDS cases notification pattern and to estimate the incubation period of the disease in different age classes and at risk groups. Mathematical methods are described to investigate the transmission dynamics of HIV, its potential demographic impact in developing countries and the importance of heterogeneity in sexual behaviour to the pattern of the epidemic. The session will also include a discussion of the estimation of epidemiological parameters, the interpretation of trends in incidence of infections and disease and data needs.

Th.A.0.10 HIV SCREENING IN LOW PREVALENCE POPULATIONS:

THE USE OF SERUM CONVERSION EXPRESSION INDEX (SEI) IN HIV-1 INDIVIDUALS
Drs. Robert McNeil, L. Dale Johnson, David Reed Research Group, Walter Reed Army Institute of Research, Washington, DC, USA

Objective: To determine if SEI/SEA positive/WB- test results in significant predictor of seroconversion after short-term follow-up in a low prevalence population of US young adults.
Methods: From October 1985 to November 1986, 24,261 soldiers on active duty in the US Army were tested for HIV-Ab on two or more occasions. The average interval between tests was 8 months. Individuals who were SEI- or SEI+/WB- were considered HIV-Ab negative. HIV seropositivity was defined as duplicate SEI-Ab plus WB- on two separate occasions.
Results: During the study period, 119 persons seroconverted (0.49%).

Zellweger's Sensitivity		Prevalence	Sensitivity	Pos. Predictive Value	1-SPN
SEI	0.98	0.49	0.92	0.80	0.88
SEI/WB	0.97	0.49	0.92	0.80	0.88
SEI/WB	0.97	0.49	0.92	0.80	0.88
SEI/WB	0.97	0.49	0.92	0.80	0.88

Conclusion: SEI positivity that is not associated with confirmatory WB reactivity significantly increases the positive likelihood of confirmed seroconversion after a short follow-up. In a low risk population, SEI positivity alone is not an adequate subsequent seropositivity for quantitative individuals (less than 1.0%). Demographic, geographic, and behavioral constants of infection risk could increase the predictive power of SEI- test results in low prevalence populations.

Th.A.0.11 INCIDENCE OF PEDIATRIC AIDS IN THE UNITED STATES:

PREDICTIONS FROM SEROPREVALENCE DATA
Dr. William Miller, Rogers M. Berkman M.D., Willoughby A.A., Novello A.A., Pappasian M.D., AIDS Program, CDC, Atlanta, GA, **NICHD, Bethesda, MD, USA

Objective: To predict incidence of AIDS in the first year of life for infants born in 1986, and compare with reported cases among infants born in 1986 and 1987.
Methods: The population-based Survey in Childbearing Women provided an estimate of the prevalence of HIV infection among United States women delivering live infants in 1986. The proportion of infants born to HIV-infected mothers who develop AIDS by 12 months of age was estimated from ongoing cohort studies. Infants born in 1986 and 1987 who were known to have developed AIDS in the first year of life were those reported to CDC.
Results: In 1986, at least 1 per 1000 childbearing women had antibody to HIV. If between 25 and 10% of their infants develop AIDS in the first year of life, approximately 225 to 450 cases of AIDS in infants under 12 months of age would be expected to occur in the 1988 birth cohort. As of January 1, 1989, 137 children born in 1986 and 120 born in 1987 had been reported to CDC with AIDS diagnosed by age 12 months.
Conclusion: A lag in case reporting complicates the comparison between HIV/AIDS cases occurring in 1986 and 120 born in 1987 and cases predicted among those born in 1988. However, seroprevalence data suggest that more AIDS cases will occur in the 1988 birth cohort that have been reported from previous cohorts to date.

Th.A.0.12 RELATIONSHIP BETWEEN CUMULATIVE INCIDENCE OF AIDS AND PREVALENCE OF HIV IN WOMEN OF REPRODUCTIVE AGE IN THE UNITED STATES.

Dr. Robert McNeil, David Reed Research Group, Walter Reed Army Institute of Research, Washington, DC, Atlanta, GA; **NICHD, Bethesda, MD, USA.

Objective: To determine whether the cumulative incidence of AIDS reflects the observed prevalence of HIV in women of reproductive age in the U.S.
Method: State-specific HIV prevalence rates (over 100,000 population at risk) in women of reproductive age in 1988 were estimated by results from blinded HIV seroprevalence surveys in childbearing women. The corresponding cumulative AIDS incidence rates in women aged 15-44 years, for 1981-1988, were based on AIDS patients reported to CDC. The Pearson product moment correlation coefficient with 95% confidence intervals, and ratio of HIV prevalence to cumulative incidence of AIDS were calculated. Using simple linear regression, cumulative incidence was regressed on prevalence.
Results: Analysis of preliminary results from 11 states showed cumulative AIDS incidence to be correlated with HIV prevalence (r = 0.89, 95% C.I.: 0.67, 0.93). 75% of the variation in cumulative incidence was explained by prevalence of HIV. The ratio of HIV prevalence to cumulative incidence varied by state, ranging in value from 9 to 43 (median = 20.7).
Conclusion: Our results suggest that despite the lengthy incubation period of AIDS, cumulative AIDS incidence rates currently reflect the HIV epidemic in women of reproductive age. The ratio of cumulative incidence to estimated HIV prevalence varied by state. Higher ratios may indicate incomplete AIDS reporting, a higher prevalence of HIV infection in childbearing women than in women of reproductive age, or an increase in HIV transmission.

Th.A.0.13 EVALUATING THE FEASIBILITY OF THE NATIONAL SEROSURVEILLANCE SURVEY (NSSL) DESIGN.

Dr. Robert T. Maltzberg, J. Robert McNeil, National Center for Health Statistics, Hyattsville, MD, USA.

Objective: To describe the major potential sources of error for the NSSL the possible impact of these errors on HIV prevalence rates, and possible methods to assess and enhance the quality of the survey estimates.
Methods and Results: Major potential sources of error for NSSL include coverage bias, nonresponse bias, misclassification bias and the validity differential nonresponse revealed that high nonresponse among high risk persons will have the greatest impact on nonresponse bias. Nonresponse bias could potentially result in an estimated prevalence of from one-third to one and one-quarter of the true prevalence. The coverage bias does not affect the estimated prevalence of HIV. Misclassification bias does not affect the estimated prevalence of HIV. For high risk persons the misclassification could be as much as 28 times the true prevalence, therefore separate estimates by risk group are not planned for this survey. Risk data will be collected for adjustment of nonresponse bias. To minimize nonresponse bias, a nonrespondent follow up study is proposed. Other methods to evaluate and reduce the bias include a randomized response, geographic stratification, and hepatitis B testing.

Th.A.0.14 APPLICATION OF LOT QUALITY ASSURANCE (LQA) SAMPLING TO HIV AND AIDS SENTINEL SURVEILLANCE

Dr. Robert T. Maltzberg, Geneva, Switzerland.

Objective: To describe possible applications of Lot Quality Assurance Sampling (LQA) to sentinel surveillance.
Methods: LQA and standard sampling techniques are described with their benefits and limitations in sentinel surveillance for HIV and AIDS.
Results: When sentinel surveillance centres are established to act as a "barometer" for HIV infection and AIDS in a target population group, it may not be necessary to screen very large numbers of people. LQA sampling techniques, which originate in industrial studies, may be used in this case. The strategy in industry is to classify a batch of items as not likely to have a level of defective items higher than a particular value, with a given probability. A similar strategy can be applied to a sentinel surveillance system for HIV infection and AIDS in which, unless a pre-determined percentage of people are found positive among a randomly selected group, one can conclude that the level of infection among the target group is not above a particular level.
Conclusion: Using LQA sampling techniques in HIV and AIDS surveillance greatly reduces the minimum sample sizes which would be needed to determine that a target group is not likely to have an HIV prevalence rate above a pre-determined critical value. In areas with very low levels of HIV infection LQA techniques would be more efficient than methods which would aim at estimating the prevalence of HIV in the target group.

Th.A.0.15 Methodological Considerations for Assessing the Impact of Condom, Spermatide and Oral Contraceptive Use on HIV Transmission

Dr. Robert T. Maltzberg, J. Robert E. Lee B. and Patricia M. Centers for Disease Control, Atlanta, Georgia, U.S.A.

Numerous investigations have been initiated or are being planned to investigate the likelihood of HIV transmission in heterosexual couples who consistently and correctly use condoms, spermatides and/or oral contraceptives. To rigorously study this critical question, a complex composite methodological concerns must be addressed including: 1) appropriate selection of the study population, 2) knowledge of HIV status at entry of all study participants, 3) the reliability of measures to assess sexual activity and contraceptive use, and 4) the temporal correlation of seroconversion with contraceptive use and HIV transmission may be misleading. Most sources of systematic error in such studies will bias toward observations of a reduced efficacy of condoms in preventing HIV transmission and 2) a positive association between oral contraceptives and HIV transmission. To maintain likelihood of identifying real HIV transmission, such bias must be minimized in design strategies and, if not eliminated, considered when study results are interpreted.

Séance thématique Specialty Session

Autres rétrovirus : le HTLV-II Other Retroviruses: HTLV-II

Th.A.0.29 HTLV II INFECTION IN U.S. BLOOD DONORS
 HALL, J. P., FERGUSON, C. M., LEVINE, W. J., SCHWARTZ, J. J.,
 LAITILA, V. A., and LEE, H. H. Abbott Laboratories, North
 Chicago, IL, USA
 *American Red Cross, ROCKVILLE, MD, USA

OBJECTIVE: With the advent of large scale HTLV II screening, the rate of HTLV II infection was determined in over 300,000 blood donors from all parts of the U.S.

METHOD: A viral based EIA was used in the initial screening followed by CONFIRMATION using Western blot (WB), SDS-PAGE RIPA, PCR and lymphocyte coculture in certain subjects.

RESULTS: A total of 301,109 donors were screened by EIA for an initial reactivity rate of 0.11% and a repeat reactive rate of 0.08% with 248 EIA repeat reactive donors known to date. Approximately one-third of these were resolved by WB alone (14% MB positive, 15% MB negative), whereas the remaining two-thirds needed to be tested by RIPA. A further 20% were confirmed to be positive by RIPA using the PAGE-EXE One-step of antibodies to 2 gene products. The remaining samples (39.8%) were negative by RIPA. None of the MB negative samples tested positive by RIPA.

CONCLUSION: The distribution of confirmed positives indicates a high density of HTLV II infection in metropolitan areas such as San Francisco, LA, New York and Miami, superimposed by a belt in the Southern region extending from California through Texas and Florida to South Carolina. PCR results using lymphocytes from over 100000 donors indicate that both HTLV I and II are present, with the majority being HTLV II. This is in contrast to our findings in IVDA from Florida which indicated an overwhelming majority (>90%) of HTLV II infection in the cohort studied.

Th.A.0.31 HTLV-II-ASSOCIATED LYMPHOMA (HAM/TSF) IS ASSOCIATED WITH HIGH INCIDENCE OF OTHER MALIGNANCIES

OSAKADA, M., YAMAZAKI, H., YAMAZAKI, T., YAMAZAKI, M., YAMAZAKI, M.,
 WAKIMOTO, M., *Hiroshima University, Hiroshima, Japan,
 *Centers for Disease Control, Atlanta, Georgia, USA, *Nagano National
 Sanatorium Hospital, Miyota, Japan.

Objective: To determine whether HTLV-II-associated lymphoma/tranoprol specific paraneoplasia (HAM/TSF) is associated with other malignancies.

Methods: National surveys of HAM/TSF in Japan in 1987 and 1988. A case of HAM/TSF was defined as a slowly progressive lymphoma with antibodies to HTLV-II both in serum and CSF. Results: In the survey, 161 cases of HAM/TSF were reported. Significantly more HAM/TSF patients reported a history of blood transfusion (24) than did HTLV-II infected patients with adult T-cell leukemia/lymphoma (19/122, 15.3%, p < .002) or than did the general population (44/1290, 3.2%, p < .001). Modeling of the population (logistic analysis) showed that the expected distribution if transfusion is the interval from transfusion to onset of HAM/TSF (median) followed a log-normal distribution, the expected distribution if transfusion is associated with HAM/TSF. In November, 1988, all Japanese blood banks stopped transfusing HTLV-II seropositive blood. Significantly fewer HAM/TSF patients show symptoms longer after screening reported a history of blood transfusion (11/59, 18.4%) than did patients whose symptoms began during a comparable period before screening (13/49, 37.1%, p < .03). Furthermore, only 1 person who developed HAM/TSF in 1987-88 reported a history of blood transfusion after 1988 compared to 2 reported cases if not screening had taken place (p < .007). Conclusions: These results demonstrate an association between blood transfusion and HAM/TSF and suggest that transfusion of HTLV-II-infected blood can cause HAM/TSF.

Th.A.0.33 SIGNIFICANCE OF POSITIVE AND INDETERMINATE HTLV-II REACTIVITY RESULTS IN BLOOD DONORS

EBBAHAR, R. M., LAIRSON, H. J., LEE, H. H., CRITCHLEY,
 D. S., DE, B. A., *CDC and *American Red Cross Atlanta
 Branch, Atlanta, Ga, and *Abbott Laboratories, Chicago, IL, U.S.A.

Objective: To evaluate virologic and epidemiologic characteristics of blood donors whose HTLV II serologic results were positive or indeterminate. Methods: From June-August 1988, sera from 1996 consecutive blood donors of the Atlanta Regional Blood Services were tested for HTLV antibodies by EIA; all reactive sera were confirmed by WB and RIPA. Interviews and a second blood sample were obtained from all HTLV-II-positive donors, and from 3 donors with indeterminate results. Peripheral blood mononuclear cells were examined by polymerase chain reaction (PCR) using 2 primer pairs designed to amplify HTLV-II proviral DNA. Results: Of 1996 blood donors tested, 20 (0.1%) showed repeatable reactivity by EIA; 3 (0.15%) were confirmed seropositive (presence of antibody to p24 and/or gene product), and 17 (0.87%) had indeterminate results (reactivity to gag only). All 3 seropositive donors were black and from the SE, compared with 1/7 with indeterminate and 0/2 with negative results. One donor a history of IV-drug use, but 1 positive donor had an IV-drug-using sex partner. The HTLV-II seroreactivities remained unchanged 4-7 months after initial donation. Cells from seropositive donors showed HTLV-II specific sequences on PCR; cells from the other showed HTLV-II. In contrast, cells from 2 of 3 with indeterminate results (0/3 with only on WB) and 3 of 3 with negative serologic results were negative for both. Conclusions: HTLV-II seropositivity in blood donors may be due to HTLV-II or HTLV-II donors with indeterminate HTLV-II serologic reactivity (0/3 with ser HTLV-I or HTLV-II).

Epidémiologie et santé publique Epidemiology and Public Health

Th.A.0.30 ANTIBODIES TO HIV-1 AND HTLV-II IN HAITI

DE LAUNAY, J., BOUAB, S., *LAWSON, A., *FICHELLETT, J., *DANAN, D.,
 DELANNOY, G., *Laboratoire d'Investigations Biologiques, Port-au-
 Prince, Haiti; *Hospital de Laseatis, Laseatis, Martinique.

Objective: Determine the seroprevalence of HTLV-II antibodies (Ab) and the association of HTLV-II in Haiti and HTLV-II in Martinique.

Methods: From September 1987 to September 1988, 896 apparently healthy individuals, (16-70 years of age; n: 30 ± 14 years, 503 female, 379 male), 107 adults AIDS patients (43 female, 64 male) and 140 female prostitutes were tested by ELISA for Ab to HIV-1 (Abbott and Dupont) and HTLV-II (Dupont). Positive specimens were tested by Western blot (Dupont).

Results: Specimens were considered positive only when reactive by Western blot. The following table summarizes the results.

Healthiness (%)	Prostitutes (107)	AIDS patients (107)
HIV-1+	51 (5.8%)	68 (36.7%)
HIV-1-/HTLV-II+	22 (2.5%)	17 (10.3%)
HIV-1-/HTLV-II-	7 (0.8%)	23 (12.4%)

The seroprevalence of HTLV-II in Haiti was 40% among apparently healthy Haitians is 5.8% and 2.5% respectively. The prevalence of the HIV-1 / HTLV-II co-infection is 0.7% among healthy individuals, 10.3% among AIDS patients and 12.4% among prostitutes.

Conclusion: The results indicate that the seroprevalence of HTLV-II in Haiti is the same as in other Caribbean islands. They also suggest that prostitutes are particularly at risk for HTLV-II infection. Cohort studies should be carried out in Haiti to determine the influence, if any, of HTLV-II on the evolution of HIV-1 infection.

Th.A.0.32 HTLV-II INFECTION CORRELATES WITH INCREASED AGE IN INFECTED BLOOD DONORS

BOHANNAN, G., ROBERT, J., NARAY, D., *Khan, S., *Khan, S.,
 LAIRSON, H. J., *CDC and *American Red Cross Atlanta
 Branch, Atlanta, Ga, and *Division of Field Services, CDC, Atlanta, GA, USA,
 *Montefiore Medical Center, Bronx NY USA

Objective: To evaluate risk factors for HTLV-II infection in a cohort of IVUD.

Methods: Subjects were participants in a longitudinal study of HIV infection in IVUD in a methadone maintenance program in Bronx NY. All participants who had blood drawn in 1987 were tested for serologic markers of HTLV-II infection. Samples were screened by enzyme immunoassay and confirmed by Western blot and radiomicroprecipitation.

Results: Of 270 persons, 21 (8%) were HTLV-II antibody (p24 and/or gene product) positive, while 12 (4%) had indeterminate results (antibody to gag gene product only), and 237 were HTLV-II-, HTLV-II persons were significantly older than HTLV-II negative persons (p < .0001). No significant differences were seen in sex, race, socioeconomic status, transfusion history, biphoria, or travel to HTLV-II endemic areas. Both HTLV-II and HTLV-II IVUD had similar duration and frequency of drug use, history of needle sharing with strangers, and visits to shooting galleries since 1978. However, no differences were seen in number of total, IVUD, or paying sex partners since 1978. HTLV-II and HTLV-II persons had similar rates of HIV infection. Analysis controlling for age did not reveal additional risk factors. **Conclusion:** In this cohort of IVUD, HTLV-II seropositivity was more common in older persons; neither sexual nor drug use behaviors since 1978 were associated with the acquisition of HTLV-II.

Th.A.0.34 PREVALENCE OF HEMAGGLUTINININ-BINDING HIV-1 IN INFECTED BLOOD DONORS

ELBAHAR, R. M., LAIRSON, H. J., LEE, H. H., CRITCHLEY,
 D. S., DE, B. A., *CDC and *American Red Cross Atlanta
 Branch, Atlanta, Ga, and *Abbott Laboratories, Chicago, IL, U.S.A.

Objective: To determine the prevalence of antibodies to human lymphotropic virus type 1 (HTLV-1), the cause of adult T-cell leukemia (ATL) and tropical spastic paraparesis (TSP), in HIV-1 seropositive individuals for the armed services of the United States.

Methods: Sera from 10,929 applicants collected during the period of March and April 1989 were screened using a enzyme linked immunosorbent assay (ELISA). All repeat reactive and 14 initial reactive ELISA samples were confirmed by Western blot and radioimmunoassay assays (RIA) to confirm the presence of antibodies specific to HTLV-1.

Results: Of the 233 (2.2%) initial reactivities by ELISA, 85 (0.58%) were repeatedly reactive. The Western blot procedure revealed 5(7.3%) positive, 20(29.0%) negative, and 44(63.7%) indeterminate. The RIA confirmed the presence of envelope protein in 2 of the Western blot positives and in 3 of the 44 indeterminate; 0/24 with only a 3 component positive.

Conclusion: The overall prevalence rate of HTLV-1 antibody in the applicants was 0.4% whereas the

M.A.P.7 SEROPREVALENCE OF HEPATITIS TO THE NEW IMMUNOPROTECTOR (NEW ICI) IN SPELTERS FOR HEMORRHOID LIGATURE IN ALABAMA

Abstract No. 100 - **Authors:** JAMES P. HAYES, William G. Miller, Donald Williams*
*Alabama Department of Health, Bureau of Clinical Laboratories (BCL), Montgomery, AL
**Naval Health Research Center (NHRC), San Diego, CA, *National Naval Medical Center,
Bethesda, MD
Objective: To evaluate the seroprevalence of antibodies to HIV in military personnel
(A) presumed heterosexual, low risk population (B) low prevalence AIDS area using repeated testing.
Methods: All specimens analyzed by ELISA* for antibody against presumed prevalent
antibody from 1 November, 1987, to 31 January, 1988 (Study 1); from 1 November, 1988, to
31 January, 1989 (Study 2) were tested for HIV antibodies in separate seroreactive studies using
direct enzyme immunoassay (EIA). Repetitive seroreactive specimens were tested by Western blot.
Results: 4694 specimens from Study 1 and 4633 specimens from Study 2 yielded the following:
Study 1
n (Number) (%) n (Number) (%)
ED-VIII* 23 0.5 5 0.1
ED-VIII* 53 1.3 1 0.02
ED-VIII* 7 0.15 0 0.0
Immunoreactive 4622 98.48 4320 99.20
Total 4694 100 4633 100
Conclusion: The decline in ED-VIII* specimens from 0.21 to 0.11 does not appear to be
statistically significant. These results indicate that within the observed seroprevalence among Alabama
military recruits (0.074, 1.3-80) and the ELISA criteria (1.64, 10.3-80).
Significance: This study provides an increase in specificity from 98.72 to 99.96 reflects overall improvements in manufacturers of the test kits and purification
of the antigen.

M.A.P.9 HIV SEROPREVALENCE AT UNIVERSITY CAMPUSES, U.S.A.

ORIG.: JOURNAL, *Journal of the American Medical Association*, 261:1800-1801, 1987.
Authors: J. P. Hayes, D. Williams, J. M. S. Garcia, T. M. Smith, M. J. Kilbourne, M. J.
Sullivan, J. P.
**Centers for Disease Control (CDC), Atlanta, GA, USA,
American College Health Association, Rockville, MD, USA

Objective: To estimate the seroprevalence of HIV infection among university
students in the United States.
Methods: We are conducting blinded HIV antibody testing on blood collected for
other routine medical purposes in student health centers. A total of
500-1000 blood specimens are being collected on 17 campuses throughout
the country and tested for HIV antibodies by ELISA and Western blot.
Non-identifying demographic data are listed with test results.
Results: To date, a total of 23 (25.2) of 13,810 specimens are positive for
HIV antibodies. All positive results are from students 210 years old; 17 (73%)
were 21-29 years old. Twenty (87%) of students with positive results were
male. Seroprevalence rates were higher for males (0.492) than females
(0.042) and increased with age from 0.063 for 18-21 years old to 0.647 for
28-29 years old. Positive results were identified in only 3 of the 17
schools; however, these schools represented all regions of the country.
Conclusions: HIV infection is present on university campuses. Although, the
rate still appears to be relatively low. These data suggest that older,
male students are at greatest risk. Universities provide a challenge to
maintain low rates of seroprevalence in what is often a relatively insular
setting with high rates of sexual activity, often with multiple partners.
Ultimately, the risk of exposure to HIV infection may increase for many
students as they leave the campus, highlighting the importance of targeting
this population.

M.A.P.11 INCIDENCE OF HIV SEROPREVALENCE IN U.S. NAVY PERSONNEL-RESULTS OF TOTAL NAVY SCREENING

ORIG.: *Journal of the American Medical Association*, 261:1800-1801, 1987.
Authors: J. P. Hayes, D. Williams, J. M. S. Garcia, T. M. Smith, M. J. Kilbourne, M. J.
Sullivan, J. P.
**Naval Health Research Center (NHRC), San Diego, CA, *National Naval Medical Center,
Bethesda, MD, **Naval Air Station, Pensacola, FL, ***Defense Eligibility
Enrollment Reporting System (DEERS), Monterey, CA, U.S.A.**

Objective: To determine incidence rates of HIV seroconversion in a young and apparently
highly mobile population of active-duty U.S. Navy and Marine Corps personnel.
Methods: Using HIV seropositivity data provided by the Naval Medical Command and
maintained in the Navy HIV Central Registry at NHRC, and population data provided by the
Reproducible Disease Database of DEERS, incidence rates of seroconversion were calculated for
the period 1986-1988 using person-years as denominator. The period at risk for each
individual began with the first negative ELISA test and continued until the first positive
Western blot assay or the last negative ELISA test. HIV seroconverters were defined as
persons with at least one negative ELISA screening test followed by two positive paired
ELISA tests and two positive Western blot assays (criteria for positive Western blot:
a specimen that exhibited at least two of three bands in p24, gp41, and gp120/160).
Results: Since 1986, 97% of active-duty Naval personnel have had a routine annual HIV
seropositivity screening test (1,170,111 persons; 1,956(0.17) total). During the three-year
period 1 Jan 1986 to 31 Dec 1988 there were more than 725 seroconversions in active-duty
personnel. Incidence rates were similar by age, race, sex, occupation, and other
relevant demographic characteristics were determined.
Conclusion: This is one of the largest studies in existence of HIV seroconversion in a non
self-selected healthy population. It provides unique information on demographic and
occupational factors related to HIV seroconversion.

M.A.P.8 ANTIBODY HIV TESTING ON SEROBERS IN 61 ITALIAN HOSPITALS: AN ESTIMATE OF PREVALENCE OF HIV INFECTION AMONG WOMEN IN REPRODUCTIVE AGE

ORIG.: *Journal of the American Medical Association*, 261:1800-1801, 1987.
Authors: J. P. Hayes, D. Williams, J. M. S. Garcia, T. M. Smith, M. J. Kilbourne, M. J.
Sullivan, J. P.
**Italian Collaborative Study Group for HIV Prevalence in Newborns, Lazzaro
Spallanzani Hospital for Infectious Diseases, Rome, Italy.**
Objective: To assess the prevalence of HIV infection in female population in
reproductive age and provide a predictive parameter to estimate future
pediatric AIDS cases.
Methods: Blood samples were collected on filter paper for routine
screening from 79,687 consecutive newborns in 61 hospital
nurses, in different Italian regions, during the period
June-November 1988. Blood saturated glassa were placed on the
collection papers, without identification, at the National
Blood Transfusion Center of the Italian Red Cross in ELISA (Pasteur Lab); the
positive results were confirmed in a Western Blot (Dugout Lab).
Results: Among the 79,687 blood samples tested 18 (0.023), Confidence
interval 95%, Poisson's distribution (0.0052-.041) were found positive for
HIV-1b.
Conclusion: The distribution pattern of the positive samples among the
different regions correlates to the AIDS cumulative incidence rate,
with a higher prevalence in the north and center. Italy's HIV
screening on the newborns, who reflect seroprevalence patterns of the
population, can provide a useful tool in evaluating the
prevalence of the infection in a relatively unselected population.

M.A.P.10 HIV SEROPREVALENCE AT THE BRONX LEHMAN HOSPITAL CENTER - A CDC SENTINEL HOSPITAL

ORIG.: *Journal of the American Medical Association*, 261:1800-1801, 1987.
Authors: J. P. Hayes, D. Williams, J. M. S. Garcia, T. M. Smith, M. J. Kilbourne, M. J.
Sullivan, J. P.
Brnxn Lehman Hospital, Bronx, NY, USA, **CDC, Atlanta, GA, USA

Objective: To monitor levels and trends of HIV seroprevalence in the South
Brooklyn.
Methods: The CDC Sentinel Hospital Surveillance Network's protocol and
sampling scheme was used. From Feb. - Oct. 1988, 2566 bloods were tested.
They came from 871 males and 1695 females; 1193 Blacks, 1181 Hispanics,
21 Whites and 169 of unknown origin.
Results: The population's mean age was 41.8; males 43.9 and females 40.1.
Western blot positive males had a mean age of 39.8 and positive females
34.8. 70 males and 70 females were positive. The ages and coasts are
listed below:

Age Group	Male	Female	Total	Male (%)	Female (%)	Total (%)
2-4	7	14	21	0	6.2	1.2
5-14	12	17	29	0	0	0
15-24	58	315	373	2 (3.6)	8	(2.1)
25-44	245	630	875	46 (18.8)	49	(7.8)
45-64	355	456	811	20 (5.6)	12	(1.5)
65+	146	283	429	2 (1.4)	0	(0.5)
Total	871	1695	2566	70 (8.0)	70	(4.1)

Conclusion: Bronx Lehman Hospital has one of the highest HIV seroprevalence
rates in the Sentinel Hospital Network suggesting the urgency of intensive,
community-wide intervention to control further transmission of HIV in this
high-risk, urban population.

M.A.P.12 HIV SEROPREVALENCE AMONG PARTURIENTS IN LOS ANGELES COUNTY, 1986

ORIG.: *Journal of the American Medical Association*, 261:1800-1801, 1987.
Authors: J. P. Hayes, D. Williams, J. M. S. Garcia, T. M. Smith, M. J. Kilbourne, M. J.
Sullivan, J. P.
**Los Angeles County Department of Health Services/LACDHIS, Los Angeles, California
Fetal and Neonatal AIDS Test Unit (FANATU), Los Angeles, CA, USA

Objective: To estimate the prevalence of human immunodeficiency virus (HIV) among parturient
in County Hospital in Los Angeles County.
Methods: Between September and December 1986, 9,400 consecutive prenatal onset blood
specimens were obtained from four County Hospital sites in Los Angeles County. Specimens were
linked to maternal demographic information and, when available, placental syphilis serology and
serology for HIV antibodies. An ELISA test was done after a positive ELISA result was
obtained. Repeat ELISA positive results were confirmed by immunofluorescence antibody and Western
Blot.
Results: The combined onset births in this sample represents approximately 58% of all Hispanic
births, 29% of all black births, and 8% of all white births in LAC in the sampling period. To
date, 626 (6.7%) have been confirmed HIV Ab positive. Sixty-two percent of all women had
information available on intravenous (IV) drug use, and of those, approximately 5% had a history
of IV drug use, but none were HIV Ab positive. Of the women for whom information was
available, 57% had a positive antibody test at the time of delivery, but again none were HIV Ab
positive.
Conclusion: HIV seroprevalence among parturients delivered at county hospitals in LAC during
the sampling period was low, and was not associated with either IV drug use or syphilis. Data
from 2,400 births will be presented.

HIV 1 ET HIV 2 EN MILIEU CARCÉRAL. A DAKAR

(SÉNÉGAL)

Sarrh, N.D.*, Bays, C.S.*, Diong, G.S.*, Siby, T.*, Sow, A.* M'Boop, Souleymane*
*Université de Dakar, Sénégal.

Objectifs: Evaluer la situation de HIV1 et HIV2 dans les prisons de Dakar et obtenir des informations en vue de la décision de Santé Publique concernant les individus incarcérés. **Méthodes:** Entre Avril et Mai 1988, 1354 prélevements de sang ont été effectués sur 1241 prisonniers (1155 hommes et 189 femmes) et 113 agents de l'administration pénitentiaire qui ont servi de population témoin. Tous les sérums ont été passés en HIV1 ELISA (Abbott) et les positifs confirmés par Western Blot sur HIV1 et HIV-2. **Résultats:** Aucun des agents de l'administration pénitentiaire n'était séropositif. Par contre 11 prisonniers étaient séropositifs (7 en HIV2 et 4 en HIV1) soit une prévalence de 0,9%. Parmi les femmes la prévalence était de 2,3% pour HIV2 et de 3,5% pour HIV1. Parmi les hommes les prévalences d'infection étaient respectivement 0,4% et 0,1%, semblable à la prévalence observée dans la population générale. Tous les sujets séropositifs étaient d'origine africaine âgés de 25 à 31 ans et avaient une sérologie positive pour le syphilis. De plus 7 femmes ou des enfants de détenus d'autres MST.

Conclusion: Le milieu carcéral est considéré comme favorable des activités à haut risque, telles que l'utilisation de drogues par IV et la pratique de l'homosexualité pouvant propager le virus. Cependant, une évaluation préjudiciale en milieu carcéral dans d'autres pays de l'Afrique de l'ouest, la prévalence d'infection par HIV parmi les hommes incarcérés était identique à celle observée dans la population générale. Cette information est d'importance pour les responsables de la Santé Publique car elle fait des ressources limitées. Les campagnes d'éducation et de prévention en milieu carcéral, à l'heure actuelle, devraient se concentrer sur les groupes à risque (femmes).

M.A.P.21

COURSE OF SEROLOGICAL MARKERS OF DIFFERENT INFECTIONS IN HIV SEROPREVALENT AND SERONEGATIVE INMATES FROM A PENITENTIARY POPULATION.

Ottis de Lejarazu R., Ertos J.G., Perledo E., Orduña A., Bratos M., R-Torres X. UNIVERSITY HOSPITAL and Faculty of Medicine, Valladolid, Spain.

OBJECTIVE: To describe the presence of markers against different infections versus HIV serological status and behaviour in a penitentiary population. **METHODS:** Sera from 323 inmates previously screened for HIV Ab by EIA and WB test and from 78 blood donors as control group were tested for HbSAb, VHBsAb, HbSg, HbSg (by EIA test) and Ab against HSV, CMV, EBV (CF test) and T.pallidum (VDRL and FTA-abs).

RESULTS: The global prevalence of markers was as follows: 265 of inmates were HIV positive; 50,2% had VHB markers (42,8% HbSAb, 1,3% HbSg, 4,5% HbSb+HbSg, 1,5% HbSg); 40,7% of inmates HbSg had VDBs; 86,5% had Ab against HSV, 50,6% for CMV, and 20,9 for EBV and 10% by FTA-abs. We found significant higher rates of VHB infection markers in HIV seropositive inmates (81,7% versus 26,5%) and also against T. pallidum (12,4 versus 4,1%). In the control group we found 2,6% of HbSAb and none for T. pallidum. We did not find any difference in the occurrence and titers of HSV, CMV and EBV Ab between HIV seropositive and seronegative inmates and the control group. The greatest prevalence of VHB and T.pallidum markers was found among 10% of inmates with antisocial behaviors. This result shows the high frequency of infections that may facilitate transmission of HIV in the penitentiary population and could act as cofactors in the progression of the disease.

M.A.P.23

RISK FACTORS ASSOCIATED WITH HIV INFECTION AMONG WOMEN INCARCERATED IN A MEDIUM SECURITY PRISON

Habibie, Chahira*, Gendreau, S.*, St-Pierre S.*,

Richard, C.**, O'Neil, J.**, Bennett, M.**,
*McGill Hospital, Centre de Contrôle & McGill University, **GLSC Abitibi, Montreal, **servical Centre AIDS, Ottawa, Canada.

Objectifs: To determine the relative contributions of needle use practices and unprotected intercourse to HIV seropositivity among female inmates. **Méthodes:** Freely given, informed consent is provided for an individual nurse-administered risk factor questionnaire and tests for HIV, Hepatitis B, and HTLV-I. Prisoners and guards are unaware of which prisoners consent to testing. Random case numbers are used. Results are available to consenting participants but not to health service per prison authorities. **Résultats:** To date 107/217 (49,3%) were injection drug users (IDU). Overall 13 (6%) seropositives (SP) have been detected. All are IDU. For a case among IDU of 12,2% (1/8,4%) report needle sharing, 0/60 current prostitutes, 9 (15%) are seropositive. Comparing SP to the total study population no significant differences were found for oral contraceptive use, sex, of male intercourse. A striking 37,4% of the total study population (vs 20,4% of SP) have had sex since 1979 with a man who has had sex with another man. SP are more likely to be engaged in prostitution (59,2 vs 27,6%), to have sexual partners (50,6 vs 38%), to be SP in the last 12 months, to have had an IDU partner since 1979 (92,1 vs 48,8%), and to have had herpes (23,1 vs 6%) or genital warts (30,8 vs 18,9%).

Conclusion: Recycled and shared needles are suspected to determine to what extent needle use versus sexual practices explain seropositivity.

M.A.P.20

ARRIVE AIDS PREVENTION TRAINING FOR

INTRA-VENOUS DRUG USERS: PRACTICE

FROM PRISON

Wesler, Harry K.**, Marder, E.S., Joseph, Jr., Bickel, R.**, Bardsley, M.**, et al.
*Narcotic and Drug Research, Inc. New York, New York, U.S.A.

Objectifs: To develop, implement and evaluate the outcomes of the first AIDS prevention training program for intravenous drug users provided from prison. The primary goals are to prevent relapses to IV drug use and associated AIDS risk behaviors, and to help clients become productively reintegrated into the community.

Méthodes: ARRIVE is based on social learning, self-aid and therapeutic community principles. The program model involves training at-risk persons for entry-level jobs in the AIDS prevention field, e.g., outreach work, peer counseling. The process of learning for clients to solve their problems is an effective means of internalizing community attitudes and behaviors. The ARRIVE program consists of an 8-week, 48-hour, 24-session group curriculum. The major behavioral themes addressed are: general AIDS facts, needles, condoms, HIV risk reduction, relapse prevention, outreach presentation, and job readiness.

Résultats: A 24-session AIDS Prevention Training Manual has been written and trained with clients during 2 group cycles. The Manual is tailored for use with offender populations with IV drug use histories. An evaluation is in progress that will compare 6-month behavioral outcomes for persons who participated in ARRIVE vs. a matched sample of non-participants.

Conclusion: At least 25% of U.S. prison inmates have IV drug use histories and are susceptible to relapse as inmates. ARRIVE is developing a strategy for reducing HIV risks within this difficult-to-treat, relatively neglected population.

M.A.P.22

HIV SEROPREVALENCE AND THE EFFICACY OF VOLUNTARY HIV TESTING AMONG HALL PRISONERS IN WISCONSIN

Exall, J.L.**, Vergosen, J.K.**, Pridy, R.W.**, Roesz, M. J.**,

Colubajentsev, R.**, Feltzer, J.**,
* Wisconsin Division of Health, Madison, Wisconsin, U.S.A., ** Wisconsin State Laboratory of Hygiene, Madison, Wisconsin, U.S.A.

Objectifs: To estimate the HIV seroprevalence among newly incarcerated male inmates (ENMI) and to assess the efficacy of voluntary HIV testing.

Méthodes: In Wisconsin, blood serum is obtained from all ENMI for hepatitis B tests; residual sera are stored at -20 degrees C. Since January 1, 1987, ENMI have routinely received HIV-related counseling and have been offered voluntary HIV antibody testing. Sera tested by HIV antibody included: a random sample representing 20% of all ENMI admitted 1/1/88-9/28/88 (n=897); all tested blindly; a 100% sample of ENMI admitted 1/2/87-8/31/87 (n=1689); a random sample voluntarily, 25% blindly; and a 100% sample of ENMI admitted 1/1/88-8/31/88 (n=1651); 75% tested voluntarily, 25% blindly.

Résultats: In 1988, 3(0,30%) of 997 ENMI tested were HIV (ELISA, Western Blot). In 1987, 9(0,53%) of 1689 were HIV; 6(0,35%) of 708 voluntarily tested were HIV; compared to 3(0,31%) of 981 tested blindly (OR=2,79; 95% CI 0,99-11,27). In 1988, 4(0,24%) of 1187 ENMI tested voluntarily were HIV.

Conclusion: From 1986 to 1987, there was a non-significant increase in the HIV seroprevalence among ENMI (OR=1,77; 95% CI 0,44-10,22). While the difference in seroprevalence in 1987 between ENMI tested voluntarily and those tested blindly is not significant, voluntary testing detected 67% of all HIV seropositives. In 1988, 71% of ENMI consented to voluntary testing. In regions of lower HIV prevalence, routine HIV counseling with voluntary testing can be a successful strategy for screening male prison inmates.

M.A.P.24

FRÉQUENTATION HOSPITALIÈRE ET INFECTION PAR LE VIH EN MILIEU CARCÉRAL.

RODRIGUEZ Isabel**, ESPINOSA P.**, STEIN S. C.**,

MOLO DROVOT J.**, HAVILLI VILLALBA F.**,
* Hospital de Pruebas (ENSP) Añejo de Thozes 92061, STEIN S. C. FRANCE
H. P. S. P.

Objectifs: Décrire les caractéristiques sociales, cliniques et biologiques des malades VIH séropositifs pour le prospectif pour le diagnostic de France, 1985 à 88

Méthodes: Etude rétrospective sur les malades hospitalisés de 1985 à 1988 ayant une sérologie VIH+. Cette étude a déterminé parmi les séropositifs, l'âge des patients, le sexe, le mode de contamination, le motif d'hospitalisation, le stade de l'infection VIH (classification du CDC), le taux de CD4 le prévalence de 2 infections VIH.

Résultats: En 1985, 103 sérologies ont été prescrites. De 85 à 87, 40 cas de VIH ont été recensés. 80 87 140 (5,8%) sur 3669 malades ont été hospitalisés, 905 sérologies prescrites, 326 (9,4%) étaient positifs. Parmi ces 206 patients séropositifs, 958 sont des hommes d'âge moyen de 27 ans. 915 sont des femmes par voie parentérale ou 155 originaires de pays d'Amérique, 23 homosexualité, 27 contaminés par voie intraveineuse, 135 par transfusion sanguine, 128 ont été hospitalisés pour la cause de l'infection VIH. 215 ont été traités de CD4 < 200/mm³, 115 ont une antigénémie VIH positive, 565 sont des séropositifs VIH+ de stade 1, 200 de stade 2.

Conclusion: L'accroissement du taux de sérologies dépistées de 85 à 88 et l'augmentation du nombre de SIDA justifient au sein de l'hôpital pénitentiaire l'adaptation des moyens hospitaliers.

Epidémiologie et santé publique Epidemiology and Public Health

M.A.P.31 BLOOD DONATION BY INDIVIDUALS WHO LATER DEVELOPE AIDS

David D. Donnell, M.D., Ziegler, P.O. Clement, M.D., Volendring, P.A., Medical Services of St. Francisco General Hospital, University of California, 50 "PL" Hillway Hospital, UCSF, San Francisco, CA, U.S.A.

Objective: To determine the past blood donations by individuals who later develop AIDS. Methods: The UCSF AIDS Registry has collected detailed medical histories since 1985 from 2605 individuals, 992 of whom had had *Pneumocystis carinii* pneumonia, Kaposi's sarcoma, or cryptosporidiosis at the time of initial evaluation. Patients are asked the date that they last donated blood. It is not known if the blood was discarded after blood bank screening.

Results: 992 patients (99%) had donated blood. 163 patients had not donated blood since 1976. A time when they were unlikely to have yet been infected. The peak year for last donation was 1980 (n=41) and only 4 individuals reported donating blood after 1983. Of these, one patient donated blood 17 months before developing Kaposi's sarcoma, two others 21 and 23 months before AIDS; one patient reported donating blood one month after PCP. Of the 992 who had AIDS, only one other patient reported donating blood after PCP (14 months).

Conclusions: In the era before HIV antibody testing, blood was donated by 13% of gay men who were later likely HIV infected. This blood was not probably discarded. By 1983, transmission had ceased.

M.A.P.33 SEROPOSITIVITE HIV CHEZ LES DONNEURS DE SANG ET ESTIMATION DU RISQUE RESIDUEL EN TRANSFUSION

Coopérite, A. M. M. et le Groupe de travail Séroécrou de la Société Nationale de Transfusion Sanguine - Paris France

Objectif: Comparer la prévalence des donneurs confirmés anti-HIV positif entre 1983 et 1989 et évaluer le risque résiduel de transmission du virus par transfusion. Méthode: Les 10 centres de Transfusion (CT) de groupes de travail regroupent environ le 1/4 de l'activité de collecte des CT français ont rassemblé leurs résultats en individuel les donneurs réguliers (RD) et les donneurs occasionnels (DO).

Résultats: 1) Prévalence des dons anti-HIV positifs

Année	RD	DO	Total (n=103)	ND/DO	DO/DO
1983 (n=604)	119	45	164	119	45
1984	118	47	165	118	47
1987	119	31	150	119	31
1988	104	32	136	104	32

2) Estimation du risque résiduel: Base de calcul = 3% de dons anti-HIV négatifs provenant de donneurs réguliers et donneurs occasionnels en délai maximum de 1 an soit infectés (J.L.M., Lancet 1988 1: 1348)

Intervalle entre dons	Estimation du risque par don
< 2 mois	1/40
2 à 3 mois	1/100
4 mois à 1 an	1/1000

Conclusion: Entre 1983 et 1989, la séropositivité HIV chez les donneurs de sang a diminué de 4 à 6 fois, cette baisse ayant porté à la fois sur les nouveaux et les anciens donneurs. Le risque résiduel transfusionnel diminue parallèlement et est estimé à 1 pour 100.000 dons en 1989.

M.A.P.35 THE EPIDEMIOLOGY OF TRANSFUSION-ASSOCIATED (TA) AIDS

IN CALIFORNIA IN THE UNITED STATES, 1981 TO 1986

James D. Hughes, M.D., Robert H. Ross, M.D., Robert H. Ross, M.D., Centers for Disease Control (CDC), Atlanta, Georgia, U.S.A.

Objective: To describe the demographic and clinical characteristics of transfusion associated (TA) AIDS.

Methods: AIDS cases reported to CDC from 1981 to December 1986 were reviewed. Pediatric TA and transfusion associated (TA) AIDS cases were compared.

Results: Through 1986, 169 children with TA AIDS were reported to the CDC (13% of the 1244 pediatric AIDS cases). The percent of pediatric AIDS cases attributable to TA infection varied by region from 4% in New York City to 50% in Los Angeles. From 1985 to 1987, the yearly incidence of diagnosed cases of pediatric TA AIDS increased from 40 to 82 cases (2X), while PA cases increased from 147 to 301 (107%). The median age at transfusion in pediatric cases was one month (range, birth to 11 years). The median age at diagnosis was 49 months in pediatric TA AIDS cases and 11 months in PA cases.

Pediatric TA AIDS cases were more likely to be male (62%) compared to PA cases (52%). The cumulative incidence of pediatric TA AIDS was 2.4 times higher in blacks and Hispanics than in whites (93% C.I., 1.6-12), although TA AIDS cases were more likely to be white than PA cases (97% vs 15%). The observed to median incubation period was longer for pediatric TA AIDS cases than for PA cases (36 mos. vs 25 mos., p<.001). The median survival after diagnosis of pediatric TA AIDS did not differ from that of PA cases (9.4 vs 10.5 months). **Conclusion:** Children with TA AIDS are distinct from PA AIDS patients. Pediatric TA AIDS cases are being diagnosed at a slower rate than PA AIDS but continue to develop. Donor screening has nearly eliminated new infections; thus this group is important in the study of incubation period in children.

M.A.P.32 SURVEILLANCE FOR UNUSUAL MODES OF HIV TRANSMISSION IN THE USA - A 3-YEAR MULTICENTER STUDY OF BLOOD DONORS

Richard L. Joffe, et al. and the HIV Blood Donor Study Group. Centers for Disease Control, Atlanta, Georgia, U.S.A. Investigators from 20 blood donation sites throughout the USA.

Objective: To monitor levels, trends, and modes of HIV infection in blood donors. Larger, lower-risk population categories for HIV. Because persons with HIV risk are excluded, infection by unknown means (eg, from a heterosexual partner without recognized risk) is relatively easily detectable.

Methods: Seropositive donors at 20 blood centers (approximately 2,000,000 donors/yr) are interviewed using a standardized questionnaire; denominators for seroprevalence rates are determined from blood donor records.

Results: Since June 1984, 147 seropositive donors have been interviewed. HIV Factors for the 114 males and 33 females were homo/seropositivity (52%); intravenous drug use (19%) (92); previous blood transfusion (87%); and sexual partner of a person at risk (89%) (113). Risk factors for the 33 females were IVUD (92); heterosexual partner (82%); 21% of males and 21% of females had no identified risk (81%). Demographic characteristics of HIV were similar to those with identified risk. Using National anonymous Red Cross HIV seroprevalence in first-time donors from 8/87-3/88 (0.037% for males and 0.010% for females), and applying the observed rate of HIV in this study, we calculated that a mean of 1 to 1.64 male and 1 to 4.17 female donors had been infected by unidentified means, such as from sexual partners with unrecognized risk.

Conclusion: Few seropositive donors have traditional HIV risk factors suggesting that heterosexual transmission from partners of unrecognized risk is another possible transmission mode are uncommon. Many HIVs in this study do not have acknowledged HIV risk factors.

M.A.P.34 THE RISK OF HIV-1 TRANSMISSION BY TRANSMISSION OF SCREENED BLOOD

N. Cohen, A. Munoz, K. Nelson, O. Franzer, T. D. Yew*

Jones Hospital Medical Institutions, Baltimore, MD; Texas A & M University, College Station, TX; St. Luke's Episcopal Hospital, Houston, TX; The Methodist Hospital, Houston, TX, U.S.A.

Objective: This prospective study will determine the risk of seroconversion to HIV-1 in a cohort receiving multiple transfusions of blood or blood components screened for antibody to HIV-1.

Method: The study will require 50-60 months to enroll and follow-up approximately 13,000 cardiac surgery patients. Based on current blood product utilization at the three study centers, an estimated 10,000 transfusion exposures will be observed. The probability of HIV-1 transmission will be estimated and the upper bound of the 95% confidence limit will be calculated using the binomial distribution.

Results: To date, serum samples from 2,177 persons representing 29,445 transfusion exposures have been tested. One seroconversion has been identified, our estimate of the risk of HIV-1 transmission by transfusion is 0.002% per screened unit with a 95% upper bound equal to 0.016% per unit.

Conclusions: The interim results of this ongoing study provide valuable information to clinicians and the blood banking community regarding the effectiveness of HIV-1 screening and permit public health officials to make statements with greater confidence about the risk of HIV-1 transmission by screened blood.

M.A.P.36 SEROPREVALENCE OF HIV INFECTION AMONG BLOOD DONORS IN BONE

Barbara L. Halliday, Ippolito, et al.; Ricci, M.; Angeloni, F.; Malin, D. Centers for Disease Control, Atlanta, Georgia, U.S.A.

*Lazzaro Spallanzani Hospital for Infectious Diseases-Rome Italy

Objective: To estimate the prevalence of positive HIV antibodies in a large blood donor population in Rome (about 50% of total blood supply in Rome), to define the epidemiologic characteristics of seropositive subjects, and to evaluate the efficacy of voluntary self-referral programs.

Methods: Since 1983 blood donations were tested routinely for HIV antibodies, and have been screened by personnel and informative materials have been distributed to invite donor belonging to risk groups, to voluntary defer. Seventy-one seropositive subjects were contacted (86%).

Results: Defined prevalence (%) by year and percentage distribution of risk factors of positive donors are reported in table.

Year	males	HIV+ve	prev%	homosex	ITRA	heterosex	Unknown
1985	38323	23	0.06	15.5	84.2	-	5.3
1986	39299	29	0.08	16.0	84.0	60.0	-
1987	47211	16	0.34	15.5	82.5	35.0	-
1988	45919	14	0.30	9.1	36.4	45.4	9.1

Conclusions: The progressive decrease in the prevalence rate among blood donors indicates the efficacy of self-deferral program and emphasize the importance of alternative sites for test, performing and the need of anonymous testing opportunities.

Epidémiologie et santé publique Epidemiology and Public Health

M.A.P.37 36 POST-TRANSFUSIONNEL (P-TRF) HIV INFECTION IN A REGIONAL CITY HOSPITAL SINCE 1980

Quaranta, J.P.; Casotto-Viguer, P.; Sanderson, F.; Virusna, M.; Casotto, J.P.; Dellamanna, Pierre; Maladies Infectieuses, C.R.H.U. Nice, France.

Objective. Nice (400,000 inhabitants) is characterized by a high prevalence of the HIV infection with a seropositive blood donor two times more higher than in France. Blood donors are screened for HIV in our country since August last 1985. At the end of 1988, a P-TRF HIV infection was diagnosed in 36 patients (19 in 82 years, 21 females).

Results. At the first examination, patients were divided 14 in II, 6 in III, 7 in IVa and 11 in IVb according to CDC groups, with low titer count ($301 \pm 205/\text{ml}$), high acute beta-2-microglobulin level ($5.7 \pm 4.3 \text{ mg/dl}$). These results related with p25 antigenemia suggested a bad prognosis which was confirmed by the outcome: 7 more AIDS occurred within 24 months and 15 patients yet alive. 35 patients had a presumed date of contamination ranged between 1980 and 1985 and one after the blood donors screening. Most of the patients were transfused during surgery ($n = 4.1$ blood units), 4 patients in emergency, 2 for haematological diseases (30 and 128 units) and 9 hemodialyzed patients (2 to 8 blood units). Only two of the investigations required to Blood Bank in search of the infected donors has resulted in a concrete proof. **Conclusion.** The P-TRF HIV infection has a bad prognosis compared to others risk groups. Despite the systematic blood donors testing, the risk is low but remains; this should warrant autotransfusion policy in scheduled surgery, or more accurate screening (e.g. antigenemia or PCR).

M.A.P.39 IMPACT OF AN AUTO-DETERMINATION FORM ON BLOOD DONOR SELECTIVITY: A Retrospective Study

Canadian Red Cross, Montreal, Québec, Canada; ** DCC, Montreal, Québec, Canada; *** DCC, St-Jac Hospital, Montreal, Québec, Canada.

Objective. To determine if the use of an auto-determination form would differentiate between blood donors at high and at low risk.

Methods. From February to May 1989, 21,692 auto-determination forms designed at a permanent site which used an auto-determination form. Donors designated their blood for: transfusion (97.7%), or laboratory purposes (1.5%) after reading a summarizing high risk activities. Of these forms only 0.8% could not be utilized. The blood from the laboratory group (LG) was tested but not used.

Results. In the transfusion group (TG) 36,21,197 (0.17%) were ELISA positive, while in the laboratory group (LG) 6,325 (1.84) were positive. WESTERN BLOT confirmation followed for 8,736 (22.24) in the transfusion group versus 4,6 (0.74) in the laboratory group. WESTERN BLOT confirmed individuals in the LG were all males aged 17-29 years. The seroprevalence of HIV antibody was 0.88 for TG and 1.238 for LG. The specificity of our auto-determination form is 98.5%. The negative predictive value was 99.91 and the global efficiency 97.7%.

Conclusion. The auto-determination form appears to be a helpful additional screening method allowing to separate donors in two sub-populations, one at high risk and the other at low risk, thus preventing the utilization of blood from high risk donors and reducing the risk of HIV transmission during the window period.

M.A.P.41 A FOLLOW-UP STUDY OF CHILDREN OF ANTI-HIV POSITIVE HAEMOPHILIACS

Goldman, Eleanor; Lee, Christine A.; Morris-Seith, J.; Griffiths, P.D.; Thompson, and Kermoff, P.S.A. Royal Free Hospital, London, England.

Objective. To monitor the progress of 10 children born to 9 anti-HIV seropositive fathers between December 1984 and May 1988.

Methods. Infants were seen soon after birth and then at yearly intervals. Their physical development was assessed with particular attention to growth. Ability and intelligence in relation to expected levels at any given age was presented using WISC-R, WPSI and other relevant tests. Laboratory tests for anti-HIV, p24 antigen and CD4 lymphocyte count were performed at each visit. The duration of seropositivity and stage of HIV disease of the father at the time of conception was assessed retrospectively from clinical records and results of laboratory tests carried out on stored serum. The anti-HIV status of the wives was checked from 1985 onwards.

Results. Ten children were conceived by 9 seropositive, p24 antigen negative, asymptomatic haemophilic fathers. All 10 children have been anti-HIV negative since birth and behave normally. Eight wives have remained anti-HIV negative, one of them after two full term pregnancies. One wife chose termination of a second pregnancy when found to be anti-HIV positive.

Conclusion. None of the babies appear to have any evidence of overt or latent HIV disease. In spite of being made aware of the risks, some anti-HIV positive haemophilic fathers and their wives have chosen to have children.

M.A.P.38 BLOOD SALE AND DONATION BEHAVIOR OF IVDRS

Chitwood, Dale, D.A.; Cosnerford, M.; McCoy, C.B.; et al. Trinidad, L.I., T.

*University of Miami School of Medicine, Miami FL., USA.

Objective. To describe the blood selling and blood donation behavior of intravenous drug users (IVDRs) between 1978-1988.

Methods. IVDRs (703) in drug treatment in South Florida who were enrolled in a longitudinal study of HIV serostatus were asked items pertaining to the sale and donation of blood.

Results. Of the 703 IVDRs, 181 (25.7%), had sold or donated blood since 1978; of these 181, 63.02 had sold and 37.02 had donated blood. There were no significant demographic (age, gender, ethnic) differences between those who donated and those who sold blood. Of the 181 IVDRs, 92 reported their last sale or donation to have occurred after 1985, the year HIV screening in blood banks was instituted. Of these 92, 63 had sold blood. The seroprevalence rate among those selling or donating since 1978 was 11.62%; 7.4% of those selling or donating after 1985 were HIV+. There was no difference in seroprevalence between those who sold and those who donated blood.

Discussion. IVDRs continue to sell or donate blood in spite of attempts to persuade them not to do so. A larger percentage sell blood than donate. While it is not known if any of this blood eventually gets into the blood bank supply for human use, the donation or selling of blood by IVDRs, a high risk group for HIV infection, poses a public health threat.

M.A.P.40 PREVALENCE OF HIV-ANTIBODIES IN BLOOD DONORS IN THE FRG

Drooghe, Dijk, K. Roemer, B. Kuzanek, G. Casper, G. Elbert, W. Graubart et al.

Dept. Transfusion Medicine, University of Ulm and German Red Cross Blood Bank, Heimbühelstrasse 10, D-7800 Ulm, FRG, for the German Red Cross Blood Bank in the FRG

Objective. In a multicenter study of the German Red Cross Blood Banks prevalence and epidemiology of HIV-antibodies in blood donors are studied.

Methods. From July 1985 to September 1988, 7.6 million donations given by about 1.5 million blood donors were tested for HIV-antibodies routinely and 200 were found to be positive in at least one Western blot (WB).

Following a rather rapid decrease in 1985/86 the overall seroprevalence remains thereafter constant with rates of less than 2 per 100,000 until the end of 1988. The geographic distribution varies with the highest prevalence in urban centers and correlates well with the geographic incidence of AIDS cases.

More than 90% of the seropositive donors were homo-bisexual men, drug abusers and heterosexual partners to known AIDS-risk persons. Age and sex distribution were comparable to the patterns in recognized AIDS patients in the FRG.

Conclusion. Our data show that in blood donors, representing one low risk segment of the general population, there is no evidence of a rapid spread of HIV infections. However, they do not imply the absence of new infections but that infection rates on a very low level. At present, we have no indication that unaware heterosexual transmission occurs frequently in blood donors. However, there is a shift to donors infected heterosexually by contact to known risk persons. This suggests a more efficient exclusion of persons with a recognized risk.

(Supported by BMFT, FKZ 1-053-88)

M.A.P.42

HENOPHILIACS DOUBLY INFECTED BY HIV-I AND HIV-II

Maasafu, Akao; Fujisaki, I.; Kojima, K.; Bada, M.; Ikematsu, S.; and Fujisaki, M.

Tokyo Medical College, Clinical Pathology, Shinjuku, Tokyo, Japan.

Objective. On the investigation of immune abnormalities and clinical courses of HIV-I infected haemophilic, we found patients infected by both HIV-I and HIV-II have a more rapid fall in their immune functions than those infected singly by HIV-I.

Subjects and Methods. 185 haemophilic are involved in this study. Anti-HIV-I antibodies are assayed by WB and RIVACOR, and anti-HIV-II antibodies are assayed by RIVACOR, PA, IIF and WB method. Immunological parameters such as lymphocyte subsets, 2 microglobulin, immunoglobulin levels and HIV-related markers are measured. **Results.** 107 of 185 haemophilic are seropositive in HIV-I (57.8%). 11 of 185 are seropositive in HIV-II. Seven haemophilic are seropositive both in HIV-I and HIV-II. Two of 7 have been at the stage IV-C(DICD) in 1986, and one other case has been at the stage IV-A in 1987. Another case has been clinically severe decomposed liver cirrhosis and the stage IV-A. Clinical features are widely varied, such like toxoplasmosis, PCP, CMV pneumonia, IDV, HIV pneumonia, perovirus infection, and so on.

Conclusion. We have already reported the presence of HIV-I infection were not different in the existence of preceed infection of HIV-II in Japanese haemophilic populations. But, at 7 double infection cases have shown advanced symptoms in this study. These data strongly suggest HIV-I seroconverted infection by HIV-II might affect in vivo on the progress of immune dysfunction by HIV-I infection. Further cumulative investigations are urgent.

Epidémiologie et santé publique Epidemiology and Public Health

M.A.P.43 ANTI-HIV SEROPREVALENCE IN BLOOD DONATIONS FROM JULY 85 UNTIL DECEMBER 85 IN SWITZERLAND

Burkhardt, Johann, L., Müller-Brunner, E., Penth, L.H. and Bachmann, P.
Kantonsspital, Geneva, Switzerland; University of Medicine, University Hospital, Geneva, Switzerland

From July 1985 until December 1986, the Central Laboratory Blood Transfusion Service Swiss Red Cross collected over 1 million units of blood from non-remunerated donors. We tested these units for anti-HIV antibodies with enzyme-linked immuno assay based on viral lysates or recombinant proteins. During this time, 1197 units were confirmed positive. We observed, however, a dramatic decrease of seropositive units and of the resulting seroprevalence between the 2nd half of 85 and the 2nd half of 86 (39 and 1% or 38.3 and 0.7% per hundred thousand, respectively). Furthermore, we noted a decrease in each of the following categories:

Seroprevalence (P/100)	2nd half of 85	1st half of 86	2nd half of 86
males (offshore)	5.5	0	0
females (offshore)	18.5	2.5	0
males (offshore)	20.2	1.5	0
repeat donors	18.5	3.8	0
first-time donors	71.8	0	0

74 % of the positive units were donated by 29 years old or younger donors, who provide about 65% of the blood. We found indeterminate results in 1 unit from females and three with increasing age. During 1986, we tested 73 units with a repeatedly negative screening test by using the polymerase chain reaction (PCR) with DNA extracted from about 1 µg peripheral blood mononuclear cells. PCR-negative units were near serologically confirmed positive. Based on the present seroprevalence figures and the fact that on average 14 units per donor per year are collected, we calculate the probability for a false negative unit to be less than 1/8500.000.

M.A.P.44 DIFFERENT EXPERIENCES OF HIV INFECTION IN SWITZERLAND (A) FROM THREE LIAISON CENTERS: GENEVA, BASEL AND ZÜRICH

Italy, France and G. Sereny are comparable in population (ca. 5 million) and number of H (ca. 3,500). Italy and Germany are also comparable for type of factor concentrates given to H and S (concentrator, FTS 50 plasma-derived plasma). In France, H is ca. 50% seropositive and 50% seronegative (P). But S is most relatively disease free. The table shows that at the end of 1987 there were more AIDS and anti-HIV-1 cases among Sereny than in Italy or G. Also there were more French H anti-HIV-1 cases than in Italy, though AIDS cases were similar. For G, cases with AIDS and anti-HIV-1 were comparable in Italy, Germany and France.

	All haemophiles		Haemophilia A		Haemophilia B				
	Total	% anti-HIV-1	Total	% anti-HIV-1	Total	% anti-HIV-1			
Germany	2478	140	1372	2332	131	1024	326	17	148
France	2458	56	1208	1007	46	903	38	18	135
Italy	2772	57	437	3459	38	312	310	32	138

and the reason for differences between France/Germany 2nd Italy is unclear. In the early 80s, when most HIV infections occurred, Sereny A was treated generally with larger Sereny B (P) units than Italy (ca. 500 L/inf vs 25,000). Hence, Sereny A had a higher cumulative likelihood of being exposed to HIV from 1978 to 1985, when viral-infected plasma was used for infection. This explanation, however, would not account for the higher prevalence of anti-HIV-1 in France, because P/II units were similar to that in Italy (25,000 L vs 25,000). Hence, there appear to be population differences in susceptibility to develop HIV infection in haemophiles.

Le VIH chez les prostitué(e)s et les sans-abri HIV in Prostitutes and Homeless Populations

M.A.P.46 HIV SPREAD IN PROSTITUTE POPULATION IN TOULOUSE (FRANCE)

Copin-Merganteau, C., Dubi-Jacques, J., Besson, S., et al.
Laboratoire de Virologie, CHU Purpan, Toulouse, France.

**Service de Dermatologie, CH La Grave, Toulouse, FRANCE.

Objective. To assess the risk of contamination through prostitution (male or female) in our city.

Methods. We systematically screened anti-HIV-1 antibodies in 97 female prostitutes living in the General Disease Centre along May 1985, to January 1986. Screenings were realized using 2 immunoenzymatic techniques (Abbott and Wellcome). All positive were confirmed by the Western-blot assay (Du Pont de Nemours). Results: 5 of the 97 prostitutes were seropositive. We screened the first one in 1985, two others in 1986, one in 1987, and one who seroconverted in 1988. But 2 of them were intravenous drug abusers, so it was not possible to incriminate sexual transmission with certainty. None of the 92 women was seropositive. Among the seropositive and transfused, one patient seroconverted in 1985, and 3 patients were seropositive (2 in 1986 and 1 in 1987). For these patients drug addiction is unknown.

Conclusion. The prostitute population of Toulouse seems to be relatively free of HIV-1 contamination. But these results do not entirely reflect the true situation as a marginal prostitution also exists with people who are generally not subject to any control. Although these results are relatively reassuring, elementary precautions must be taken to prevent the spread of the disease, since contamination through prostitution has been shown to be a real risk.

M.A.P.45 HEPATITIS B AND HIV COINFECTION IN HEMOPHILIACS.

Radzinski, Paul, White, C., Milliken, C. Lewis, S.M.
Department of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC USA

Objective. Like HIV, HBV also infects lymphocytes, alters the immune response, and has reverse transcriptase. The clinical significance of HBV and HIV coinfection was investigated.

Methods. Serial HIV and HBV tests were determined in a cohort of 155 severe Factor VIII deficient haemophiliacs between 1982-1988. Lymphocyte subset analysis and clinical status were evaluated at regular intervals. Results: By 1982 the majority of severe VIII deficient patients demonstrated serological evidence of HBV (92%) and HIV (49%) exposure. Seven HIV infected patients reverted from anti-HIV to HBsAg positive suggesting persistence, reactivation, or reinfection of HBV in this population. A trend toward lower immune status deterioration was noted in patients with persistent HBsAg carriage.

	HIV (n = 10)	HIV anti-HB+ (n = 98)	
mean CD4+	396.5	278.0	*p<0.05 (Kruskal Wallis
mean CD4+	465.5	259.0	Chi Square)
% developing AIDS	0/10	22/98	*p<0.09 (Chi Square)

Conclusion. HIV infection may allow HBV reactivation or reinfection which might worsen HIV viraemia of haemophiliacs with even anti-HIV seropositive HIV infected patients. Active HBV infection perhaps by infecting lymphocytes may alter HIV induced immune deterioration.

M.A.P.47 CLONES OF PROSTITUTES - A REVIEW. Provenza, M., Pignatelli, G., Murelli, B., HIV Counseling Clinic, National Virus Laboratory City Hospital, SIRMING, Scotland.

Objective. To study the response of clients of prostitutes to health risks including HIV and sexually transmitted diseases (STD).

Methods. The City Hospital HIV Counseling Clinic offers self referred individuals confidential pre-test counseling. The number of clients of prostitutes using condoms, who regular sexual partners, history of STD, HIV antibody status and socio-economic status were noted.

RESULTS	of 1627 patients who have attended between October 1985 and October 1988, 73 were clients of prostitutes. Their socio-economic status was as follows:- 17 professional/managerial, 27 skilled, 16 semi-skilled, 2 unskilled, and 11 Unknown. 21% of clients tested HIV sero-. They were also injection drug users (IDU), still sharing needles, never using condoms and each had regular partners.				
Condom Use	N	Regular Partner	History of STD	Client	HIV Test
Always	11	0	0	also IDU	0
Sometimes	12	10	0	0	9
Never	50	14	0	0	11
					2

CONCLUSIONS: 1) Suffer sex not being practiced.
2) The clients with regular partners tend not to use condoms.
3) Prostitutes are at risk from clients.
4) Given the relatively high socio-economic status of the group it is surprising that education has not altered behaviour.

M.A.P.48 HIV SEROPREVALENCE AND RISK BEHAVIORS OF ITALIAN PROSTITUTES

Tirelli, G., De Marco, R., Caporali, P., et al. Giardini, M.M.
Sergio, Alberto*** and Ressa G.
From the CICAT AIDS Activity Unit, General Infirmaries Ombelino Infirmary; ** Istituto Dermologico S. Galliciano, Rome; *** Istituto Nat. Inf. Osp. "Sacco", Milano; ** Clinica Medica Univ. Proffitt; ** Ministry of Health, Rome, ITALY.

Objective. To estimate HIV seroprevalence among prostitutes in different Italian areas. To study risk behaviors associated to HIV seropositivity in female prostitutes.

Methods. The study has been conducted in Rome, Milan, Naples and Foggiana. Different sources have been utilized in order to contact female prostitutes: STD clinics, AIDS facilities, organized prostitutes agencies. In particular, a collaboration with the Committee for Civil Rights of Prostitutes was set up. Serological, clinical, demographic and sociological data were collected. An individual questionnaire was administered in order to collect information about risk behaviors and sexual practices.

Results. Three hundred and five female prostitutes were studied. Anti-HIV antibodies were found in 3 out of 192 non-drug-injecting prostitutes (1.5%) one of those developed AIDS, representing the only clinical case reported in a non-addicted prostitutes in Italy. Among drug-injecting prostitutes, 4 out of 113 were anti-HIV seropositive (34.5%).
Conclusion. HIV seroprevalence is very low in non-drug-injecting prostitutes. The high prevalence of seropositivity among drug injecting prostitutes suggest attention for the spread of HIV infection in the heterosexual active population.

HIV SEROPREVALENCE IN HETEROSEXUAL MEN AND WOMEN. DENVER METRO STD CLINIC, 1980-1986. John, Franklin; Oles, R.; Douglas, J. Denver Public Health, Denver, Colorado, USA

Objective: To monitor the course of the HIV epidemic through serologic surveys in an urban STD clinic.
Methods: Each year, 1985-86, over 2000 consecutive, unselected STD clinic patients in defined risk behavior (RD) groups were tested for HIV serology (ELISA, WB confirmed). HIV positive patients without a stated risk for HIV infection were retested to assess correct RD categorization.

RD Group	No. HIV Positive/No. Tested (%)				Total
	1985	1986	1987	1988	
Gay Men	20/104 (4.7)	60/125 (6.4)	72/192 (3.7)	67/160 (4.3)	257/521 (44.3)
Female Prostitutes	1/12 (8.3)	0/13 (0.0)	2/13 (15.4)	1/39 (3.0)	4/32 (1.1)
MSM					
Male	2/29 (6.9)	1/42 (2.0)	0/16 (3.2)	0/49 (0.0)	7/221 (2.6)
Female	0/10 (0.0)	0/20 (0.0)	4/26 (15.4)	2/38 (7.7)	2/170 (1.2)
Heterosexuals					
0/229 (0.0)	1/361 (0.3)	1/340 (0.3)	3/470 (0.4)	5/368 (0.3)	
Female	0/111 (0.0)	0/222 (0.0)	1/225 (0.3)	0/281 (0.0)	0/960 (0.2)

Of 2.5% non RDV heterosexual men and women at high risk of STD only 7 (0.3%) were HIV positive including 3 with RDV sexual contact. Three of 4 positive female prostitutes were RDV.

Conclusions: By 1988, at least 10 years after the first HIV infection in Denver, there is no evidence that the HIV epidemic is affecting beyond gay men, MSM, and their sexual contacts. Accurate epidemiology requires correct RD categorization using confidential interviews.

M.A.P.55

COMPARISON OF RACE/ETHNICITY AND TRANSMISSION CATEGORY IN HETEROSEXUAL HIV SEROPREVALENCE SURVEYS. G.S.; Kirby, C. Centers for Disease Control, Atlanta, Georgia, U.S.A.

Objective: An evaluation of voluntary HIV counseling and testing services by 1988 and transmission category in the United States.
Methods: Sixteen States were surveyed. A total of 142,000,000 (43% of the total U.S. population), provided demographic and risk factor information on all persons attending public sector, voluntary HIV counseling and testing services. There were a total of 83,851 persons tested, 52 were female and 178 were male. Compared to 124 risk categories, 117 were positive. The population of these States (77% White, 13% black, 10% Hispanic, 1% other) was similar to the total U.S. population. A higher proportion of respondents (11%) who selected "other races" as their race were seropositive. The highest risk transmission category was heterosexual (34%).

Conclusions: The demand for counseling and testing services in the U.S. is increasing rapidly. A higher proportion of persons receiving CT services are from minority populations than their representation in the U.S. population. The highest risk transmission category was heterosexual. The highest risk group was men and 11% of HIV drug users were selecting testing services.

M.A.P.56

HIV SEROPREVALENCE IN PATIENTS WITH PID SPENDING. Rhoda, S., Friedman, F., Dept. of OBGYN, Mount Sinai Medical Center, NY, NY, USA.

Objective: 1. To determine the seroprevalence of HIV in women with PID and 2. To determine whether HIV seroprevalence in PID patients is related to non-IV cocaine use and/or serologic evidence of past/present syphilis.
Methods: The STD Clinic Service provides care to indigent outpatient women from areas of NYC hit hard by AIDS. From 11/7/88-1/15/89, all clinic PID admissions had serum samples, which were drawn for syphilis serology, serologically screened for HIV antibody. All PID patients were routinely offered HIV testing in addition to routine GC, chlamydia, and syphilis screens. Sexual and drug use history were obtained on all patients.

Results: 21 patients were admitted; 16 had specimens suitable for anonymous testing; 3/18 (16.6%) were seropositive; 12/21 (57%) patients requested confidential screening; 3/12 (25%) were seropositive.
Of the known seropositives:
11 reported illicit drug use (1/3 IVDA; 2/3 non-IV cocaine)
2/3 reported sexual contact of men at risk (1/10M; 1 non-IV cocaine)
0/3 had positive syphilis serology
1/2 (14.2%) of PID admissions had past serologic evidence of syphilis.
2/3 (67%) were consistent with coinfection.

Conclusions: In the small sample of PID patients screened, 16.6% seropositive rate. 1. HIV antibody found in non-IV cocaine users without other known risk behavior. 2. No association between HIV seropositivity and positive syphilis serology was demonstrated.

M.A.P.57

RISK FACTORS FOR HIV-1 INFECTION IN A BRITISH POPULATION. Brock, E.; Dore, C.; Gomez, G.; Galloway, G.; Hens, C.; Ross, V.; Wai, T.; Barry, P., et al.

Objective: Determine risk factors for HIV-1 infection and monitor testing trends in attendees at a London sexually transmitted diseases clinic.
Methods: Behavioral characteristics of individuals attending for HIV-1 testing were collected. HIV tests performed by screening with a competitive ELISA (Mellcor) and antibody capture ELISA (Abbott) as confirmatory test. Results: Between September 1985 and June 1988, 6923 individuals were tested, 558 (8%) were seropositive. Of these 523 (94%) were men and 35 (6%) women. The seropositive pattern conforms to that currently observed in other industrialized nations. However, risk factors for HIV-1 seropositivity in the non-IVDA were heterosexual intercourse with an HIV infected partner (RR 14; 95% CI 7-25.8), intravenous drug use (RR 60; 95% CI 18-200) and heterosexual contact with a Central African resident (RR 27; 95% CI 10-74). Risk factors for men (n=555) were heterosexual contact with HIV infected partner (RR 15; 95% CI 6.5-207), being homosexual or bisexual (RR 9; 95% CI 3.6-15.5), intravenous drug use (RR 42; 95% CI 21-83) and heterosexual contact with a resident from Central Africa (RR 12; 95% CI 6-40). Testing trends showed a sustained increase in number of individuals tested, this coincided with media of increased media attention on HIV infections/AIDS, involving both Government and popular news/TV campaigns. The most pronounced increase was observed in heterosexual males and females with no other risk factors.
Conclusions: 1) Heterosexual and homosexual transmission were implicated in this British population. 2) The media campaigns have increased awareness of HIV infection/AIDS as a major public health problem.

M.A.P.58

HETEROSEXUAL TRANSMISSION OF HIV IS RARE AMONGST ATTENDERS AT AN STD CLINIC IN LONDON. Burt, D.; Mulholland, C.; Tolin, N.; Christie, I.; Palmer, D.; J. Palmer, D.; Benavise, J. E. Dept. Of Medicine and Virology, St. Thomas' Hospital, London, UK

Objective: To assess HIV seropositivity amongst attendees in an STD clinic.
Methods: All patients having routine chlamydia tests for gonorrhoea between June 1988 and April 1989 were offered an HIV test. All seropositive, irrespective of the result of which could be anonymous.
Results: By the end of December 1989, 4,972 patients had been entered into the study. Of these, 453 patients (9.1%) declined the HIV test. Those declining included 14 higher risk patients. 4,519 patients had sera obtained similar to those agreeing to the test. 4518 attendees were tested, 814 (18%) of whom wished their result to be anonymous.
15 of 4518 (0.3%) were HIV antibody positive, 27 of 247 heterosexual or bisexual men (10.91) and 8 (3 women, 5 men) of 426 heterosexuals (0.38) were positive. 11 heterosexual women were negative, 2 of 27 homosexual positives and 6 of 8 heterosexual positives were Afro-Caribbean. 211 partners from Africa (164 from West Africa) were negative for HIV2.

	HETEROSEXUAL POSITIVES		Total tested
	IWA Contact	No risk factors	
Male	3	1	2236
Female	2	1	2025

Conclusion: This sexually active population with a higher than average prevalence of gonorrhoea, chlamydia and other STD's has low HIV seropositivity in spite of the potential for importing cases from endemic areas.

M.A.P.59

HIV PREVALENCE IN AN AIDS COUNSELLING CENTRE IN ISRAEL. Handzel, I.; Bar, J.; Burstein, B.; Herz, M.; Levinstein, B.; Nave, N.; and Ben-Zvi, J., N.

Explo Hospital, Hebrew University School, Rehovot, Israel.

Objective: To determine HIV prevalence among risk groups in an AIDS center in Israel.
Methods: All applicants to the AIDS clinic started at our center in 1983, were interviewed and tested for HIV antibody. In 1984, 1985, 1986, 1987, I.V. drug addicts (IVDA), recipients of blood transfusions (BT) as well as non-risk group applicants (N) were tested.

Results: The number of individuals tested and results were as follows:

Groups	1985	1986	1987	1988
IVDA	2	7	11	22
BT	1	2	4	9
N	56	106	514	415
Total	406	299	769	661
% HIV - in risk group	10	10	8.7	6.4

Thus, the proportion of non-risk group applicants clearly increased while that of MSB and percentage of HIV seropositivity diminished.
Conclusions: a) The low prevalence of HIV infection among risk groups in Israel may be correlated with the still low incidence and growth of AIDS in Israel. b) The AIDS counselling center is being frequented by the wide public, while risk group members do not use it sufficiently.

M.A.P.60 TRENDS IN HIV SEROPREVALENCE AMONG SELF-IDENTIFIED RISK GROUPS UTILIZING ANONYMOUS TEST SITES IN SAN FRANCISCO

Greenhalgh, John E.*; Wilson, N.P.*; Nguyen, D.H.*; Long, G.P.*
*San Francisco Department of Public Health and **California Department of Health Services, San Francisco, California, U.S.A.

Objective: Describe trends in HIV seroprevalence within specific risk groups using Anonymous Test Sites (ATS) in San Francisco.

Methods: During the 36-month period July, 1985 to June, 1988, demographic and risk information was collected by self-administered questionnaires from 41,800 clients visiting the ATS for the first time for HIV antibody testing.

Results: HIV SEROPREVALENCE BY QUARTER (7/85 - 6/88)

	1985			1986			1987			1988		
	%	N	%	%	N	%	%	N	%	N	%	
Metropolitan	2%	24	3%	3%	3%	3%	3%	3%	3%	3%	3%	
Gay/Bisex/Men	34	36	36	37	35	33	37	44	42	35	35	
IV Drug Users	9	5	9	9	5	8	3	7	12	6	6	
Gay/BT (VDUs)	57	72	60	74	54	71	68	85	82	74	85	
ST clients	27	28	30	23	22	18	17	21	20	22	20	

Complete risk group data were available for 63% of those tested for HIV antibody. Overall seroprevalence declined from 27% in July, 1985 to 12% by June, 1988 (p<0.001). Due to increasing rates of heterosexuals served (37% of all clients initially) vs. 63% during the final quarter) and decreasing usage by gay/bisexual men initially, declining to 24%.

Conclusions: Despite marked shifts in utilization patterns at the ATS, HIV seroprevalence within major risk groups has remained relatively constant.

M.A.P.62 EFFECTIVENESS OF VOLUNTARY HIV ANTIBODY TESTING PROVIDED AT A CLINIC TREATING SEXUALLY TRANSMITTED DISEASES

Stenberg, Michele A.*
*San Diego County Department of Health Services, San Diego, CA, U.S.A.

Objective: To characterize Sexually Transmitted Disease (STD) clinic attendees who elect to receive HIV antibody testing and fail to return for results.

Methods: Patients presenting at STD clinic were offered the opportunity to have HIV antibody testing to obtain the result of a second visit. Patients who participate complete a questionnaire regarding sexual orientation, if drug use, etc. ELISA positive specimens were tested by Immunofluorescent Antibody.

Results: Between June and August 1986, 1065 patients attending clinic for evaluation of STD were tested for HIV antibody. Forty-six percent returned for test results. Rate of return was as follows: positive/0.5%, negative/41.7%, total males/30.3%; total females/36.5%. Rate of return by treatment category:

gonorrheal males/25%, gonorrheal females/38.8%, heterosexual males/38.7%, heterosexual males IV drug users/37.5%, heterosexual females/36.9%, female IV drug users/36.8%. Return rates by ethnic group: white/55%, black/26.3%, Hispanic/41.8%.

Conclusions: While for HIV antibody test results among patients tested while awaiting STD services are poor, gonorrheal and gonorrheal males, groups with highest awareness of their risk of HIV infection, were most motivated to return for results. Immunofluorescent, if drug users, females and non-blacks had high failure rates. Increased educational efforts and improved strategies to motivate these groups must be developed.

M.A.P.64 HIV SEROPREVALENCE SURVEYS IN THE SAN FRANCISCO BAY AREA

Wilson, N.P.*; Greenhalgh, J.P.*; Long, G.P.*
*San Francisco Department of Public Health and **California Department of Health Services, Sacramento, California and** California Department of Public Health, San Francisco, California, U.S.A.

Objective: To estimate HIV seroprevalence in sexually transmitted disease (STD), women's health, tuberculosis and drug treatment clinics were begun in the San Francisco Bay Area in 1984.

Methods: Seroprevalence surveys in sexually transmitted disease (STD), women's health, tuberculosis and drug treatment clinics were begun in the San Francisco Bay Area in 1984. In 1984, 1985 and 1986, we will collect an additional 35,000 in 1989. With active participation from all health jurisdictions and the Centers for Disease Control, standardized research protocols were developed for conducting non-blinded and blinded HIV serosurveys. Available data on blinded HIV antibody testing from 5 health jurisdictions adjacent to SF were analyzed by demographic characteristics and risk group. Comparable data are not yet available from SF clinics.

Results: SF (1986) of 2770 specimens were retested by ELISA reactive and confirmed positive by Western blot analysis. Among STD clients, males had a significantly higher rate of positivity (2.7%) than did women (0.7%).

Among non-blinded (1984) men were significantly more likely to be positive (22%) than those with undetermined risk (3%) or all other risk groups (0.7%) for HIV antibody. Among women, risk factors were obtained.

Seroprevalence among STD clients did not significantly differ across age groups or across counties.

Conclusion: The 1.3% seroprevalence in selected clinics demonstrates the scope and geographic distribution of the HIV epidemic for counties adjacent to a major AIDS epicenter.

M.A.P.61 TRENDS IN HIV SEROPREVALENCE IN AN URBAN SEXUALLY TRANSMITTED DISEASE CLINIC, 1984-1989

Goodfield, E. S.; Bunker, S.; Sobberg, S.; Hopkins, S.; Swanson, D.; Hayes, M. Seattle-King County Department of Public Health and University of Washington, Seattle, Washington, U.S.A.

Objective: To determine trends in the prevalence of HIV infection in an urban sexually transmitted disease (STD) clinic over 2.5 years.

Methods: In a public STD clinic, HIV antibody was assayed in initial-visit patients who had syphilis blood tests in Oct-Nov 1986 (N=367), Aug-Sep 1987 (N=352), Feb-Mar 1988 (N=382), and Sep-Nov 1988 (N=610); 1989 results are pending. Serum and demographic/risk data were de-linked from identifiers

prior to HIV ELISA; positivities (TPVs) were confirmed by Western blot. Trends were analyzed by chi square for linear trend, non-homogeneous and seasonal, non-homogeneous (NHN) and HIV-1 seroconversion drug users.

Results: HIV+ rates for the 4 periods were: 10% (14/24) (58%), 7/18 (39%), 17/30 (57%), and 41/201 (21%) (p<0.1); NET 1986/1987, 0/215 (0%), and 5/779 (0.6%) (p<0.001); all NET 0/241, 1/330 (0.3%), 1/352 (0.3%), and 17/1502 (0.8%) (p<0.001); among NET in Sep-Nov 1988, HIV+ included 8/67 (0.8%) males and 4/528 (0.8%) females; 2/358 (0.24) whites and 9/466 (1.9%) blacks (p<0.001); and rose steadily with age through age 35-39 (p<0.002).

Conclusions: In 1989, HIV seroprevalence was apparently stable in STD clinic HIV. By contrast, the HIV rate rose in NET, primarily in blacks and IVUD, and with increasing age. STD clinic patients, especially ethnic minority NET, IVUD, and their sex partners, are among the highest priority target groups for HIV counseling and testing and other behavioral interventions.

M.A.P.63 EPIDEMIOLOGICAL OBSERVATIONS OF A TERRITORIAL HIV SCREENING CENTRE IN MILAN

Schiavarelli, Ilario; Battelli, M.; Nelli, N.C.; Nelli, M.; Dra, M.; Nili, G., A.S.

Vigorelli Cal' Grande Hospital, Milan, Italy. * Public Health Office of Milan, Milan, Italy

Objective: To study epidemiological patterns of HIV diffusion in one population in an Italian urban territory.

Methods: During the period October-December 1988, a territorial tuberculosis Department for AIDS research had been operating in a town district (Milan II, population 80,000) dealing with information, spontaneously requested diagnostic examinations and follow-up of people at risk. 1,200 subjects asked for serological study and were examined (1,020 males, 180 females); 501 declared themselves intravenous drug addicts (106), 180 men or women, 1,020 being non-heterosexual intercourse partners, 72 family contacts, 57 blood recipients. It passed to professional risk, the determination of anti-HIV Ig was performed by ELISA and WB methods.

Results: Evidence of infection was determined in 270 (26.4% of the group), 160 heterosexual (16.8%), 102 non-heterosexual (20.2%), 102 men or women intravenous drug users (20.2%), 72 family contacts, 57 blood recipients. It passed to professional risk, the determination of anti-HIV Ig was performed by ELISA and WB methods.

Conclusions: In the population considered, the group of IVUDs suffers the highest percentage of seropositivity, at comparable levels as in Italian cities, whereas the percentage of non-heterosexual is lower than the national average. 5.8% among partners of early seropositive subjects resulted infected, indicating the important standard of risk of HIV diffusion via heterosexual intercourse.

M.A.P.65 RETROSEROLOGICAL DETERMINATION OF HIV: PREVALENCE AND RISK FACTORS

Quilley, Robert; Stone, C.*; Merlet, A.*; Gold, J.*
* Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia.

Objective: To determine the prevalence and risk factors associated with HIV infection in heterosexuals requesting HIV antibody testing.

Methods: Between March and December 1988, risk factors of heterosexuals who tested positive for HIV antibody testing were assessed. Results: Positive results were obtained in 42 heterosexuals (1984 men and 1938 women) who were tested for HIV antibody. Fifty one (0.9%) were found to be HIV antibody positive. These included 27 men (14.2%) and 24 women (1.2%) who were intravenous drug users (IVDU's), with more male IVDU's infected (23) than women (8). Seven clients (15 men and 2 women) were found to be infected by contaminated blood, and one woman by a contaminated artificial insemination. Sexual contact was the only identified risk factor in 25.5% (12). Seven of these were men who postulated prostitute contact as a risk factor, while all of the remaining 6 HIV antibody positive heterosexuals (3 men and 3 women) had sexual partners who were not HIV infected.

Conclusions: Intravenous drug use was the major HIV risk factor among heterosexuals. However, sexual intercourse was also a major HIV risk factor in a sizable proportion of clients. These results indicate that although IVDU's remain a high priority group to be targeted in education and behaviour change programs, sexual behaviour change in the broader population is also necessary if HIV transmission is to be arrested.

M.A.P.66

CHARACTERIZATION OF HIV INFECTED STD CLINIC PATIENTS IN ANTWERP, BELGIUM

Eric Smits, Léon Van der Bruggen R., Sylvie E. Vercauteren G. and Pieter P. Institute of Tropical Medicine, Antwerp, Belgium.

Objective: To define the prevalence of HIV unassociated infections among STD patients unaware of their HIV serostatus.

Methods: In 1988 all new patients consulting an STI-clinic in Antwerp, Belgium, and unaware of possible seropositivity, were screened for the presence of HIV-antibodies. During the same year 20 persons with test results were not followed at the clinic. Confirmed HIV positive patients were screened as well as those who wanted to know their serostatus, whereas anonymous testing results were not identifiable for patient and physician) was performed for the others. Only patients residing in Belgium were included in the study. HIV was examined by enzyme-linked immunosorbent assay (ELISA) using anti-HIV-1-microcylinder system. Serogel technical and positive sera were confirmed with Western Blot (Dupont de Nemours).

Results: Prevalence of HIV-infected patients: 1 and 95% confidence interval: (0,1).

RELATIONS	number/total	% (95% CI)
male heterosexuals	1/278	0,36 (0,01-1,42)
male homosexuals	1/44	2,27 (0,10-12,02)
female heterosexuals	2/255	0,78 (0,10-2,06)
female prostitutes	0/44	0 (0,00-5,90)
seam	0/45	0 (0,00-7,87)

Of a total of 252 patients tested, 222 (88%) were tested confidentially and 30 (12%) anonymously. From 750 patients tested, 562 (75%) and all were tested confidentially.

Conclusions: These data suggest a low prevalence of HIV-infection in heterosexual Belgian patients consulting for STI-related problems, despite a high proportion (100%) of men WHO heterosexuals among Belgian STD patients.

M.A.P.68

CHARACTERIZATION OF HIV INFECTED STD CLINIC PATIENTS IDENTIFIED THROUGH ROUTINE VOLUNTARY SCREENING IMPLICATIONS FOR FUTURE HEALTH CARE NEEDS

Richard Etkon, Stephen Glanville, James McNeil, J.N., Joseph Kompane, A.M.,* Braithwaite, W.* and Hood E.L.W.** * Baltimore City Health Dept., ** Johns Hopkins Univ., Baltimore, USA.

Objective: To describe demographic and historical characteristics of HIV infected patients identified by a routine voluntary screening program in Baltimore STD clinics. **Methods:** Consenting patients are screened for HIV-1 using commercially available EIA, confirmed using a licensed Western Blot test, and are given appointments to return for test results. During January-October 1988, there were 18,907 patient visits to the STD clinics; 12,795 (68%) were tested for HIV. Of patients tested, 531 (4%) were HIV-infected and to date, 321 (60%) have returned for results and further evaluation.

Results: HIV infected patients were predominantly (approximately 2/3) young, black, single males. High risk behavior was common among infected patients: 33% reported homosexual exposure, 37% reported prior IV drug use, and 39% reported exposure to a sex partner at risk for HIV. No traditional risk factors for HIV infection were acknowledged by 18% of infected patients. STDs were also common in infected patients: 47% reported prior syphilis and 17% had been treated for syphilis in the preceding year. The majority of patients were asymptomatic (18%) or had generalized lymphadenopathy (18%) at the time of diagnosis. Many of these patients have few health care resources available; 93% were unmarried and 69% had either no health insurance (6%) or were covered solely by public assistance health plans (24%). **Conclusion:** Routine, voluntary HIV screening is a well accepted, useful means to identify HIV infected individuals in high risk settings such as STD clinics. Identification of these individuals may provide useful information for projecting future health care needs.

M.A.P.70

ANALYSIS OF TRENDS OVER TIME IN CLIENT CHARACTERISTICS AT MINNESOTA (MN) HIV-1 ANTIBODY COUNSELING AND TESTING SITES

Banilla, Richard*, Shultz J.*; Osterholm M.*; Henry Kew* Simpson M**; MacDonald E** *900 Dept. of Health, ** Hennepin County Community Health Dept., Minneapolis; ***St. Paul Division of Public Health, St. Paul; MN, USA.

Objective: To evaluate the role of Minnesota HIV-1 antibody counseling and testing site programs (CTS) in HIV-1 transmission prevention efforts.

Methods: CTS client demographic and risk factor data were analyzed for 18,483 CTS clients with HIV-1 serology from 7/85-6/88.

Results: The highest seroprevalence rates were in male homosexual/bisexual intravenous drug users (27 of 145; 18%) and homosexual/bisexual men (705 of 5,310; 13%). A significant decrease in seroprevalence for all clients was noted from 14.3% for the first six months of operation to 3.2% for the last six months (p<0.001). This corresponds to changes in client characteristics over time: 1) the number and proportion of female first-time clients who were at low risk for HIV-1 infection increased (p<0.001); 2) the number and proportion of homosexual/bisexual males decreased and correspondingly the number and proportion of low-risk heterosexual males increased (p<0.001); 3) for homosexual/bisexual males, a significant decline in HIV-1 antibody prevalence over time was noted (p<0.05).

Conclusions: These data indicate that CTS programs in Minnesota have progressively served fewer clients at high risk for HIV-1 infection over time. Outreach programs that identify and serve persons at highest risk for HIV-1 infection may be more effective, use of limited public health resources.

M.A.P.67

HIV-1 INFECTION IN NEW YORK CITY STD CLINIC PATIENTS:

EVIDENCE FOR STABLE SEROPREVALENCE, 1987-1988

Greenberg, B.; Iwim, J.; et al. New York City Department of Health, NY, NY, U.S.A.

Objective: To determine HIV-1 seroprevalence in patients at New York City STD clinics, and to compare rates over time in one clinic.

Methods: Blinded serosurveys were conducted among STD clinic patients in one clinic in 1987 and in all 12 STD clinics in 1988. The interval between the 2 surveys was 18 months. Specimens were obtained from routine syphilis testing and were analyzed for HIV-1 by ELISA with confirmatory Western Blot. Data on age, race/ethnicity, diagnosis and RPR result were collected.

Results: In 1988, 195/2533 (7.7%) of clinic attendees were HIV-1 positive. The highest rate (12.1%) was found among clinic attendees age 30-39. Among those diagnosed with a genital ulcer (GU) at the time of visit, 23/73 (31.3%) were HIV-1 positive as opposed to 223/1782 (6.9%) with other diagnoses (p<0.05). For the clinic surveyed in both years, 26/348 (7.5%) were positive in 1987 and 34/694 (4.9%) positive in 1988. This difference was not statistically significant. In both 1987 and 1988 patients with GU were significantly more likely to be HIV-1 seropositive than were patients with other diagnoses. (OR=2.3, p=0.02 and OR=0.9, p=0.04 respectively).

Conclusions: HIV-1 is a common infection in New York City STD clinic patients and those with a GU are more likely to be infected. Seroprevalence remained constant in one STD clinic over an 18 month interval. The data support expanding the availability of HIV-1 counseling and testing in all STD clinics.

M.A.P.69

FREQUENCY OF HIV INFECTION AMONG PATIENTS OF STD OUT-PATIENT CLINIC

Stepinski A., Mazurkiewicz W., Wójciszewski U., Nagórniak T., Biedrzycki L., Medical Academy, Lodz, Poland

Objective: The incidence of HIV antibodies has been investigated in 1327 patients with various STD, 1022 males and 305 females,

seen in the STD out-patient clinic. Sixty six males/6.5% were homosexual or bisexual. **Methods:** The HIV antibodies were tested by the EIA method, and positive tests were confirmed by the Western-blot technique. **Results:** The HIV antibodies were found in 45 male patients and 2 females, i.e. 1.5% of all individuals studied. Thirteen of 47 were homosexual or bisexual, which represents 19.2% of patients with such a sexual behaviour one of them was also IV drug addict, two of 3 heterosexuals cases with positive HIV test were IV drug users. Seven of 13 of HIV-positive homosexual/bisexual/23.0% had syphilis recently or in anamnesis, whereas among all homosexual/bisexuals studied there were 42.4% of cases with history of syphilis. The frequency of HIV infection in homosexual STD out-patients is markedly higher than in heterosexual STD out-patients, 0.4% as well as in another group of homosexuals without STD 2/2.6%.

Conclusion: Patients of the STD out-patient clinic represent high risk group of HIV infection, predominantly homosexual with diagnosis of syphilis. These patients should be tested for the presence of HIV antibodies.

M.A.P.71

BLIND HIV-AB AND SYPHILIS-AB SEROPREVALENCE SURVEYING IN NEW YORK STATE STD CLINICS

D'Errandino, George Jr.; Arthur, K.; Hipp S.; Murphy D. New York State (NYS) Department of Health, Albany, NY, USA.

Objective: To monitor over time the HIV and syphilis seroprevalence among STD clients in all regions of NYS, excluding NYC.

Methods: Sera of clients receiving syphilis testing (RPR, FTA) at 19 STD clinics in 8 NYS counties during 1988 were tested anonymously for HIV (ELISA, WB). Clients were excluded if they had been tested within the previous 90 day period.

Results: All sites had a substantial percentage of clients with HIV-AB (1.14 to 3.17%) and syphilis-AB (1.66 to 16.08%) positive. Of 1001 clients, 179 (19.9%) had HIV-AB, 247 (24.7%) had syphilis-AB. Among counties, however, the association between HIV-AB and syphilis-AB varied greatly (odds ratios ranged from 0.56 to 15.3). **Conclusion:** The HIV epidemic has spread throughout NYS in the STD clinic population. Although HIV-AB status is strongly associated with sero-evidence of current or previous syphilis infection, this association varies widely between clinic location, and those without evidence of syphilis-AB still have a substantial rate of HIV-AB positivity.

M.A.P.72 HIV-1 INFECTION IN PERSONS ATTENDING SEXUALLY TRANSMITTED DISEASE (STD) CLINICS IN MINNESOTA (MN)
Methods: 1094 patients attending two STD clinics from 4/1/88-11/1/88 were systematically selected; participants were interviewed for HIV-1 infection risks and had blood drawn for HIV-1, syphilis, and hepatitis B serology.
Results: Questionnaire and serologic data were completed for 932/1094 (85%) participants. HIV-1 infection was associated with male-to-male sex (p<0.001), and among homosexual/bisexual males, receptive anal intercourse (p<0.05). HIV-1 sero-prevalence rates were: white 1.3% (7/529); black 1.1% (4/352); Hispanic 6.3% (1/16); other 0.0% (0/35).

Objective: To determine HIV-1 seroprevalence and risk factors associated with infection in persons attending STD clinics in Minnesota.

Methods: 1094 patients attending two STD clinics from 4/1/88-11/1/88 were systematically selected; participants were interviewed for HIV-1 infection risks and had blood drawn for HIV-1, syphilis, and hepatitis B serology.

Results: Questionnaire and serologic data were completed for 932/1094 (85%) participants. HIV-1 infection was associated with male-to-male sex (p<0.001), and among homosexual/bisexual males, receptive anal intercourse (p<0.05). HIV-1 sero-prevalence rates were: white 1.3% (7/529); black 1.1% (4/352); Hispanic 6.3% (1/16); other 0.0% (0/35).

HIV-1 Seroprevalence by Risk Factors

Risk Category	Male		Female	
	HIV-1 Pos./Total (%)	95% CI	HIV-1 Pos./Total (%)	95% CI
Homosexual/bisexual	9/70 (12.9)			
IV drug user (IVDU)	1/52 (1.9)		0/17 (0.0)	
Homo./Bi./IVDU	1/7 (14.3)			
Heterosexual	0/561 (0.0)		1/225 (0.4)	

Conclusions: In Minnesota, HIV-1 infection in STD patients is primarily limited to those with a history of male-to-male sex or IV drug use. Thus, in low prevalence areas, HIV-1 antibody testing should be targeted to STD patients known to be at highest risk.

M.A.P.74 HIV SEROPREVALENCE IN SEXUALLY TRANSMITTED DISEASE CLINICS IN LOS ANGELES COUNTY

ERIC WATKINS, L., ROSE, T., KERND, P., OROSCO, L., WATERMAN, S.

Los Angeles County Department of Health Services, Los Angeles, California, **Centers for Disease Control, Atlanta, Georgia, USA

Objective: To estimate the seroprevalence of human immunodeficiency virus (HIV) among patients attending sexually transmitted disease (STD) clinics in Los Angeles County (LAC).

Methods: Between July and December 1988, consecutive attendees at 4 public STD clinics were screened for HIV Ab. Repeat ELISA positives were confirmed by the immunofluorescent antibody and Western Blot. HIV Ab results were linked without personal identifiers to self-reported demographic and risk factor information.

Results: Of the 2,578 STD patients tested, 2.9% (76) were confirmed HIV Ab positive; the rates were 3.8% (66/1,796) in men, and 1.9% (6/312) in women. The infection rate among Hispanics was 4.5% (52/1,078); whites 2.5% (5,000); and blacks 2.4% (39/1,608). Hispanics comprised 27.3% of the STD patients tested, but accounted for 42.1% of the seropositives. In contrast, whites and blacks made up 7.8% and 62.6% of the study population, and 6.6% and 51.9% of the seropositives, respectively. Among the 133 persons reporting psychosocial behavior, 30.8% (41) were seropositive; 38.5% (24) Hispanic; 34.1% (14) black; and 7.9% (3) white. Seropositivity among heterosexuals was 1.4% (44/3,276); 1.6% (27/1,637) for men, and 0.9% (7/739) for women. The highest rate of infection for heterosexuals was among black men 1.9% (19/1,025), and the lowest rate among Hispanic women 0.6% (0/773). Approximately 3.0% of those reported recent IV drug use, and 8.0% of those (6/75) were seropositive.

Conclusion: HIV infection among patients at STD clinics in LAC is substantial and warrants routine testing and counseling. The large proportion of minorities attending public STD clinics affords an opportunity to provide AIDS education and risk reduction counseling to high risk members of minority populations.

M.A.P.76 INCIDENCE OF HIV INFECTION IN GAY AND BISEXUAL MEN ATTENDING A COUNSELING AND TESTING SITE OR AN AIDS PREVENTION PROGRAM. COHN, DAVID; KOLETS, J.; COOPER, S.; COLE, V.; JUDSON, P. Denver Disease Control Service, Denver, CO.

Objective: To determine incidence of HIV infection in gay and bisexual men (GM) using a counseling and testing site (CTS) or enrolled in an AIDS Prevention longitudinal cohort study (APS).

Methods: GM who attended Denver's voluntary CTS from July, 1985 through December, 1988, and GM enrolled in APS from January, 1987 thru December 1988 (visits every 6 months), were evaluated for incidence of HIV infection, as indicated by seroconversions (SC). Included in the analysis were GM who were seronegative at initial visits and retested at least once. SC was defined as reactive ELISA and Western blot antibody tests on a 2nd or later visit.

	CTS	CTS	APS
	1985-1986	1987-1988	1987-1988
No. seroconversions	42	3	4
No. persons observed	596	183	348
No. person-years observed	633.2	151.7	296.5
Mean years/person observed	1.0	0.83	0.85
Rate SC/100 person-years	6.43	1.98	1.35

Conclusion: In Denver, the incidence of HIV infection in GM has decreased significantly between 1985-1986 and 1987-1988. Lower incidence rates were observed both in GM attending a CTS and in GM enrolled in an AIDS prevention program, who likely were self selected for higher motivation for behavioral change.

M.A.P.73 HIV SEROPREVALENCE OF STD CLINICS IN HOUSTON, TEXAS, U.S.A.

ENOCHA, M., FALLETTI, ROBERT L., SULLIVAN, KJ, SANCHEZ, DJ, PENALOSA, D., AND HONEYCUTT H.

Bureau of Epidemiology, Houston Dept. of Health & Human Services, Houston, Texas, U.S.A.

Objective: To present statistical data supporting the growing threat of HIV infection with specific sexual activity positive populations attending an STD clinic.

Methods: A blinded survey was conducted at a large STD clinic servicing a predominantly black area of Houston. All blood samples taken for standard RPR screening were also tested for HIV using the ELISA and Western blot tests. Points included in the survey were taken consecutively until predetermined gender quotas were obtained. No ethnic or age bias was imposed on the selection procedure.

Results: A total of 1,140 samples were collected with 6% HIV positive. Seropositivity is highest in the age groups between 25-34 (22%). Overall, whites are 10% positive with 76 samples tested, blacks are 6% positive with 360 samples tested, Hispanics are 7% positive with 36 samples tested and other ethnic populations are 25% positive with 8 samples tested. Data on heterosexual males (n=543) and females (n=592) indicate whites are 1% positive, blacks are 2% positive and Hispanics are 4% positive. Data for homosexual males (n=72) show whites and blacks to be over 50% positive.

Conclusions: The results of the survey allow us to draw certain conclusions: 1) large sampling from the black population permits us to place greater confidence in the high seropositivity found in that group; 2) homosexual males show a high seropositivity in all age groups and ethnic classifications; 3) samples collected are representative of the clinic population and 4) persons seeking treatment at Houston STD clinics are showing an overall prevalence of 6% HIV positive.

M.A.P.75 DEVELOPMENT AND FUNDING OF PUBLIC HIV COUNSELING AND TESTING SERVICES IN THE UNITED STATES

PHILLIP KAGAN; BOVEN, G. R. RIBBY, G. A.

Atlanta, Ga., U.S.A.

Objective: To describe the history and development of public sector funded HIV counseling and testing (CT) services in the U.S. since 1985.

Methods: We reviewed quarterly reports from State HIV/AIDS prevention programs and the CDC funding awards of State AIDS prevention cooperative agreements in order to document the levels for CT, number and location of CT sites and the number and seropositivity rates of clients served. Data were also collected on the number of counseling and testing services became one of the strategies to prevent HIV infection in 1985. Client numbers for such services has increased from 1985 to 1988 and there were 874 alternate testing sites that tested 79,083 persons nationwide. There were 26,400 sites that tested 1,196,000 persons in 1985 and 4,000 tested in 1987. Reports show 213,000 persons were tested (annual rate of 84.6 million) during July-September of 1988. Funding for risk reduction counseling and testing services increased from \$9.1 million in 1985 to \$17.5 million in 1988. The rate of seropositivity has decreased from a high of 17.3% in 1985 and 15.0% in 1986, to 5.8% in 1987 and 4.9% in 1988.

Conclusion: Although the original purpose of HIV antibody testing was to prevent the blood supply, risk reduction counseling combined with testing has become one of the important intervention strategies available to change sexual and needle sharing behaviors. The increase in funding for these programs in the U.S. has enabled an expansion of CT services to community based testing facilities in sexually transmitted diseases, women's health and drug treatment facilities in 1988 and 1989.

Autres rétrovirus : le VIH-2

Other Retroviruses: HIV-2

M.A.P.77 HIV2 INFECTION. SOME CLINICAL AND EPIDEMIOLOGICAL ASPECTS IN PORTUGAL

Botas-Julliano, L., Licínio, F., Feliciano, M., Antunes, F., et al. Dep. Inf. Diseases, Hosp. Sta Maria, Lisboa, Portugal.

Objective: To assess the frequency of HIV2 infection in HIV seropositives studied at our Department.

Methods: The charts of 225 HIV seropositives (ELISA and Western Blot) were analysed. Tests for HIV2 were performed in HIV1 negative individuals. Sexual partners of HIV2 positives or possibility of infection in Africa.

Results: Nineteen (8.4%) 8 women, 11 men, 11 men HIV negative and HIV2 positive. They all denied homosexual contacts or IVDU. Only 2 had received blood transfusions (1 man in 1974, in Portugal and his wife was also positive; another man in 1968, aged 3, in Africa, who has lived in Portugal ever since. In 1974, his 5 women, 4 men were from Guinea-Bissau. One man had visited several African countries and his wife was also positive. Four men had been in Africa for military service (2 in Guinea, 1964-69 and 7-73; 2 in Angola, 65-66 and 66-68). One woman, prostitute, could not deny sexual contacts with African men. Eight were asymptomatic carriers, 3 ARC and 8 AIDS. Five of them died.

Conclusion: HIV2 infection may be more common outside Africa than generally accepted, should be thought in HIV1 negatives suspected of AIDS and excluded in blood donors, at least in those who have ever been in Africa.

M.A.P.78 HIV-2 IN ITALY: NO EVIDENCE, YET.

Cedeno P.P., Carola L., Piccinicola G.S., Albertini A.S., Carosi G.

Dept. of Infection Tropical Disease, Dept. Chemistry, University of Brescia, Brescia, Italy.

Objective. The authors have carried out a wide-scale seroepidemiological survey in the region of Lombardy (Italy) to verify the presence of HIV-2 infection among risk categories.

Methods. 1069 subjects (946 drug addicts, 80 homosexuals, 25 homosexuals and sexual partners) have been screened for HIV-1 and HIV-2 infections (HIV-1 and HIV-2 ELISA and W.B. by Diagnostic Pasteur).

Results. Among the 1069 HIV-1 seropositive subjects, 233 sera reacted positively to HIV-2 ELISA test. Confirmation by HIV-2 W.B. has been obtained in 29 cases. When submitted to the specific synthetic peptide assay, the 29 HIV-1/HIV-2 W.B. positive sera strongly reacted to the HIV-1 peptide, while only 2 showed a weak HIV-2 reactivity. The same pattern of serological reactivity has been obtained on the same 29 subjects 10 months later.

Conclusions. Our results don't confirm the existence of HIV-2 among risk categories in Italy. This conclusion is also supported by the absence of isolated HIV-2 pattern of seropositivity. The high false positivity rate in ELISA (31, 28) and, to a lesser extent, in W.B. (3, 28) demonstrates the presence of antigenic cross-reactivity among envelope proteins of the two viruses. Specific synthetic assay proved to be sensitive and specific. The constant presence of weak HIV-2 reactivity in 2 HIV-1+ samples at 10 months interval rules out the possibility of early HIV-2 seroconversion.

M.A.P.79 HUMAN IMMUNODEFICIENCY VIRUS TYPE 2 (HIV-2) SCREENING OF A HIGH RISK POPULATION IN ADDIS ABABA, ETHIOPIA.

Zewdie, D.P., Woolly, J.,** (Amara, A.), Constantine, N.,**

Chabwiler, S.P., Moselem, A.,**

* National Research Institute of Health, Addis Ababa, Ethiopia.

** WHO Reference Center for AIDS, Cairo, Egypt.

*** AIDS Prevention and Control Programme, Ministry of Health, Addis Ababa, Ethiopia.

Objective. The major objective was to evaluate a high risk population from Addis Ababa, Ethiopia, for evidence of HIV-2 infection.

Methods. Sera previously collected from 130 prostitutes residing in Addis Ababa were included in the evaluation. Sixty of these had been previously confirmed as HIV-1 reactive sera. A commercial ELISA (Genetic system) designed to detect antibodies to HIV-2 and HIV-2 Western Blot (Dupont) were used.

Results. Of the 330 sera analyzed, 60 were known to be confirmed HIV-1 positive. Thirty-four of these 60 were also reactive to HIV-2 screening ELISA. Assessment of these 34 HIV-2 reactive sera by Western Blot revealed that 10 reacted in a manner that fulfilled the criteria for HIV-2 positivity all of these were strongly reactive for HIV-1 by Western Blot.

Conclusion. Almost all HIV reactivity in this population are characteristic of exposure to HIV-1. However, 10 sera reacted with both assays and could represent either dual infection or cross reactions.

M.A.P.80 DETECTION OF ANTIBODIES AGAINST HIV-2 PROTEINS IN HIV-1 SEROPOSITIVE SUBJECTS FROM FRANCE AND GREECE.

FORTOLINI P., KAMBAKI A., BERTOLI A.M., ZAPPALÀ A., PALLIANGORIS P.P., JORDAN C.P., GOSDOLINI V.J.

1. AIDS Reference Center of Crete, Venetian Hospital, Greece, 2. INRHEC/IDU, Hospital Paul Broca, 93000 Vitry, France.

Objective. To determine the prevalence of HIV-2 infection in HIV-1 seropositive subjects from France and Greece.

Methods. HIV-2 infection was always confirmed by Western blot analysis. Antibodies against HIV-2 proteins were detected by Western blot and determined between HIV-1 and HIV-2 infection was based on the serum reactivity with synthetic peptide homologous to the 263-307 region of p41 (gp120 HIV-1) and the corresponding region of gp85 (gp120 HIV-2).

Results. Western blot analysis of the sera revealed a frequent reaction with isolated HIV-2 proteins. However, frequently they reacted with isolated HIV-2 proteins only (75.6% and 100% of 44 and 10 sera of French and Greek origin, respectively). Stripped antibodies against HIV-2 with both the gp85 and the gp120 of HIV-2, respectively, 42.7% and 42.7% revealed reactivity with both the gp85 and the gp120 of HIV-2 whereas none of the 9 Greek sera were reactive with the gp120. However, HIV-2 infection was confirmed in an asymptomatic Greek blood donor in the absence of HIV-1 infection.

Conclusions. These findings seem to indicate that although double HIV-1/HIV-2 can be observed in a small number of HIV-1 seropositive subjects and HIV-2 is present in Greece, there is still a different transmission rate of this virus in different European countries.

M.A.P.81 HIV-2 IN DRUG ABUSERS OF SPAIN

Hernandez Hernandez, J. Ter, A. Baeza, J. Claver, J. Garcia, J. Hernandez

Departamento de Microbiología, Bacteriología, Parasitología y Laboratorio Clínico, Facultad de Medicina de San Sebastián, Instituto de Estudios Vascos (I.E.V.), Hospital de San Sebastián, San Sebastián, Guipúzcoa, España.

Objetivo. Estudiar la prevalencia de infección por el virus de inmunodeficiencia humana tipo 2 (HIV-2) en un grupo de drogadictos.

Métodos. Se realizó un estudio serológico en 100 individuos que usaban drogas. Se usó un método de ELISA para detectar anticuerpos contra el virus de inmunodeficiencia humana tipo 2 (HIV-2) y un método de Western Blot para confirmar los resultados positivos.

Resultados. Se detectó la presencia de anticuerpos contra el virus de inmunodeficiencia humana tipo 2 (HIV-2) en 10 individuos (10%).

Conclusiones. Se detectó la presencia de anticuerpos contra el virus de inmunodeficiencia humana tipo 2 (HIV-2) en un grupo de drogadictos.

Palabras clave: HIV-2, drogas, infección.

Abstract. HIV-2 infection was detected in 10% of 100 drug abusers.

Methods. A serological study was carried out in 100 individuals who used drugs. An ELISA method was used to detect antibodies against HIV-2 and Western Blot method to confirm positive results.

Results. The presence of antibodies against HIV-2 was detected in 10 individuals (10%).

Conclusions. The presence of antibodies against HIV-2 was detected in a group of drug abusers.

Key words: HIV-2, drugs, infection.

Summary. HIV-2 infection was detected in 10% of 100 drug abusers.

Methods. A serological study was carried out in 100 individuals who used drugs. An ELISA method was used to detect antibodies against HIV-2 and Western Blot method to confirm positive results.

Results. The presence of antibodies against HIV-2 was detected in 10 individuals (10%).

Conclusions. The presence of antibodies against HIV-2 was detected in a group of drug abusers.

Key words: HIV-2, drugs, infection.

Abstract. HIV-2 infection was detected in 10% of 100 drug abusers.

M.A.P.82 EPIDEMIOLOGY OF AIDS IN PORTUGAL.

Alves, Laura; Piate, A.; Bessito-Garcia, A.; Paredes, C.; Jarillas, F. Instituto Nacional de Saude, Lisboa, Portugal.

Objective. As far as AIDS is concerned, Portugal is a country with no parallels in Europe due to the prevalence of HIV-2 infection of 199 cases notified by HIV-1/2 ELISA.

Methods. A total of 2046 sera were from male homosexuals, 1700 prostitutes, heterosexuals, pregnant women and families of AIDS were tested for HIV-1 and HIV-2 antibodies by ELISA, confirmed by Western Blot.

Results. are as above:

Conclusions. HIV-2 infection is endemic in Portugal, although with less expression than HIV-1. Due to past and present contacts with Africa and the presence of Portugal of immigrant African countries, an epidemiological surveillance of the population is in progress to learn the natural history behaviour in terms of sex or drug use, other viral infection, etc.

Abstract. HIV-2 infection is endemic in Portugal, although with less expression than HIV-1. Results. are as above:

Conclusions. HIV-2 infection is endemic in Portugal, although with less expression than HIV-1. Due to past and present contacts with Africa and the presence of Portugal of immigrant African countries, an epidemiological surveillance of the population is in progress to learn the natural history behaviour in terms of sex or drug use, other viral infection, etc.

Abstract. HIV-2 infection is endemic in Portugal, although with less expression than HIV-1. Due to past and present contacts with Africa and the presence of Portugal of immigrant African countries, an epidemiological surveillance of the population is in progress to learn the natural history behaviour in terms of sex or drug use, other viral infection, etc.

Methods. A total of 2046 sera were from male homosexuals, 1700 prostitutes, heterosexuals, pregnant women and families of AIDS were tested for HIV-1 and HIV-2 antibodies by ELISA, confirmed by Western Blot.

Results. are as above:

M.A.P.83 AIDS CAUSED BY HIV-2 IN SOUTHERN AFRICA

Lynn Saxon, P.J. McMillen, P.J. Schab, D.R. Smith, A.M. Glimmer, L.W.

*Medical Research Council AIDS Virus Research Unit, National Institute for Virology, Department of Virology, University of the Witwatersrand and

**Chamber of Mines, Johannesburg, South Africa.

Objective. The RAPID CLAVIA HIV-1 ELISA first generation ELISA developed to detect antibodies to both HIV-1 and HIV-2, was introduced into our routine HIV screening laboratory in Jan 1988.

Methods. 1593 routine sera were received. Seres repeatedly reactive on the RAPID CLAVIA HIV-1 assay were further evaluated using individual ELISAs for HIV-1 and HIV-2 (ELAVIA 1 or ELAVIA 2 respectively). Three sera, reactive in the RAPID CLAVIA HIV-1 assay, were unreactive in the ELAVIA 1 but reactive in the ELAVIA 11 ELISA.

Results. Western blotting, using the Dupont HIV-1 IgG Blot, revealed reactivity against core and envelope components of HIV-2.

Conclusions. Two of the HIV-2 positive were from black Malawian males with symptoms suggestive of HIV infection. The patient had presented with weight loss and neurological symptoms while the second was a patient with mild tuberculosis that was unresponsive to standard tuberculosis therapy. Blood drawn from the second patient 16 days before he died showed decreasing reactivity with the core protein p24 and loss of reactivity to the envelope protein gp120. The third specimen was from a black Mozambican male who also presented with tuberculosis that did not respond to therapy. The patient developed Kaposi's and died after 18 months.

Abstract. Two of the HIV-2 positive were from black Malawian males with symptoms suggestive of HIV infection. The patient had presented with weight loss and neurological symptoms while the second was a patient with mild tuberculosis that was unresponsive to standard tuberculosis therapy. HIV 2 INFECTION IN FEMALE AND MALE BRAZILIAN PROSTITUTE GROUPS

Santos-Ferreira, M. O., Menez, C. M., Lourenco, R. M., Faccaria, R. M., Vermeil, R. M.
*Fac. Pharmacy, Univ. de Lisbon, Portugal. **Faculty of Medicine, Univ. São Paulo, Brazil

Objective: The identification of the second type of human immunodeficiency virus designated HIV 2 in patients originating from West Africa with the acquired immunodeficiency syndrome opened a new area of seroepidemiological investigations. Therefore we studied the presence of HIV 2 infections in Brazil.
Subjects and methods: The presence of specific HIV 2 antibodies was investigated in 173 sera obtained from individuals belonging to a risk group of 73 male homosexuals of a cohort of prostitutes (professional prostitutes) with activity in São Paulo, Brazil, 100 women prostitutes with activity in Santos, Brazil. Sera were tested for HIV antibody by ELISA. Repetitive positive ELISA results were confirmed by indirect immunofluorescence assay and Western-blot. Sera giving cross reactivity at a peptide level of HIV 1 and HIV 2 large glycoproteins were further tested for reactivity against a peptide corresponding to the dominant epitope of transmembrane protein (HIV 1 gp41) glycoprotein and HIV 2 gp36 glycoprotein.

Results: The number of their partners varied between 1 (minimum) and plus 100 (maximum) partners a week. The average number of partners a week was 27 (standard deviation = 21). All the individuals had been practicing their activity for at least one year before the study. In the cohort of prostitutes we found 22/75 (30.0%) seropositives to HIV 1 and 5/75 (4.1%) seropositives to HIV 2. Seropositivity for HIV 1 and HIV 2 was seen in five men (6.8%). In the group of women prostitutes we found 10/100 (10%) seropositives to HIV 1 and 2/100 (2.0%) seropositives to HIV 2. Seropositivity for HIV 1 and HIV 2 was seen in one woman (1.0%).

Conclusion: These Brazilian cases confirm the presence of HIV 2 in this country.

EFFICACITE DANS LE DÉPISTAGE DES SÉRUMS HIV

CROQUET Anne-Marie et le groupe de travail «Métrovirus de la Société Nationale de Transfusion Sanguine - Paris, France

Objectif: Analyser le gain obtenu dans le dépistage des sérums HIV par des trousses mixtes (HIV-1 + HIV-2) par rapport aux trousses HIV1

Méthodes: 35 sérums HIV-2 (dont 11 dons de sang) prélevés de sujets résidents en France ont été étudiés parallèlement à des trousses Abbott. HIV1 recombinant = A1 et Combo HIV1 + HIV2 = A2) 3 trousses Du Pont de Nemours (Env 9 version 1 = D1 et Env9 version 2 = D2) et 2 trousses Diagnostica Pasteur (Elavia 1 = P1 et Elaiva mixte = P2)

Résultats: 18 sérums ont fourni un résultat positif avec les 6 trousses. Les 7 sérums donnant un résultat négatif avec au moins 1 trousses HIV(A1,D1 ou P1) ont tous été reconnus par les trousses HIV1+HIV2 (A2,P2) ou la trousses version 2 (D2). Les résultats de ces 7 sérums sont fournis ci-dessous (Ech/Seuil).

	A1	A2	D1	D2	P1	P2
26 PV*	0,5	>8	1,5	4,1	0,8	>8
35 MJ	1,4	5,0	0,4	>5	1,3	>8
51 GA	0,6	>8	0,5	>8	1,1	>8
5 GRM*	3,2	>8	0,4	>5	4,0	>8
12 MJ	1,5	>8	0,2	>5	3,0	>8
52 CB	2,5	>8	3,7	>5	0,8	>8
LEG	0,3	4,8	0,2	2,5	0,2	>8

Conclusion: Bien que ces 3 trousses HIV1 détectent de 81 à 86 % de sérums HIV2, l'utilisation en transfusion de trousses de dépistage reconnaissant la totalité des HIV2, à condition qu'elles aient une excellente sensibilité HIV1 et une bonne spécificité, est très satisfaisable.

Progression : marqueurs de laboratoire et cofacteurs

Progression: Laboratory Markers and Cofactors

M.A.P. 87

THE LEVEL OF EPSTEIN-BARR VIRUS EXCRETION IS A

PREDICTOR OF DISEASE PROGRESSION IN HIV INFECTION.

Diaz-Mitoma, Francisco, Ruiz, A., Houson, S., Rosenow, D. B., Perlebas, J., and Tyrrell, D. L. J. University of Alberta, Edmonton, Alberta, Canada

Objective: To analyze the relationship between HIV and EBV infections in a cohort of homosexual men.

Methods: Twenty seven HIV-seropositive and 25 HIV-seronegative homosexual and 52 age-matched heterosexual men were serological men. Patients were classified according to the CDC criteria for HIV infection. Individuals in group IV were excluded. Patients were evaluated at 0, 2, 6, 12 and 18 to 24 months. EBV and human (hDNA) DNAs were measured in oropharyngeal washes by dot hybridization and densitometry scanning. **Results:** Twelve and individuals among the 27 HIV-seropositive had low level (<0.7log of EBV DNA) of hDNA and 3 had undetectable levels of EBV DNA in mouth washings. None of these subjects demonstrated progression of the HIV infection. In comparison, 17 of the 27 HIV-seropositive men had high levels of EBV DNA excretion (>0.7log₁₀ hDNA) and 9 demonstrated progression of disease. At the 18 month follow-up, 16 asymptomatic HIV seropositive (group I), 3 progressed to group III and 1 to group IV. Of the 11 group III individuals, 5 developed AIDS. Patients who progressed to group III or IV disease had significantly higher levels of EBV excretion (2.7 ± 2.0 log₁₀ hDNA) on initial assessment than HIV-seropositive individuals in whom progression of HIV infection was not demonstrated (0.34 ± 3.0 log₁₀ hDNA, p<0.001).

Conclusion: The positive predictive value of high levels of EBV excretion for progression of HIV infection was 75% at 18 months. High EBV excretion was found in 3 of 25 HIV-seronegative and 4 of 52 heterosexual men. This would suggest that high EBV excretion is not solely on the basis of HIV-induced immunosuppression.

M.A.P. 86

PREVALENCE OF HIV-1 AND HIV-2 ANTIBODIES IN INDIVIDUALS ATTENDING A CLINIC FOR S.T.D., A TWO YEAR FOLLOW UP.

Cardoso, J.*, Avilés, F.**, Santo, I.**, Pista A.**, Ayres-Laura **.

*Lisbon Regional Health Administration, Lisbon, Portugal.

**National Institute of Health, Lisbon, Portugal.

There is in Portugal a population with great contact both in the past and at present with individuals from African countries.

With this reason we decided to determine, during a period of about two years the antibodies to HIV-1 and HIV-2 in individuals attending a clinic for STD in Lisbon.

During this period we tested 1253 sera (640 males and 613 females). We found 32 seropositive for HIV 20 males and 12 females).

Eight individuals were seropositive for HIV-2 (2 males and 6 females) and 24 were seropositive for HIV-1 (18 males and 6 females).

In the male seropositive group there are 6 homosexuals, 6 bisexuals and 6 heterosexuals. Among the seropositive females 11 are prostitutes (of a total of about 350 prostitutes followed) and one is an IVDU.

We conclude that HIV-1 and HIV-2 are present in all the groups. The studies are in progress in order to have a better knowledge of the problem and also the role of some of its infected people in the heterosexual transmission of infection especially as sexual behaviour is concerned.

M.A.P. 88

PROGNOSTIC VALUE OF ANEMIA IN ASYMPTOMATIC HIV-POSITIVE MEN

Battagay, Manuel, Ledergerber, B., Brühlwiler, J., Siegenthaler, W. and Lüthy, R., Department of Medicine, University Hospital Zurich, Switzerland

Objective: To study the prognostic value of anemia in 225 asymptomatic HIV-positive men and to assess the correlation to thrombocytopenia.

Methods: We measured hemoglobin (Hb) and platelets (pl) in 225 consecutive asymptomatic homo- or bisexual men with at least two visits and more than one month follow-up. The mean or bisection time of the cohort was HIV 1 advanced stages (ARC and AIDS) was analyzed for patients with anemia (Hb < 14.0 g/dl) and without anemia using product limit estimators and the Cox proportional hazard regression model.

Results: The median observation time of the cohort was 617 days (range 1 - 1240) and did not correlate with pit counts. The following table summarizes the results obtained:

	with anemia	without anemia
Number	207	92%
Median age [years]	44 (26-53)	36 (19-67)
Mean hemoglobin [g/dl]	13.3 (SD 0.5)	15.7 (SD 0.87)
Mean platelets [10 ⁹ /l]	233 (SD 53.7)	245 (SD 66)
Progression to ARC/AIDS	44 (6.8%)	26 (12.6%)

The one year progression rate after developing anemia was 30% (95% CI: 15-57%), for non anemic patients 5.5% (3-10%). The relative risk for progression to advanced stages was 4.8 (p<0.001) for a 20% decrease in hemoglobin and 1.5 (p<0.001) for a 20% decrease in platelets. **Conclusion:** Anemia and thrombocytopenia both have an independent prognostic significance in asymptomatic homo- and bisexual men.

M.A.P. 89

AGE AT TIME OF HIV INFECTION AS COFACTOR OF PROGRESSION TO ADVANCED IMMUNE DYSFUNCTION AND AIDS

Karaoufolidou, A.**, Polychronaki, J.**, Gialavaki, A.**, Economidou, J.**, Trichopoulos, D.**, Athens Univ. Medical School, Athens, Greece. *Lisbon Hosp., Athens, Greece. **Evangelismos Hosp., Athens, Greece. **Objective:** To study whether age at the time of acquisition of HIV infection is associated with progression of HIV infection and to determine the pattern of the age dependency.

Methods: 122 HIV positive men followed up in follow up studies since 1980, seroconverted between 1980-1985. Serconversion was documented by ELISA and WB or RIP. By November 1989, 30 cases have progressed to advanced immune dysfunction (AIDS).

Results and Conclusions: Age was a statistically significant variable for AIDS or AIDS/ARC2 progression in univariate and multivariate analyses (allowing for duration of HIV positivity and controlling for the amount of immune factor (VIL)). However, the age effect, estimated by Cox model, was limited to the age above 30 (RR=5.5, p=0.006, 95% CI 1.6-18.3).

TABLE 1	Age (years)	Incidence	19	20-29	30-39	40-49	≥50
Com. Incid.	AIDS/ARC2	2.4	22.9	19.0	20.0	30.0	
Rate Ratio	AIDS/ARC2	2.5	3.1	2.5	2.3	13.9	
Rate Ratio	AIDS/ARC2	1.0	1.2	1.1	0.9	5.5

M.A.P.102 EVOLUTIVE PROCESS TOWARDS AIDS IN THE MAJORITY OF ASYMPTOMATIC HIV-INFECTED SUBJECTS.

Authors: Jean-Louis Lelanc, J.L. Lelanc, P. Domet, C.J. Couroucé, A.M. P. Institut National de Transfusion Sanguine, Paris, France.

Objective: To estimate the progress of asymptomatic HIV infection. **Methods:** 68 asymptomatic (stage II or III CDC) HIV 1 seropositive subjects, with more than 100 CD4 lymphocytes/mm³ at the onset of the study, were followed-up during a 4 year period. Nine biological markers considered as predictors of AIDS (CD4 lymphocyte count < 400/mm³, loss of anti-p24 or anti-p18 antibodies, positive p24 antigenemia, serum IgG17gI, serum IgA17gI, erythrocyte sedimentation rate ≥ 20mm in first hour, serum neopterin ≥ 10 nmol/l, serum s-2-microglobulin ≥ 2.5 mg/l) were annually evaluated. **Results:** Number (and percentage) of subjects having biological predictors of AIDS during the study period:

Predictors	1985	1986	1987	1988
None	23 (28%)	8 (12%)	6 (6%)	2 (3%)
One	21 (31%)	15 (28%)	10 (9%)	11 (16%)
Two	17 (28%)	23 (38%)	18 (26%)	14 (20%)
Three or more	7 (10%)	18 (28%)	36 (59%)	41 (60%)

The increase of the number of significant (Chi-2 test p < 0.01). At the end of the study period, 4 subjects (8.8%) were AIDS and corresponded to the cases having at the same time the greater number of predictors (3 or more).

Conclusion: These results strongly suggest an evolution towards AIDS in the great majority of asymptomatic HIV-infected subjects. This constitutes an important argument in favour of antiviral treatment for all HIV-infected subjects.

M.A.P.104 LACK OF ANTIBODIES AGAINST p17 AS PREDICTIVE VALUE FOR AIDS.

Authors: J. Delgado, Sanchez C, Malloja E, Planas J, Niro JM, Gatalán J, and Castillo R. Blood Transfusion Diseases Unit, Univ. Barcelona, and Infectious Res. Dept. Hospital Clinic Barcelona, Spain.

Objective: To determine the relationship of p17 antibodies and disease progression in HIV infected people.

Methods: 87 HIV-1 seropositive patients were classified according to the CDC and 61 were followed for 23±7 months. The presence of antibodies against p17 was investigated in an optimized Western blot using H-9 viral lysate (Organon Corporation, USA).

Results: The loss of reactivity against p17 correlated with the clinical stage of patients. The negativity for p17 was observed in 41% of patients in CDC-2 stage, 81% in CDC-3 stage and 100% in CDC-4 stage. Progression to AIDS was observed in 37% of patients without p17 Ab and in 10% of patients with p17 Ab (p < 0.01). The progression to AIDS in p17-Ab- patients was observed in 13% of CDC-2 patients and 40% of CDC-3, and 37% patients in CDC-2 progress to CDC-3.

Conclusion: The loss of reactivity against p17 seems to have predictive value since it has been observed in patients without before developing AIDS and before antiretroviral could be detected.

M.A.P.106 SIGNIFICANCE OF INCREASE OF CD8 LYMPHOCYTES IN ASYMPTOMATIC HIV INFECTION.

Authors: J. Delgado, Gatalán J, Lelanc J, Rouger, P. Institut National de Transfusion Sanguine, Paris, France.

Objective: To determine the significance of the increase of CD8 lymphocytes in asymptomatic HIV-infected subjects.

Methods: 18 asymptomatic (stage II or III CDC) HIV seropositive subjects were followed-up during a 28 month period, with controls at the 1st, 6th and 24th month. All had more than 400 CD4 lymphocytes at the 1st control. Two groups were studied: subjects with an increase of 50 percent or more of CD8 between the 1st and the 6th month (group I) n = 7/9 and subjects without such an increase (group II) n = 7/1.

Results: A significant decrease of mean CD4 between the 1st and 24th months was observed in the two groups, but the group I subjects had a mean CD4 count at the 1st and 24th month significantly lower than the group II subjects.

	Group I	Group II	
CD4 at 1st month control	466	412	p < 0.001 (Mann-Whitney test)
CD4 at 24th month control	309	411	p < 0.02
	ns	ns	ns (Wilcoxon test)

On the whole, for the subjects of the study, no correlation existed between the 1st and 6th months and the CD4 count at the 24th month. On the increase of CD8 between the 1st and 6th months and the decrease of CD4 between the 1st and 6th months. A negative correlation (r = -0.33, p < 0.003) existed between the CD4 count at the 1st month and the increase of CD8 between the 1st and the 6th months.

Conclusion: The increase of CD8 in HIV-infected subjects when the CD4 count decreases below the threshold value of 400/mm³ and probably indicates an evolutive process towards AIDS.

M.A.P.103 DIFFERENT COURSES OF HIV INFECTION IN POLAR/OF FRANKFURT UNIVERSITY OUTPATIENT CLINIC.

Authors: E. Kiederhaver C., Szaszewski S., Gottschal S., Kamp S., Helm B., Universitätsklinik Frankfurt, Zentrum der Inneren Medizin, Infektiologie, Th.- SternstraÙe 7, 6000 Frankfurt/F.R.G.

Objective: To describe courses of PGL/ARC significantly differing in temporal and clinical respect.

Methods: 607 pts (599 fam) with HIV infection were followed up by physical examination, immunological, routine lab and serological tests. Only non-AIDS pts followed up > 6mo, and not taking anti-HIV agents, were evaluated.

Results: We found the following value changes per patient per year (average):

	CD4	CD8	CD4/CD8	CD4	CD8
1	169	-16	+68	+109	+14
2	107	+64	+73	+142	+11
3	116	-87	+76	+126	+16
4	63	+68	+142	+89	+1
5	22	-78	-18	+1	-109

In cases with monitoring period > 90mo and CD4 cell count < 1/2 of min. normal value, we found significant correlation between increase in LDH, decrease of Ab A leukocytes, immunological changes, and clinical findings (oral thrush, weight loss, regression of lymph nodes, frequency > 4 severities of herpes infections and lact. psoriasis). We could not find any correlation between varying and stage of immunodeficiency, and other investigated factors.

Conclusion: Courses of HIV infection vary in pts with initially equal condition. With increasing immunodeficiency, courses get more uniform.

M.A.P.105 PROSPECTIVE EVALUATION OF HIV PROGRESSION IN HOMELESS INJECTION DRUG USERS.

Authors: J. Kohnen PH, Kohnen M, Schellung U, Whitlatch JM, Whittam TS, "Institute, City Hospital, Immunology, Royal Victoria, Edinburg, Scotland.

Objective: To assess the clinical and immunological progression of HIV infection in a cohort of serologically infected injection drug users (IDU).

Methods: 248 persons (153 male, 95 female) infected with HIV between 1983 and 1984 via injection drug use have been prospectively evaluated for the last 3 years, with 3 monthly clinical and laboratory assessments.

Results: At 5 years post seroconversion, prevalence of asymptomatic HIV infection (CDC IV) and AIDS are 22.1% and 3.7% respectively. There have been 1 AIDS related and 10 non-AIDS related deaths.

Months Post Seroconv.	Mean Value (n (10/19))	(gw/l)	CD4 IV	AIDS				
24	30	1.99	0.57	0.62	0.92	1.90	4	0
30	35	1.60	0.50	0.56	0.95	2.17	10	0
36	42	1.31	0.49	0.71	0.86	2.72	19	1
42	46	1.04	0.77	0.63	2.85	2.99	29	2
48	54	1.73	0.42	0.72	3.17	3.11	41	4
54	60	1.52	0.33	0.70	0.53	3.11	55	8

At 54 - 60 months 228 have 7% counts < 0.2 x 10⁹/l. **Conclusion:** Progression in this cohort of HIV infected IDUs is occurring at a slower rate compared with other risk groups such as San Francisco homosexual. However, there is a significant non-AIDS mortality as has been reported in New York.

M.A.P.107 CLINICAL AND LABORATORY PROGRESSION OF HIV INFECTION IN BLOOD RECIPIENTS AND THEIR SPOUSES.

Authors: J. Delgado, J. Lelanc, J. Rouger, J. Lelanc, P. Institut National de Transfusion Sanguine, Paris, France.

Objective: To compare laboratory test results of HIV-infected transfusion recipients and their spouses with clinical progression to disease.

Methods: Blood samples were treated every six months for up to four years and compared to physical examination for 75 HIV-1 seropositive and 25 seronegatives. Tests include p24 antigen, p24 antibody, and absolute CD4 cells.

Results: Infected blood recipients progress to clinical disease (AIC/AIDS) in an average of 40 months. A decline in p24 antibody and CD4 cells and the appearance of p24 antigen predicted progression. 4/26 sexual partners of infected recipients are now anti-HIV positive. Although some of the sexual partners are clinically ill, several have laboratory abnormalities.

Conclusion: Infected blood recipients appear to progress to clinical disease at a rate comparable to that of infected individuals from other disease at a rate comparable to that of infected individuals from other high risk groups. The rate of heterosexual transmission is low. Laboratory parameters of viral replication and immune dysfunction correlate with, and may predict, disease progression.

M.A.P.108 PREDICTION OF HIV-RELATED CLINICAL OUTCOMES BY USING BETA-2 MICROGLOBULIN (B2), p24 ANTIBODY (Ag), AND ANTIGEN (Ag) IN A COHORT OF HIV-1 SEROCONVERTING GAY MEN

Hayat, Kenneth¹; Hodsdorf, A.***; Falk, L.***; Saltman, S.; Dawson, G.; McCusker, J.***, et al. ¹Massachusetts General Hospital, Boston, MA; ²Farmington Community Health Center, Farmington, CT; ³Memorial Hospital, Pawtucket, RI; ⁴University of Massachusetts, Amherst, MA; ⁵Abbott Lab., N. Chicago, IL, USA.

Objective: To assess the clinical utility of p24 Ab, Ag, and B2 in predicting the likelihood of clinical progression and mortality among initially asymptomatic (AS) HIV+ persons.

Methods: Serological methods including logistic regression and survival analysis in a cohort of 86 initially ASX HIV+ gay men followed for more than 3 years who are part of a Boston cohort study (N=212) initiated in 1985. Subjects are screened every 6 months. p24 Ab levels are determined by competitive EIA using a recombinant protein (Abbott).

Results: A higher % of men who were p24 Ag(+) at entry were asymptomatic (AS) 1 year later than those who were p24 Ab(-) alone or those with < 2 (30% vs 19% vs 16%), but > 2 (50% vs 40%) were independent predictors of outcome. Survival at 3 years was .76 for those with normal B2 vs. .41 for those with high B2; it was .76 for those initially p24 Ab(-) and .43 for those who were p24 Ab(-) on enrollment.

Conclusions: p24 antigenemia predicts clinical progression sooner than B2. Twice as many Ag(+) subjects became SZ in 1 year as those with < 2. Survival at 3 years is similar in ASX HIV+ subjects who are p24 Ab(-) or have > 2.

M.A.P.109 EVALUATION OF GROUP SPECIFIC COMPONENT AS DETERMINANT OF HIV SUSCEPTIBILITY AND PROGRESSION

Agmon, Hatzidakis¹; Mandakalis²; R. Butler³; R. Pilgusbaugh⁴; C. Tsoukalas⁵; K. Katsouelis⁶; et al. ¹Athens University, Athens, Greece; ²Harvard School of Public Health, Boston, MA; ³University of California, San Francisco, CA; ⁴AIDS Program, University of Colorado, Denver, CO; ⁵University of Pennsylvania, Philadelphia, PA; ⁶Red Cross Foundation, Bern, Switzerland.

Objective: To study whether Group Specific Component (G) phenotype are associated with HIV susceptibility and progression. **Methods:** 239 hemophilia patients were included in serological follow-up studies since 1980. Seroconversions to HIV occurred between 1980 and 1985 and were documented by ELISA and WB or RIF assays (122 HIV(+), 107 HIV(-)). By November 1986, 20 AIDS or ARC2 (ARC plus T4-CD4) cases have been documented. The G-C phenotypes were tested using isoelectric focusing.

Results: The G-C phenotypes are not associated with HIV susceptibility (Table). The G-C 2-3 phenotype was associated to faster progression to AIDS (The age-adjusted RR by Cox model was 3.97, 95% CI 1.08-14.46).

TABLE	G-C phenotypes (%)		G-C phenotypes (%)	
	2-3	2-2	2-3	2-2
HIV(-)	107	9.3	1.9	36.3
HIV(+)	102	9.8	4.9	32.3
Healthy HIV(+)	-	-	35.0	15.0
AIDS, ARC2	-	-	4.1	8.3
Incidence Rate (cases/1000 person-yr)	-	-	4.1	8.3

M.A.P.110 FACTORS ASSOCIATED WITH HIV PROGRESSION IN MAIROBI PROSTITUTES.

Bolton, C.***, Cameron, D.M.**, Stanses, J.R.***, Mwiru-Achola, J.O.***, Ngugi, E.***, Plummer, F.K.***, et al. ¹University of Maryland, Baltimore, MD; ²University of Ottawa, Ottawa, Canada; ³Case Western Reserve University, Cleveland, Ohio, U.S.A.; ⁴University of Nairobi, Nairobi, Kenya.

Objective: To determine factors associated with progression of HIV disease in a cohort of HIV seropositive female prostitutes living in Nairobi, Kenya.

Methods: In February 1985, 595 female prostitutes living in Nairobi were enrolled in a longitudinal cohort study. Continuing recruitment has enrolled a further 352 women. In November 1986, an educational program was introduced which resulted in increased use of condoms. The women attend the clinic for treatment of STDs. They were re-interviewed at 6 month intervals for clinical progression of HIV disease. Markov models determined 4 distinct time periods. Women who did not change CDC staging were compared to women who advanced in CDC staging using univariate and multivariate analysis. Factors assessed were age, years prostitution duration, use of oral contraceptives, pregnancy, incidence of genital ulcer disease, episodes of gonorrhoea and use of condoms.

Results: Among the variables evaluated, condom usage correlated with disease progression. Women who advanced in 'C01' of their sexual contacts were statistically more likely to advance from CDC stage III to CDC stage IV (p<.05).

Conclusion: In addition to preventing HIV transmission, condom use may also delay HIV progression.

M.A.P.111 THE NATURAL HISTORY OF HIV INFECTION IN A COHORT OF HOMOSEXUAL AND BISEXUAL MEN: COFACTORS FOR DISEASE PROGRESSION, 1978-1989

Nancy A. Hanson¹; L. Barnhart²; P. O'Malley³; A. Lifson⁴; S. Buchbinder⁵; L. Doll⁶; et al. ¹Department of Public Health, San Francisco, CA; ²AIDS Program, University of Colorado, Denver, CO; ³University of California, San Francisco, CA; ⁴University of Pennsylvania, Philadelphia, PA; ⁵University of California, San Francisco, CA; ⁶University of California, San Francisco, CA.

Objective: To identify possible cofactors for progression of HIV infection in a cohort of homosexual and bisexual men.

Methods: We evaluated 268 HIV-infected homosexual and bisexual men with well documented seroconversion (SC) dates, from 1977 to 1988, for cofactors for progression of HIV infection to AIDS using both odds ratios and Cox proportional hazard stepwise analyses. Analysis was restricted to those exposures following estimated date of SC. Spearman rank correlation test compared latency time (from HIV SC to AIDS diagnosis) to survival time (from AIDS diagnosis to death) among the 77 men who died of AIDS. **Results:** Univariate analysis showed that HIV-infected men who developed AIDS were more likely to report a history of amebiasis, gonorrhea, and herpes simplex, and less likely to report using AZT. Cox multivariate analysis showed significant association with progression to AIDS and history of amebiasis and gonorrhea. Age at SC, race, history of recreational drug use, use of other antivirals and vitamins, and history of other sexually transmitted diseases (STDs) were not statistically associated with progression to either AIDS diagnosis or death. There was no significant correlation between latency time and survival time.

Conclusion: Infection with certain STDs following HIV seroconversion is associated with progression to AIDS. Investigation into cofactors which increase or decrease the likelihood of progression to AIDS is warranted.

M.A.P.112 NO EVIDENCE FOR RISKFACTORS FOR PROGRESSION OF HIV INFECTION IN A COHORT OF HIV SEROCONVERTING MEN

van Griensven, Goffard JF, De Vuose, ENH; De Wolf, F; AIDS study group Amsterdam, The Netherlands.

Objective: To identify riskfactors for progression of HIV infection.

Methods: Between Oct. 1984 and May 1987 746 homosexual men, 224 HIV+, entered a cohort study for HIV infection and AIDS. During the follow-up until 1988 52 men seroconverted. Subjects are seen every 7 mo. for medical history, physical examination and collection of blood samples for psychosocial and behavioral data. The 286 HIV- individuals were classified in a high and low risk group for progression to AIDS. High risk was defined as the presence of HIV or the absence of antibody to HIV once in a no. of 74 cells < 0.5 during three or more subsequent sample sera. For statistical comparison high and low risk subjects were matched at random in taking the data of the first high risk bloodsample as a reference.

Results: Of the 224 seropositive 40 (17%) were high risk at entry and 98 (42%) became high risk during the study. From the 52 seroconverters 9 (18%) were high risk immediately after seroconversion and 11 (21%) became high risk later. In bivariate analyses herpes co-infection was associated positive with risk status (p<.05) while the level of education was associated negative (p<.01). Multivariate analysis revealed that serological response, intercourse was related to low risk status (p<.05). No relation was found with the use of nitrite, sex with a partner with AIDS, history of STD's, expression of emotions and experience of social support.

Conclusion: After primary infection no riskfactors are found for progression of HIV infection among homosexual men.

M.A.P.113 COFACTORS OF PROGRESSION TO AIDS IN A COHORT OF MALE SEXUAL CONTACTS OF MEN WITH HIV DISEASE

Randall Coates, V. Parrett, J. Raboud, S. Reed, D. MacFadden, L. Catzwarz, et al. University of Toronto, Toronto, ON, Canada.

Objective: To investigate potential cofactors for progression to AIDS in a cohort of male sexual contacts of men with HIV disease. **Methods:** At recruitment, 143 cohort members were seropositive and 16 were negative during oral sex, smoking and drinking status, recreational drug use and history of sexually transmitted and other diseases were obtained from interviews at inclusion into the cohort. Cox proportional hazards models examined the potential effects of recreational drug use and infections one at a time (and then in combination) while simultaneously controlling for age, smoking and drinking status, and either time from first sexual contact with the index case to inclusion or calendar year of infection.

Results: 35 cohort members developed AIDS while under study. No significant association with risk of progression to AIDS was noted for use of various recreational drugs (single or in combination), history of specific infections, age, or smoking and drinking status.

Conclusions: We could not demonstrate a significant association of any of the potential cofactors and risk of progression to AIDS. In this analysis, estimated length of time that one has been infected was the only variable associated with risk of progression to AIDS.

T.A.P.13

ARE MISSIONARIES AT RISK OF AIDS?
Lange, W. Robert¹; Dav, E. F.; Kovacs, R.; Kreider, S.;
Harris, J.²

¹ Johns Hopkins Medical Institutions, Baltimore, MD, USA.
² ARC, National Institute on Drug Abuse, Baltimore, MD, USA.
³ Associated Missionaries, New York, NY, USA.

Objective: To ascertain whether Protestant missionaries serving in regions of high AIDS incidence have been at enhanced risk of HIV-1 infection.
Methods: Serum specimens (N=6048) obtained from 2027 Protestant missionaries serving in 37 countries, including 26 African nations, between 1967 and 1984 were assayed for HIV-1 antibodies by ELISA screening and Western Blot (WB) confirmatory testing. A positive WB was defined as one with either band gp41 or p24 in association with either gp120 or gp160.
Results: Seventy seven (1.3 percent) from 61 missionaries (1.6 percent) were ELISA positive; however, only six diagnostic of HIV-1 infection on WB testing. Twenty-two WBs (43 percent) were read as indeterminate, defined as the presence of bands in such a pattern that the criteria for being positive was not met. Band p17 occurred with the greatest frequency (67 percent) followed by p24 (20 percent), either alone or in combination.

Conclusions: The significance of indeterminate WB results is unclear, but they do not appear to be a consequence of exposure to either HIV-1 or HTLV-I. We conclude that missionaries were not at high risk of HIV-1 infection between 1967 and 1984, even when serving in regions of high AIDS endemicity.

T.A.P.15

PREVALENCE OF HIV INFECTION AMONG MIGRANT FARMWORKERS
John F. Barbone¹; G. Castro²; S. Raig³; and Migrant Health
Program⁴

¹Centers for Disease Control, Atlanta, GA and ²HRSA, Migrant Health
Program, Rockville, MD, USA

Objective: To determine the seroprevalence of HIV infection in seasonal and migrant farmworkers attending migrant health centers in the United States.
Methods: A total of 3,130 seasonal and migrant farmworkers were tested for HIV antibody in a blinded manner. Basic demographic data were collected and bloods tested by the EIA and by WB at the CDC.

Results: A total of 15 (1.5%) HIV seropositives were detected, of whom, 8 (53%) were female, the racial/ethnic background were: Black 1 (7%), Hispanic 5 (33%), Mexican 8 (53%), and white 1 (7%). The state of residence was as follows: Florida 8 (53%), North Carolina 2 (13%), and 1 each from five other states. Of the 15 HIV seropositives, 11 (73%) were migrant workers and 4 (27%) were seasonal farmworkers.

Conclusions: The prevalence of HIV antibody in this population of seasonal and migrant farmworkers was found to be relatively low (1.5%). However, it is interesting to note that 13 (87%) of the seropositive were detected in eastern coastal states where a large number of persons move in a migrant stream which emanates from Florida. This survey suggests that seasonally active migrant farmworkers in the eastern coastal states may be at greater risk for HIV infection than migrants in others areas of the U.S. and that appropriate testing, counseling and prevention programs should be directed at this population. Due to difficulties inherent in reaching such a mobile and hard-to-reach group, it will be important to develop innovative outreach programs in order to reach them.

T.A.P.17

SEROPREVALENCE OF HIV AMONG TRANSMETTES IN THE
CITY OF SÃO PAULO

Neulman, J.¹; Suleiman, G.² and Salvo, Paulo Augusto Ayres³
¹Hospital Emilio Ribas, São Paulo, São Paulo, Brazil.

Objective: To define the HIV seroprevalence among transmettes.
Methods: On account of their characteristics and modes of dressing and behaviour transmettes find difficulty in attending regular health care services. In order to minimize this difficulty we move our medical team to their own quarters. There they were clinical and laboratory studied and provided with educational and psychological help. The tests were made by ZELISA and confirmed by W.B.

Results: Studies on 37 transmettes, from July to September 1985, have shown a HIV seroprevalence of 62% (23) of these 5.9% (17) were intravenous cocaine users and 1.4% (2) heroin users. From the 37 only 2 belonged to group IV by the CDC criteria.

Conclusion: Transmettes have an important role in the chain of HIV transmission. Considering that among their clients are married men, this group has a significant potential role in heterosexual and vertical transmission of HIV.

T.A.P.14

HIGH-RISK HETEROSEXUALS: DIFFERENCES BETWEEN PRIVATE AND
COMMERCIAL PARTNERS IN SEXUAL BEHAVIOR AND CONDOM USE

Van der Linden, P.J.¹; van den Pligt, J.²; Van Doornum, G.J.J.³;
* Municipal Health Service Amsterdam, Amsterdam, The Netherlands, ** University
of Amsterdam, Amsterdam, The Netherlands

Objective: To study prevalence of HIV, sexual behavior and condom use among heterosexuals with multiple partners. **Methods:** Heterosexuals with no other risk factors than 3-5 partners in the preceding 6 months were recruited through a STD-clinic. Blood was taken, and questions were asked about number of partners, frequency of practicing sexual techniques and condom use with private and/or commercial partners. **Results:** In 1986, 193 women (136 prostitutes) and 157 men (99 customers) entered the study. Prostitutes had 115 customers and 171 women had 6 and 122 men had 7 private partners in 4 months. vaginal intercourse was reported often to always by all participants, anal contact was seldom reported. Non-risky sexual techniques were reported more frequently with private than with commercial partners (p<0.01). Condom use was reported more frequently with commercial than with private partners (p<0.01), and prostitutes reported using condoms more often than customers (p<0.01). Prostitutes had 14 in 4 months with more partners (± 40 unprotected vaginal intercourse than customers (± 7), and 10 with more private partners (± 14). None of the participants was HIV positive, but 103 had positive STP-antibody, 52 were TBPA positive and 433 were diagnosed with 2 STD.

Conclusion: Despite frequent condom use, prostitutes and customers are at higher risk for HIV than heterosexuals with multiple private partners only.

T.A.P.16

PREVALENCE OF HIV-1 INFECTION AMONG COLLEGE STUDENTS;
Scolfield, Eugene¹; Teckert, C.¹; Erdwain, M.²; Cowan, J.³

¹University of Maryland School of Medicine, Baltimore;
²University of Maryland, College Park; ³National Institute of Allergy and
Infectious Diseases, Bethesda, Maryland, U.S.A.

Objective: To determine the prevalence of HIV-1 infection and high risk practices among undergraduate college students attending a university located in a metropolitan area with a high prevalence of HIV-1 infection.
Methods: In 1984, undergraduate students attending the University of Maryland at College Park were recruited to participate in a voluntary HIV-1 serosurvey and educational campaign. Each student gave informed consent, completed a questionnaire on risk behaviors, donated a blood sample, and received pre- and post-test counseling. Sera were analyzed by ELISA and western blot for HIV-1 antibody.

Results: A total of 3,449 students volunteered for the survey. All students were between 16-40 years old, 41% were male, and 81% were white. 87% of the students were sexually active (88% of males and 87% of females), with a median of 1 lifetime partners (range 0-200). A history of behavioral practices a student at risk for HIV-1 infection was acknowledged by 21% of men and 21% of women, when their risk behaviors were defined as male homosexual intercourse (5% of men), IV drug use (1%), previous sexually transmitted disease (13%), and heterosexual intercourse with a high risk individual (6%). Despite the high frequency of risk behaviors, the HIV-1 infection rate was only 0.6 per 1000 students, with HIV-1 infections documented in 2 homosexual men, both of whom engaged in other high risk behaviors.
Conclusion: Despite the presence of risk behaviors, the rate of HIV-1 seropositivity among this group of college students was low, and infections were confined to high risk homosexual men.

T.A.P.18

DO HOMOSEXUAL MEN ENJOY HIV-TESTING?
Vello Sirkkälä¹ and Sarna S.²

¹University Central Hospital, Helsinki, Finland
²University of Helsinki, Finland

Objective: To analyze the change in the sexual preference category of the newly identified HIV-seropositive individuals and the prevalence of AIDS.
Methods: As of Sept. 1985, HIV-testing has been available free-of-charge for all men in Helsinki. HIV-testing is possible in 5 AIDS Support Centres. As of Sept. 1985, HIV infection has been a notifiable disease in Finland requiring mandatory reporting on every HIV case to the National Board of Health. Anonymous HIV testing has been a notifiable disease (SAC) as are gonorrhoea, genital Chlamydia infections and hepatitis-B. Supplemental disease (SAD) is reported by name and sex. Data is collected on the age, profession and place of residence of the patient as well as on the most likely transmission route of the virus.

Results: As of 1.1.86, there are 241 cases of HIV infection, 41 of whom have AIDS. The distribution of the sexual preference among the annually found HIV cases is the following:

	1983	1984	1985	1986	1987	1988
HIS	10	14	29	41	33	22
HS	0	16	17	40	40	59

Out of the 41 cases of AIDS, 31 (75.6%) have been in homosexual men (HS) and 10 (24.4%) in men in HIS. In 1986, 3/16 had AIDS and 5/13 had AIC when HIV infection was confirmed.

Conclusion: The decrease in the number of newly identified HIV-seropositive HIS can partly be due to decreased risk but may also reflect a delay in voluntarily taking the diagnostic test.

Session d'affichage Poster Session

Épidémiologie et santé publique Epidemiology and Public Health

T.A.P.19 DIFFUSION DES PRÉCAUTIONS SEXUELLES ET ÉVOLUTION DE L'ÉPIDÉMIOLOGIE DES LAZÉTIQUES LA POPULATION HOMOSEXUELLE FRANÇAISE: 1985 - 1988
Pollet, Michèle; Schiltz, Marie-Ange; Pison, Pierre.
 *INSERM, Paris; *Muel (ed. Medec. Paris)

Objectif: Suivre la diffusion des précautions sexuelles, et l'évolution du recours au test de dépistage volontaire et de ses résultats dans la population homosexuelle française.

Méthodes: Sondage annuel par questionnaire inséré dans une revue hebdomadaire diffusée sur tout le territoire (en 1980 en 1985, 1986 et 1988), complété par un sondage (in-situ) auprès d'homosexuels choisis selon les quotas correspondant à la population masculine.
Analyses: Depuis 1986 le préservatif tend à s'imposer comme mode privilégié de protection contre le VIH. (usage régulier: 1985: 55; 1986: 39%; usage irrégulier: 1985: 21%; 1986: 25%). Le présermier sif est aujourd'hui accepté, y compris dans la tranche d'âge des moins de 25. Les plus réticents initialement. Néanmoins des différences subsistent entre Paris et la province, et selon le degré d'éducation et la catégorie socio-professionnelle. Entre 1986 et 1988 la proportion des homosexuels testés est passée de 33% à 95%, avec une stabilisation du taux de séronegativité à 19%. Les ouvriers sont la seule catégorie où ce taux a eu tendance à fortement augmenter (1986: 65; 1987: 111; 1988: 31%).
Conclusion: Le retard d'adaptation au risque de contamination observé dans les classes populaires se traduit rapidement par la progression de la maladie dans ces groupes.

T.A.P.21 INCIDENCE OF HIV-1 INFECTIONS AMONG HOMOSEXUAL MEN IN DALLAS, TEXAS, 1987-1988.
Haley, Charles E; Freeman A.; Anderson P.; Petty A.; O'Reilly K.
 *Dallas County Health Department, Dallas, Texas; **Centers for Disease Control, Atlanta, Georgia; USA.

Objective: To estimate the incidence of HIV infections among high risk men in Dallas, Texas.

Methods: Between 6/87 and 12/88, 662 homosexual or bisexual men enrolled in a cohort and were re-interviewed every six months. At each visit a confidential anonymous questionnaire linked to test results.
Results: The mean age of the cohort was 33.3 yrs; 92% were white; 87% had never used IV drugs. 64% of the cohort members admitted a history of >10 sexual partners since 1980. 178 (27%) were HIV infected at the first visit. Among the 447 HIV negative men, retention in the cohort is 96% at 6 months and 84% at 12 months. Of the 176 previously negative persons who returned for the 1st 6-month visit, 3 (1.7%) had seroconverted; of the 57 who returned for the second 6-month visit, 1 (1.8%) had seroconverted, for an annual incidence of 3.5%.
Conclusions: The incidence of HIV-1 infections is less than 5% per year among homosexual men in this population.

T.A.P.23 TRENDS IN HIV ANTIBODY POSITIVE ADMISSIONS TO A CONNECTICUT COMMUNITY HOSPITAL
Madden, Lizzy and Smith C. St. Francis Hospital and Medical Center, Hartford, Connecticut, USA

Objective: Identify demographic trends in HIV infected (HI) patients admitted to a Connecticut community teaching hospital over 3 years.

Methods: Data compiled on sex, race, risk-group and average length of stay per admission (ALOSPA) in all known HI patients admitted to our 592 bed hospital from 1986 to 1988 were reviewed.

Results: From 1986 to 1988, HI adult patient admissions increased 489%: 1986 - 50, 1987 - 166, 1988 - 294. The ALOSPA for admissions decreased from 18.9 days (4) in 1986 to 13.8 d in 1988, while the ALOSPA for non-AIDS HI patients increased from 7.5d to 10.7d. 170 adult HI patients were admitted in 1988, 70% IVDU and 85% Hispanic (His) or Black (Bl). Similar percentages of IVDU, His and Bl HI patients were seen in 1986 and 1987. From 1986 to 1988, among the HI patients, female (F) increased from 17% to 31% (P<0.1), His/F increased from 2% to 13% (P<0.1), and heterosexual risk-group (HRG) patients increased from 0% to 3% (P<0.5). HI pediatric cases increased from 0 in 1986 to 9 in 1988, all were children of IVDU.

Year	Total	His	Bl	His	F	HRG
1986	41	24	10	27	1	0
1987	112	69	43	28	2	1
1988	170	91	52	119	52	19

Conclusions: From 1986 to 1988 the Black, Hispanic, and IVDU composition of our HI adult admissions trended similar. The data were statistically significant increases in HI, F, His/F, and HI adults with heterosexual contact as their only risk factor.

T.A.P.20 CHANGES IN SEXUAL BEHAVIOR CONNECTED TO STRONG DECLINE IN HIV INCIDENCE AMONG HOMOSEXUAL MEN
Van Griensven, Godfried JF; De Vroome, EMH; *Goudits, J.; *Dourhien, RA.
 *National Health Service Amsterdam, **State University Utrecht, ***University of Amsterdam, The Netherlands

Objective: Study of the relation between changes in sexual behavior and the incidence of HIV infection among homosexual men.

Methods: Between October 1984 and May 1985 765 homosexual men were entered in a seroprevalence study on HIV infection and AIDS in Amsterdam. From these 234 (31.4%) were HIV+ at entry. Subjects are seen every 3 months for the collection of blood samples. Every 6 months a written questionnaire is completed regarding the sexual lifestyle in the preceding half year.
Results: During follow-up until December 1988 59 seroconversions were seen, 34 in 1985 (incidence 72), 16 in 1986 (incidence 3.9%), 3 in 1987 (incidence 0.8%) and 6 in 1988 (incidence 1.7%). The cumulative incidence rose from 31.4% in 1984 to 40.1% in 1988. During the study period the mean no. of partners with whom seronegatives practiced anogential receptive intercourse declined from 3.7 to 0.4. Among seropositives the number with whom anogential insertive intercourse was practiced declined from 10.6 to 1.4. The majority of subjects restricted anogential intercourse without a condom to a steady partner. Anogential intercourse with non steady partners was practiced more frequently by seropositives, but in a majority of cases while condoms were used.
Conclusion: This study shows that it has been possible to bend the course of the HIV epidemic through the modification of sexual behavior. A strong reduction of sexual activity during a long period of time was needed to affect the incidence of HIV infection.

T.A.P.22 PREVALENCE AND SEROCONVERSION FOR HIV INFECTION IN HOMOSEXUAL AND BISEXUAL MEN IN MADRID
Francisco, M.; F. Babín, C. Colomo, L. Pascual, M. Rúa-Figueroa, A. García-Seco, J. C. S. Castro, Madrid Council, Madrid; **CNM e. I. Sanitaria Majadahoca, Madrid, Spain.

OBJECTIVE: To study the changes of prevalence of HIV infection in homosexual and bisexual men in Madrid, the incidence of seroconversion was also studied in the cases that returned for the first visit.

METHODS: In the first visit information about medical and epidemiological aspects was recorded and a sample of serum was obtained for HIV test. All the reduction of sexual activity in a personal and individualized interview. Annual follow-up was offered.

RESULTS: In 625 homo and bisexual men the prevalence of HIV infection was of 14.7% (92/625). The prevalence of HIV infection was 14.7% (92/625) in September 1988. The incidence of seroconversion was also studied in the cases that returned for the first visit.

YEAR	FIRST VISIT	INTERVIEW	INTERVIEW	LAST VISIT	ANNUAL SEROCONVERSION				
1986	166	17	10.2	1492	20.8	92	6	12.5	0.8
1987	213	25	11.7	427	12.9	33	2	0	0
1988	625	104	16.6	2714	18.3	146	14	9.4	6.2

CONCLUSIONS: In 1984 an increase in HIV seroprevalence was found which corresponded to the first visit. After 1986 no significant changes were found in HIV seroprevalence. The seroconversion rate (see table) was similar over the period of time studied in spite of health education activities.

T.A.P.24 HIV SCREENING IN AN URBAN HOSPITAL OUTPATIENT POPULATION
Marmor, Michael; Krasinski, K.; Sanchez, M.; Cohen, H.; Debra, N.; Wynn, USA
 *New York University Medical Center, New York, NY, USA; **Bellevue Hospital Center, NY, NY, USA

Objective: To ascertain seroprevalence of risk factors for human immunodeficiency virus (HIV) infection in a general population.

Methods: Patients attending the outpatient clinic at Bellevue Hospital Center, Manhattan, New York City, were offered HIV screening. Male patients who had taken seroprevalence drugs at any time since 1/1/77, or who had engaged in sex with other men since that date were asked not to participate. Sera were tested for HIV antibodies with ELISA with Western blot confirmation.

Results: 1119 subjects with no prior indication of HIV infection were interviewed and HIV tested. After exclusion of 2 subjects with indeterminate HIV serology, seroprevalence was 7.1% (26/368) among men, and 5.9% (44/749) among women. Seroprevalence among heterosexuals without other risk factors was 3.3% (10/302) among males and 2.4% (15/619) among females. Rates were substantially higher among Blacks and Hispanics than among Whites. The data were suggestive of an HIV risk among men associated with sexual contact with prostitutes. Among heterosexual women, the primary risk factor was sex with a male intravenous drug user (IVDU). The most common method of birth control reported to be used by both men and women was "no method". 37% of 34 female IVDUs were HIV seropositive; a primary risk factor was the number of years since last injecting illicit drug. Logistic regression analysis identified significant risk among all women IVDUs; a significant negative interaction between these two terms was found. **Conclusions:** Heterosexual HIV transmission has been documented, particularly from male intravenous drug users to non-drug-using women. HIV seropositivity among drug users in the general population may be less than previously reported because of the importance of the number of years since last injection. Mathematical modeling of data obtained from women suggests that intravenous drug use and a history of sex with male IVDUs have not been synergistic in their association with HIV infection.

REPORT ON AN EXTREMELY LOW RATE OF SEROPOSITIVITY AMONG I.V. DRUG USERS (IVDU) IN A LOCAL HEALTH DISTRICT (LHD) OF NORTH-EST ITALY

Rezzani¹, Pizzoli², Lombardi³, Pizzetti⁴, Vercellotti⁵, Briceo⁶, Neri⁷

¹ Istituto di Patologia Speciale Medica - University of Verona - Italy
² Center for Drug Abuse - Local Health District 16 of Veneto Region - Bassano del Grappa - Italy

From December 1985 to December 1988 the center for drug addicts of the SDU 24 of Veneto Region (North-East Italy), under Verona (about 70000 IVDUs) - The population of this district is 130,000. Population aged 15-64 for addiction (age 15 - 39) is 52,000. In this group the amount of IVDU is estimated ranging from 400 to 600. The IVDU tested (ELISA plus Western blot) is positive were 345. 301 (81) addicts resulted seropositive (sero rate is 75%). Patients were studied with regard to age, sex, length of i.v. addiction, methadone treatment, therapeutic community program, conviction, kind of work, kind of partner relationship. Seropositive and seronegative groups showed no significant difference in age.

There is no evidence for a different source of the HIV in this district which is in a tourist and well developed area of North-East Italy. The first reported case of IAD in Italy occurred in this district. The following treatment strategies may be accounted for the extremely low rate of seropositivity as suggested by the study of the Center:

- 1 - a methadone maintenance program was extensively implemented between 1981-84;
- 2 - a carefully designed psychosocial program, implying a one-to-one long term therapeutic relationship was performed in these years;
- 3 - sterile syringes are easily available day and night in the local dispensary;
- 4 - an intensive campaign against viral hepatitis transmission was extensively performed by the center.

T.A.P.32

PREVALENCE OF SYPHILIS(S), HTLV-II(I), HTLV-III(I) & HIV-1 AMONG CRACK(C) AND OTHER DRUG USERS(DUS).

Glasser¹, Jordan², Monnier³, D'Angelo⁴, Drakotas⁵, A.*

¹Poless, B.**; ²Enrich, C.**; ³Et al.
⁴Richmond Memorial & Staten Island Hospitals, St. **SURY at Syracuse, NY, USA.

Purpose: To study prevalence rates of S, I, II and HIV-1 among C & other DUS in view of concern of S-enhanced heterosexual retroviral transmission.

Methods: During 1988, all 957 admissions (624M; 517 white) to RHR detox unit underwent RPR. S was confirmed by RMA-7P. Voluntary retroviral testing was offered. I & II was documented by polymerase chain reaction (PCR). I, II and HIV-1 ELISA were also done. HIV-1 was confirmed by western blot.

Results

	S	I	II	HIV-1
C alone	154/281 (4.7%)	1/37 (2.7%)	2/37 (5.4%)	7/181 (5.0%)
IVDU alone	104/388 (2.3%)	6/58 (10.3%)	6/58 (10.3%)	79/274 (28.8%)
C & IVDU	1/110 (0.9%)	1/18 (11.1%)	1/18 (5.6%)	28/82 (34.1%)
Other DU	1/138 (0.7%)	0/10 (0.0%)	0/10 (0.0%)	0/54 (0.0%)

*7/8 tested were HIV-1 negative. 4/7 tested were HIV-1 positive.

For HIV-1+ C users: All 35 belonged to high risk groups (28 IVDUs, 3 male homosexuals, 3 long-term sex partners of IVDU, 1 from endemic region) and only 1 had S. Four DUS had both I & II. For both I & II, 2/9 (22%) DUS were PCR+ but ELISA-. Two male C users with prostitute contact had either I or II.

One black female C user with no known risk factor had II. No C user with I or II had S.

Conclusions: C and IVDUs had a high rate of S. S in C users was not associated with HIV-1. The high rate of HIV-1 among C users was related to concurrent risk factors and not widespread heterosexual transmission.

T.A.P.34

THE AIDS PROBLEM AND DRUG-REHABILITATION IN THERAPEUTIC COMMUNITIES (TC)

Diazin¹, Merco

Department of Social Psychiatry University Hospital, Zürich, Switzerland.

Objective: Determine rate of infection and the effects of AIDS on the members of TC's and their human relations.

Methods: The study covers 523 heroin-addicts who were treated in 40 TC's in Switzerland in 1986. N=433 patients were tested.

Results: Rate of infection of the tested persons: 50% HIV-positive and 11.3% of the positive patients already suffered from typical symptoms related to the infection. Of particular interest was to study the communication and discussion about AIDS preventing measures and their implementation in TC. The findings were, that large and hierarchically structured TC's were more conscious of AIDS and its effects than small and family-like structured TC's.

Discussion: Prevention efforts should be established as a regular issue within the therapeutic programs of TC's. But as well, there should be opportunities of talking in private atmosphere with a therapist and other residents in a trustful relationship.

T.A.P.31

LONG TERM FOLLOW-UP AND ASSESSMENT OF HIV SEROSTATUS AND BLOOD TAPPING IN A COHORT OF 203 INTRAVENOUS DRUG USERS

Edinburgh Drug Addiction Study, Hairhouse Medical Group, Edinburgh, Scotland

OBJECTIVE: To evaluate current infection and immune status in a group of intravenous drug users previously known to have high seroprevalence (1985) and to evaluate current risk taking and behaviour change.

METHODS: A phased recruitment was carried out between 1983 and 1985 into a cohort of 203. In 1987 and 1988 follow-up was carried out and individuals were interviewed and, where appropriate, venesected. Validation included a questionnaire for the primary care physician responsible for the patient at the time of follow-up.

RESULTS: Two hundred and three individuals were contacted, 137 sero (67.5%) of whom 132 (94). One hundred and sixty four had HIV antibody tests subsequent to 1984 (when the virus is thought to have entered the group); 60 had been given 500 mg and 1988 of these tested were HIV antibody positive, 41.8% had been injecting drugs in the 12 months prior to interview and 28.3% were seropositive (12 years). Forty four percent of the group had children and 40% had a sibling who had used drugs. Sixty six per cent had been in prison; 50% of the group started injecting between 1980 and 1982, 37% thought they were at risk of HIV from needle sharing but only 23% due to possible sexual transmission. Fifty three percent had not changed sexual partners since they were first interviewed. Forty five percent used no contraception (23% of whole group had used a barrier method). Forty six percent had had more than one sex partner since test (range 2-100). Detailed demographic and immunological data are recorded.

CONCLUSION: The natural history of drug injecting had important implications for understanding HIV transmission. Behaviour change was considerable in drug taking and needle sharing but not noticeable in sexual risk factors. The implications for future serosurveys are discussed.

T.A.P.33

NEEDLE SHARING PRACTICES AMONG INTRAVENOUS DRUG USERS IN A STATE ALLOWING THE PURCHASE OF INJECTION EQUIPMENT

Lawrence, B.*; Alford, J.*; Burch, F.**; Moore, S.**

*Tulane University School of Medicine and Tropical Medicine, New Orleans, LA, USA, **Louisiana State University School of Medicine, New Orleans, LA, USA

Objective: To determine the frequency of needle sharing practices among intravenous (IV) drug users in Louisiana, a state which does not control needles by prescription.

Methods: During March-August 1988, 380 self-identified IV drug users seeking treatment in a large public hospital in New Orleans were interviewed regarding needle sharing practices, frequency of use and drug(s) of choice. Hospital records were reviewed to obtain demographic information and HIV serologic status.

Results: Eighty-one percent of subjects were male and 73% were black. Mean age was 32.5 yrs (range 16-69 yrs). The most frequent drug injected was cocaine (31%). Drugs were injected > once per day by 76%. Overall 68% of subjects admitted that they regularly use needles which had been used by others. No significant differences in needle sharing were found by sex, race, frequency of injection or drug of choice. Two of forty (5%) subjects tested were HIV seropositive.

Conclusions: Needles are not controlled by prescription in Louisiana. More than 65% of subjects admitted to sharing needles, similar to the rate found in areas in which needles are controlled. This suggests that legal availability of injection equipment does not significantly reduce sharing behavior in this population.

T.A.P.35

COORDINATED COMMUNITY PROGRAM FOR HIV SURVEILLANCE AMONG IVDU

Lawley, Benjamin¹; Sullivan, J.**; Birch, F.**; Moore, S.**

¹Coaker, J.**; Koblin, S.**; et al.

*Spectrum House, Inc., Westboro, MA 01581. ** Worcester Health Department, Worcester, MA, ***University of Massachusetts, Amherst, MA, U.S.A.

Objective: To conduct a community-wide surveillance for HIV-high-risk behaviors among an estimated 3000 IVUDs and sexual contacts in the second largest city in New England (175,000).

Methods: The Worcester (MA) AIDS organizations, a network of drug treatment, public health and criminal justice organizations enrolls, interviews, counsels and tests IVUDs at multiple sites. Active and passive follow-up is implemented for HIV+ and admissions to drug treatment and public health programs.

Results: Of 1200 tested, 482 were needle users (40%), 131 (male). 18% of needle users tested 60 of Hispanic IVUDs 35% tested 60 Blacks 30%, Whites 60%; of IVUDs in jail 21%, in drug treatment 14%. Use of bleach has increased from 5% to 64%. Over 100 persons testing entered drug treatment. Results on 3000 contacts will be presented.

Conclusions: HIV prevalence among IVUDs has increased by 22 over the past year to 18% with the greatest increase in the jail (5%). Higher seropositivity among minority groups may in part be explained by differences in drug-use behavior. The surveillance has been instrumental in targeting resources to the minority community. This model has applicability to moderately-sized cities where HIV prevalence is still low.

Epidémiologie et santé publique Epidemiology and Public Health

T.A.P.36 NO TENDRY IN TRAVEL HIV-SEROPREVALENCE RATES AMONG IVUDM IN AMSTERDAM: 1986-1988.
Van Tilburg J, Van den Broek J, Van Goolbeek B.
Municipal Health Service, Amsterdam, The Netherlands.

Objective: To describe and explain HIV-seroprevalence rates over time.
Methods: From December 1985 till December 1988, 560 IVUDM entered a long term follow-up study. HIV-seroprevalence among these IVUDM at entry into the study, were analyzed.
Results: In 3 consecutive years (1986-1988) HIV-seroprevalence rates were 35.2%, 38.3% and 27.8% respectively, showing no significant trend over time here. In that cases with the highest risk for HIV-infection participated earlier in the study than others, an attempt was made to control for this possible bias. Preventing this bias, seroprevalence rates (relative to 1986): HIV-infection were multivariately controlled for, resulting in odds-ratio estimates for HIV-infection the consecutive years (relative to 1986): that hardly differed from the uncontrolled ones: 1987: 0.67 vs 0.62; 84; 1988: 0.60; 75 vs 0.87 for uncontrolled and controlled respectively. However, conventional confidence-intervals encompass were quite large. Increases in the rate of HIV-infection from 1986 onwards, so caution is needed in interpreting these results.
Conclusion: HIV-seroprevalence rates among IVUDM in Amsterdam appear to be relatively stable since 1986. This result needs confirmation by larger scale seroprevalence studies to be conclusive.

T.A.P.38 SECOND NATIONAL SURVEY OF HIV INFECTION, AT RISK BEHAVIORS AND BEHAVIORAL CHANGE AMONG ITALIAN DRUG USERS.
Bianchi, S. *; Sestini, S. *; Costi S.
Istituto Superiore di Sanità, Rome, Italy.

Objective: To estimate, among drug users attending public assistance centres in Italy, the prevalence of HIV-1 infection and of at risk drug use behavior and sexual conduct, to evaluate tendency to change behaviors at risk and determinants of the change.
Methods: In each centre attending subjects during October 1988 have been interviewed according to a standard questionnaire, collecting information on personal characteristics, on syringes/needle sharing on kind of sexual relationships. Moreover changes of any at risk behaviors and reasons for changing were investigated. Presence of serum antibodies against HIV-1 was assayed for all enrolled subjects.
Results: Fifty four centres (out of a total of 467 in the country) completed the survey. A total of 1350 subjects from 16 regions were included. Detailed elaboration is in progress. According to results of the first national survey, expected seroprevalence is around 40% of tested subjects, with increased risk associated to sharing of syringes/needles either for preparing or for injecting the drug.
Conclusion: Although prevalence studies among subjects attending public health assistance centres can be affected by biases such as self-selection of drug users, correct confounding bias, reliability of answers, a series of surveys conducted with the same methodology is a useful tool for monitoring trends in the spread of infection and in behaviors at risk, more than for extracting absolute prevalence of such changing factors.

T.A.P.40 RETROVIRAL TRANSMISSION OF HIV AMONG INTRAVENOUS DRUG ADDICTS (IVDA).
Rizic, L. *; Brown, L. * * *
National Institute on Drug Abuse, Rockville, MD, USA; *MSA Research, Alexandria, VA, USA; **Addiction Research Treatment Center, New York, NY, USA

Objective: To examine the extent to which HIV is transmitted among heterosexual IVDA through sexual contact.
Methods: IVDA who received treatment in New York City during 1987-88 were tested for HIV antibodies by ELISA, confirmed by Western blot. Demographic, drug use, and sexual history were obtained by standardized interview. Heterosexual IVDA who reported having sex with IVDA sex partners (IVDA) (n=114) were compared with those who reported having no IVDA sex partners (n=125) using bivariate and logistic regression analyses.
Results: Initial bivariate analyses indicated that IVDA with any IVDA sex partners were more likely to be HIV+ than those with no IVDA sex partners, while the number of IVDA sex was not related to infection. Analyses by gender indicated that the relationship between IVDA and HIV held for males (p<0.1), but not females. There was no statistically significant relationship between having an IVDA sex partner and seropositivity, for either the total sample or males, when selected demographic and drug use variables were controlled.
Conclusion: The increased HIV risk associated with having IVDA appears to be due to differences in drug use practices, not sexual transmission. The study supports necessary attention to the primary mode of HIV transmission among IVDA. The possible contribution of sexual transmission should not be ruled out. Possible effects may be too subtle to be detected in these analyses.

T.A.P.37 EPIDEMIOLOGY OF AIDS ASSOCIATED WITH INTRAVENOUS DRUG USE, UNITED STATES, 1979-1988.
Kushner, J. * * *
* Centers for Disease Control (CDC), Atlanta, GA, USA
** Rockefeller Burnet Center for Medical Research, Philadelphia, Australia.

Objective: To describe characteristics of, and trends in, AIDS cases in intravenous drug users (IVDA) in the United States (US).
Methods: We reviewed AIDS cases reported to CDC through 1988.
Results: There were 21,914 cases of AIDS in IVDA. 57% heterosexual men, 27% homosexual men, 14% women, 1,457 in sex partners of IVDA, and 761 in children born to mothers who are IVDA or sex partners of IVDA. From 1984 to 1985, heterosexual IVDA increased from 17% to 21% of adult AIDS cases (in part due to the 1987 revision of the case definition), while homosexual IVDA declined from 5% to 4% of adult cases. For heterosexual IVDA cases, relative risk for cumulative incidence among blacks and Hispanics compared to whites was 1.9 and 2.2 for males and 1.9 and 1.4 for females, respectively. In the northeast, cumulative incidence for IVDA AIDS cases was as high as 1/200 among blacks and Hispanic in some urban areas, and cases in IVDA and other IVDA-associated cases exceeded all other AIDS cases by the end of 1988. Age at diagnosis of AIDS has been increasing for minority heterosexual IVDA (black and Hispanic males 4-3 months per year since 1983) but not for other IVDA.
Conclusion: Heterosexual IVDA represent an increasing proportion of the AIDS epidemic in the U.S. The burden of AIDS associated with drug use falls most heavily on blacks and Hispanic, particularly in the northeast.

T.A.P.39 INTRODUCTION OF HIV INFECTION AMONG INTRAVENOUS DRUG ADDICTS (IVDA) IN LOW PREVALENCE CITIES
Bianchi, S. *; Sestini, S. *
National Institute on Drug Abuse, Rockville, MD, USA

Objective: To examine possible mode of introduction of HIV into IVDA populations in areas with low HIV infection rates.
Methods: IVDA admitted to methadone treatment in 1987-88 in Trenton, NJ, Chicago, IL, San Antonio, TX, and Los Angeles, CA were tested for HIV antibodies by ELISA, confirmed by Western blot (w-1,154). Demographic, drug use, and sexual history were obtained by standardized interview. Seropositives (n=34) and seronegatives (n=1160) were compared with seronegative controls were compared on relevant AIDS risk factors.
Results: Seropositives and seronegative controls did not differ in frequency of IV use, needle sharing or needle cleaning, or number of drugs injected. There were also no differences between the two groups in rates of males reporting sex with other males, blood transfusions since 1982, injecting drugs or having sex in high HIV prevalence areas, and acquaintance with persons with AIDS. Seropositives, however, more likely report sharing a needle with a homosexual or bisexual male (25.0%) than were seronegatives (5.1%) (p<0.001) OR 1.5; 2.2-3.0. Differences between seropositives and seronegatives reporting injecting in shooting galleries (52.5% vs. 39.2%) approached statistical significance (p=0.07).
Conclusion: Comparisons of seropositives and seronegative controls suggest that transmission of HIV infection by needle sharing between homosexual, bisexual IVDA and heterosexual IVDA may be an important means by which HIV is introduced among heterosexual IVDA in low prevalence areas.

T.A.P.41 INCIDENCE AND RISK FACTORS OF HIV INFECTION IN A COHORT OF ITALIAN DRUG ADDICTS (IVDA) STUDY.
Alfano Nicotri, Northern Italian Serogene Drug Addicts Study, National Research Council and University of Milan, Milan, Italy.

Objective: To study the incidence of HIV infection in a population at risk, to identify risk factors, to describe natural history of infection and transmission dynamics.
Methods: Intravenous drug addicts (IVDA) are recruited from methadone clinics, hospital wards, contacts of infected persons and other high risk settings. IVDA who agree to participate in the study are first administered a questionnaire about: (1) socio, marital and serology status; (2) a positive serology; (3) a negative serology.
Results: HIV 1/200 has been recruited from January 1987 to December 1988 and followed for different periods of time. It is reconstructed how has observed. The prevalence is very high of 50% of HIV infection, of 10% of HIV infection, of 20% (1987) in the active population. The mean number of IVDA is 100, with 10% of subjects practicing less than 100 calls. Previous infections, type of drug use and patterns of drug acquisition, sexual behavior and demographic variables have been related to seropositivity in order to verify their role in the risk of HIV infection.
Conclusions: The number of seropositives is not sufficient yet to order to draw firm statistical inferences about risk factors, although it is possible to say that HIV is first seen in significantly less in individuals who share seropositives. Seropositives and follow-up are continuing, that it is very a high level of risk factors as well as of behavior and preventive attitudes of IVDA.

Session d'affichage Poster Session

Epidémiologie et santé publique Epidemiology and Public Health

T.A.P.48 DRUG ABUSE PATTERNS AND RESISTIVITY IN IVDA DURING THE EARLY YEARS OF THE HIV EPIDEMIC

Smith, David, M.*; Trigg, M.*; Doe Jarvis, D.C.**; Frithson, S.R.**; Vidler, M.J.***; Hines, S.***; 3rd Israel Medical Center, New York, N.Y., U.S.A.*; N.Y. State Division of Substance Abuse Services, New York, N.Y., U.S.A.**; Heronick and Drug Research Inc., New York, N.Y., U.S.A.**; Johns Hopkins Univ., Baltimore, MD, U.S.A.***; The Rockefeller University, New York, N.Y., U.S.A.

Objective. To determine factors associated with HIV infection in intravenous drug users (IVDA) during the early years of the HIV epidemic in New York. **Methods.** Records from studies of chronic liver disease (CLD) in IVDA during 1978-83 were reviewed. In these studies, limited clinical and demographic data had been linked to case numbers of virus which had subsequently been tested for HIV antibody by ELISA (Abbott) and Western blot. Available data included age, sex, race, marital preference, heroin only vs. heroin and cocaine, and duration and age of onset of IVDA and of alcohol abuse. **Results.** Only 2 (11%) of 18 white patients with CLD were HIV-infected, compared with 24 (39%) of 60 black or hispanic patients (p<0.03). Among all factors of cocaine with heroin, 30 (52%) of 58 had anti-HIV compared with 5 (13%) of 44 injected only heroin (p<0.0001). No other factors listed above were linked to anti-HIV. In a multiple logistic regression, anti-HIV was associated with injection of cocaine with heroin (p<0.0001), black patients (p<0.02), anti-hepatic patients (p<0.05). **Conclusion.** IV cocaine users as well as black and hispanic IVDA were disproportionately HIV-infected during the early years of the epidemic. Cocaine with heroin and ethnicity were independently linked to anti-HIV.

T.A.P.50 INTRAVENOUS DRUG USE AS A RISK FACTOR FOR AIDS AND HIV INFECTION IN LOUISIANA

McLeland, L.*; Louisiana Department of Health and Hospitals, New Orleans, LA, USA; *Louisiana University School of Public Health, New Orleans, LA, USA.

Objective. To determine trends in intravenous drug use (IVDU) as a risk factor for AIDS and HIV infection in Louisiana (LA). **Methods.** AIDS cases are identified by an active hospital-based surveillance system. Case data is collected by hospital record review, and physician and patient interview. Seroprevalence data is from blinded testing of new entrants at two drug treatment centers in New Orleans. **Results.** As of 12/30/86, 1003 adult and 14 pediatric cases of AIDS were identified. IVDU use was associated with 172 (18%) of all cases in adults (SDVD, 100-non-Hispanic and 722), 78-Hispanic). Contact with IVDA in the four (25%) of pediatric cases were from IVDU in a parent. IVDU use was the primary risk factor for AIDS in 148 of blacks vs. 24 of whites. The proportion of AIDS cases with IVDU as the primary risk factor increased from 28 in 1985 to 38 in 1986. Of 175 new entrants to IVDA treatment centers in New Orleans in 1986, 6.2% were found to be HIV seropositive. **Conclusion.** IVDU accounts directly or indirectly for 16% of AIDS cases in LA. The proportion of AIDS attributable to IVDU has increased significantly in the past three years. Blacks account for a disproportionate number of cases among IVDA. The prevalence of HIV in IVDA in New Orleans in 1986 is relatively low (6.2%).

T.A.P.52 COMPARISON OF PREVALENCE OF HIV INFECTION IN IVDA DRUG USERS (IVDU) FROM FOUR DIFFERENT TESTING AND TREATMENT PROGRAMS.

Chen, David; Douglas, J.; Koles, J.; Feeley, F.; Juson, F.; Denver District Health Dept., Denver, CO, USA

Objective. To compare the prevalence of HIV infection in IVDA assessed through a different testing and/or treatment program in Denver in 1986. **Methods:** In 1986, 1000 IVDA were tested by Denver in 4 programs: (1) counseling and testing site (CTS), (2) sexually Transmitted Diseases (STD) Clinic, (3) Substance Treatment Services (STS-a voluntary maintenance program), and (4) Project Safe (PS)-an anonymous street outreach program for IVDA not in treatment. **Results:**

	No. HIV positive / No. tested (%)			
	CTS	STD	STS	PS
Gay/bisexual men	20/51 (39)	17/50 (34)	0/1 (0)	2/7 (28)
Female prostitutes	2/40 (5)	2/69 (4)	1/6 (16)	1/22 (5)
Metropolitan men	14/305 (5)	3/227 (1)	1/73 (1)	3/160 (2)
Metropolitan women	2/168 (1)	1/123 (1)	0/34 (0)	0/37 (0)
TOTAL	38/564 (7)	24/489 (5)	2/114 (2)	6/164 (4)

Conclusions: The prevalence of HIV infection in IVDA who are not gay or bisexual men is low in these samples in programs with different selection criteria. Determining prevalence rates among different programs is useful both to monitor secular trends and to better estimate the community burden of HIV infection in IVDA.

T.A.P.49 DEMOGRAPHIC AND BEHAVIORAL FEATURES OF HIV INFECTION IN INTRAVENOUS DRUG USERS (IVDA) IN NEW YORK CITY DRUG TREATMENT PROGRAMS: 1981-1986

Brann, Lawrence S.*; Phillips, R.*; Aljuchukwa, D.*; Katsirji, R.*; Fisman, R.*; and Hensler, T.*. Addiction Research and Treatment Corporation, Brooklyn, NY, USA. **National Institute on Drug Abuse, Rockville, MD, USA.

Objective. To examine the trends in demographic and HIV-related behavioral factors of IVDA enrolled in methadone treatment. **Methods.** Following informed consent, standardized questionnaires of drug use, sexual behaviors, and medical history were administered to IVDA recently admitted to drug treatment. Sera was analyzed for HIV-1 using ELISA and western blot techniques. **Results.** Year Number Tested Number (%) HIV Seropositive
1985 469 255 (54)
1986 263 158 (59)
1987 218 131 (60)
1988 222 115 (52)

The tendency in '85, '86 and '88 toward higher infection rates for non-whites, as compared to whites, did not hold for '87. Differences in HIV infection rates between these cohorts were most appreciated in black and male IVDA. Between 1987-8, there were important differences between IVDA and sexual behaviors. IVDA with white chest findings suggest modification of behaviors among IVDA, as the HIV infection rate may be equally explained by serostatus.

T.A.P.51 TRANSMISSION OF HIV BY SEXUALITY IN INTRAVENOUS DRUG USERS (IVDU)

McClellan, J.M.*; Jones, G.*; Davidson, C.*; Haimet, S.*; Barua, S.*; N.Y. State, Rockefeller University; *National Drug Institute, City Hospital, BIRMINGHAM, Scotland.

Objective. To establish those areas in which Birmingham based IDU had shared injection equipment. **Methods:** All IDU attending the Edinburgh Counseling Clinic were asked about injection practices including sharing equipment in non-Birmingham locations. **Results:** By the end of 1987, 1143 patients had attended the clinic of whom 376 (34.6%) were IDU, 17 had never injected in Birmingham. The mean age of the remaining 379 was 26 years (16-46) with a M/F ratio of 1.72:1. In 351 HIV status was determined and 110 (48.8%) of the 225 males and 73 (55.2%) of 139 females were positive. 101 (26.6%) IDU, 73 males and 28 females, admitted to sharing equipment in 140 non-Birmingham sites. Those had shared sites in Southern Europe and retrospective tests of stored sera showed that one seroconverted for HIV shortly after returning to Birmingham. This individual went on to share with numerous other users with later seroconversion dates. **Conclusion:** The IDU related HIV epidemic in Southern Europe began in 1981 and the unexpected mobility of drug users explain the pockets of IDU related HIV infection as well as other blood borne viruses in Southern Europe. This mobility must be taken into account when considering preventative strategies for HIV.

T.A.P.53 HUMAN IMMUNODEFICIENCY (HIV) AND HUMAN T-LYMPHOTROPIC (HTLV-1/II) VIRUS INFECTIONS ASSOCIATED WITH INTRAVENOUS DRUG ABUSE (IVDA).

Strawick, Rod, M.D., J. Sasseoff, G., and Harris, D. New York State Health Department, Albany, U.S.A.

Objective. To describe the prevalence of HIV and HTLV-1/II infections among people in N.Y. State with IVDA as a risk factor for the transmission of blood borne infections. **Methods.** Specimens submitted for HIV test from anonymous subjects with a history of IVDA (343 sera) of with no associated risk for HIV infection (1965) were tested for HIV and HTLV-1/II antibody by EIA and western blot. EIA reactive sera with HIV blot bands at 24 and 41 and/or 120/160 kd or HTLV-1/II bands at 24 and 46 and/or 65/68 kd were recorded as positive. Results were merged with age, sex, geographic origin and race/ethnicity data and analyzed on an sero-prevalence basis. **Results.** In IVDA subjects the prevalence of antibody to HTLV-1/II or HIV and HTLV-1/II was 5.6 and 4.1% respectively. In people with no associated risk it was 0.8% and 0.7%. For both populations studied, HIV prevalence was highest at age 30-39; HTLV-1/II in both HIV plus HTLV-1/II was higher at age 30 or greater. Proportion of IVDA sera positive for HIV also positive for HTLV-1/II was 142/845 or 7.8% of sera positive for HTLV-1/II also positive for HIV, it was 142/196 (72.4%). **Conclusions:** About 1 in every 13 IVDA subjects infected with HIV in N.Y. State is also infected with HTLV-1/II. Conversely, about 72% of HTLV-1/II infected IVDA subjects are infected with HIV.

HIV INFECTION AMONG INTRAVENOUS DRUG USERS (IVDU's) IN NYC
Truman, Benedicte, Johnson, J. S., Brown, L., Peyser, R., Peters, L., DeLuca, J., et al.

*New York State Department of Health, Albany, New York, USA, **Addiction Research Treatment Corp., NY, NY, USA, ***Beth Israel Medical Center, NY, NY, USA, ****New York State Division of Substance Abuse Services, NY, NY, USA.

Objective: To compare current HIV seroprevalence and risk factors among "new entrants" and "old clients" of Methadone Maintenance Treatment Programs (MMTP's) in New York City (NYC).

Methods: Since June 1986, sera from IVDU's at 28 MMTP clinics were tested blindly for HIV by ELISA and WB. Non-identifying demographic and treatment data were collected at entry or on annual physicals. Logistic regression models identified risk factors for infection in "new entrants" and "old clients".
Results: As of Jan. 1988, 33.4% of 1062 clients were HIV+. Data were complete for 403 "new entrants" (45.9% HIV+) and 305 "old clients" (27.2% HIV+). "New entrants" have higher infection rates than "old clients" in all subgroups.
RACE
BOROUGH OF RESIDENCE
Ever
Bl. Hisp. Wh. Bronx Brook. Manh. Queens St. Isl. Treated?
New 52.8 41.8 39.1 31.0 48.0 49.7 43.8 33.3 21.4
Old 32.1 37.9 17.0 28.6 19.4 35.2 14.6 12.5 84
HIV infection was associated with a history of previous treatment for drug abuse among "new entrants" (OR=5.0 CI=1.4,11.5), and with black race (2.2 (1.1,4.4)), Hispanic ethnicity (2.5,1.2,4.9) and Manhattan residence (2.8,1.2, 6.9) among "old clients".
Conclusion: In NYC MMTP's, "new entrants" are 1.7 times as likely as "old clients" to be HIV+. Prevalence was lower than previously reported by both groups.

T.A.P.56

HIV SEROCONVERSION IN A GROUP OF IVDAs (1985-1988)
Giorgio, Barbantini, S. Edo, T. Gola, S. Guerin, S. Lopez, F. Salmadori, et al.

Clinic of Infectious Diseases IRCCS S. Matteo University of Pavia - ITALY

Objective: To demonstrate the incidence of seroconversion for HIV in a cohort of IVDAs.
Methods: Since first months of 1985 a group of 491 drug addicts, followed by Drug Abuse Surveillance Organisms of Abbottegrasso (USL 73), Crema (USL 53) Sagenta (USL 72), Vigevano (USL 78) and Voghera (USL 79) in southern Lombardy, has been tested every six months for HIV antibodies.
Results: At June 1985, we found 253 seropositive IVDAs (1202 males and 51 females); at December 1988 28 of the previously negative drug addicts (16 males and 12 females) were found positive.
In the cohort of earliest HIV positive subjects 21 developed AIDS until now.
Conclusion: These data suggest that intravenous drug abuse put IVDAs at increased risk for HIV infection as long as drug behaviour continues, even followed by appropriate contacts, and this is not a good result of preventive measures.
So the possibility of sexual spread from IVDAs (many drug addicts, either women, either men, sell themselves for buying drug) to common people requires great attention.

T.A.P.58

SEXUALLY TRANSMITTED DISEASES (STD's) AND HIV SEROPREVALENCE IN A COHORT OF IV DRUG USERS
Miles, Ernest E., Vlahov D., Selomsen L., Chowdhry, N., U.S.A.

Objective: To correlate the history of a sexually transmitted disease and HIV seroprevalence in a cohort of active IV drug users (IVDU's).
Methods: A cohort of IVDU's, without AIDS, was recruited for a study of the natural history of HIV infection by community outreach. Histories of STD's at baseline were correlated with HIV seroprevalence.
Results: Overall 44 (44.7%) of 1780 participants were HIV seropositive at baseline. STD histories by HIV serostatus were as follows:

	HIV -	HIV +	P-Value (Chi-square/Fisher's)
Syphilis	17.5%	12.2%	0.005
Gonorrhoea	96.7%	92.9%	0.16
Genital Warts	5.0%	2.2%	0.09
Genital Herpes	7.7%	6.4%	0.34
Other STD's	18.9%	19.2%	0.77

Among male homosexual/bisexual IVDU's a syphilis history was strongly associated with HIV seropositivity (20/44; 45%) compared with HIV negatives (18/114; 16.7%; p < 0.001). Among heterosexual (65/972; 14.2%) of HIV seropositives and (143/1194; 11.9%) of HIV seronegatives had a history of syphilis (p < 0.05).
Conclusion: Our study suggests that sexual transmission may account for some HIV infections among active IV drug users, especially in those who are male homosexual/bisexuals. Prospective studies are required to more clearly define the risks of sexual transmission of HIV in IVDU's.

T.A.P.55

HIV SEROPREVALENCE IN INJECTING DRUG USERS IN SOUTH LONDON
1985-88
S. Sabin, J. T. McCann, M. S. G. Smith, et al.

Objective: To estimate the HIV seroprevalence in injecting drug users as monitored by an HIV testing laboratory in South London.
Method: The frequency of HIV antibody positivity in injecting drug users attending clinics and General Practitioners in the South London area was estimated. 555 men and 286 women were tested. 619 of those tested were over 25 years of age.
Results:

	Prevalence of HIV antibody in IVDU's									
	1985 No (%)	1986 No (%)	1987 No (%)	1988 No (%)	1985-88 No (%)					
Male	0 (130)	11 (203)	8 (198)	9 (141)	28 (553)					
Female	1 (61)	7 (90)	4 (115)	2 (75)	14 (286)					
Total	1 (193)	18 (293)	12 (313)	11 (216)	42 (843)					

These results compare with a seroprevalence of 19% among homosexual men and <1% in heterosexual men and women tested in the same areas over the same period. Most of those found to be HIV Ab positive (97%) were patients attending the sexually transmitted disease clinic requesting HIV antibody testing.
Conclusion: The HIV antibody seroprevalence in this group rose very rapidly but appears to have levelled off. The majority of those tested were over 25 years of age and gave evidence of having changed their needle sharing habits. More younger addicts need to be tested and outreach methods are being used to reach them.

T.A.P.57

HIV PREVALENCE AMONG DIFFERENT GROUPS OF INTRAVENOUS DRUG USERS IN SEATTLE, WASHINGTON
McGough, James P., Wood, R. E., Harris, N., Kleyn, J., Carlisle, M., et al.

AIDS Prevention Project, Seattle, Washington USA, **University of Washington, Seattle, Washington, USA ***King County Detoxification Facility, Seattle, Washington, USA

Objective: To estimate HIV antibody seroprevalence among different groups of intravenous drug users (IVDU's) in Seattle and King County.
Methods: IVDUs were tested at the AIDS Prevention Project (APP), a testing site promoted for persons at high risk of HIV infection, at the King County Jail, from the streets of Seattle, and at the County drug and alcohol detoxification facility.
Results:

	APP	Jail	Street	Detox	TOTAL
	Tested	Tested	Tested	Tested	Tested
Gay/bi men	356 (30.9%)	31 (6.2%)	11 (10)	10 (808)	408
Other men	254 (4.2%)	12 (2.4%)	15 (0.6%)	101 (5.0%)	356
Women	224 (2.6%)	42 (4.9%)	7 (0.6%)	56 (2.6%)	345
TOTAL	855 (14.6%)	161 (3.7%)	27 (0.9%)	167 (5.4%)	1216

Conclusion: Preliminary data indicate that HIV seroprevalence among IVDU's varies greatly by site. The prevalence is greatest among male IVDU's who report having had sex with other men.

T.A.P.59

SERO-EPIDEMIOLOGY OF HIV-1 INFECTION AMONG INJECTING DRUG USERS SEEKING HELP IN MONTREAL: 1985-1988
Brennan, Julie, Lapointe, F., Soto, J., Brabant, M., Vinciguerra, J., and Fauriol, M., et al.

CRC Andre-Viallet, Centre Hospitalaire Saint-Jacques, Université de Montreal, and **Laboratoire de microbiologie publique du Québec, Montreal, Canada.
Objective: To determine the prevalence and trends of HIV-1 infection among IVDUs hospitalized for detoxification and correlate seropositivity with risk factors.
Methods: Every IVDU hospitalized between March 1985 and Sept. 1988 had a serum taken, tested for Hepatitis B markers and stored frozen at -20°C in a serum bank. Sera were retested for HIV-1 antibodies using ELISA and RIBA & IFA confirmation tests. Patient records and serologic results were matched and analysed anonymously using an unlinked method.
Results: From a total of 294 patients, 13 were HIV-1 seropositive (4.4%). There was no association between HIV-1 infection and sex, age, ethnic origin, sexual orientation, prostitution, drug use, or mode of needle sharing. Of 234 patients with known sexual orientation, 224 were heterosexual. Only one of the seropositive was bisexual. Twelve of the thirteen seropositive were hepatitis B markers positive in contrast to 111 of the 281 negative (p < 0.001). The annual prevalence of HIV-1 infection at the Detox Unit was: 1985, 7.1%; 1986, 3.0%; 1987, 2.0%; 1988, 6.4%; overall, 4.5% (confidence limits: 2.2 - 6.7%).
Conclusion: HIV-1 infection prevalence in Montreal IVDUs seeking detoxification remained stable between 1985 and 1988 and is associated with the presence of hepatitis B markers. The opportunity for preventive strategies is great.

T.A.P.60 COMPARATIVE MONITORING OF HIV-SPREAD IN THE IVUO

T.O.P. OF BERLIN AND HAMBURG
Bischof, Friedrich*, Bornemann, R.*; Puschke, K.*; Rax, R.*; Pätz, W.*; Uebig, R.* et al.
*Friedrich Universität Berlin, **Humboldt Hamburg FRG, ***Justizvollzug Berlin (West), ****Karl-Bonhoefer-Nervenklinik Berlin(West), *****Justizvollzug Hamburg (West) (Justizvollzug West Germany)
Objective: Local monitoring of HIV-spread in IVUO population
Methods: Since 1985 nearly all cases of drug related deaths in Berlin(West) were HIV-AB tested: 86282; test ratio (78) 37%. Since 1988 we try to broaden the HIV-indicator-normally by including data of defined groups of living IVUOs* on a voluntary basis: entrants in detoxification, admissions in prison.

Results: In the autopsy cases the following seropositivity rates were found:

Region	1985	1986	1987	1988
Berlin	305	495	495	385
Hamburg	78	125	163	135

Because of selfselection of the data-gathering in the groups of living IVUOs we full of gaps, especially in Berlin. In Hamburg the positive test results in clinical diagnosis, or employment status. Individuals receiving ATW are detox-cases 1988 was 135 (18 73%), in prison cases 125 (18 93%), were very close to the autopsy rates. In Berlin the difference was great: detox cases 1988 295 (38 28%), in prison cases 125 (18 not known).
Conclusion: Seropositivity rates in drug related deaths seem to represent quite a realistic picture of the HIV-situation. In cities of similar structure the HIV-spread in the IVUO population may show great differences.

T.A.P.61 UNDERREPORTING OF AIDS CASES, SOUTH CAROLINA, 1984-1987

Comay, George A., and M. Alexander, B.A., Ed. PH
*Centers for Disease Control, Atlanta, Georgia, USA, **South Carolina Department of Health and Environmental Control, Columbia, South Carolina, USA
Objective: To assess the completeness and accuracy of AIDS case reporting in South Carolina.

Methods: Approximately 400,000 hospital discharge billing records from January 1984 through June 1987 were searched by computer for AIDS-defining conditions. The resulting 1,313 clinical records were manually reviewed.
Results: Of these, records for 335 discharges for 183 individuals were classified as being definitely AIDS-related by the 8/87 revised CDC AIDS case definition. 133 of these individuals met the older (pre 8/87) case definition, and should have reported to the State AIDS case registry. After controlling for reporting lags, 92 of these were indeed reported. Thus, 39.5% of all AIDS cases and 50% of those with an interval were not reported. Reported versus non-reported groups were not significantly different by age, race, sex, risk behavior, primary diagnosis, clinical diagnosis, or employment status. Individuals receiving ATW were significantly more likely to have been reported ($p < .001$). Percentage of cases reported by ICD 902 (down to 0/4 0/2). There was also a considerable range in reporting compliance among physicians.
Conclusion: There was considerable underreporting of AIDS cases in South Carolina for the study interval. Similar studies should be repeated in other states, and may have important implications for the interpretation of surveillance data and for planning in the epidemic.

T.A.P.62 USING DEATH CERTIFICATES (1985-1987) TO ESTIMATE THE

COMPLETENESS OF AIDS CASE REPORTING IN ONTARIO
L. Lilly, M.D., R. J. Johnson, E.M. Wallace*,
Epidemiologist, Public Health Branch, Ontario Ministry of Health*Assistant in Community Medicine, University of Toronto, Canada****Assistant in Public Health Branch, Ontario Ministry of Health, Toronto, Ontario, Canada

Abstract. The completeness of AIDS case reporting in Ontario was assessed by reviewing all AIDS death certificates compiled by the Registrar General between January 1, 1985 and December 31, 1987. Several demographic variables were used to match death certificates with cases reported to the provincial AIDS registry and the Census form and Dosing method was used to estimate the completeness of case reporting. The estimated completeness of case reporting was 80.9% in 1985 (95% C.I., 75.5% to 85.9%), 71.4% in 1986 (95% C.I., 67.4% to 75.6%), 75.3% in 1987 (95% C.I., 70.4% to 79.2%), and 75.1% overall for 1985-1987 (C.I., 71.2% to 78.0%). The completeness of reporting in 1985 was significantly higher than in 1986 (chi-square, $p < 0.01$) but was not significantly different from that calculated for 1987 (chi-square, $p > 0.05$). Cases who were never married were 1.5 times more likely to be reported in 1985 than in 1986, and there was a significant increase in the proportion of such unreported cases from 1985 to 1986 (chi-square, $p < 0.02$). Reporting was not associated with the patient's age, sex, occupation or place of residence. The deficiency in AIDS case reporting could adversely affect the long-term planning of health care resources and the development of programs to prevent and control the spread of AIDS.

Key Words: AIDS, Case reporting, Death Certificates, Registry

T.A.P.63 RISK GROUP DIFFERENCES IN REPORTED DEATHS IN AIDS PATIENTS

Berling, Olov*, Swelander, Eli, Karen, J.N.
AIDS Program, Centers for Disease, Atlanta, Georgia, USA

Objective. To determine any variation among risk groups in the percentage of AIDS cases diagnosed at death and in the delay by reporting date. Male, deaths of known AIDS patients are reported to CDC by state and local health departments. All deaths in adult patients diagnosed between 1984 and 1988 were examined. Patients with death in the same month as diagnosis were classified as diagnosed at death. The number of months between death and report was calculated for all deaths reported in 1988 (date of death report was first recorded in October, 1987). Risk group was defined by the mode of HIV transmission.
Results. For cases diagnosed in each of the years 1984 and 1987, 100-11% of AIDS cases in homosexual/bisexual males who were not intravenous drug users (IVDU) were diagnosed "at death," compared to 50-10% in heterosexual IVUDs diagnosed in the same years. Roughly one fifth of all transmission related AIDS diagnoses were made "at death" between 1984 and 1987. Deaths among heterosexual IVUDs were 50% more likely to be reported after a delay of 12 or more months than deaths in non-IVUD heterosexuals. Eleven percent of the known deaths occurring among homosexual/bisexual non-IVUDs in 1986 were not reported until 1988 compared to 19% of the heterosexual IVUDs who died the same year.

Conclusion. Both the proportion of cases diagnosed at death and the delay in reporting deaths may vary among risk groups. Survival estimates must consider these possible sources of bias. It may be desirable to estimate survival only among AIDS patients with reported survival of at least one year period (month or calendar quarter).

T.A.P.64 HIGH PERCENTAGE OF NON-REPORTED CASES OF AIDS IN

THE FEDERAL REPUBLIC OF GERMANY
Eckardt, Gert D.

Max von Pettenkofer-Institut, University of Munich, FRG.

Objective. Estimation of non-reported AIDS-cases in the FRG.
Methods. Questionnaires sent to all hemophilia treatment centers in the FRG revealed in October 1987 the presence of 183 hemophiliacs with HIV-antibodies. In addition, 1111 were registered as clotting factor associated cases of AIDS were officially registered at that time (44.8 %). In a similar evaluation done end of October 1988, the number of cases was 351, but only 133 (37.9 %) were registered. Between first and second evaluation the number of hemophiliacs with AIDS increased by 168, the number of registered cases by 51 (30.4 % of new cases registered).
Results. The data suggest an increase in percentage of non-reported AIDS cases. In 1987, reported cases in hemophiliacs show a decreasing trend: doubling time decreased to 18 months, but in still 13 months in reality. Assuming the same percentage of non-reported cases for all risk groups, not 2380 reported but 6807 cases of AIDS might have occurred in the FRG till November 1988. The doubling time case might still be 12 months instead of 13 months, as deduced from reported figures.
Conclusion. Probably more than half of all diagnosed cases of AIDS are not reported and the percentage of non-reported cases seems to increase. The complete voluntary reporting system of the FRG will not give completely reliable data.

T.A.P.65 ACTIVE SURVEILLANCE FOR PEDIATRIC HIV INFECTION IN LOS ANGELES COUNTY

Bevilacqua, Leonard V., Bann, S.J., Frederick, J., Chan, H., Brown, James, Towns, A., et al.

*Los Angeles County, Dept. Health Services, Los Angeles (CA), Calif.; **University of Southern California, L.A., Calif.; ***University of California, L.A., Calif., USA

Objective. To describe the development and implementation of an active surveillance system for pediatric HIV infection in Los Angeles County (LAC), California, and to present data from January 1982 through December 1987.
Methods. As of March 1985, pediatric and adult cases satisfying the CDC's surveillance criteria for AIDS were reported through a combination of active and passive surveillance measures. In March 1985, an active surveillance system for all cases of pediatric HIV infection (PHI) was initiated. Cases were classified using the classification system for HIV in children (1) (see Table 1). Initial telephone survey and a supplemental information form is filled out on each case.
Results. As of December 31, 1987, 189 (PHI) (100%) had been reported; 50 (26%) of AIDS had AIDS. This represents a 22% increase in reported pediatric AIDS since March 1985. From 3/85 to 12/86, adult AIDS cases increased overall by 298 and 40% among men. Sixty-three percent of all pediatric HIVs were male; 24% are dead. About one-third (100) of HIVs were seroepidemiologic (I-2) yet not classifiable as pediatric AIDS. Thirty-two percent had a parent at the time and 35% were among minorities. In contrast, among the 13 most recently reported HIV cases since September 1986, 7% had a parent at risk, and 75% were among minorities. Of the pediatric AIDS cases, none were had opportunistic infections, 14% had Lip and only 4% had Kaposi's sarcoma.
Conclusion. This active surveillance system for active surveillance system for HIV in children (1) was initiated. Cases were classified using the classification system for HIV in children (1) (see Table 1). Initial telephone survey and a supplemental information form is filled out on each case.
Results. As of December 31, 1987, 189 (PHI) (100%) had been reported; 50 (26%) of AIDS had AIDS. This represents a 22% increase in reported pediatric AIDS since March 1985. From 3/85 to 12/86, adult AIDS cases increased overall by 298 and 40% among men. Sixty-three percent of all pediatric HIVs were male; 24% are dead. About one-third (100) of HIVs were seroepidemiologic (I-2) yet not classifiable as pediatric AIDS. Thirty-two percent had a parent at the time and 35% were among minorities. In contrast, among the 13 most recently reported HIV cases since September 1986, 7% had a parent at risk, and 75% were among minorities. Of the pediatric AIDS cases, none were had opportunistic infections, 14% had Lip and only 4% had Kaposi's sarcoma.
Conclusion. This active surveillance system for active surveillance system for HIV in children (1) was initiated. Cases were classified using the classification system for HIV in children (1) (see Table 1). Initial telephone survey and a supplemental information form is filled out on each case.
Results. As of December 31, 1987, 189 (PHI) (100%) had been reported; 50 (26%) of AIDS had AIDS. This represents a 22% increase in reported pediatric AIDS since March 1985. From 3/85 to 12/86, adult AIDS cases increased overall by 298 and 40% among men. Sixty-three percent of all pediatric HIVs were male; 24% are dead. Conclusion. This active surveillance system for active surveillance system for HIV in children (1) was initiated. Cases were classified using the classification system for HIV in children (1) (see Table 1). Initial telephone survey and a supplemental information form is filled out on each case.
Results. As of December 31, 1987, 189 (PHI) (100%) had been reported; 50 (26%) of AIDS had AIDS. This represents a 22% increase in reported pediatric AIDS since March 1985. From 3/85 to 12/86, adult AIDS cases increased overall by 298 and 40% among men. Sixty-three percent of all pediatric HIVs were male; 24% are dead. About one-third (100) of HIVs were seroepidemiologic (I-2) yet not classifiable as pediatric AIDS. Thirty-two percent had a parent at the time and 35% were among minorities. In contrast, among the 13 most recently reported HIV cases since September 1986, 7% had a parent at risk, and 75% were among minorities. Of the pediatric AIDS cases, none were had opportunistic infections, 14% had Lip and only 4% had Kaposi's sarcoma.
Conclusion. This active surveillance system for active surveillance system for HIV in children (1) was initiated. Cases were classified using the classification system for HIV in children (1) (see Table 1). Initial telephone survey and a supplemental information form is filled out on each case.
Results. As of December 31, 1987, 189 (PHI) (100%) had been reported; 50 (26%) of AIDS had AIDS. This represents a 22% increase in reported pediatric AIDS since March 1985. From 3/85 to 12/86, adult AIDS cases increased overall by 298 and 40% among men. Sixty-three percent of all pediatric HIVs were male; 24% are dead. About one-third (100) of HIVs were seroepidemiologic (I-2) yet not classifiable as pediatric AIDS. Thirty-two percent had a parent at the time and 35% were among minorities. In contrast, among the 13 most recently reported HIV cases since September 1986, 7% had a parent at risk, and 75% were among minorities. Of the pediatric AIDS cases, none were had opportunistic infections, 14% had Lip and only 4% had Kaposi's sarcoma.

T.A.P.66 MEDICAL SCHOOL SUBCONTRACT ENSURES STATE-WIDE ACTIVE AIDS SURVEILLANCE IN NEW JERSEY

Schneider, D. Jean, and Lavenhar, M.
UMDNJ - New Jersey Medical School, Newark, New Jersey, U.S.A.

- Objectives:** To expand New Jersey Health Department capacity to obtain surveillance data.
Methods: Unique subcontract with state medical school effected to produce increase in active AIDS surveillance activities on a state-wide basis.
Results: Two years of experience with subcontract resulted in:
1. State-wide active surveillance sites increased as responsibility for 12 sites (affiliated hospitals) was shifted to medical school.
2. Concentration on active rather than passive surveillance within New Jersey made possible.
3. Partnership provided data on approximately 40% of New Jersey AIDS cases.
4. Accessibility to hospital AIDS data improved by use of medical school personnel.
5. Teaching hospitals provided with accurate AIDS census data.
6. Retrospective surveillance activities made possible.
7. More complete and accurate AIDS data made available for CDC, state and hospital planning, resource allocation and development of intervention programs.

Conclusion: This unique partnership between a state health department and a state medical school has proven a successful method for expanding active AIDS surveillance efforts and has enabled New Jersey to lead the nation with the first total active AIDS surveillance system.

T.A.P.68 USE OF AUTOMATED MEDICAL DATA FOR AIDS SURVEILLANCE

Healy, Cyrus, Haskins, J.¹
¹Maryland Department of Health and Mental Hygiene, Baltimore, Maryland, USA.

- Objective:** To describe an evaluation method for AIDS surveillance using alternate data sources to identify unreported AIDS cases.
Methods: Maryland hospital discharge records from January 1, 1982 to December 31, 1987 were reviewed using an automated evaluation method for AIDS surveillance using alternate data sources to identify unreported AIDS cases.
Results: Hospital discharge records from January 1, 1982 to December 31, 1987 were reviewed using an automated evaluation method for AIDS surveillance using alternate data sources to identify unreported AIDS cases. A total of 831 admissions from 54 hospitals were then investigated. By December 1987, 623 (75%) had been reviewed. Of these 623 records, 55 (8.8%) were previously reported AIDS cases, 162 (26.0%) were AIDS cases who were not reported for HIV with an AIDS-indicative opportunistic infection, 31 (2.0%) records were not locatable, and 22 (3.5%) cases were found which were not previously reported.
Conclusions: According to this method of enhancing the surveillance system, 87% (57.4%) of all Maryland AIDS cases diagnosed between January 1, 1982 and December 31, 1987 were reported. It was found that the earlier coding methods were being used after the establishment of the ICD-9-CM code for AIDS in October 1986. In addition, it was shown that a much higher number of Maryland non-residents were using Maryland hospitals than anticipated. Finally, based upon this pilot study, this evaluation technique can be used on a periodic basis to routinely evaluate the surveillance system.

T.A.P.70 EVALUATING COMPLETENESS OF NEW YORK CITY CASE REGISTRY

Blum, S., Thomas P., Nicholas A., Miller G., Schultz S., and the others in the New York City Dept. of Health AIDS Surveillance Unit, New York City, NY, USA.

- Objective:** To categorize, as CDC AIDS cases or non-cases, persons with NYC death certificates (DCerts) giving AIDS, Pneumocystis carinii pneumonia (PCP), or Kaposi sarcoma (KS) as cause of death but not reported through routine surveillance.
Methods: All New York City DCerts 7/86-6/87 with AIDS, PCP, or KS as underlying cause of death were identified. The hospital records of those not already in the AIDS Surveillance Registry are being reviewed.
Results: Three thousand and one such records were identified of which 882 were not in the Registry. Follow-up is completed for 616; for 130 there is no hospital record and 4 were excluded. Among the other 482, 148 were missed by routine surveillance (31); 87 were reportable cases only according to the 9/87 expansion of the CDC case definition (CDC def) (11); 98 did not fulfill the CDC def only because of no serology (111); 1 had other HIV-related illness not fulfilling CDC def (19). HIV risk factors for these 482 by group (I-IV) and for cumulative NYC cases (17,754 as of 12/88) (V):
Risk Category I II III IV V
Men Sex w/MSM 15X 21X 39X 15X 51X
IVUD (IV Drug Use) 36X 46X 50X 62X 34X
MSM & IVUD 5X 6X 8X 6X 4X
Other 15X 27X 12X 18X 10X
Conclusion: Risk factor distribution differs significantly by type of HIV-related illness. DCerts are useful for evaluating routine surveillance.

T.A.P.67 EVALUATING RACIAL CLASSIFICATION AMONG NATIVE AMERICAN INDIANS WITH AIDS IN LOS ANGELES COUNTY, CALIFORNIA

Leib, Leslie; Karmali, P.; Holdeman, M.; Chane, E.; Yasa, T.; Conway, O.
Los Angeles Co. Dept. of Health Services, and AIDS Project Los Angeles, Los Angeles, Calif.
¹American Indian Prox Clinic, Long Beach, Calif., ²BHS, Calif., ³CDC, Atlanta, Georgia, USA

- Objectives:** To evaluate race classification, method of race assessment and case ascertainment of Native American Indians (NAI) with AIDS in Los Angeles County (LAC).
Methods: Nine community-based AIDS service organizations (CSAOs) in LAC were surveyed to determine the number of NAI AIDS cases in their client population and methods of race assessment. Death certificates for all male NAI age 15-54, from 1980 to 1987, were reviewed to identify cases possibly related to AIDS. The names of suspected deceased NAI AIDS cases were compared to the LAC AIDS surveillance registry. Personal identifiers were not available for active CSAO clients.
Results: The CSAOs reported that of their clients with AIDS, 61 were NAI (30 active and 33 deceased or inactive), compared to 6 AIDS cases (2 living and 4 deceased) among NAIAs reported to the LAC AIDS surveillance registry as of January 18, 1989. Twenty-five of 30 active NAI clients were re-interviewed regarding their sex; 8 (28%) clients were confirmed to be NAI and 17 were reclassified to other races. The 17 racially misclassified clients had selected *Native American* from a list of race categories included on the CSAO intake form. The names of deceased CSAO NAI clients were matched to the LAC AIDS surveillance registry; 27 of 33 (82%) were reported, of which only 1 was recorded as NAI. Of 108 deaths reported among NAI males age 15-54 between 1980 and 1987, 3 were AIDS-related and had been reported to the LAC AIDS surveillance registry; 1 was reported as NAI.
Conclusion: Race was reclassified for 68% of CSAO clients initially recorded as NAI. If the proportion of racially misclassified deceased clients is the same as that of re-interviewed active clients, then NAIs may be under-represented by as much as 50% in LAC AIDS surveillance statistics.

T.A.P.69 A RECORD LINKAGE STUDY TO DETERMINE THE DEGREE OF UNDER-REPORTING OF AIDS CASES IN CANADA

Chilavert, Ljiljana; Craib, K.**, Coles, R.**, Schechter, M.**, Johnson, J.**, Elmle, K.**, University of Toronto, Toronto, Ontario, Canada, **University of British Columbia, Vancouver, B.C., Canada, ***Federal Centre for AIDS, Ottawa, Ontario, Canada.

- Objectives:** To estimate the rate of under-reporting of AIDS to the Bureau of Epidemiology & Surveillance, Federal Centre for AIDS (FCA), Canada.
Methods: In January and October 1988, initials, birthdates and place of residence of 66 cases of AIDS known to the Toronto Sexual Contact Study (TSCS) and 64 cases known to the Vancouver Lymphadenopathy-AIDS Study (VLAS) were sent to the FCA along with comparable information on 1041 other study participants who were not known to have AIDS. A manual record linkage was conducted by the FCA linking this data to the national registry of reported cases.
Results: The rate of under-reporting ranges from 10.5% (7/64) (VLAS) to 18.2% (10/66) (TSCS). The TSCS data show that under-reporting has increased from 19% in 1984 to 40% in 1987, whereas rates have been stable in the VLAS. In the TSCS, AIDS diagnoses are established and reported by physicians not involved in the research in contrast to the VLAS where physicians involved in the research are also responsible for reporting cases.
Conclusions: If the under-reporting rates observed in this study are reasonable estimates of the national rate then 253 to 423 cases of AIDS have not been reported as of January 1, 1989. Differences in responsibilities for case reporting between centres may explain differences in observed rates of under-reporting.

T.A.P.71 LINKAGE OF RECORDS OF PERSONS IN THE NEW YORK CITY (NYC) AIDS CASE REGISTRY WITH DEATH CERTIFICATES FILED IN NYC

Blum, S.,*; Bontenborg K.**, and the others in the New York City (NYC) Dept. of Health (DOH) AIDS Surveillance Unit, NYC, USA, **NYC DOH Office of Epidemiology and Statistical Services, NYC, USA.

- Objective:** To analyze a data set which links AIDS Registry (AR) records of New York City (NYC) cases with their NYC death certificates (DCerts).
Methods: A computerized search of all NYC DCerts 1980-87 linked cases in AR to DCerts. The linking process was iterative and utilized sequentially less stringent criteria for the identification of possible matches.
Results: Among the 11,132 files with name known in AR, 7,052 (63%) were linked to DCerts. Among the 7,052, 17X had not had vital status updated prior to linking the files. Doert underlying cause Number (%) of 7052 cases
279.1-042-044 136.3, 173/ AIDS, HIV-related, PCP, KS 6274 (89.0)
485-486/Broncho/Pneumonia, organism unspecified 112.7 (1.6)
010-018/Tuberculosis 28 (0.4)
Other HIV-associated condition (cf. *MMW* 36 No.3-7) 102 (1.4)
Other ICD-9 Codes 388 (5.5)
Cases 485-4 and 304.9 are more common causes of death among AIDS cases whose DCerts are in the surveillance data set than other causes of death.
Conclusion: Linkage of AR files with DCerts is a useful tool for increasing the information available for individual cases and for updating vital status.

T.A.P.72 TRENDS IN THE OUTPATIENT DIAGNOSIS OF AIDS: IMPLICATIONS FOR EPIDEMIOLOGIC ANALYSIS AND SURVEILLANCE

Winkles, Sharon*, Lafferty, M*, Roney, J*, Burlich, M*. *Seattle-King County Public Health, Washington State Department of Social and Health Services, Seattle, Washington, USA.

Objective: We sought to monitor trends in the site (inpatient vs. outpatient) of AIDS diagnosis. This information is used to varying active AIDS surveillance programs in interpreting epidemiologic data.

Methods: The site of initial AIDS diagnosis was determined as part of routine AIDS surveillance and entered into the AIDS computerized database.

Results: An increasing proportion of AIDS cases in King County are diagnosed outside of hospitals. Prior to 1980, 52 of cases were diagnosed as outpatients (OPDs), most rising by year to 23% of cases diagnosed in 1988.

Year	# AIDS Cases	No. OPDs (%)
1982-83	155	35 (23)
1986	183	19 (10%)
1987	244	52 (21%)
1988	219	55 (25%)

Conclusions: Most local AIDS surveillance programs depend heavily on hospital-based reporting and validation studies to determine completeness generally use hospital-based methods such as discharge databases. Our data indicate that the proportion of AIDS cases with outpatient diagnosis is rapidly increasing, making hospital based surveillance systems less effective. Outpatient diagnosis may also influence the analysis of epidemiologic parameters. For example, of Washington State AIDS cases diagnosed prior to 1988, cases with outpatient diagnosis survived significantly longer than other cases (41.1 months vs. 31.8 months). Confirmation of these trends in other jurisdictions is needed. Provider and clinic-based surveillance and validation techniques should be developed in light of these findings.

T.A.P.73 HOSPITAL-BASED AIDS REPORTING IN A HIGH INCIDENCE AREA, HOUSTON, TEXAS, USA

Colin, N.J. Falletti, Robert L. & Pharo, A.F.
Bureau of Epidemiology, Houston Dept. of Health & Human Services, Houston, Texas, USA

Objective: To provide a mechanism to facilitate and evaluate the timeliness and completeness of AIDS reporting in selected hospital areas of an indigent core hospital.

Methods: The selected hospital areas were evaluated through observing and interviewing staff to assess current reporting practices. Recommendations were made based on the assessment. Recommendations included implementing a new reporting system utilizing a re-designed report form and protocol. These changes were carried out in a pilot study for two months. The pilot consisted of three stages, education, implementation, and evaluation of the program.

Results	Before Pilot May-June 1988	During Pilot Nov-Dec 1988
Number of cases	20	29
Mean log time (Dx to Report)	19	3.9 months
Completeness	0%	77%

Conclusions: It has been generally accepted that in areas of high AIDS incidence hospitals are experiencing limitations in time and staff to report AIDS cases. With the implementation of this pilot, there has been an increase in case reporting at the facility. Through assessment, education and tailored procedures, hospitals in high incidence areas can continue to meet their legal obligation to report AIDS cases to the local health authority.

T.A.P.74 EVALUATION OF AIDS CASE REPORTING IN MASSACHUSETTS

O'Neil, Kathleen*, Reine-Sacer, H*, Bakaraian, L***, Day, J***, Seage, G.* *Boston and **Massachusetts AIDS Surveillance Program (MASP), Boston, MA, USA

Objective: To assess completeness and timeliness of MA AIDS case reporting.

Methods: To validate timeliness of reporting, MASP modified inpatient control logs and case lists at 20 reporting sites with >25 cumulative cases. Three-patient cases were recorded. Death certificates (DC), tumor registry (TR) and Necroscopist (N) reports were also reviewed for unreported cases. The timeliness (reporting delay) of cases reported in 1987 and 88 was calculated as months between diagnosis and report.

Results: Completeness. Ninety-three unreported cases were found in the audit, representing 7% of all cases diagnosed at audited hospitals. No differences were found in underreporting rates by risk, sex, race, or case definition. Rates differed by site; 3 hospitals had 0% of unreported cases. Underreporting was mostly due to a lack of individuals assigned the duty to report at these sites. DC, M, and TR reviews found 59 cases, 3% of all cases diagnosed. Timeliness. Of reported cases, 70% are received within 2 months of diagnosis; 90% within 6 months. No differences in reporting delay were found by risk, sex, race, or case definition; however, differences by site were significant.

Conclusions: Regular audits of hospital infectious control logs as well as reviews of M, DC, and TR reports are needed to maximize reporting completeness. MA AIDS case reporting is 92% complete, with 90% of reported cases received within 6 months after diagnosis.

T.A.P.75 DMAC - A software for cooperative epidemiology of HIV infection

Ruel G. Lander, S. Longhini, D. Jaffar, A.J.
Centre Coopérative de Données en Épidémiologie de l'Université Moncton, MONCTON, CANADA

Objective: The French Ministry of Health has set up a national system of information on HIV infection based on 33 major hospitals (Centres d'Information de la Santé et d'Immuno-diagnostic Humain: CII) scattered all over the country. Concerning epidemiology, the aim of the system is to provide a global view of the infection as it differs among and in a core for further collaborative clinical/epidemiological studies.

Method: A software (DMAC - Dossier Minimum Annuel Commun) has been derived to facilitate the cooperative epidemiology between all collaborating centers. It runs on IBM PC compatible, with MS-DOS.

Results: The functions of the software include: derivation of an anonymous code corresponding to each patient (Sex, Ethnic, Surname, Sex, Marital, Age, Date of Birth, 1988, 82, 84-87) which grants confidentiality but allows to automatically retrieve the patients who consult in different places and correct accordingly the national database; data entry and editing of the information; at each visit of follow-up automatic comparison of the status of the patients according to CDC or ICD-9; automatic generation of the notification of AIDS in the Central Division of Health whether the patient satisfies the criteria of AIDS; coding of the file using the software of the Versant which is used to fully guarantee the security when data are exchanged between the clinical centers and the Coordinating Data Center; minimal facilities to allow each participating center to analyze locally its own data. The computerized information include: only those biological measurements and clinical data which, by nature, cannot have been found to be routinely recorded on retrospective patients. Modifications of the software can easily be performed for those clinical centers who want to derive collaborative studies for which additional information have to be collected.

The system has received the agreement of the Commission Nationale de l'Information et des Libertés. The written and informed consent of the patient must be obtained.

The software may be obtained upon request to the coordinating data center.

T.A.P.76 TEMPORAL TRENDS FOR PAST SEXUALLY TRANSMITTED DISEASES IN MEN WITH AIDS IN SAN FRANCISCO

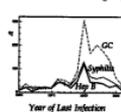

Finkel, Daniel W.*, Hollander, J.M.***Ziegler, J.M.***, Cadden, M.***Vulberding, P.A.***
Medical Services of * San Francisco General Hospital, * University of California, SF, * PA, * Miley Hospital, UCSF, San Francisco, CA, USA.

Objective: To describe the temporal trends of the last prior sexually transmitted diseases (STD) in patients with AIDS in San Francisco, in conjunction with changes of sexual practices which may also transmit HIV.

Methods: The UCSF AIDS Registry has collected detailed medical histories since 1985 from a cohort of 2605 individuals who had the dates of their last episode of syphilis, gonorrhea (GC), and hepatitis B as well as dates of HIV associated conditions and onset of AIDS.

Results: Dates of last GC (n=1497), syphilis (n=770), and Hepatitis B (n=544) which peaked in 1980 and by 1982 were approximately 50% of the 1980 rates. The hepatitis B rate fell most rapidly, even though affecting the smallest proportion of the cohort probably reflecting saturation of infection in a subgroup with the highest behaviors. The mean time from hepatitis B to AIDS onset was 8.3 years (n=240) and from syphilis 7.8 years (n=144) which corresponds to estimates of the mean incubation time of HIV in AIDS. Of 645 men with GC who developed AIDS 45 (7%) had GC within 1 year, 35 (5%) 2 years before, 82 (13%) 3 years before AIDS onset. The decreasing rate of infection may reflect safer sex education and for the development of professional syndromes.

Conclusions: The use of prior STD peaked and began declining even before there was an awareness of AIDS. However, as indicated by GC which was widely acquired within one year of onset of AIDS by 14 patients, there is a need for continued interventions to slow transmission before HIV sexual practices.

T.A.P.77 IMPACT OF THE REVISION OF THE OLD AIDS CASE DEFINITION ON CASE REPORTING

Halliday, Guy*¹, Minkley, J.*², Rogers, A.¹

Objective: To describe the impact of the September 1987 revision of the AIDS case definition on case reporting through December 31, 1988.

Methods: Following the AIDS case definition revision, the Division of AIDS Surveillance contacted all reported cases to whether they met the older case criteria or the new, broader definition. Inexpensive case audits were conducted to verify the accuracy of reporting using hospital discharge records and by re-interviewing of previously-reported cases which had met the older case definition.

Results: The percentage of cases meeting each case definition by December 31, 1988 is as follows:

Definition	Before 1985	Year of Diagnosis	1987	1988	Total
Old	125 (76%)	107 (86%)	336 (72%)	339 (72%)	799 (82%)
Revised	31 (18%)	18 (14%)	110 (23%)	127 (27%)	295 (30%)
UNA	0	0	276	646	922

The 703 revised definition cases do not include 41 cases that were reported as revised definition cases but developed conditions which reclassified them under the old definition. Of these 292, 127 (44.7%) had died by the end of 1988 without having been reported as progressing to old definition AIDS. This resulted in a 30.6% increase in reported cases (168 total cases) if permanent revised definition cases due to the revised AIDS case definition, in the 10 month period after implementation.

Conclusions: The revision has had a number of consequences. First, patients now can meet case criteria without being admitted to a hospital. To minimize resource requirements, surveillance systems should place greater emphasis on out-patient clinics and private physicians' offices. Second, revised definition cases who succumb before meeting old definition criteria suffer special attention. Third, outcomes of future cases need to reflect the revision. The increased sensitivity of the revised definition must be taken into account when planning for future resources needs of AIDS centers.

T.A.P.96 COMPARISON OF RISK FOR HIV INFECTION AMONG SELF-REFERRED AND PROVIDER-REFERRED HETEROSEXUALS IN A STUDY OF HIV TRANSMISSION
Laufer, L.; Feingold, L.; Zieler, A.; Meyer, Kenneth.
New England Behavioral Health Study, Fortuick, N.I., U.S.A.

Objective: To assess risk for a self-referred population-based cohort compared to a provider-referred group in a prospective HIV transmission study, and to assess efficiency of outreach recruitment in reaching at-risk groups.
Methods: Risk assessment interviews and serologies from the first 210 participants in a prospective study of the heterosexual spread of HIV. Outreach includes TV and radio announcements, newspaper ads, brochures, booklets, seminars, talks on college campuses and informing providers serving populations at risk.

Results: Of the first 215 seronegative, 91 were provider-referred and 124 were self-referred. 41% of the provider-referred participants are HIV+, compared with 7% of self-referred. 50% of self-referred participants were more likely to be female (52% vs 48%), young (11% in the 18-24 age group vs 3% in the older age groups), and white (41% vs 43% for all other ethnic categories). Self-referred were more likely to have had 2 or more partners in the last year, but less likely to know their partners' risk (52% vs 38% of provider-referred did not know their partners' risk). Self-referred were also more likely to have had 10 or more lifetime partners (56% vs 44%). Self-referred participants were less likely to use condoms (59% reported "regular" or "never" vs 41% of provider-referred), and were twice as likely to consider themselves at an or slight risk for HIV infection (33% vs 13%).
Conclusion: Self-referred seronegatives are less likely to perceive themselves at risk but may be, due to having multiple partners of unknown risk status, and not practicing safer sex.

T.A.P.98 HETEROSEXUAL TRANSMISSION OF HIV: A RECEPTION STUDY.
The University of California, San Diego, La Jolla, CA, U.S.A.
Community Study of HIV Infection and AIDS Risk Factors

OBJECTIVE: To determine risk factors of male-to-female HIV transmission.
METHODS: Between March 87 and October 88, 201 couples were recruited from 6 European countries. All seronegative females and their heterosexual partners (HP) are collected every 6 months. HP presenting risks for HIV infection other than sexual contacts with the IC were excluded. The cross-sectional analysis of data from the first interview is presented.
RESULTS: Of 201 females HP, 49 were HIV+. Male IC were mostly TW0 (64% or bisexual) (184). The following 3 risk factors were identified: practice of anal sex (OR=2.2 [1.9-2.6]); male index with full-blown AIDS (OR=1.1 [1.1-1.1]); history of sexually transmitted disease (STD) in the past 5 years for the IC and/or the HP (OR=3.0 [1.9-4.8]). Lymphocyte counts were available for 131 male IC. HIV male transmitters (IC=HP+) had lower CD4 (p<0.001) than non-transmitters (IC=HP-). Total lymphocyte counts tended to be lower in seropositive than the difference was not significant. P04 antigen test was performed for 100 male IC. The risk listed for a positive test was 1.8 [0.9-4.8]. Duration of relationship (median 3 years), frequency of sexual contacts, sexual practices other than anal sex, and contraceptive behaviour were not found to be associated with partner infection.
CONCLUSION: The great influence of the 3 identified risk factors on male-to-female transmission is shown by differences in HIV prevalence in partners:

Sex of IC (years)	0-5 (years)	6-10 (years)	11-15 (years)	16-20 (years)
Male IC AIDS	0	1	2	3
Male IC STD	0	1	2	3

T.A.P.100 BEHAVIOR MODIFICATION IN COUPLES ENROLLED IN A STUDY OF HETEROSEXUAL TRANSMISSION
Paterson, J.; Collins, N.; Goss, S.; Morono, A.; Alpert, J.; Waddy, C.
University of California, San Francisco, California, USA

Objective: To evaluate behavior change in couples who participated in a prospective study of heterosexual transmission.
Methods: We provided education and counseling about safe sex practices as a component of our heterosexual partner study. Participants were evaluated every six months following entry into the study. Behavior at enrollment and last follow-up is compared.
Results: 54 couples were interviewed of which 43 were discordant (index HIV+, the partner HIV-). Amount of sexual intercourse among the discordant couples at last follow-up is as follows: no intercourse = 2/43; less intercourse = 30/43; same amount of discordant couples having sex intercourse = 7/43. Condoms were used by 24/30 of the discordant couples having sex intercourse. By 1/3 of those having the same amount of intercourse, and by 6/7 of those engaging in more frequent intercourse. Anal intercourse was practiced by 8 of the discordant couples at trials, only 4 of whom used condoms. Only 2 of those couples continued the sexual practice by the time of last follow-up, both of whom used condoms.
Conclusions: Partner referral and provision of education and counseling in a heterosexual partner study continues to remain an effective vehicle for behavior modification. Failure to practice safer sex results from unwillingness, on the part of the partner, to adopt such measures of risk reduction.

Epidemiology and Public Health**

T.A.P.97 HETEROSEXUAL BEHAVIOR AND HIV STATUS IN A COHORT OF PERSONS AT INCREASED RISK FOR HIV INFECTION
Meyer, Kenneth; Zieler, A.; Laufer, L.; and Laufer, D.
New England Behavioral Health Study (NEBHS), Brockton, U.S.A.

Objective: To correlate heterosexual activity and HIV status in a cohort from a region where almost 6% of the new HIV+ are heterosexual.
Methods: Cross-sectional analysis of interviews and serologies from the first 215 seronegatives of a community-based prospective study of the heterosexual spread of HIV in U.S. New England.
Results: 22/104 (21%) of the women and 24/104 (23%) of the men were HIV+. 40/74 (53%) of the HIV+ subjects and 39% of the whole cohort are or were IVUDs 61% of the cohort is white. Other notable results include:

HIV+ men	HIV+ women	HIV- men	HIV- women
>10 lifetime partners	13	102	21
>10 partners in the past year	13	102	102
Sex with known high risk partners	67	50	44
History of STD (ever)	62	372	302
IC does not use the condom	202	502	442
IC with known high risk partners	67	50	44

Conclusion: Although 77% of the HIV+ subjects perceived themselves to be at increased risk to develop AIDS, 40% of the seronegatives were men with known high risk partners in the past year, usually steady, non-paying partners. Most of the HIV+ subjects in this cohort are IVUDs, but many who are HIV+ knowingly engage in unsafe sex. Risk reduction programs may have to target couples and do more than identify risky behaviors.

T.A.P.99 Alberto Saccaro, and the Italian Multicenter Study Group on HIV Heterosexual Transmission, Infectious Diseases Clinic, University of Milan, Milan, Italy.

Female steady partners of HIV-infected subjects, without other risk factors for infection, have been enrolled since January 1987 in a study of the role played by behavioral and biological variables in heterosexual transmission of HIV infection. Every HIV positive subjects observed at participating centers was considered an index case (IC) and asked about their heterosexual partner(s). Every partner not already known as HIV infected was invited for screening test and interview. The interview concerned sexual behaviour and contraception in the contacts with IC, previously sexually transmitted diseases (STD) and HIV hepatitis were investigated as well. HIV infection was checked by two immunoenzymatic assays and confirmed by western blot. Data about the IC were collected through medical records. Preliminary analysis on 235 female has confirmed previously reported risk factors such as history of STD and genital infections and anal sex. Other more controversial possible risk factors such as length of relationship and frequency of sex have been investigated and found, with some limitations, to be associated with HIV transmission. Conclusions have been thoroughly investigated and found to be protective. Data on recruited population by May 89 will be presented and discussed, with particular reference to controversial matter.

T.A.P.101 CHANGES IN SEXUAL AND REPRODUCTIVE BEHAVIOR IN HETEROSEXUAL COUPLES AFTER HIV TESTING
Vogler, Mary; Dupan, L. and Seidlin, M.
New York University School of Medicine, New York, NY, U.S.A.

Objective: To determine the impact of HIV testing on sexual behavior in heterosexual couples. Data from a prospective study of heterosexual transmission.
Methods: Partners (Pa) of infected individuals (I) were enrolled if Pa had never used IV drugs, had 2-10 episodes of vaginal intercourse (VI) with I, were not separated from I and were capable of additional intercourse with I.
Results: 3 couples were available with a mean duration of follow-up of 12.4 months. HIV were (22). Because of drug use, 10 were HIV+ at entry, none seroconverted during the period of observation. 54% of HIV+ and 25% of HIV- Pa had used non-IV drugs in the year prior to entry. There were no significant differences in marital status, length of relationship, education, or family income between HIV+ and HIV- Pa. All couples were primarily monogamous. All Pa who reported a change in sexual practices after testing, 4 HIV+ and 3 HIV- Pa became abstinent. The others instituted condom use for VI, but 66% of intercourse (AI) prior to I's reported incident sex. Half of the couples reported anal sex. Pa prior to testing only one couple continued to have AI after testing. Seven Pa were pregnant at the time of their first test, 4 of whom were HIV+. One HIV+ and 3 HIV- completed the pregnancy. Two seropositive occurred 4 after HIV testing, but HIV+ who claimed to be using safe sex practices.
Conclusions: HIV testing of Pa resulted in safer sexual practices, however Pa using condoms for VI do so inconsistently. Because such gaps were especially frequent among HIV+ Pa vertical transmission of HIV remains a persisting risk.

T.A.P.102 HIGH PREVALENCE OF HIV-1 ANTIBODIES IN STD PATIENTS WITH GENITAL ULCERS

Debrework Zewdie,¹ Abdurrahman, M.², Ayuhnia, S.³

¹Med. Coll. Trikebe, ²Yamanba, Bahir Dar, ³et al.

* National Research Institute of Health, Addis Ababa, Ethiopia.
** Araris Clinic, Addis Ababa, Ethiopia.
*** ALERT, Addis Ababa, Ethiopia.

Objective. To determine the prevalence of HIV-1 infection in STD patients with genital ulcers.

Methods. Patients attending an STD clinic were randomly selected. Blood specimens were obtained from patients with a past and present history of genital ulcer disease screening for HIV-1 antibody was tested using ELISA (Wellcozyme) and confirmed by Western Blot (BLORAD).

Results. Of the 226 (75 females and 151 males) tested, 63 (27%) were seropositive for HIV-1. The seroprevalence rate in those with past history of genital ulcer disease was 34.7% and 28.6% in patients with gonorrhoea.

Conclusion. The high seroprevalence rate is indicative of the role other STDs play in the transmission of HIV infections in hyperendemic STD areas. The prevention of other sexually transmitted diseases and the behavioral change along with this may be one way of curbing the AIDS epidemic in these areas.

T.A.P.104 PRELIMINARY ANALYSIS OF FACTORS ASSOCIATED WITH SEROCONVERSION IN A STUDY OF HETEROSEXUAL SEXUAL TRANSMISSION OF HIV IN MONOGAMOUS COUPLES

Nichols Margrett, Parooki P., Sampson G., Leibel J., Kennedy M.J. - Woodhull Medical and Mental Health Center, Brooklyn, NY, USA

Objective. To present a preliminary analysis of factors associated with seroconversion in a study of heterosexual sexual transmission of HIV in a cohort of monogamous couples.

Methods. The Northern Brooklyn Partner Study, begun in September 1988 with funding from the CDC, is a three year longitudinal study of monogamous heterosexual couples in which one partner has as his/her only risk factor sexual contact with the other partner. The sample is drawn from a community based primary health care facility which services a population that is 93% black or Hispanic and 86% IVDU's and their sexual partners. Data gathered are retrospective as well as prospective, and include sexual and drug use behavior, psychological measures, and medical parameters (stage of disease of index partner, p-24 antigen, HIV cultures, concurrent VD, etc). All subjects are reinterviewed and examined at 3 month intervals.

Results & Conclusions. Preliminary data presented here will be a comparison between couples where sexual transmission has already occurred (concordant couples), and couples where the exposed partner is seronegative at the time of entry into the study (discordant couples). Data will be presented on at least 10 discordant couples, with at least 10 concordant couples used as a comparison.

T.A.P.106 RISK OF HETEROSEXUAL TRANSMISSION OF HIV-1 FROM RECIPIENTS OF BLOOD AND BLOOD PRODUCTS

Transfusion Safety Study Group* represented by **Donegan,**

Elizabeth.**

*Transfusion Institutions, New York City, Miami, Detroit, Seattle, San Francisco, Los Angeles, USA, **University of California, San Francisco, California, USA.

Objective. To assess the potential for transmission of HIV-1 by persons infected by contaminated blood, to heterosexual contacts before and after learning about their status.

Methods. The Transfusion Safety Study is a longitudinal study of recipients of blood and blood products. Information concerning sexual behavior prior to and at 6-month intervals after enrollment was obtained by interview and evaluated for anti-HIV-1 (+) subjects probably infected through blood reproduct

Results. 522 anti-HIV-1 (+) subjects probably infected through blood reproduct one or more heterosexual contacts between 1979 and enrollment. This potential sexual exposure of others included prostitutes (20 subjects). After informed consent, 337 of 469 with follow-up continued to have sexual contacts. Of these, 80 (21%) reported that they were sexually active with multiple partners. Two (10%) of 21 anti-HIV-1 (+) primary sexual partners also continued having sex with additional partners.

Conclusion. Transfusion-transmitted HIV-1 infections, although responsible for a small percentage of all infections, increase the reservoir in the community and the potential for further transmission through heterosexual contact. (Sponsored by Contract No. N01-HB-7003 of the National Heart, Lung, and Blood Institute.)

Transmission hétérosexuelle (partie 2) Heterosexual Transmission (Part 2)

T.A.P.103 HIV-1 TRANSMISSION IN HETEROSEXUAL COUPLES C.Papetti, A.H. Pesce, I.Mezzarona, E.Pinter, G.O'ffizzi, G.Luzi and F.Aiuti

Dept. of Allergy and Clinical Immunology, University of Rome "La Sapienza", Rome, Italy

Objective. - To study immunological features and transmission risk in heterosexual couples with one seropositive partner.

Methods. - 43 heterosexual couples were evaluated; one partner was seropositive at the first medical check who previously belonged to a high risk behaviour category. The study included 34 seropositive at risk males and 9 females. Number of sexual intercourse, condom use, sexual behaviour, immunological features were evaluated for each couple.

Results. - At the first control 17 couples were found to have both positive partners, whereas 26 had seronegative partner not belonging to a risk category. After one year follow up 2 out of 26 seronegatives were infected (77%).

Conclusions. - Among the evaluated parameters condom use was found to be important to prevent HIV transmission: 95% of couples with both infected partners did not use condoms, whereas in 42% of couples with one seropositive partner the condom was not correctly applied. Among the immunological parameters CD4+ T lymphocytes and skin tests were found to be relevant biological conditions favouring HIV-1 transmission from a seropositive subject to a seronegative one.

T.A.P.105 THE RISKS FOR HETEROSEXUAL HIV TRANSMISSION FROM INFECTED BLOOD TRANSFUSION RECIPIENTS

Ward, John¹; Perkins, R²; Donegan, E³; Ou, C-Y⁴;

Leussink, S⁵; Geynor, S⁶; et al

¹CDC, Atlanta, GA; ²Trinity Blood Bank & ³Univ. Ca. Med. Ctr., San Francisco, CA; ⁴Health Dept. & ⁵Brooklyn Center, New York, N.Y., USA.

Objective. To identify risk factors for heterosexual HIV transmission.

Methods. HIV-infected transfusion recipients and their partners were asked about sexual practices, medical history, and examined and tested for signs of infection; polymerase chain reaction (PCR) with SE 38-39 primer pairs was used to identify HIV genetic material in peripheral mononuclear cells.

Results. Through 1988, 74 HIV-seropositive recipients were identified and 39 had partners; 5 (19%) of 30 female partners and none of 9 male partners were HIV-seropositive. When tested by PCR, specimens from 29 seropositive partners were PCR-negative; 20 of 24 specimens from seropositive recipients and 3 of 3 from seropositive partners were PCR positive. The 39 recipients with partners had been infected for a median of 60 months (range 11-108 mos.); 14 (36%) had AIDS. Partners of recipients with AIDS were not more likely to be infected compared to other partners (2/14 vs. 2/25). Although compared to uninfected female partners, infected wives tended to be older (38 yrs. vs 30 yrs.), to have fewer sexual contacts (median 84 vs. 186, p=.17), and to more likely bleed after intercourse (1/4 vs. 3/25, p=.46), these differences were not statistically significant.

Conclusion. HIV-seropositive partners had no evidence of occult infection. A recipient having AIDS was not associated with HIV heterosexual transmission. Older age and bleeding after intercourse suggest that age-associated changes in the vaginal mucosa may facilitate HIV transmission.

T.A.P.107 NO MORE SEROCONVERSIONS AMONG GROUPS OF PATIENTS OF THE BONY DEMOPHILIC COHORT STUDY

Kanok, Berndt, S.; Niese, D.; Brackmann, H.H.;**

Euler, P.*; van Loon, B.**; Kramert, J.***

*Universitätsklinik Bonn, FRG, **Institut für experimentelle Hämatologie, Bonn, FRG, ***Massachusetts Institute of Technology, Cambridge, MA, U.S.A.

Objective. To evaluate the risk of heterosexual HIV-transmission. **Methods.** In 1981, 150 HIV-negative female partners of HIV-positive hemophiliacs were informed about possible transmission risks and enrolled in a prospective study. Both Elisa and Western Blot were performed at intervals of 6 to 12 months.

Results. 7 couples stopped having sexual contact. Regular condom use was reported by all but 6 of the remaining couples. On one occasion, one woman had a borderline Western Blot result which was not reproducible. All other women always tested negative.

Conclusion. Barrier contraceptives used in monogamous relationships seem to be efficient in preventing heterosexual HIV-transmission.

T.A.P.108 REAL VALUE OF SERONEGATIVITY IN LONG-TERM EXPOSED SEXUAL PARTNERS OF HIV-1 INFECTED HEMOPHILIACS
Picchio, G., Bazzani, M., Balon, A., Mochini, J., Pichini, G., Pérez Bianco, A.
IDR696, Academia Nacional de Medicina, Buenos Aires, Argentina.

Objective: To investigate, using a sensitive virus culture method, whether seronegativity in female (spouses of HIV Ab pos. hemophiliacs) (Hem) was due to undetectable Ab levels or was really reflecting absence of infection.
Methods: Virus culture was performed on PBMCs from Group (G) 2: hem with AIDS; G2/VL hem; 2 female-sexual partners and 1 nonhem/asymptomatic HIV-pos individual; G2:2 hem with PGL. Four sexual partners were defined as asymptomatic HIV Ab-neg individuals who had maintained a seronegative sexual relationship with an HIV Ab-neg hem for a minimum of 2 years without the use of barrier contraceptives. Virus culture was also performed on 2 low-risk HIV Ab-neg individuals. HIV Antigen (Ag) (Eitest) presence was tested in all samples.
Results: From GA, both individuals resulted culture-pos (100%), only 1 Ag pos. From GB, 4 out of 5 resulted culture-pos (80%). From GC, both individuals resulted culture-pos (100%), only 1 being Ag pos. The 4 sexual partners as well as the 2 low risk controls resulted both culture- and Ag neg.
Conclusion: Absence (Ag neg) can be confirmed in the 4 sexual partners which resulted virus culture-neg. Ag neg. The Ag capture assay proved to be less sensitive than virus culture (2 out of 5 pos cultures) (25%).

T.A.P.110 HETEROSEXUAL TRANSMISSION OF HIV-INFECTION FROM

HEMOPHILIACS TO THEIR SPOUSES
Balif, Nigge*, T.G.A. Karand*, B.S. Kampa*, K.E. Schenkel*, P. Euler*, J.L. Hirsch*, J. Hirsch*, J. Hirsch*,
* Department of Internal Medicine *** Institute for Clinical Microbiology *** Institute for Experimental Hematology, Hemophilia Center, University of Pennsylvania, Philadelphia, PA
Objective: To determine rate and cofactors for heterosexual transmission of HIV-infection in hemophiliacs.
Methods: 176 female and one male partner of HIV-seropositive hemophiliacs were examined serologically. 13 infected as well as 19 uninfected partners have been examined clinically and immunologically. Regarding the index cases, 12 transmitters and 119 non-transmitters have been examined.
Results: 18 female and one male partner (12%) were anti-HIV-positive in ELISA and Western blot analysis until september 1st 1988. 86 have been retested in until January 1st 1989, no additional seroconversions have been observed. All infected partners have stage CDC II-III disease. In 17/29 seronegative partners CD4+ counts were >700/p. Regarding the index cases, CD4+ counts are significant lower in transmitters than nontransmitters. Virus isolation was successful in 6/11 transmitters and 11/86 nontransmitters. In 308 hemophiliacs, who have been examined at least twice, the CD4+ count is declining by 110/159 p/year.
Conclusions: Low CD4+ counts, successful virus isolation, and p24 antigenemia are important risk factors for heterosexual transmission of HIV in hemophiliacs. Additional factors will be discussed.

T.A.P.112 RISK FACTORS FOR HIV-1 INFECTION IN STD CLINIC PARTNERS:

STUDY ON HETEROSEXUAL TRANSMISSION
Chabany, R., Katz, A., Stoenberg, H., Telzak, R.,
Hirschfeld, D., Haber, P., Jaffe, H.,
** Memorial Sloan-Kettering Cancer Center, NY, *** CDC, Atlanta, GA.

Objective: To evaluate heterosexual transmission of HIV-1 in STD clinic patients in an area of New York City where the cumulative incidence of adult AIDS is 44.5/1000/yr. The study was conducted in a community. **Methods:** Volunteers enrolled in an ongoing study beginning 1/88. HIV-1 antibody was measured and data on demographics and sexual and drug use behavior were collected by an interviewer using a structured questionnaire. **HIV-1 INFECTION BY RISK AND SEXUAL BEHAVIOR**

RISK	NOV	DEC	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	TOTAL
Gay/Bisexual	37	37	39	39	39	39	39	39	39	39	39	39	39	39	39
IV drug user (IVDU)	36	44	42	37	37	37	37	37	37	37	37	37	37	37	37
Sex Partner Person at Risk (SP)	17	14	13	12	11	11	11	11	11	11	11	11	11	11	11
Not Identified Risk (NIR)	12	11	11	11	11	11	11	11	11	11	11	11	11	11	11
TOTAL	102	115	122	120	119	119	119	119	119	119	119	119	119	119	119

NIR HIV-1 was more likely (91%) to report previous contact than HIV-2 (74/88), 0.8-2.1, p=0.07. 1/12 sex crack user and 3/12 had sexual contact with known crack users. NIR HIV-1 women were more likely to be crack using prostitutes (4/8) than were HIV-2 women (3/14), 0.3-0.95, p=0.01.

Conclusions: Although most HIV-1 infections in this population occurred in gay/bisexual men, IVU, or their heterosexual partners, sexual behavior associated with crack use continued to be transmitted among persons who deny other AIDS risk factors (NIR).

T.A.P.109 RESULTS OF HIV ANTIBODY TESTING IN SEXUAL PARTNERS OF

HEMOPHILIACS OVER A 7 YEAR PERIOD
Forsberg, A.M., Sullivan, J.L., Wittits, D.L.,
New England Hemophilia Center, Worcester Memorial Hospital and **Mathew of Massachusetts Medical Center, Worcester Medical Center, Worcester, MA

Objective: To determine the rate of seroconversion among sexual partners of hemophiliacs tested between September 1981 and January, 1989.
Methods: 73 sexual partners of 73 HIV antibody positive hemophiliacs were tested over a five yr. period. 45 of the hemophiliacs were requested to inform their partners about confidential HIV antibody testing done at the New partners), 5 partners refused testing. Partners were told due to death of the hemophiliac or divorce, 43 agreed to be tested at 30 and 43 retested or their test results performed at an alternate test site. Of the 25 tested, 31 were tested at least twice (range 1 to 8 tests) and 86 had their individual or most recent test done since July, 1987. Medical records were examined to determine clinical status, presence of antibodies and CD4 cell level of the hemophiliac partner.

Results: 31 out of the 32 tested (96%) were HIV seropositive. This group included the sexual partners of 9 hemophiliacs with AIDS, 4 with p24 antigen positivity and 8 with CD4 cell levels <200 cells/uL. One spouse was seropositive at time of first testing in 1982. At the time of her positive test, her hemophiliac husband had no clinical AIDS or antigenemia and a CD4 cell level of 396 cells/uL.

Conclusion: In this group of sexual partners it appears the rates of transmission in low risk partners are not expected to increase as hemophiliacs deteriorate clinically and immunologically. This rate may be lower than in other clinics in the U.S. The reasons for this are not clear. Extensive counseling regarding safer sex practices begun in 1983 may be a factor in this lack of seroconversion among sexual partners.

T.A.P.111 TRANSMISSION HETEROSEXUELLE DE L'INFECTION HIV CHEZ LES PARTENAIRES DE DES

CONJUGES VIH-SEROPositifs (CIV)
Grattis, Isabelle, Drué A.M., Nelli M.L., Gagnep, L., Ferrasi G., Schmitt I.,
Hôpital Nigardo - G. Grand-Hôtel, Bureau d'Hygiène de la ville de Milan, Italie.

Objectif: Evaluer le risque de transmission hétérosexuelle de l'infection VIH et l'efficacité des mesures de prévention chez les partenaires hétérosexuels de toxicomanes VIH.

Méthodes: Entre décembre 1985 et décembre 1988 on a observé la sérologie VIH chez les partenaires hétérosexuels habituels (relation de couple supérieure à 6 mois), sans facteurs de risque connus sauf la contamination isolée de 103 toxicomanes VIH. Le test a été effectué par sérologie ELISA en deux étapes. Resultats: On a observé 13 sérologies VIH-positives chez les partenaires hétérosexuels habituels de 103 toxicomanes VIH. Les tests ont été effectués pendant une période d'un an et demi de 13 à 26 mois. A tous les couples on a conseillé l'usage du préservatif.

Conclusion: Dans 13 cas le partenaire hétérosexuel VIH-positif ou non (28 partenaires, 145, 2,8%). Dans 12 cas une femme (11 partenaires, 148%). Au premier test aucun partenaire sexuel n'était infecté, tandis que 13 femmes, partenaires de toxicomanes VIH, étaient sérologiques. Dans 13 partenaires VIH-positifs sans autres à la sérologie hétérosexuelle de la sérologie VIH. Il n'y avait aucune corrélation significative entre le statut de sérologie VIH-positif et le statut de sérologie VIH-positif. On a observé, en outre, que dans ce dernier groupe on a observé 2 séroconversions (33,3%) au cours de 12 mois.

Conclusion: Les toxicomanes VIH peuvent représenter une source importante de contamination par VIH hétérosexuelle, indépendamment du statut clinique de l'infection VIH, surtout à cause des résistances à l'utilisation du préservatif.

T.A.P.113 TRANSMISSION OF HIV INFECTION IN HETEROSEXUAL

PARTNERS OF HIV POSITIVE MEN
Petrone, Lucinda, Forbe, L., De Stefano, G.,
Hirschfeld, P., Albertson, F., Hirschfeld, P.,
Dept. of Infectious Diseases, Lattin General Hospital, Lattin, Italy

Objective: To evaluate the prevalence and incidence of HIV infection in heterosexual partners of HIV-1 v. drug addicts (d.a.) with no other known risk factors.

Methods: The sexual partner of each HIV d.a. attending our out patient clinic was tested every six months by a commercial ELISA kit (Abbott) positive results were confirmed by Western Blot (Eitest). Advice on effective means of prevention of sexual transmission of HIV was given to each couple.

Results: Thirteen of 60 monogamous partners, 52 F and 8 M, of an equal number of HIV d.a. 18/8 partners of AIDS cases, 14/4 of IAD/ARC and 4/0 of asymptomatic subjects were found positive when first tested. The seronegative partners were followed for a median of 12 months but none seroconverted. Of the 47 couples with a negative woman, 19 couples used condoms while 12 used no preventive measure during the follow up period no evidence of 12 pregnancies.

Conclusion: Our data confirm the importance of heterosexual transmission of HIV infection; the absence of seroconversion observed can be explained by the short period of follow up. However the tests used are not able to evidence the early stages of infection.

Section d'affichage Poster Session

Prévalence du VIH chez les femmes et les enfants HIV Prevalence in Women and Children

W.A.P.1 SEROPREVALENCE OF HIV ANTIBODIES IN NEONATES AND CHILDREN

Higler, V., Wilber, R., Masoff, F.,*; Patel, J.,*; Fenn, D.,*; Hines, S.,*; Hines, S.,* et al.
*Department of Health and Rehabilitation Services, Tallahassee and Miami, Florida, USA. **CDC, Atlanta, USA.

Objective: To assess the magnitude and steps of HIV infection in neonates and young children from low socio-economic populations in Miami, Florida.

Methods: Between 7/20/88 and 1/11/89, 2941 children in two age groups (0-6 weeks and 15-36 months) attending Public Health well-baby clinics for routine examination, were also blindly screened for HIV antibodies by EIA and confirmed by Western Blot.

Results: Demographic characteristics of the mothers and HIV test results of their neonates/children are as follows:

Variable	Mothers (11-23 weeks)	Children (15-36 months)
Mothers age	15-19 (25.3%)	15-20 (27.6%)
Mothers race	Hispanic 474 (41.8%)	Hispanic 448 (31.8%)
All HIV +	12 (1.07%) (20.7%)	4 (2.26%) (3.3%)
104 CI	(0.4-1.24)	
318/364 HIV +	12 (3.5%) (3.4%)	3/605 (0.5%)
904 CI	(1.18-2.74)	

Conclusion: These results suggest that between 100 and 270 of the approximately 10,000, mostly black and hispanic neonates born in Miami during 1989 will be exposed to HIV. The rate for 15-24 month old black and hispanic children (0.94/1.04) is similar to other studies that suggest approximately 30% of these children born to HIV seropositive mothers will be infected.

W.A.P.3 EPIDEMIOLOGY OF HIV INFECTION IN WOMEN FROM

FRANKFURT AM MAIN
EISENBERG, H., Schick, E., Rehmet, S., Odewald, J., Miller, S.,
Reim, E.R., Tillig, W.,
Universitätsklinik Frankfurt am Main, Medizinische, Infektiologie, Thiersch-Kal 7, 6000 Frankfurt/Main, Federal Republic of Germany

Objective: To investigate the spread of AIDS in women from Frankfurt area. Methods, Epidemiological and clinical examination of 917 HIV-positive women of HIV outpatient clinic, Frankfurt.

Results: The no. of HIV-infected women increased from 2 (1984) to 21 (1988), 103 (1989), 102 (1987) to 91 (1988). In the years mentioned, the female proportion of all HIV-infected patients was 43, 15%, 26%, 27%, and 25%. 74% were drug addicts, 21% got infected through heterosexual contacts, 2% through blood or coagulation factors, resp., 2% had no known risk. The proportion of heterosexually infected patients increased from 14% in 1986 to 29% in 1988. At the same time, proportion of drug addicts decreased from 100% to 49%. 34% of drug addicts and 9% of heterosexually infected women were prostitutes. 10 of 63 heterosexually infected women are Africans; in 12% male index persons were drug addicts, in 18%, prostitutes, in 10%, hemophiliacs, and in 8%, Africans. For the rest, risk of male index partners was not known. 77% women were asymptomatic, 4% had AIDS. Most common opportunistic infection was PCP (56%). Remarkable was the occurrence of Kaposi's sarcoma in 2 cases.

Conclusion: The no. of HIV-positive women in the Frankfurt area has increased significantly since 1985. The increase in heterosexually infected women is most remarkable.

W.A.P.5 SERODIAGNOSIS OF HIV ANTIBODY SEROPOSITIVITY IN

THE SOUTH BRONX
Mand, L.J., Chocola, R.T., Vintia, Andrew, Kim, M.K., Noble, L.K., Yoon, J.J., Albert Einstein College of Medicine, Bronx, New York, USA.

Objective: HIV antibody seropositivity (HIV+) was studied anonymously in a group of healthy (with and without) 133 neonates (w/o) in the South Bronx, N.Y., a socioeconomically disadvantaged area, to obtain incidence data and identify risk factors in this high risk population.

Methods: Histories and physical exams were performed on all newborns, matched with cord blood samples, and anonymously coded before screening for HIV antibody using an EIA test with Western blot confirmation.

Results: The incidence of HIV in healthy newborns without a history of maternal drug abuse was 6.0%. The incidence of HIV in newborns admitted to the neonatal intensive care unit (NICU) was 25.5%. There were significant differences between the HIV+ and HIV- NICU groups for incidence of smallpox for gestational age (53% vs 2.4%, p<.001) and microcephaly (25% vs 3.0%, p<.005). Maternal drug abuse as defined by a positive history and/or urine toxicology was found in 66% of HIV+ and 27% of HIV- infants, p<.001.

Conclusion: There is an alarmingly high incidence of HIV+ in our screened population. Growth failure and microcephaly appear to be related to HIV. Neither through effective control of the fetus or associated factors such as maternal drug abuse. The fact that 34% of our HIV+ NICU population and none of our well baby population had a maternal drug history implies an increasing percentage of perinatal AIDS may be transmitted by heterosexual contact rather than by maternal drug usage. This study highlights the need for universal HIV screening in high risk areas to ensure the best health care for these infants.

Épidémiologie et santé publique Epidemiology and Public Health

W.A.P.2 RISKY HIV ANTIBODY SCREENING IN LOS ANGELES COUNTY FEDERAL CLINICS:

A PROSPECTIVE STUDY
COHEN, RENEZ, Bawole, L.J., Gillis, M.,* Hines, S.,* Hines, S.,* Hines, S.,*
*Los Angeles County Department of Health Services, Los Angeles, California, USA.

Objective: 1. To offer HIV antibody (Ab) screening to all pregnant women as a means of primary prevention and/or early detection of perinatal AIDS. 2. To evaluate a model program of HIV testing for pregnant women using universal screening and initially sensitive absorbent serological.

Methods: Five Los Angeles County (LAC) Health Centers are participating in a pilot program to offer optional HIV antibody testing as part of routine prenatal care, starting in January 1989. A bilateral (EIA/Western blot), multi-center consent form was developed, incorporating 7 routine prenatal laboratory tests along with HIV. Patients provided pre-test counseling and informed consent to HIV testing in the face of an 8-ounce bilateral urine type assay in group specimen sessions during their first prenatal visit. HIV testing is done in 100% of the women at the laboratory using EIA, with immunofluorescent antibody and Western blot as confirmation of repeat EIA positive results. HIV positive patients are notified individually and then interviewed to assess potential high risk behavior. Positive women are referred to a tertiary care center for continued prenatal care.

Results: 1. Preliminary results show that 265 pregnant women (w/35%), consented to HIV testing, giving an acceptance rate of 85%. 2. Of 170 HIV antibody tests performed to date, one woman is positive. The patient is 28 weeks old, single, black, 16 years old, and has no other high risk behavior for both herself and her partner.

Conclusion: 1. The acceptance rate for HIV Ab testing in LAC prenatal clinics is high, reflecting general acceptance of the fastest of presentation of the HIV test. 2. In contrast, universal prenatal screening for HIV Ab, as HIV positive women frequently do not acknowledge high risk behavior, and may not be detected in pregnant women suspecting only high risk individuals.

W.A.P.4 EPIDEMIOLOGY AND OUTCOME OF HIV SEROPOSITIVE CHILDREN IN

MARINE COUNTY, CALIFORNIA
* M.D. Gerardo Gutierrez, ** R. Bueno, *** J. Herrera, *** M. Mora, **** F. Omedea, ***** J. Ruiz de Alcazar, *** R. G. Garcia Hernandez, ** Regina Health Services, *** H. Cruz Garcia, **** H. Clinico S. Carpio, ***** H. La Par, ***** H. 12 de Octubre, MARINE COUNTY, CALIFORNIA

Since 1988 the Marine Regional Health Service has required, every 6 months, a report of all cases of HIV seropositive (HIV+) children of Marine Hospital. Up to the present date the reports at Feb. 1988 and at Jun 1988, have been studied.

In Feb. 1988, 205 HIV seropositive children were reported (EIA and Western Blot). Aged between 0 and 18 years, the 103 were males. Risk factors for HIV transmission were: 808 HIV+ parents; 134 hemophiliacs; 1.54 blood transfusion. Children were clinically classified (CDC 1987) into P-1 (80.14); P-1-32 and P-2-30.

In Jun. 1988, 202 children were reported, classified into P-2 (135); P-1-30 and P-1-47. In that period 1988-1991, 69 new HIV seropositive children were found. Fifty three children became seronegative, 43 before 15 months old and the remaining after that age. Fourteen were lost during the follow up. There were 5 deaths, 3 out of 5 without direct relation to AIDS. All children with hemophilia were included into P-2 status. Twenty one out for 202 children lived in public institutions. The last reports (Dic. 88) are presently analyzed.

W.A.P.6 HIV RISK FACTOR PREVALENCE AMONG YOUNG WOMEN OF CHILD-

BEARING AGE ATTENDING WOMEN'S ADVISORY CARE CLINIC
Harris, R.T.,* Wong, Robert E.,* et al.
*Epidemiology Unit, Seattle-King County Department of Health, Seattle, WA 98144.

Objective: To estimate the HIV risk factor prevalence among women of childbearing age.

Methods: In December 1988, we asked clients of 3 Seattle-area women's clinics to complete anonymous questionnaires regarding their age, race, sexual activity, condom use, IV drug and needle use and transfusion history.

Results: 1,317 women, aged 18-44 years, young (50%), median=22) mostly white (51.7%), unmarried (17.0%), and of low family income (range=\$0-\$39,000, median=\$11,000). Reasons for the clinic visit included: "Birth control" (64.8%), "Prenatal care" (6.3%), "AIDS test" (2.9%) and "Other" (20.8%). Of these 384 women, 143 (37.8%) reported sex with multiple partners (number of partners, range=2-10, median=3), and 172 (44.8%) with casual partners in the past year.

Women, 143 (37.8%) reported sex with multiple partners (number of partners, range=2-10, median=3), and 172 (44.8%) had at least one STD, 40 (10%) had an intravenous drug using (IVDU) or bisexual male sex partner. 20 (5%) disclosed IV drug use, 17 (4.3%) shared needles, and 21 (5.0%) had sex for drugs or money. By contrast, for the past 12 months, merely 8 (2.1%) disclosed IV drug use and 11 (2.8%) shared needles. 11 (2.8%) were concerned that her partner was HIV positive. We will present these and early 1989 data to profile women who are practicing behaviors which place them at risk for HIV infection.

Conclusions: Clients of Seattle women's clinics have taken significant risks with regard to HIV acquisition: unprotected sex with multiple/casual partners.

W.A.P.7 HERPES SIMPLEX, SYPHILIS, AND HEP B: ASSOCIATION

WITH HIV-1 AND HIV-1 IN PREGNANT HAITIAN WOMEN
 HOLLAND, RUTH M.*; HALESS, M.*; BUI, F. A.**;
 Adrien, M.*; QUIN, T.C.**; BAHUIS, A.M.*; EL-BI***.
 *Centers for Disease Control, Atlanta, GA; **Johns Hopkins University, Baltimore, MD, USA; ***Emory
 University, Atlanta GA, USA; ****Centers for Disease Control,
 Atlanta, GA and National Cancer Institute, Bethesda, MD, USA

Objective. To determine associations of HIV-1 and HIV-1 infections with herpes simplex types 1 and 2, syphilis, and hepatitis B in pregnant women residing in a periurban slum, **Methods.** Pregnant women were screened for HIV-1 and HIV-1 and a weighted sample was selected for further antibody testing. **Results.** Percent positive

	HIV-1 POS. (n=251)	HIV-1 POS. (n=41)	NEG. (n=25)
Syphilis	14.38	0.0	0.0
HSV-1	55.18	97.74	97.78
HSV-2	88.44*	81.84**	53.44

*p<0.02, **p = 0.0005, vs. seronegative women
 Based upon the 9.1% seroprevalence rate for HIV-1,
 approximately 10% of pregnant women in this population were
 HIV-2 seropositive, similar to inner city populations in other
 countries.

Conclusions. Both HIV-1 and HIV-1 infections were associated
 with HIV-2 seropositivity suggesting sexual transmission of
 these viruses in this population.

W.A.P.9 THE SEROPREVALENCE OF HIV INFECTION IN NEW YORK CITY

CHILDREN.
 WALKER, JESSIE B.*; THOMAS, P. J.*; O'NEIL, M.*; BUCK, S.*;
 STEVENS, R.**; BERNA, D.**; HANCOCK, M.*** at al.
 *New York City Department of Health, New York, NY; **Centers for
 Disease Control, Atlanta, GA; ***New York State Department of
 Health, New York, NY, USA.

OBJECTIVE. To determine the seroprevalence of HIV infection in selected
 NYC pediatric populations.

METHODS. Two populations of children were surveyed: children aged 1 to 10
 screened in their households by neighborhood home testing for lead
 poisoning and 1 to 3 year old children attending pediatric clinics run by
 the New York City Department of Health. All specimens were collected on
 filter paper and tested for HIV by ELISA and Western Blot. Both surveys
 were blinded.

RESULTS. To date, 976 specimens from the lead screening survey have been
 collected. Serums are available on 910. Of these, two children were
 positive by ELISA and Western Blot (0.2%, 95% CI, 0.01% - 0.35%) and 2
 others ELISA positive and Western Blot inconclusive. In the pediatric
 clinic survey, 20 of the 35 clinics are being surveyed and approximately
 2,000 children tested.

CONCLUSIONS. Based on newborn screening surveys in New York City showing
 an infection rate among pregnant women of about 1.5%, a seroprevalence of
 HIV in these children is less than is expected. Furthermore, these
 surveys demonstrate further uses of the filter paper technology for HIV
 testing.

W.A.P.11 NO CHANGE IN HIV-1 SEROPREVALENCE AMONG PARTURIENTS AND

NEWBORN HAVING INCREASED ANTIBODIES IN NEW YORK CITY, 1987-1988

ARANDA, MARY ANN S.*; THOMAS, P. J.*; HANCOCK, L. J.*; WEINFUS, J.*; SCHULTZ S.*
 *New York City Department of Health, New York, New York, United States

OBJECTIVE. To determine the change in HIV-1 seroprevalence in a population
 based sample of women giving birth and having induced abortions in New York
 City in 1987 and 1988.

METHODS. A repeat serosurvey of a representative sample of 3,556 women
 giving birth or having induced abortions in 20 obstetric and 15 abortion
 facilities in NYC from July to December 1987 and July to December 1988 was
 conducted. Currently, 1988 data are available for 1,537 women from 23
 facilities and are compared to 1987 data from the same facilities.

RESULTS. HIV-1 antibody seroprevalence did not change significantly
 (1.41% (95% CI: 1.02%-2.02%) vs. 1.53% (95% CI: 1.09%-2.13%), p=0.90)
 between 1987 and 1988, nor by pregnancy outcome, racial, age, nor payment
 status categories. Similar to 1987, multiple logistic regression identified
 receiving Medicaid and being between 25-29 years of age as significantly
 associated with HIV-1 seropositivity.

	1987 HIV-1 Total (%)	1987 HIV-1 Total (%)	P-value
Total	36/2525 (1.38)	34/2223 (1.53)	0.90
Abortions	21/2327 (0.87)	19/1237 (1.54)	0.87
Medicaid Recipients	15/1100 (1.36)	15/1100 (1.36)	0.85
25-29 years	17/1200 (1.42)	26/1714 (1.52)	0.36
25-29 years	17/1200 (1.42)	12/640 (1.87)	0.88

CONCLUSIONS. HIV-1 seroprevalence among pregnant women remained stable
 during a one year period in the city with the highest reported incidence of
 adult female and pediatric AIDS.

W.A.P.8 HIV INFECTION IN PREGNANT WOMEN AT A PUBLIC HOSPITAL IN

NEW ORLEANS, LOUISIANA
 ROBINETTE, LINDSEY DEAN, M.*; TRAHAN, B. J.*; WILCOX, D. J.*
 Louisiana Department of Health and Hospitals, New Orleans, LA, USA.

Objective. To determine the rate of HIV infection among prenatal clients
 in a public hospital in New Orleans from May 1988 to December 1988.

Methods. Routine HIV counseling was given to all prenatal clients.
 Clients consenting for testing (CPT) were administered a risk assessment
 questionnaire and were categorized as low risk (LR) or high risk (HR) for
 acquiring the HIV infection. Basic demographic data was collected from each
 CPT. HIV antibody tests were performed using ELISA and Western Blot methods.
 Results: A total of 3,903 HR were counseled, 3,846 (98.5%) clients agreed to
 be tested, 62 (1.6%) declined testing. Of clients tested, 1,981 (78%) were
 black females, 508 (18%) whites and 111 (3%) hispanics. Five hundred
 twenty-four clients (13.2%) were also categorized as low risk and 322 (16.4%)
 as low risk. Prevalence of HIV infection in prenatal clients was found to be
 0.50/848 (0.06%) of the twenty positive, 16 (80%) were black females and 4
 (20%) were whites. Among the high risk clients, 7 (1.3%) were seropositive
 for HIV. There were thirteen (1.8%) low risk clients testing HIV positive.

Conclusions. These data show that high risk prenatal clients appear to be at
 a greater risk for testing HIV positive. This study also shows a lower HIV
 seropositivity rate compared to earlier studies in inner city hospitals.
 Although the risk assessment questionnaire was used as a method for identifying
 high and low risk clients, it should not replace the availability of HIV
 counseling and testing for all pregnant women. Routine HIV counseling and testing
 should be an important component of total obstetrical screening during pregnancy.

W.A.P.10 HIV INFECTION IN LESBIANS.

REID, JUDITH; MORTON, C.; KELLY, J.; RAYAS, C.; RODGERS, P.;
 WILCOX, J. J. Louisiana Health/Communicable Health Project, NY,
 NY, USA.

HIV infection and AIDS is a leading cause of morbidity and death in
 women aged 25-34 years in New York City. In a study we have considered
 only heterosexual and pregnant women in transmission and seroprevalence data.
 Lesbian women have not been studied for transmission risk and seroprevalence
 despite national, U.S. AIDS surveillance data indicating 10% cases
 of AIDS in lesbians.

At a community-based, primary care AIDS assessment clinic and in a support
 group for women with HIV infection, AEC and AIDS, there are 31 cases
 of HIV-1 seropositivity in lesbians. Data on risk factors for HIV
 infection are as follows: UIVM-1; prior sexual contact with infected
 man (by consent), by force or by sperm donation; and seroprevalence
 to female transmission-2 and contaminated transfusion recipient-1.

It is clear that there are lesbians with HIV infection and AIDS, and
 it is important to include them in transmission studies and seroprevalence
 studies. The false notion that women who define themselves as lesbians
 are not at risk for HIV infection can lead to tragic misdiagnosis by
 practitioners and lack of risk awareness by the women themselves.

Incidence du SIDA AIDS Incidence

W.A.P.12 THE EVOLVING EPIDEMIOLOGY OF AIDS IN NEW YORK CITY: TRENDS

IN AIDS CASE SURVEILLANCE DATA. GREENBERG, ALAN M.*; **;
 THOMAS, P. J.*; KLININ, DEB.*; HANCOCK, M.***; REID, J.***; HANCOCK,
 S.M.* NYC Dept of Health AIDS Surveillance Unit, **AIDS Program/CDC, Atlanta

Objective. To monitor trends in the epidemiology of AIDS in New York City.

Methods. In NYC, AIDS cases are counted through active surveillance
 conducted by the Dept of Health in collaboration with 77 hospitals. A
 transmission category is assigned for each case and trends are monitored.
 Beginning 4/6 of 12/88, NYC had reported total of 12,052 AIDS cases, or 23%
 of the USA total. Trends in specific categories were assessed.

Transmission Category	1988	1987	1986	1985	1984	1983	1982	1981	1980
Total	9	43	87	131	224	317	362	394	394
INTRV(1)	2	25	48	68	129	170	170	161	161
INTRV(2)	0	2	22	41	68	103	129	165	165
NONSEX/PROXY	0	4	6	15	12	14	10	10	10
SEX/PROXY(3)	0	0	0	2	5	9	12	12	12
Child(1)	0	1	0	4	4	7	8	8	8

* Through 8/18 (13) Men who have sex with Men (3) Intrauterine device users
 (3) 95% of heterosexual cases represent male to female transmission
 Simulations: NYC conditions do not serve as an epitome of the AIDS epidemic in
 the USA; as of 12/88, the number of cases reported to CDC from NYC (16,022)
 exceeded the combined total from San Francisco (6,602), Los Angeles
 (6,002), Houston (2,578), and Newark (1,460). The number of cases diagnosed
 monthly among total cases, INTRV, and heterosexuals has increased, whereas
 the number of cases among NONSEX appears to have stabilized.

Epidémiologie et santé publique Epidemiology and Public Health

W.A.P.13 THE EPIDEMIOLOGY OF AIDS IN SAN FRANCISCO'S ELDERLY POPULATION

Payne, Susan F.; Wilson, C.; Rutherford, GW. San Francisco Department of Public Health, San Francisco, CA, U.S.A.

Objective. To describe the epidemiology of AIDS among San Francisco (SF) residents aged 60 and older.

Methods. We analyzed the demographics and transmission categories of 5,834 AIDS patients reported to the SF Department of Public Health between July 1981 and December 31, 1988.

Results. 125 (2.1%) of patients were > 60 years, corresponding to an incidence of 90/100,000. Of these 125 patients, 107 (86%) were 60-69 years, 16 (13%) were 70-79 years, and < 3% were > 80 years. Among patients 60-69 years, 75% were homosexual/bisexual males, 17% were transfusion recipients, and 7% were in other risk groups. Among patients > 70 years, 31% were homosexual/bisexual males and 69% were transfusion recipients (p<.001). AIDS patients > 60 years were more likely than younger patients to be female (7% vs 1%, p<.001); transfusion recipients (24% vs 4%, p<.001); to have a primary diagnosis other than KS (62% vs 67%, p<.001); and to live outside SF (18% vs 10%, p<.01). Older AIDS patients did not differ from younger patients by race/ethnic group. Among homosexual/bisexual patients, patients > 60 years were less likely to be intravenous drug users than younger patients (5% vs 12%, p<.05).

Conclusion. SF AIDS patients > 60 years were more likely to be female, transfusion recipients and have a primary diagnosis other than KS. AIDS patients 60-69 years were primarily homosexual/bisexual males, while patients > 70 years were primarily transfusion recipients.

W.A.P.15 THE AIDS EPIDEMIC IN EUROPE

Accella-Park, Rosmarie; Coururier, E.; Lavioie, G.; and Brunet, J.B.

* WHO Collaborating Centre on AIDS, Paris, France

Objective. To determine the trends of the AIDS epidemic in Europe.

Methods. Cumulative quarterly surveillance data are collected from 31 European countries. Variations in trends between December 1984 and 1988 are analysed and presented for Europe as a whole and by country.

Results. By December 1988 over 18,000 cases had been reported to the Centre. There has been a steady increase in reported cases between Dec. 1984 and Dec. 1987 and a 1.5-fold increase between Dec. 1987 and Dec. 1988. The rates per million population are highest in Switzerland (106.4), France (101.7) and Denmark (70.2), and lowest in eastern European countries. The overall doubling time of the number of cases reported in Europe is 12.7 months (June 1988). Doubling times have lengthened since the start of the epidemic in all countries except Greece. Distribution of cases by country shows a predominance of the IVDU transmission group reported in the southern European countries and the homosexual group in the northern countries. A continuous increase in the percentage of cases reported in Europe among IVDU is noted: Dec. 84: 1%; Dec. 85: 7%; Dec. 86: 14%; Dec. 87: 20%; Dec. 88: 25%. In the global data, variations over time in the distributions of disease categories, age, sex transmission groups of children's mothers are directly related to this increase.

Conclusion. Doubling times of the number of cases have lengthened since the start of the epidemic. Geographic variations persist, with a majority of IVDU in southern countries. Variations noted in global European surveillance data are directly related to the steady increase in the percentage of IVDU.

W.A.P.17 EPIDEMIOLOGY OF AIDS-ASSOCIATED LYMPHOMAS: UNITED STATES

Beral, V.; Peterman, Thomas A.; Berkelman, KL. Centers for Disease Control, Atlanta, GA, USA.

Objective. To characterize patients with AIDS-associated lymphomas and evaluate whether these lymphomas might be due to an infectious agent.

Methods. We reviewed cases of AIDS reported to CDC by 3 December 1988.

Results. A lymphoma considered indicative of AIDS was reported for 2183 (Burkitt's, 474 (0.62); and primary lymphoma of the brain (PLB), 443 (0.62). The three types differed in age distribution: No cases of Burkitt's and only one case of immunoblastic were reported in children < 2 years of age but 4 cases of PLB were reported in this age group all types peaked at age 5 to 19; after age 25 immunoblastic rose to a peak while PLB and Burkitt's remained constant. In other respects, the distributions of the types of lymphomas were similar. After stratifying by age, heterosexual drug users or cases attributed to heterosexual transmission had rates half that of homosexual men, while men with hemophilia had rates twice that of homosexual men. Lymphomas were twice as common in white as black patients with AIDS in the same age and risk group.

Conclusion. The age differences in AIDS-associated lymphomas are the most striking epidemiologic finding. The other differences could be attributable to differential medical care. If these lymphomas are due to an infectious agent, it does not appear to be sexually transmitted.

W.A.P.14 THE EPIDEMIOLOGY OF AIDS-RELATED NON-HODGKIN'S LYMPHOMA IN SAN FRANCISCO

Shm, George E.; Payne, S.F.; Neal D.P.; Rutherford, G.W. San Francisco Department of Public Health, San Francisco, California, U.S.A.

Objective. To describe the epidemiology of non-Hodgkin's lymphoma (NHL) in AIDS patients diagnosed in San Francisco (SF).

Methods. We evaluated 5834 AIDS cases reported in SF from 1981 through 1988 with regard to an initial or subsequent diagnosis of NHL. All patients with NHL met the CDC definition of AIDS-indicative NHL. Medical survival was calculated using the Kaplan-Meier product-limit method.

Results. 179 (2.1%) AIDS patients were initially diagnosed with NHL. NHL as an initial diagnosis rose significantly (p<.01) from 1.0% of total cases in 1983 to a peak of 4.3% of cases in 1987, then declined slightly to 3.3% of cases in 1988. These trends do not appear to be a reporting artifact since a significant (p<.05) rise in NHL was also found for patients diagnosed at three active surveillance hospitals where prospective laboratory and medical record review has been conducted since 1983. 238 (4.1%) AIDS patients had NHL at some point during their illness. AIDS patients with NHL did not differ significantly from those without NHL with respect to age, gender, race/ethnicity, risk group, or residence in 19 contiguous census tracts with the highest incidence of AIDS in SF. Medical survival for AIDS patients presenting with NHL (6.6 months) was significantly shorter than that for patients without (12.6 months) (p<.001).

Conclusion. NHL has risen significantly as an AIDS-related manifestation. Demographics of AIDS patients with NHL are similar to patients without. Survival is shorter for AIDS patients with NHL.

W.A.P.16 FOUR-FOLD INCREASE IN TUBERCULOSIS/AIDS PATIENTS IN NEW YORK CITY, 1985-1988

Laroche, Eddy; Araneta, HRG; Stoneburner, RL; Adler, JJ New York City Department of Health, New York, New York, United States

OBJECTIVE. To evaluate the prevalence of Tuberculosis (TB) and to assess its contribution to TB morbidity in New York City (NYC).

METHODS. A computer match was performed using culture diagnosed adult cases (age >15) related to NYC TB registry from 1979 through 1988 and CDC defined adult AIDS surveillance cases from 1981 through 1988.

RESULTS. A total of 1116 patients with TB/AIDS were identified. TB/AIDS cases increased 4-fold since a similar study was conducted in 1985 where 261 patients were identified. The proportion of TB/AIDS as a percentage of AIDS cases between 1985 and 1988 remained fairly stable, from 5.2% to 6.3%. Whereas the proportion of TB/AIDS cases increased significantly from 2.2% to 8.1%. The proportion of TB/AIDS cases with IVDU histories or with extrapulmonary TB also remained stable between 1985 and 1988.

	1979-1988	1979-1988	R=Match O.R.
TB/AIDS/AIDS	1116/17,749 (6.3%)	261/4980 (5.2%)	1.07
TB/AIDS/TB	1116/13,820 (8.1%)	261/11,640 (2.2%)	<10 ⁻⁶
% of TB/AIDS			
w/extrapulmonary TB	203/1116 (18%)	58/261 (22%)	1.07
IVDU only	587/1116 (52%)	127/261 (49%)	0.8

CONCLUSION. AIDS remains a significant risk factor for clinical manifestation of Tuberculosis in New York City. The proportion of TB/AIDS cases with extrapulmonary TB was less than expected. The increase in TB/AIDS patients is most likely due to the increase in the number of IVDU.

W.A.P.18 CHANGING PATTERNS OF HETEROSEXUALLY ACQUIRED AIDS IN FLORIDA

Holtzman, Deborah*; Brandenburg, N.A.**; Sims, J.*; Wittes, J.*

*Department of Health and Rehabilitative Services, Tallahassee, Florida, USA; **University of South Florida, College of Public Health, Tampa, Florida, USA.

Objective. To describe secular trends in heterosexually acquired AIDS in Florida by demographic and risk group characteristics.

Methods. Based on the CDC surveillance definition for heterosexual transmission (HT), secular trends among HT cases in Florida were analyzed over the interval, 1980-88.

Results. As of January 12, 1989, Florida reported 567 (9% of total) non-US-born HT AIDS cases and 304 (5%) US-born HT AIDS cases. Among men, the proportion of non-US-born HT cases (N=15) decreased from 33 to 32 from 1980-88 (p<.001). Among women, the non-US-born HTs declined from 67 to 131 over the same interval (p<.0.001). In contrast, the proportion of US-born HT men (N=14) increased from .6 to 3.5% from 1980-88 (p<.0.001), while a comparable increase among women from 9 to 22% (p = 0.01). The majority (61%) of US-born HT women reported intravenous drug use (IVDU) among their partners. Further, the proportion of female cases attributable to sexual contact with an IVDU partner rose from 6 to 18% over the interval (p = 0.002). Most (60%) of these women were black; this percentage did not vary significantly over time. Among US-born HT women, no secular trends in age at diagnosis were observed, nor were age differences apparent by race.

Conclusion. The proportion of cases among non-US-born HTs is declining in Florida, while coincident increases are occurring among the US-born HTs. The increase in the US-born HTs does not seem to be due to declining risk factors at this time. Continued surveillance may help to explain these trends.

W.A.P.25

ANALYSE DES TENDANCES DES CARACTÉRISTIQUES SOCIO-DÉMOGRAPHIQUES DES CAS DE SIDA RAPPORTÉS EN FRANCE
Lipicitz, S., Marchandin, A., Cluzon S., Straet JR.
Direction Générale de la Santé, Paris, France.

Objectif: A partir de caractéristiques socio-démographiques des cas de SIDA, étude de la dynamique de développement de l'épidémie en France.

Méthodes: Analyse des 5527 cas de SIDA diagnostiqués de Janvier 1984 à Décembre 1986, présence des différents groupes de transmission, en fonction du temps et des variables socio-démographiques.

Résultats: Les tendances globales sont: un vieillissement de la population des cas de SIDA (diminution de la classe 30-49 ans, augmentation de la classe des plus de 50 ans); une persistence de la diffusion géographique en 3 zones (région parisienne, sud de la France, région Antilles-Guyane); un glissement des catégories professionnelles intellectuelles et commerciales vers les catégories des ouvriers et des sans profession. Les modifications de la part relative des différents groupes de transmission (baisse de celle des homosexuels et augmentation de celle des injections) par années de diagnostic ainsi que la modification des caractéristiques de ces groupes au cours du temps expliquent les tendances globales.

Conclusion: L'épidémie de SIDA en France est la somme de plusieurs épidémies indépendantes et découlées dans le temps. Certaines modifications des variables démographiques traduisent une augmentation de la proportion des cas à l'incubation longue.

Mortalité liée au SIDA

AIDS/HIV Related Mortality

W.A.P.27

IMPACT OF AIDS ON MORTALITY IN SAN FRANCISCO: 1979-1986.
Samuels, J.D., Hershfield, George, Leap, OJ, Barnhart, L.
Department of Public Health, San Francisco, California, U.S.A.

Objective: To describe the increase in AIDS-related death and years of potential life lost before age 65 years (YPLL-before age 65) for San Francisco residents between 1979 and 1986.

Methods: Death certificate data for San Francisco residents for 1979-1986 were used to calculate the number of deaths and YPLL-before age 65 for the following six AIDS-related diseases: cytomegalovirus infection (ICD-9 078.0); cryptosporidiosis (ICD-9 117.5); pneumocystis carinii pneumonia (ICD-9 136.9); other malignant neoplasms of the site, site unspecified (ICD-9 171.9); immunodeficiency with predominant T-cell defect (ICD-9 279.1); and immunodeficiency unspecified (ICD-9 279.3).

Results: The number of AIDS-related deaths (both sexes, all ages) increased from 7 (0.1% of all deaths) in 1979 to 536 (8.6%) in 1986. YPLL-before age 65 increased from 123 years in 1979 to 113,776 years in 1986. AIDS-related deaths increased between 1979 and 1986 from 0 to 44 (24.7% of all deaths); 0 to 157 (43.5% of all deaths); 0 to 150 (35.2% of all deaths) in males aged 20-29 years; 30-39 years; and 40-49 years respectively. In 1986 AIDS-related diseases were the third leading cause of death and the leading cause of YPLL-before age 65 among San Francisco male residents.

Conclusions: There was a dramatic increase in AIDS-related deaths in San Francisco residents between 1979 and 1986 especially in males aged 20-49 years.

W.A.P.29

ESTIMATE OF HIV-RELATED DEATHS IN YOUNG ADULT MEN, UNITED STATES, 1986.
Berkley, James, Berkman, K., Devine, O.
Centers for Disease Control, Atlanta, Georgia, USA.

Objective: To estimate the number of HIV-related deaths in 1986 in the U.S. among young adult men using multiple causes of death records for men 25-44 years of age for the years 1980-1986, we calculated excess deaths in 1986, based on mortality rates in 1980 and the lowest rates for selected causes.

Results: In 1986, there were 68 deaths (0.21 deaths/100,000) with any listing of well-defined immune deficiency. Known HIV seronegative, AIDS, Pneumocystis carinii pneumonia, and 7,737 such deaths (20.5 deaths/100,000) in 1986 (excess = 7,650). In the absence of these diagnoses, excess deaths occurred in 1986 (following a nadir in rates in 1980-1983) for other conditions in the AIDS definition: Infections, 132; non-Hodgkin lymphoma, 135; monophagocytosis, 15; and for other conditions that are increasing in association with the HIV epidemic: pneumonia and influenza, 193; pulmonary tuberculosis, 31; septicemia, 134; other infections, 101; other immune deficiency, 15; blood disorders, 37; and non-specific causes, 349. Thus, 7,655 to 9,182 excess deaths may be HIV-related, compared to 7,023 deaths in men 25-44 reported in the surveillance system in 1986. Excess deaths in HIV-related deaths may be high if excess deaths are not all due to HIV and low if baseline rates are declining, rather than stable, or if increases in other conditions (e.g., respiratory, drug abuse) are HIV-related.

Conclusion: National surveillance of AIDS cases detected roughly 75-90% of HIV-related deaths in 1986 among men 25-44 years of age.

Épidémiologie et santé publique Epidemiology and Public Health

W.A.P.26

AIDS IN THE DEPARTMENT OF VETERANS AFFAIRS: DEMOGRAPHICS AND EPIDEMIOLOGY
Allen, Robert E., Mather, S.H., Peterson, M.R.
AIDS Program Office, Department of Veterans Affairs, Washington, D.C., USA.

Objective: To describe the characteristics of the individual AIDS patients cared for in one of the largest medical systems in the world, the Department of Veterans Affairs (DVA) of the United States.

Methods: The DVA has collected data on AIDS patients since 1979. The reporting form is identical to those used by the Centers for Disease Control (CDC). From these figures computerized data has been collected to describe the age, sex, ethnic and risk groups for these patients. The results of these analyses will be reported.

Results: At the end of 1986 the DVA had cared for 5,434 AIDS patients in 141 VA medical centers across the USA. This represents approximately 4% of all of the AIDS patients reported in the USA. VA patients are different in risk behavior for the disease in the following way: Injected drug users account for 27% of all of the DVA cases, 7% are both IV drug abusers and homosexual. In other characteristics they are very similar, e.g. 46% are white, 57% are male and they are on the average 44 years of age. In addition, the AIDS epidemic has also been concentrated in epidemics, i.e. 57% of the patients have been cared for in 11 of the VA medical centers. The details of these findings will be further elaborated at the meeting.

Conclusion: The AIDS epidemic continues to involve an ever increasing number of patients in the USA. The DVA cares for 4% of these cases. These patients differ from the USA reported AIDS patients in risk group percentage. The IV drug users account for 27% of all of the patients cared for since 1979. These data will be presented and discussion encouraged.

W.A.P.28

HIV-ASSOCIATED MORTALITY IN ENGLAND AND WALES IS GREATER THAN THAT IDENTIFIED BY AIDS SURVEILLANCE MONITORING.

Office of Population Censuses and Surveys, London WC6B 6JP and HHS Communicable Disease Surveillance Centre, London, United Kingdom.

Objective: To estimate the total number of deaths resulting from HIV infection.

Methods: Ninety-five causes of death were identified as possibly HIV-related. Trends in death rates due to these causes by age, sex, marital status and geographical distribution were identified for 1980-87. Reports to CDC of HIV infected people who have died but who were not included in the AIDS surveillance programme because they did not meet the WHO definition were analysed. The AIDS surveillance programme was extended in February 1989 to include deaths among HIV-positive people who did not meet the WHO AIDS definition. Unreported mortality ratios due to HIV-related causes in 1987, but there was no similar increase for men of other marital status, or for single women. This increase was only partially accounted for by deaths for which AIDS was stated as the cause. Geographical distribution was similar to that of reported AIDS cases. Preliminary results from the extended surveillance programme will be presented.

Conclusion: People in England and Wales are dying as a result of HIV infection without developing AIDS as defined by the WHO. There is a need for surveillance programmes to be extended to include HIV infection severe enough to cause death but not meeting the WHO definition if the true size of the epidemic is to be identified.

W.A.P.30

CAUSES OF DEATH IN A LARGE COHORT OF I.V. DRUG USERS (IVDU) IN MILAN: AN UPDATE
Galli-Maino, Costini, G.*; Carite, M.*; Orucov, V.*; Zampini, L.*; Cianci, D.* et al.
Infectious Diseases Clinic and "Rho" Abuse services, Milan, Italy.

Objective: To evaluate the variations of causes of death during the last two years in a large cohort of IVDU recruited in Milan between Nov.80 and Dec.87. Since the beginning of the IVDU attending the Hospital Center are included, 103 subjects deceased before '87; 3664 IVDU have been followed-up with repeated investigations at registry offices.

Results: (N) Overdose AIDS Liver cirrhosis Violent death Other* Total
1980-1986** 18(20) 11(11) 8 (5) 20 (20) 25(26) 101
1987 18(22) 19(34) 1 (2) 8 (14) 10(18) 57
1988*** 20(39) 22(43) 3 (6) 5 (10) 21(2) 56
TOTAL 57(57) 52(51) 9 (4) 33 (16) 37(18) 208

* Only two cases of so-called HIV-related deaths (bacterial pneumonitis) were recorded. **retrospective data; ***up to Dec.1988 information were available in 20-25% HIV serology was available in 42 AIDS patients (deaths 10-13% were HIV pos).

Conclusions: Despite the increasing number of overdose related deaths in Italy during the last two years, in this cohort AIDS 'is now the first cause of death, not reflecting the large spread of HIV infection among IVDU in Milan.

Session d'affichage Poster Session

Epidémiologie et santé publique Epidemiology and Public Health

W.A.P.37 REPRODUCTION OF FACTORS RESPONSIBLE FOR HIV TRANSMISSION IN MALE HOMOSEXUALS

Antonis Boulikas, G. Kallitros, G. Kotsani, A. Papanicolaou, M. Nestoridis, A. Papanicolaou, E. Papanicolaou, G. National School of Hygiene, Athens, Greece.

Objective: To study factors affecting the prevalence of HIV infection in male homosexuals.

Methods: Male homosexuals self-selected for counselling and HIV screening at the National Center for AIDS were asked to complete a detailed questionnaire. The sample included 90 anti-HIV positive and 100 anti-HIV negative male homosexuals. All of them were also screened for serological evidence of HSV infection, syphilis and history of past gonorrhoea.

Results: Table 1 shows epidemiological characteristics and the prevalence of HIV in the seropositive anti-HIV positive and negative male homosexuals.

Characteristics/Disease	Anti-HIV(+)n=90	Anti-HIV(-)n=100
Median age (years)	28.9	26.0
Number of sexual contacts / month	5	5
Use of condoms (1) last year	26.7	26.0
1-7. Drug use (2)	6.7	2.0
Active and passive sexual behavior (3)	72.3	50.0
1-7. Drug use (2)	72.3	50.0
Syphilis	33.3	15.0
Gonorrhoea	55.0	20.0

Conclusions: There is a close correlation between HIV infection and other sexually transmitted diseases. Protected sex and both passive and active sexual behavior are mainly responsible for HIV infection in male homosexuals.

W.A.P.39 RELATIONSHIP OF STD HISTORY TO HIV SEROPREVALENCE IN A COHORT OF HOMOSEXUAL MEN IN DALLAS, TEXAS

Billy Charles E. Anderson, P. Frances A. Petty, A. Dallas County Health Department, Dallas, Texas, USA.

Objective: To determine the relationship between STD history and anti-HIV. **Methods:** Between 6/77 and 12/87, 644 homosexual or bisexual men volunteered to return every six months for HIV testing. All answered questions about previous episodes of syphilis, gonorrhoea, genital warts, and hepatitis. **Results:** 150 (23%) of the men had a history of either syphilis, gonorrhoea or warts; 153 (24%) had a history of hepatitis.

History of a Sexually Transmitted Disease:

	Syphilis	Gonorrhoea	Warts	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	11th	12th
N	104	238	131	320	60	110	140	140	140	140	140	140	140	140	140
HIV	40(47%)	92(56%)	51(39%)	120(38%)	20(40%)	46(42%)	46(42%)	46(42%)	46(42%)	46(42%)	46(42%)	46(42%)	46(42%)	46(42%)	46(42%)
OR	1.9	1.9	1.5	2.0	1.8	1.6	1.6	1.6	1.6	1.6	1.6	1.6	1.6	1.6	1.6

95% CI: 1.5-2.5, 1.5-2.4, 1.1-2.0, 1.5-2.6, 1.3-2.4, 1.1-2.2, 1.1-2.2. When stratified by the number of partners in the year before learning of AIDS, the risk for HIV infection in those with a history of syphilis, or of warts was 1.8 (95% CI: 1.4-2.4), and for those with a history of gonorrhoea or hepatitis was 1.4 (95% CI: 1.1-1.8). HIV infections were related to the number of episodes of gonorrhoea (p<0.001) and to the number of partners (p<0.01).

Conclusions: HIV infection may be related to history of STD due to the facilitation of HIV transmission, but the similar relationship with non-STD hepatitis suggests that HIV infections and STD may be independent events associated with a common mode of transmission.

W.A.P.41 FAILURE TO CONFIRM HERPES SIMPLEX VIRUS TYPE 2 (HSV-2) INFECTION AS A RISK FACTOR FOR HIV-1 SEROCONVERSION AMONG HOMOSEXUAL MEN

Klausen, Lennart, Armstrong, J. Rahman, A., Ho, M. and Khalifa, C. University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania, USA.

Objective: To determine if prior infection with HSV-2 is associated with HIV-1 seroconversion in homosexual men.

Methods: Western blot confirmed HIV-1 seroconverters (n=49) were matched with non-HIV-1 seroconverters (n=49) for the number of partners with whom anal receptive intercourse was performed and the visit of HIV-1 seroconversion. HSV-2 lab testing was performed on blind-coded sera utilizing immunofluorescence (IF) in an immunoassay assay.

Results: At the visit of HIV-1 seroconversion, the same prevalence of HSV-2 infection was observed for both HIV-1 seroconverters and non-seroconverters (52.0% vs 47.8%). Matched pairs analysis failed to detect any association between HSV-2 infection and HIV-1 seroconversion (odds ratio = 1.0). Self-reported rates of genital and anal-rectal sexual were very low (4.5%), as well as physical exam findings suggestive of HIV infection (2.8%).

Conclusion: No evidence was found in this study to support the hypothesis that prior/current infection with HSV-2 is a risk factor for HIV-1 seroconversion among homosexual men. A suggested explanation is that anal intercourse is the major risk factor for both HIV-1 and HSV-2 infection. HSV-2 infection among homosexual men may be only a marker of, not a causal factor for, acquisition of HIV-1 infection. Due to both cultural and biologic differences in sexual transmission of HIV-1, these findings should not be generalized to other risk groups.

W.A.P.38

SIZE FACTORS OF HIV INFECTION RISK MALE PROSTITUTE IN ATLANTA

John E. Fife, Jr., Brian M. Smith, Georgia State University, Atlanta

John E. Fife, Jr., Brian M. Smith, Georgia State University, Atlanta

Objective: To assess HIV seroprevalence among male prostitutes and to identify risk factors associated with HIV infection. **Methods:** HIV seroprevalence was determined by HIV-1 antibody testing and HIV-2 antibody testing. HIV-1 antibody testing was conducted and HIV-2 antibody testing was conducted in the presence of a trained interviewer. Interviews focused on sexual activity, drug use, history of STD, and other factors associated with HIV infection. **Results:** HIV-1 antibody testing was conducted on 100 male prostitutes and HIV-2 antibody testing was conducted on 100 male prostitutes. HIV-1 antibody testing was conducted on 100 male prostitutes and HIV-2 antibody testing was conducted on 100 male prostitutes.

Risk factor	n	% HIV-1	% HIV-2
Age (years)	100	17.0	1.0
Sexual activity (times/week)	100	17.0	1.0
Drug use (times/week)	100	17.0	1.0
History of STD (times)	100	17.0	1.0
History of syphilis (times)	100	17.0	1.0
History of gonorrhoea (times)	100	17.0	1.0
History of warts (times)	100	17.0	1.0
History of hepatitis (times)	100	17.0	1.0

Conclusions: HIV-1 antibody testing was conducted on 100 male prostitutes and HIV-2 antibody testing was conducted on 100 male prostitutes. HIV-1 antibody testing was conducted on 100 male prostitutes and HIV-2 antibody testing was conducted on 100 male prostitutes.

W.A.P.40 HIV-DISCORDANT COUPLES IN THE BALTIMORE BACS STUDY

Francis J. Beck, Jr., Fox R. Odoms, E. Aramant, H. Baruch, J. Barry W. Taylor, Jr., et al. The Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.

Objective: To determine infection status, sexual practices and coinfections of HIV-1 seropositive and HIV-1 seronegative couples. **Methods:** Thirty-four self-identified seropositive HIV-1 discordant, 8 HIV-1 seronegative and 18 seronegative concordant couples had detailed sexual histories taken and blood drawn for laboratory tests.

	Concordant Seropositive	Discordant Seronegative	Concordant Seronegative
Number of persons	10	34	34
C CD4	407	440	1140
C CD8/CD8 ratio	0.6	0.6	1.0
HIV-1 culture positive	6/10	28/33	2/33
HIV-1 RNA detected (PCR)	1/1	7/7	0/7
Anal insertive sex:			
- with primary partner	8/10	27/34	30/34
- never using condom	2/8	13/27	8/20
Anal receptive sex:			
- with primary partner	10/10	29/34	30/34
- never using condom	3/10	11/29	12/20

Conclusions: Sexually active HIV-1 discordant couples exist without evidence of viral transmission. The presence of a virus positive seronegative person in this high risk population requires further investigation.

W.A.P.42 SEROEPIDEMIOLOGICAL STUDY OF HIV INFECTION AMONG HOMOSEXUAL MEN ATTENDING A MEDICAL CLINIC IN MONTREAL

John E. Fife, Jr., Brian M. Smith, Georgia State University, Atlanta

John E. Fife, Jr., Brian M. Smith, Georgia State University, Atlanta

Objective: To determine the prevalence of HIV infection and characteristic sexual behavior among homosexual men attending a medical clinic in Montreal. **Methods:** A cross-sectional study of HIV infection, comparing anti-HIV testing and a HIV-1 antibody test. **Results:** HIV-1 antibody testing was conducted on 100 male prostitutes and HIV-2 antibody testing was conducted on 100 male prostitutes.

Conclusions: HIV-1 antibody testing was conducted on 100 male prostitutes and HIV-2 antibody testing was conducted on 100 male prostitutes. HIV-1 antibody testing was conducted on 100 male prostitutes and HIV-2 antibody testing was conducted on 100 male prostitutes.

RISK FACTORS IN HOMOSEXUAL TRANSMISSION OF HIV
Ennio Ricchi¹, P.Cestigiolla¹, N.Borneri¹, N.Bentale²,
P.C. Ma¹, P. DiStefano¹
¹ICG Istituto Nazionale Tumori, ²Instituto di Microbiologia,
Universita' di Bologna, Bologna, ITALY.

Objective: To evaluate the risk factors linked to HIV infection in a cohort of Italian homo-bisexual men enrolled in 1980-1986, and to look for their modifications during that period.

Methods: We have studied 854 homo-bisexual men (i.e. drug addicts excluded) from Northern Italy that refer at one's own free will to HIV screening program. All answered an epidemiological interview about sexual habits in 8 partners/year, "safe-sex", sexual intercourse behavior and underwent HIV test (performed by ELISA and confirmed). A cohort of 378 subjects which were HIV test every six months for a follow up period of 12-36 months.

TABLE I	# HIV Ab +ve	%
1985	258	12.9
1986	129	17
1987	211	18
1988	248	9

change seen in Italian homo-bisexual community, mainly the reduction of preactivity, which can explain the slow diffusion of HIV in this group.

Conclusion: The earlier behavior change seen in Italian homo-bisexual community, mainly the reduction of preactivity, which can explain the slow diffusion of HIV in this group.

W.A.P.45

THE DEVELOPMENT OF ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS) AMONG TWO COHORTS OF SEXUALLY TRANSMITTED (STD) PATIENTS WITH DIFFERENT VENEREAL DISEASE HISTORIES. Wayne J. Shandera
Dallas County Health Department, Dallas, Texas, U.S.A.
Ben Taub Hospital, Baylor College of Medicine, Houston, TX, U.S.A.

OBJECTIVE: To assess the risk of acquiring HIV infection among 2 cohorts of homosexual men treated for syphilis and other venereal infections in Dallas County, Texas.

METHODS: Two groups of homosexual male patients with venereal exposures were analyzed by a prospective chart review. The first included 302 individuals with a history of early (primary or secondary) syphilis during 1986; the second, 114 controls (matched by first initial of last name with a history of culture-negative gonorrhea or chlamydia but without any history of syphilis). The rate of AIDS in the 2 groups was assessed by reviewing a registry of local AIDS cases that had been diagnosed by mid-1988.

RESULTS: The number of AIDS cases among the two groups was similar: 14 (4.5%) among the patients with a history of early syphilis during 1986 and 6 (5.3%) among the matched control patients with a history of gonorrhea during 1986 (p = 0.252, p < 0.25).

CONCLUSION: Among American homosexual men, a relationship between a history of early syphilis and an increased rate of AIDS cannot be conclusively established 2 years after the episode of early syphilis and suggests that a history of syphilis does not serve conclusively as a risk factor for HIV infection and AIDS among American homosexual men as it does among AIDS patients belonging to other at-risk populations such as those treated and reported from central Africa.

Vertical Transmission

W.A.P.47

MATERNAL FACTORS AND NEONATAL CHARACTERISTICS ASSOCIATED WITH HIV INFECTION IN INFANTS OF SEROPOSITIVE MOTHERS.
Nair, Pragnanand; Johnson, J., J. Bines, S., Alger, L. and Seiden, S.
Department of Pediatrics, University of Maryland School of Medicine, Baltimore, Maryland, U.S.A.

Objective: To correlate maternal and neonatal characteristics with perinatal transmission of HIV.

Methods: In a prospective study of perinatal transmission, infants born to seropositive women were assessed for anti-HIV IgG, IgM, and HIV antigen at 2, 4, 6, 9 and 12 months of age. Data on 35 infants born to HIV positive women, 15 of whom show evidence of being infected, are presented.

Results: All mothers of infected infants and 90% of mothers of non-infected infants had history of IV drug use. There was no significant difference in age, education, type of family, marital status, parity or age at first pregnancy. The incidence of STD infections during pregnancy was higher in mothers of infected babies (40% vs 25%) and their participation in methadone treatment program was significantly lower (37% vs 55%). Birth weights, gestational ages and perinatal problems were similar in both groups except for a significant abstinence syndrome due mostly to methadone withdrawal which was higher in the non-infected (76.2% vs 27%).

Conclusion: In this group of infants transmission of HIV appeared to be associated with maternal lifestyle characteristics.

W.A.P.44

EPIDEMIOLOGICAL, IMMUNOLOGICAL AND SEROLOGICAL CHANGES IN A COHORT OF HOMOSEXUAL MEN: RISK FACTORS OVER SIX YEARS

Miller, Roger J., Chaves, J., Pappas L.J.
CDC Center for Infectious Diseases, Atlanta, GA; ¹Primeri Atlanta's Hospital, Atlanta, Georgia.

Objective: To determine rates of seroconversion and predictors of seronegativity and their relation to social lifestyle. In 1983 a cohort of 1000 homosexual men was recruited for a prospective study at a major teaching hospital. 100 seroconversion and immune function measurements were performed at six monthly intervals. In addition, all patients have completed and information on social lifestyle was obtained by questionnaire.

Results: The prevalence of antibody to HIV rose from 0% to 1.8% in 1986. There has been no further seroconversion. Two patients have developed group B disease, and the AIDS risk score (a composite score of seronegativity, seroconversion, and immune function) was significantly higher in the seronegative group. For CD4 counts the mean of annual partners and the number of reported STD's (p < 0.001). There has been a highly significant decrease in the number of sexual partners and the number of reported STD's (p < 0.001). There has also been a significant fall in the frequency of sexual acts, though not statistically significant. This applies to receptive and active partners, but not to oral transactions.

Conclusion: The fall in the number of sexual partners and the number of reported STD's is associated with a fall in the frequency of sexual acts, though not statistically significant. This applies to receptive and active partners, but not to oral transactions.

2 Although there are clear group trends, for a single individual, seronegativity and seroconversion are not predictive of seronegativity.

3 The combination of seronegativity and increasing risk resulted in a reduction of problems perceived to be unsafe.

W.A.P.46

RECENT HIV SEROCONVERTERS (SC) IN A SAN FRANCISCO COHORT OF HOMOSEXUAL/BISexual MEN: RISK FACTORS FOR NEW INFECTION.
Lillian Alan, E., O'Malley, P.M., Hessel, N.A., Bell, L.S., Cannon, L., Rutherford, S., Department of Medicine, San Francisco, CA; ²Centers for Disease Control, Atlanta, GA, U.S.A.

Objective: To describe homosexual/bisexual men (HBM) who recently seroconverted to HIV antibody (Ab) and behavioral risk factors for these SC.

Methods: Since 1983, follow-up studies have been conducted on a cohort of HBM recruited from 1970-1980 for hepatitis B studies. Eleven HBM were seronegative to HIV antibody at recruitment during 1986 (6) or 1987 (5) compared to 288 persons who remained seronegative (SN).

Results: During an interview period of 12-33 months (median=18) preceding the estimated date of seroconversion, SC reported a median of 30 sexual partners (range=1-25); 1 SC reported only 1-2 partners. 6/11 SC reported engaging in receptive anal intercourse without a condom, 2/11 SC reported only insertive anal intercourse without a condom, and 1 SC denied anal intercourse and reported only receptive and insertive oral-genital contact with multiple partners. Prior to the date of seroconversion, 7 SC had been told that they were HIV Ab negative based on a previous sample. Compared to SN, SC had a greater number of both steady and nonsteady sexual partners; SC were also more likely to have engaged in both receptive and insertive anal intercourse without a condom. SC and SN did not differ with respect to age, race, education, sexual contact with a female, or use of IV drugs.

Conclusion: A small number of HBM continue to seroconvert to HIV, primarily in association with unprotected receptive or insertive anal intercourse. Although multiple partners are also associated with an increased risk of seroconversion, some SC reported only 1 or 2 partners.

W.A.P.48

RISK FACTOR(S) IN SPONTANEOUS HIV SEROCONVERSION (SP) CHILDREN IN THE SAN JUAN CITY HOSPITAL, SANTIAGO, PUERTO RICO

Elizabet Jimenez, M.L., Corvea, L., Lopez, L., Paves, C., Reyes.
Department of Pediatrics, Pediatric Hematology Service, San Juan City Hospital, San Juan, Puerto Rico.

Objective: To determine the risk and mode of transmission of HIV infection in symptomatic children from 0-13 years of age at SJC.

Methods: 95 SP pts. were identified. 70-97 (41%), P-5-42 (44%), P-5-20 (52%), of the 32 symptomatic pts., 48 (92.3%) were perinatally infected (PI) and 4 (7.7%) blood acquired. The RF of parents in the PI children were:

None	45 (93.2%)	19 (42%) father
1	3 (7.7%)	19 (42%) mother
2	0	3 (7.7%) both parents
3	0	3 (7.7%) husband

Several Sex Partners... 4 (2%)

Disease... 2 (5%)

Conclusion: Perinatal infection was found to be the predominant mode of transmission (92.3%) in the symptomatic pts. at SJC. TDD was also most important RF in parents and directly related to this mode of transmission. The majority of the SP mothers were infected by a HIV sexual partner. Both perinatal infection and TDD are higher in 53% area than in the rest of P.R.

W.A.P.55 INCIDENCE OF AIDS IN SPANISH HIV INFECTED PATIENTS
 J. Pérez, M. Bellón, P. Sureda, C. Clotet, B. Gadea, J. Estany, C. Riera, J. de la Torre and BARDOLAN AIDS STUDY GROUP. Hospitalis Clinic, Bellvitge, Terrasa, Sarriena Trias, and Vall d'Hebron, Barcelona, Spain.

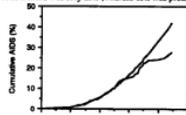

Objective: To describe the incidence of AIDS (CDC criteria of August 1987) among persons infected with the HIV in Barcelona (Spain) where drug addicts are the most frequent risk group and tuberculosis the most common initial manifestation of AIDS.
Methods: A total of 8100 people who were at high risk for AIDS, had enrolled in cohort's studies of homosexual men, parenteral drug users and haemophiliacs before december 1986. A total of 952 were either HIV seropositive at enrollment or seroconverted subsequently, and could be followed-up. 646 (70%) of the 952 were parenteral drug addicts.
RESULTS: The AIDS developed in 93 (10.3%) during a median follow-up period of 30 months (range 1 to 78 months); using actuarial survival calculations, the estimated 6-year cumulative incidence of AIDS among all HIV seropositive subjects was 23.8% (range 18 to 30.4%; 95% confidence interval). Among the homosexual, drug addicts and haemophilic cohorts the incidence at 6 years was 12%, 15% and 32% respectively (P<0.05). Comparing the survival functions the risk of developing AIDS was significantly greater among those presenting with the CDC stages IV and V (P<0.0001).
Conclusion: The risk of AIDS development after 6 years of HIV infection was 23% and the progression rate among drug addicts was not significantly different than the progression rate of male homosexuals or haemophiliacs.

W.A.P.50 NATURAL HISTORY OF HIV INFECTION IN WOMEN OF CHILD BEARING AGE IN SPAIN.
 Dr. E. M. Moreno, Dr. S. Kipoti - Makereve University, P.O. Box 7077, Kampala, Uganda.

Objective: To determine the morbidity and mortality rates associated with HIV infection among women of child bearing age in Uganda.
Methodology: 87 HIV Seropositive mothers were recruited from an antenatal clinic at Nsambugu Hospital in Kampala City. They were prospectively followed-up at monthly intervals for 0 - 35 months.
Results: During the follow-up period most of the women had delivered twice, 3 mothers had died, 3 of whom had seropositive AIDS (SIDA). 1 had seroneurological manifestations, 41 are still being followed-up but 4 of whom currently have SIDA. The rate of progression to the next stage in this cohort of women who delivered children and lactated is comparable to what has been found for the general population in other studies elsewhere.
Conclusion: From this study pregnancy and lactation did not accelerate the rate of progression to AID/AIDS.

W.A.P.57 DEVIATION OF AN AIDS PROGRESSION CURVE IN A GAY COHORT
 Schechter, Martin L.; Crab KP; Le TN; Wilbongby P; Montaner JSO. The Vancouver Lymphadenopathy-AIDS Study, Vancouver, BC, Canada.

To study patterns of AIDS progression, we fit a Weibull distribution to the first 60 months of AIDS progression in a cohort of 553 HIV men (232 seropositive CD4, 118 seronegative CD4). We first estimated 18 months of lead time for SP based on laboratory parameters and compared with SI. The model was then fit to 60 months (Feb-79), extended to 88 months, and graphing with the actual progression as below.
 The model (upper curve) gave rise to projections that agree with published studies. The actual progression (lower curve) deviated away from the model after 60 months. The observed Kaplan-Meier projection at 88 months was only 28% (whereas 42% predicted by the model).

AIDS progression in a seropositive gay cohort appears to have deviated from a Weibull distribution. We speculate this may be an early effect of the wider use of zidovudine. Drug effects will have to be accounted for in natural history studies and in epidemiologic projections.

W.A.P.58 PROGRESSION TO AIDS IN COHORTS OF SEROCONVERSION AND SEROCONVERTING GAY MEN: RESULTS AT 4 YEARS
 Crab Kera J.P.; Schechter M.P.; McLeod W.A.; Weaver M.S.; Wilbongby P.; Douglas P.; Scalet P.; Le TN; Wilbongby P.; Montaner JSO et al.

The Vancouver Lymphadenopathy-AIDS Study, St. Paul's Hospital and the University of British Columbia, Vancouver, BC, Canada. *Federal Centre for AIDS, Ottawa, Ontario, Canada.

Objective: To determine the rate of progression to AIDS in a cohort of seropositive gay men stratified by those who were seropositive at entry and those who seroconverted under study.
Methods: We identified all seropositive subjects in our prospective study who completed at least 2 visits during the period 11/82 to 12/86. This group was divided into seropositive at entry (seropositive: SP) and those who seroconverted under observation (seroconverting: SI). AIDS was diagnosed in this cohort according to CDC criteria. Methods of survival analysis were used to calculate progression rates to AIDS. Kaplan-Meier estimates of cumulative progression were calculated as were actuarial annual attack rates, namely the conditional probability of AIDS among those AIDS-free at the beginning of the year. Cox regression was used to model predictors. **Results:** A total of 351 seropositive subjects were included in the analysis (232 SP, 118 SI). The median lengths of observation while seropositive were 62.0 mos (range-72) for SP and 48.5 mos (range-16.6) for SI. A total of 69 cases of AIDS were observed (59 SP, 10 SI). Product limit estimates of cumulative progression were 28.7% (95% CI 24.5 to 32.9%) for SP and 11.1% (95% CI 6.4 to 16.0%) for SI at 60 months. The annual AIDS attack rates for the first 6 years in SP were 3.1%, 3.9%, 7.8%, 5.3%, 9.0% and 5.2% respectively and 0.0%, 1.0%, 3.0%, 6.0% and 2.1% for the first 5 years in SI respectively. CD4 counts, CD4 loading, and IgA levels independently predicted AIDS.
Conclusions: Progression by 5 years in SI, a true seroconversion cohort, is estimated to be about 11%. SP appears to have a mean lead time infection period of about 18 months. The drop in annual attack rate seen in the final year in both SP and SI could be due to reporting delay but we speculate it is more likely due to recent wider use of zidovudine.

W.A.P.59 PROGRESSION OF HIV DISEASE MOST IMPROVED OVER 88 MONTHS (1984) : A THREE-YEAR PROSPECTIVE STUDY. Iijima, Shiro, Iwashiro S., Suzuki S. et al. National AIDS Institute, Tokyo, Japan.

Objective: To determine the progression rate of HIV disease related to various stages 1984 and 1987. A prospective evaluation of 318 HIV men aged 19-39 (202) were HIV seropositive (Iliac with positive RIA) confirmed (Iliac with positive Western blot) and 116 (37) with seronegative western blot (serum III of CDC classification), 27 (8%) and 10 (3%) with seronegative western blot (Iliac II and IV) respectively, only 136 (19) were followed regularly for a median duration of 81 months (range 1-88), and were the object of this evaluation. Results: At first clinical evaluation 87 were HIV negative and 72 HIV positive, and of the latter group none had full-blown AIDS, no were symptomatic and 32 asymptomatic. Progression of HIV disease is summarized in the Table.

Seroconversion	1987 (82)	1984 (192)
Disease progression: asymptomatic ->	0	11/22 (54%)
symptomatic ->	0	15/24 (62%)
AIDS	0	4/42 (10%)
Full-blown AIDS	0	4/42 (10%)
Deaths	0	3/42 (7%)
Survival	100%	100%

Conclusion: After a median follow-up of 76 months, 1/87 (1%) of previously HIV negative 1984 seroconverters, and 4/72 (6%) of HIV-seropositive full-blown AIDS. In addition, despite educational efforts, a large number (80%) of newly positive 1984 still exchange syringes and needles and only a few (17%) use condoms.

W.A.P.60 DEVENIR DE SILETTS INFECTES PAR LE VIH : PREMIERS RESULTATS D'UNE SURVEILLANCE HOSPITALIERE.
 Schmitt, A. et al. Groupe d'Épidémiologie Clinique de Bordeaux (GEECA).

Centre Hospitalier Régional Universitaire (CHRU), Bordeaux, France.

Objectif: Un système de surveillance épidémiologique a été mis en place au CHRU de Bordeaux. Il permet d'analyser l'évolution clinique des sujets infectés par le VIH.
Méthodes: Les services hospitaliers participent toutes les semaines depuis 1986. A chaque consultation, les données sont recueillies sur un questionnaire standardisé, puis sont analysées et interprétées. La classification utilisée est celle des Centres for Disease Control. Les probabilités cumulées d'évolution au stade IV ou au stade SIDA sont calculées par la méthode de Kaplan-Meier.
Résultats: Au 30 octobre 1988, 446 sujets atteints ont été inclus. Parmi ceux-ci 253 patients étaient classés III et 193 au stade IV ou au stade SIDA. Les probabilités cumulées sont respectivement: 79% pour les hommes et 17,2% pour les femmes au stade IV et 10,2% pour les hommes et 1,2% pour les femmes au stade SIDA. Les sujets ayant atteint le stade IV (n=30) sont tous tombés IV 6 mois après leur entrée au CHRU. Les sujets ayant atteint le stade IV (n=30) sont tous tombés IV 6 mois après leur entrée au CHRU. Les sujets ayant atteint le stade IV (n=30) sont tous tombés IV 6 mois après leur entrée au CHRU.
Conclusion: Les données actuellement recueillies ne permettent pas de conclure sur le VIH soit comparativement avec la littérature. Le rôle en faveur du système de surveillance épidémiologique de l'hôpital pour le VIH semble important pour repérer le temps de passage des sujets asymptomatiques vers le stade IV et le stade SIDA. De plus, on a pu constater que les sujets asymptomatiques vont au stade IV de façon plus précoce que les sujets symptomatiques.

W.A.P.61 RISK ESTIMATES OF AIDS IN HEMOPHILIACS
 Joyce F. Killinger, PG Rosenber, JJ Goedert, LM Alton, CA Kessler, NE Gall, et al.
 *NHL, Research Triangle Park #2709 USA; #NCI, Bethesda MD 20892; #HHS, Stet Medical Ctr, Cambridge, MA; #CDC, Atlanta, GA 30307; #George Washington Univ Hospital, Washington DC 20037 for the NCI Hemophilia AIDS Study Group.

Objective: To estimate the proportion of HIV-infected adult and juvenile hemophiliacs who will eventually develop AIDS and to evaluate the uncertainties in these estimates.
Methods: A mixed Weibull survival model was fit to AIDS incidence data from 328 hemophiliacs whose dates of HIV seroconversion were known, including 33 AIDS cases among 174 adults (age at seroconversion >21) and 11 AIDS cases among 154 children. AIDS estimate parameters such as 74 counts were analyzed. The AIDS-free survival distribution was given by $f(t) = p \cdot \exp[-\lambda(t-t_0)^{\alpha}] + (1-p)$, the proportion p who will ever develop AIDS was estimated from its profile likelihood together with confidence intervals. Results: For adults, the profile likelihood was very flat, and indeed one could not strongly reject the possibility that $p=1$. However, our best estimate of p was .34 with 95% confidence interval (.27, .41). Results for children were similarly uncertain, with an estimate of $p=1$ with 95% confidence interval of $p=.24$, with a 95% confidence interval (.16, .66).
Conclusion: Our data yield very imprecise estimates of the proportions who will ever develop AIDS and certainly do not demonstrate that all HIV-infected hemophiliacs will develop clinical disease. Indeed, our estimates of p are much lower than those reported for studies of homosexual men.

W.A.P.63 FOLLOW-UP OF A COHORT OF EX IVDDs RESIDENT IN THERAPEUTICAL COMMUNITIES IN ITALY
 Marco Giannone, Fiume A., Marchionni C., Masai V., Prestivo T., Zampieri A. et al.

Istituto Superiore di Sanita, Rome, Italy; *Comunità Incontro, Terzi, Italy.
Objective: To describe the natural history of HIV infection in an IVDDs no longer exposed to intravenous drug use in the progression of the infection.
Methods: During 1988 all 2,028 residents in the 73 therapeutic communities (TC) administered by Comunità Incontro were clinically evaluated and tested for HIV. Risk factors for HIV infection were assessed by face to face interviews using a structured questionnaire. For those who were HIV seropositive a prospective follow-up was initiated while clinical and serological retrospective data were actively searched.
Results: All 2,028 residents were tested for HIV and 1,992 (97%) were found seropositive. Complete retrospective data are available for 710 (35.1%) HIV sero-positive, median follow-up 12.5 months (range 1-41 months). No AIDS cases were admitted at the TC and no AIDS cases occurred in the cohort during 1988. 304 (31.5%) subjects were asymptomatic at first visit and still such at last recall. The remaining 204 (28.9%) subjects were symptomatic either by persistent generalized lymphadenopathy or with constitutional disease or both. During the follow-up period 98 subjects (48.5% of the asymptomatic) showed no signs of progression or regression, 58 subjects (28.7%) showed clear signs of improvement, while the remaining 46 subjects (22.8%) showed clinical regression. A complete analysis will be presented at the conference.
Conclusion: Former intravenous drug users infected with HIV infection, living in a semi-protected conditions do not seem to show a faster progression to AIDS than other groups. However it is still to early to say whether HIV sero-residents in TCs have a better prognosis than others.

W.A.P.65 NATURAL HISTORY OF HIV-1 INFECTION FOLLOWING PROXENY
 Jay J. P. Braddick, M.D.,
 Krishna, M.D., *Mehra-Agila, S.J., Plummer, J.A., M.,
 *University of Nairobi, Kenya; **University of Manitoba, Winnipeg, Canada, #Mediastate Hospital, University of Washington, Seattle, U.S.A.

Objective: To study the influence of pregnancy on HIV-1 disease progression.
Method: Women attending a maternity hospital in Nairobi, Kenya were screened for HIV-1 Ab at delivery. HIV+ women were enrolled in a prospective cohort study and followed for HIV related illness.
Result: One hundred and twenty eight HIV+ women were enrolled and followed for 11 months of HIV related illness. 15 (9%) were asymptomatic, 15 (9%) asymptomatic (AS) and 13 (10%) had systemic disease (SD) 16 chronic pruritic rash (R), 1 hairy leukoplakia (L), 5 herpes zoster (Z). 8 Kaposi sarcoma (KS). Using logistic analysis, the cumulative probability (C) of AS women developing SD or dying was 21% (died of HIV related illness at a mean of 4.7 (range 0.5-9) months), 5 had at 19.6 (range 12-20) months, 5 developed chronic oral and/or vaginal candidiasis at 16.5 (range 12-20) months, and 1 developed R at 6 months. Four initially AS mothers delivered second infants and remained asymptomatic at 25.5 (range 24-27) months. Of the 15 women with SD at delivery a C of 5% had progression of HIV disease or died 2 died of AIDS (1 R, 1 wasting illness) at 7 months after delivery, 10 developed additional manifestations of HIV (8 with oral & vaginal candidiasis at 7 months, oral candidiasis at 1 month).
Conclusion: In this cohort of women who were initially asymptomatic HIV+ women progressed to HIV related illness/death within 2 years after delivery, and one half of the women with systemic disease at delivery had further progression of HIV disease or died within 9 months.

Epidémiologie et santé publique Epidemiology and Public Health

W.A.P.62 Enhanced prediction of AIDS in HIV sero-positive asymptomatic men:
 Rafaela Velaz de Calvario and Serologic Methods Group and its Collaboration,
 LA, El Paso, JM Taylor, R Delea, B Holman, J Mariani, P Nahnian, J (J) Giorgi UCLA School of Medicine and Public Health, Los Angeles, California, U.S.A.

Objective: To evaluate B cellular and serologic markers singly and in combination for their ability to predict the occurrence of AIDS within 4 years.
Methods: CD4+ T cell number, percent, and CD4/CD8 ratio were determined by flow cytometry. Serum neopterin, beta-2-microglobulin (B2M) soluble IL-2 receptor (sIL-2R), IgA, and p24 HIV antigen were determined by serologic tests. The relative hazard from abnormal levels of these were calculated using the proportional hazards model. A random sample of 366 individuals were chosen from 813 seropositive individuals, participating in the Los Angeles Center of the Multicenter AIDS Cohort Study and were followed for 4 years to until the diagnosis of AIDS.
Results: CD4+CD8 ratio and CD4+ T cell percent were reduced and/or serum neopterin levels were elevated in more than half of the subjects (baseline the normal 100-500 counts per microliter). Reduced CD4+ T cells (number, percent or ratio) was the best single predictor of AIDS. Neopterin and B2M are similar in their predictive ability and slightly less good than CD4+ T cells. The combination of B2M, IgA, and sIL-2R both have predictive ability but not as strong as neopterin or B2M. Neopterin, B2M, sIL-2R, IgA, and p24 antigen all have statistical significance independent of CD4+ T cells. In addition to predictive ability, Neopterin appears to add the most. In a stepwise procedure the following variables were chosen in order: CD4+CD8 ratio, neopterin, IgA, sIL-2R, antigen.
Conclusions: These studies indicate that measurements of multiple parameters reflecting different facets of HIV infection add to predictive value regarding the occurrence of AIDS. The most important parameters are CD4+ T cell number (or number) and serum neopterin or B2M. Soluble IL-2R, IgA, and p24 antigen, can be useful to add predictability if the other measurements are made.

W.A.P.64 AIDS YEARLY INCIDENCE IN 1984 HIV SEROPOSITIVE COHORT:
 NO DEFINITE TREND 1985-1988
 J. English, P. Chantel, J. Ho, K. W. and Painovich, G. Multicenter AIDS Cohort Study, Los Angeles, California, U.S.A.

Objective: To observe temporal trends in the incidence of AIDS in a cohort of seropositive men.
Methods: Approximately 1870 homosexual men seropositive on 1984 enrollment in the Multicenter AIDS Cohort Study (MACS) have been followed for progression to AIDS. Encouraging the first semester which was incomplete, and the last semester for which reporting is not yet finished, the semi-annual incidence rates per 100 person semesters of follow-up were calculated for each center and for the MACS as a whole.
Results: Incidence of AIDS in Seropositivity by Semester:

Semester	AIDS cases	Person semesters	AIDS Inc. (%)	AIDS Incidence/Center
1/85-6/85	28	1451	1.9	0.9 2.5 2.1
7/85-12/85	60	1807	3.3	2.8 3.9 3.2
1/86-6/86	84	1975	4.3	3.1 4.3 4.9
7/86-12/86	45	1291	3.5	2.1 3.8 3.0
1/87-6/87	75	1870	4.0	4.8 7.4 5.0 3.2
7/87-12/87	71	1201	5.9	5.2 1.9 2.8 2.9

Conclusion: The AIDS incidence is seropositive men differs by center, but there is no clear increasing trend over this period of time.

W.A.P.66 THE INCIDENCE OF ANTISEROLOGIC HIV INFECTION: THE UNITED STATES AND OTHER HIGH INCOME COUNTRIES

Rafaela Velaz de Calvario, JM Taylor, J. O'Connell, K. Yamamoto, K. J. Department of Historical Research, War Reser Army Institute of Science and Technology, Fort Belvoir, IL, U.S.A.

Objective: To describe the natural history of early HIV infection and delineate prognostic parameters. Methods: The characteristics of HIV infection in the stratification of the US Army. All HIV seropositive individuals are clinically evaluated and staged per the Walter Reed Staging Classification. Recruitment occurs at 3-6 month intervals. Results: To date 1500 individuals have been enrolled including over 1200 with follow up visits greater than 1 year.

Stage	PRELIM UP STAGE				DEATH
	MC	MC	MC	MC	
MC1	447	468	28	28	0.26
MC2	479	668	198	68	18.06
MC3	266	608	28	28	28
MC4	23	578	248	138	48
MC5	49	198	198	228	228

Conclusion: Progression of asymptomatic HIV infection to clinical immunodeficiency correlated with CD4 count, CD8 cell reactivity, and initial WR stage of infection and duration follow up. This observation holds for each variable independently and in combination will be presented.
Conclusion: All asymptomatic HIV seropositive white can be clinically classified by the Walter Reed Staging Classification providing important prognostic information. Wide scale clinical application is feasible as demonstrated in the US Army Health Care System.

Session d'affichage Poster Session

W.A.P.73 PROGRESSION OF HIV-1 DISEASE IN A POPULATION OF SEROPOSITIVE NAVY AND MARINE CD4+ CELL COUNTS
 HARRIS, Douglas A., Wilson, D.S., Hagner, K.F., et al.
 * National Naval Post Center, Bethesda, Maryland and ** Henry W. Jackson Foundation, Rockville, Maryland

Objective: To determine the rate of HIV-1 disease progression (prog) in screened seropositive active duty military personnel.

Methods: We have evaluated 517 HIV seropositive personnel with serial evaluations. 129 patients were evaluated at 9 to 15 months (1 year) and 57 patients were seen at 21 to 27 months (2 years). Each evaluation was point staged using the Walter Reed classification based on the clinical data for that visit alone.

Initial Stage	1 YEAR			2 YEARS		
	N	%	AIDS	N	%	AIDS
1-2	115	22	0	45	42	2
3-4	22	4	0	29	11	0
5	3	68	4	25	75	2
All Stages	159	28	67	43	78	2

Conclusions: There was 47% progression in Walter Reed stage and 9% progression to AIDS at 2 years in this population sample. There was an average 14 cell count decline per year with a normal distribution about the mean. For patients with T4 cell counts between 680 and 200 cells the rate of decline was essentially linear ranging from 68 to 82 T4 cells lost per year in each 14 interval examined.

W.A.P.74 PROSPECTIVE HELIXIBINUM COHORT STUDY IN HOMOSEXUAL MEN IN THE A-4 TROOP FOLLOW UP. SEROLOGICAL RESULTS.
 HERRING, Richard, For Study Group.
 AIDS-Serum in Helixibinum, Berlin, Federal Republic of Germany

Objective: To evaluate the natural course of HIV-infection.

Methods: In 1984 a prospective multicenter cohort study was started in FRG. A total of 771 homosexual men were recruited in 7 centers in metropolitan areas. At time of enrollment 412 (53%) men were positive to HIV-antibody, 25 of those had full blown AIDS. Cohort members are examined twice a year.

Results (Serological): 75 of the HIV-infected homosexual men developed AIDS during 11 months of observation. The incidence of AIDS was a constant 38 per year. For only 2 cases with AIDS the time of infection is known. To gain a better figure of the course of HIV-infection and the time of latency, we calculated the probability that CD4-count counts fall below certain limits. On the basis of these calculations a model was developed which allows the prognosis of the development of HIV-disease in the cohort. In 12 years after HIV-infection 90% of the infected individuals will have less than 300 CD4-cells/ml.

Discussion: The beginning (time of infection) and the end (AIDS) of the course of HIV-infection is not known for the vast majority of HIV-infected individuals. A stochastic model, on the basis of data from our cohort may help to gain a better understanding of the time course of HIV-infection.

Survie des personnes atteintes du SIDA Survival of the AIDS Patient

W.A.P.76 DEGREE OF HIV-RELATED CNS INVOLVEMENT AND LONG-TERM SURVIVAL: PRELIMINARY RESULTS.
 KERRY, F.A., MacFadden, D.K. Dept. Medicine, University of Toronto, Toronto Western Hospital, Toronto, Ontario, Canada.

Twenty-three homosexual men at various stages of HIV-related illness and 6 seronegative men have been entered into a longitudinal study of HIV-induced CNS dysfunction. All subjects were given an initial (baseline) set of clinical, immunologic, CT and neuropsychological assessments and then re-assessed at 6 month intervals. Results indicate that ARC patients (1/23) are most cognitively impaired at the time of admission while AIDS patients (17/23) show a wide diversity of impairment; however, there appears to be an inverse relationship between the extent of impairment at baseline and survival among AIDS patients (high impairment/short survival). Furthermore results indicate that CNS involvement precedes the development of AIDS (presentation with PCP) in many cases and that ARC patients have considerable CNS involvement despite the absence of opportunistic infection. In the majority of AIDS patients there is a progression of CNS involvement across assessments but 20% of patients survive for over 2.5 years without significant CNS impairment; long-term survival may depend heavily on this relationship.

W.A.P.75 NATURAL HISTORY OF HIV INFECTION IN MEN IN GREAT BRITAIN IN MARINE COUNTRY
 HARRIS, Douglas A., Iribarren, J.H., Soren, G., Gillis, R., et al.
 P. Zaluska, G. Hospital Nuestra Señora de Arce, San Sebastian, Spain.

Objective: To describe the natural history of HIV infection among MSM.

Methods: Of 314 MSM screened in 1985 for HIV, 107 (34%) were seropositive. Of these, 103 entered a follow-up study. After an initial evaluation, they were screened every 6 months. We present the preliminary data obtained at 24 months follow-up.

Results: In the initial study 83% were asymptomatic. 81 only presented one analytic abnormality (anemia under hemogram) and/or (immunogram) and 14 had lymphadenopathy syndrome (LAD). After 24 months we evaluated 76 of them. 31 (39.5%) are asymptomatic; 37 (48.6%) are in group II with one analytic abnormality; 11 (14.5%) are in group III; 7 (9.1%) of them with analytic abnormality; one 16 in group IV; 10 (13.2%) of them meeting AIDS criteria (group IV-C); 8 (10.5%) in group IV-B and 1 (1.3%) in group IV-A. In 7/16 patients the disease has progressed.

Considering the group of 1006 who initially presented analytic alterations, 100 (10%) developed AIDS and in 10,400 (10.4%) the disease progressed. Of the patients originally asymptomatic, 6,100 (10.8%) now developed AIDS and 61,700 (10.8%) the disease has progressed. We discuss the behavior of the clinical and analytic findings of these patients over the course of 24 months.

Conclusion: We conclude by indicating that 10.8% of the group who developed AIDS and that the course of the disease is greatly influenced by the patients' initial status and analytic status.

W.A.P.77 DEMOGRAPHIC AND VIROLOGIC DETERMINANTS OF SURVIVAL IN AIDS: ROLE OF CYTOMEGALOVIRUS, CMV AND CD8+ LYMPHOCYTES
 FELD, N.H., Cole, L.A., Schwartz, L., Karmali, M., Torrealba, J., et al.
 * Massachusetts General Hospital, Boston, MA; * Los Angeles, CA; ** VA Medical Center, Los Angeles, CA; *** UCLA Medical Center, Los Angeles, CA; **** VA Medical Center, Los Angeles, CA, USA.

Objective: To study virologic and immunologic characteristics of patients surviving over 1 year first AIDS-defining event.
Methods: Sixty patients admitted with AIDS to Eisenhower Medical Center have been followed and the survivors evaluated by serum p24 antigen, polymerase chain reaction and culture for CMV, lymphocyte flow cytometry and ophthalmological examinations. Since 1987 the survivors have been treated with zidovudine and, since 1989, two also with human interferon.

Results: All 24 patients with CMV retinitis have died (median survival of 166 days) and 28 of 26 patients without retinitis died (median survival of 302 days). One probability of survival in the 2 groups = 0.543. The survivors have been free of CMV retinitis (except for one patient with inactive retinitis) and have had undetectable HIV p24 antigenemia, median count of 40 CD4+ cells/mm³, median count of 537 CD8+ cells/mm³, and CD4+/CD8+ ratio double-bearing cells ranging 126(152) - 554(31.52)/mm³. The patients dying with disseminated CMV infection had 31-202cp/ml of HIV p24 antigen, 0-9 CD8+ cells/mm³, and 2-174 CD4+/CD8+ cells/mm³. The patients dying with inactive CMV retinitis had 0-100cp/ml of HIV p24 antigen and with residual presence of CD4+ and CD8+ cells. Disseminated CMV infection had a better adverse prognostic factor in AIDS.

W.A.P.78 PREDICTORS OF SURVIVAL FOR AIDS IN BARCELONA SPAIN
 BERRAS, Gerard A.P., Vila, J., et al.
 * Hospital Municipal de San Sadu, Barcelona, Spain; ** Hospital de San Sadu, Barcelona, Spain.

Objective: To analyze the predictors of survival of 208 AIDS patients from Barcelona (Spain) where the survival percentage of drug addicts is high and represents the most common initial manifestation of AIDS.

Methods: 163 adults older than 14 years old with AIDS referred to the local health authorities were available for a longitudinal follow-up. Age, sex, group of sex for HIV infection, AIDS manifestation at diagnosis and the date of diagnosis were the variables included in the univariate analysis (Kaplan and Meyer survival curves) and in the multivariate analysis (Cox regression model) for overall survival.
Results: 102 (50.8%) were males and 58 (28.8%) were older than 40 years. 164 (53.3%) were parenteral drug addicts, 100 (34.5%) male homosexuals and the remaining 39 (17.2%) were categorized as other. 16 of them (7.9%) were seronegative for AIDS cases (33.3%) presented with a form of extrapulmonary tuberculosis, 148 (51.2%) with another opportunistic infection, 34 (11.8%) with a Kaposi Sarcoma and the remaining 11 cases with lymphoma. 31 (10.1%) were diagnosed before 1980. The survival probability dropped from 82% 300 days after diagnosis of AIDS, in the remaining patients the survival probability was significantly greater in those presenting with a tuberculosis (< 0.0001), among the drug addicts were the remaining groups (< 0.0001); in those diagnosed in 1980 or later (< 0.001) and in those younger than 40 years (< 0.0001). The multivariate analysis selected the year of diagnosis, group of sex, age and the clinical presentation with a tuberculosis. Conversely the women proposed were for male homosexuals, seronegatives or recipients of a contaminated blood transfusion, older than 40 years and presenting with a Kaposi Sarcoma or lymphoma. The best prognostic factor for drug addicts younger than 40 years whose initial manifestation of AIDS was an extrapulmonary tuberculosis.

W.A.P.79 **PREDICTING IN-HOSPITAL MORTALITY FOR AIDS PATIENTS: A VICTORIA STUDY**

Macdonald, S., Gillman, S., H. Gillman, S., Palmer, C., Macdonald, S., Campbell, R. Palmer, C. and Macdonald, S. Victoria Hospital, Memorial University, St. John's, Nfld., Canada.

Estimating prognosis for a hospitalized AIDS patient is essential for optimal clinical management. We developed a prediction model for in-hospital mortality using admission data abstracted from 128 patient admissions to the Royal Victoria Hospital (R.V.H.). This model was subsequently validated on 62 patient admissions to the Memorial General Hospital (M.G.H.).

Using univariate analyses, stepwise logistic regression analysis, and clinical judgment, we identified independent predictors of in-hospital death including mean albumin (ALB) ($P = < .01$), serum lactate dehydrogenase (LDH) ($P = < .01$), and leukocyte count (WBC) ($P = < 0.27$) ($n = 60$). High, medium, and low-risk groups for in-hospital mortality were defined where the probability of dying was $\leq 100\%$, 100% to $> 95\%$, and $> 95\%$ respectively. Using the resulting BMD regression scores and 2x2 contingency table analysis, we tabulated the cutoff score that corresponded to each risk group. The validity of the BMD model was then tested by classifying admissions at M.G.H. We in-hospital mortality for the high, medium and low-risk groups was 100% (2/2), 42% (10/24) and 14% (5/36) respectively.

We conclude that routine admission laboratory tests associated with infection (ALB), pneumoniae pneumonia (LDH) and other infections (WBC) help predict the outcome of hospitalizing patients with AIDS.

W.A.P.80 **EFFECT OF MULTIPLE DISEASE MANIFESTATIONS ON LENGTH OF SURVIVAL FOR AIDS PATIENTS IN SAN FRANCISCO**

Palme, Susan E.; Lamp, G.F.; Rutherford, R.L.; Neal, J.P., U.S.A. Teunis, T. San Francisco Dept. of Public Health, San Francisco, CA, U.S.A.

Objectives: To evaluate the effect of multiple manifestations of AIDS-indicative diseases on length of survival. Methods: We evaluated survival following AIDS diagnosis for 4524 patients reported in San Francisco between July 1981 and Dec. 31, 1987. Cases were followed at 6-month intervals from diagnosis to death. 10% of cases were lost to follow-up. The number of AIDS-indicative disease manifestations occurring within 3 months of initial diagnosis was calculated, and median survival was calculated separately for patients with 1, 2, and 3 or more disease manifestations using the Kaplan-Meier product-limit method.

Results: The median survival for all patients was 12.8 months, with a 3-year survival rate of 5.8%. Survival decreased significantly as the number of separate manifestations of AIDS-indicative diseases increased. This trend was consistent for all patients regardless of initial diagnosis.

Median Survival by Number of Disease Manifestations

Initial Diagnosis	1 Disease	2 Diseases	3 Diseases	P-Value
KS	1000 17.0 mos	150 9.5 mos	30 5.3 mos	<.001
PCP	214 12.9	100 10.5	57 7.6	<.001
COI	591 8.8	165 6.8	---	<.05
Total	3763 13.5	516 8.8	112 5.8	<.001

Conclusion: The occurrence of multiple disease manifestations within 3 months of initial AIDS diagnosis significantly decreases survival.

W.A.P.81

IMPROVED SURVIVAL OF AIDS PATIENTS IN DALLAS, TEXAS AFTER 1986

Reisz, Charles E; Reif V, Freeman A, Baslund I, Karpf E, Dallas County Health Dept, Dallas, TX, USA.

Objective: To determine survival among AIDS patients in Dallas. Methods: Diagnosed AIDS patients have been reported to the Dallas County Health Department since 1981. The registry has been maintained using standard methods; validation surveys verify the completeness of reporting. Survival analysis was performed using Kaplan-Meier product limit estimates. Results: 1464 persons have been diagnosed with AIDS in Dallas between 1981 and 1988. Variables associated with survival include age at diagnosis, race, sex, and risk category. Among the 1044 homosexual males, aged 30-65, without a history of IV drug use, the median survival for those diagnosed pre-1986, 1986, and 1987 are 305, 386, and 402 days, respectively; trends for 1988 indicate a longer median survival. The survival times for those diagnosed pre-86 were different from those for each of the other years ($P < .01$); the difference between the other years may have occurred by chance ($P < .05$). Conclusions: There has been an improvement in AIDS patient survival. Potential reasons include "lead time bias" due to earlier diagnosis with the widespread use of HIV testing; antiviral therapy with AZT; or improved management of opportunistic infections. All three reasons may play a role in improved survival, but the effect for those diagnosed as early as 1984, before the widespread use of AZT, argues for lead time bias as an important factor.

W.A.P.82

IMPROVED SURVIVAL IN

Washington State Office on HIV/AIDS, Seattle; Seattle-King County Department of Health, AIDS Education & Prevention Center, Seattle, WA, U.S.A.

Objective: To monitor AIDS clinical care for people with AIDS (PWA) by diagnosis and disease state. Methods: Death dates were searched for death certificate review of every vital record for surviving PWAs. End-of-year product limit survival analysis was applied to the statewide HIV Surveillance Database for those diagnosed prior to 1987. Results: Overall median survival for all 777 cases was 465 days. Median survival significantly improved for people with IV drug use and for those cases diagnosed prior to 1986 compared to those diagnosed in 1986, while no increases were seen during this time interval for people with other diagnoses. This significant increase was seen in all categories for cases diagnosed in 1987 compared to those diagnosed in 1986. The decline of disease and curing episodes significantly prolonged survival in 1987. Cases with outpatient diagnosis survived significantly longer than other cases (1333 vs 641 days). Only six definitive episodes of PCP also had prolonged survival over each of the time intervals (data not shown).

Risk	0-50 Survival	51-100	101-150	151-200	Median Survival
CRS	238 / 2	260	289	407	289
KS	196	239 / 25	487	447	737
PCP	228 / 12	428	289	447	525/17*

*1/2 of cohort still alive. *Includes deaths and curing episodes.

Conclusions: The increase in survival time of PWAs is multifactorial and reflects improved medical care, HIV therapy, earlier diagnosis, and expansion of the DC case definition. Updated information and the relative contribution of each of these factors will be outlined.

W.A.P.83

REVIEWALIAN-BASED SURVIVAL ANALYSIS OF QUEBEC AIDS PATIENTS

Denis, Robert, W. H. Palmer, Robert, H. Quebec Regional des maladies Infectieuses Montreal, Quebec, Canada.

Objective: To assess survival of AIDS cases following diagnosis and to evaluate survival by age and sex. Methods: The vital status of the AIDS cases reported to January 15, 1989 was assessed through an analysis of the Quebec AIDS Registry (QAR) using a product limit method and the Cox proportional-hazards analysis were performed. Results: Of the 742 cases diagnosed, 359 were known to have died. The median survival following diagnosis was 9.0 months; the cumulative probability of survival at one, two and three years were 41%, 18% and 9.8%, respectively. Univariate analysis showed that survival was significantly shorter for children than for adult cases (7.0 vs. 9.8 months, $p = 0.002$). Among adult cases, there were no significant differences in survival by sex or age at diagnosis. Median survival time was significantly shorter for those born in a Western II country (9.1 vs. 10.0 months, $p = 0.06$). AIDS-related diseases were the strongest predictors of survival. The diagnosis of Kaposi's sarcoma (KS) was associated with longer survival (median 11.4 months, $p < 0.001$). In multivariate analysis, independent significant decreases in survival were found for age at diagnosis (1.33 vs. 3.39 years (relative risk (RR) of death at any time of 1.34) and for AIDS-related diseases when compared with the diagnosis of KS (RR = 1.55; 1.37 and 1.39 for B-cell lymphoma, Kaposi's sarcoma, and other opportunistic infections and other AIDS-related opportunistic syndromes, respectively). Conclusions: Active surveillance of AIDS cases permitted the evaluation of survival after diagnosis. Our study did not find shorter survival among city males or temporal improvements in survival, but confirmed the positive association of KS and a younger age at diagnosis with improved survival.

Prevention Through Partner Notification**

W.A.P.84

REVIEWALIAN CONTACT TRACING IN A NEW YORK CITY STD CLINIC

Schultz, S. and Struchiner, E. New York City Dept. of Health, NY, NY, U.S.A.

Objective: To measure contact tracing among STD clinic patients with implications for HIV partner notification by comparing the results of traditional contact tracing intervention (CTI) which require naming partners with results of a confidential structured questionnaire (CSQ) where only the number of partners was required. Methods: 100 patients with diagnosed syphilis participated in a CTI performed by clinic personnel and also were enrolled in an HIV seroprevalence study where information on sexual behavior and risk factors for HIV infection were collected by an interviewer using a CSQ. Results: Data from 64 participants were analyzed: 21 (17%) were positive; 19 (32%) reported positive contacts; 4 (9%) reported IV drug use and 6 (9%) were HIV antibody positive. On CTI, 22 (34%) gave no information identifying contacts. There was a significant difference ($P < .001$) between number of contacts given in CSQ and CTI: 41 (64%) gave a larger number, 20 (33%) gave identical results and 3 (5%) gave a smaller number. Mean number of contacts for CSQ was 3.1 compared with 1.0 for CTI. From the CSQ, mean number of contacts for 3 months, 1 year, 3 years and since 1974 were 3, 7, 21, and 55, respectively. Conclusions: These data suggest that HIV partner notification in New York City may be seriously hampered by partner anonymity, lack of testing information, and concerns for confidentiality.

W.A.P.85 SEXUALLY TRANSMITTED DISEASE (STD) CLINIC CLIENT OPINIONS ON HIV PARTNER NOTIFICATION

Spencer, W., Dagnan, G.; Wolf F.A., Sims, C.,**
*Colorado Department of Health STD/AIDS Section, Denver, Colorado, USA,**
University Hospital Health Sciences Center, STD Clinic, Denver, Colorado, USA.

Objective: Determine opinions on acceptance of HIV partner notification services by STD clinic clients.
Methods: Consecutive clients attending the University of Colorado Health Sciences Center STD clinic during October and November 1989 were asked to complete an anonymous 6 question survey.
Results: 212 clients responded to the survey (male 120, 56.6%; mean age 26.6; white 128, 60.4%). Almost all (206, 97.2%) felt a need for those exposed to HIV to be informed. Consistent results were obtained when questions were personalized; important to inform respondents partners (201, 97.2%), and respondent would want a trained professional to inform them (189, 89.6%). Over half (109, 51.4%) indicated difficulty in informing partners themselves yet most (171, 80.7%) would assist a person trained to do so. Respondents selected multiple factors of concern. Of 452 selections: 86 (40.6%) feared disclosure of their positive test result, 85 (40.2%) were concerned that partner be notified privately, 61 (28.8%) feared rejection by partner, and 43 (20.3%) feared harm by an angry partner.
Conclusion: STD clinic clients recognize the need for and will participate in HIV partner notification programs. Greater participation can be expected if confidentiality concerns are addressed with the client.

W.A.P.86

Title: Study of sexual contacts of the HIV seropositive persons

Authors: Galban, E.; Menendez, J.; Gil, R. and Terry, N.
Ministerio de Salud Pública, Habana, Cuba.

The Cuban Program of struggle against AIDS has as a most important goal the study of the sex contacts of each case infected by HIV detected through our screening system. Each of these contacts is subjected to a serological examination for the HIV determination and the same time they are given educational advice regarding their future sexual behavior while waiting for the result or results of the examinations. In general, all contacts are kept under surveillance for a year starting from the date of the last sex intercourse with the index case, serological examinations being done quarterly, except for the spouses who are followed-up every three months indefinitely. We have been able to control 80% of the 1317 sexual contacts of the HIV seropositive persons. Male homosexual relations were infecting 5.1%, while heterosexual ones were so in 10.4% and 3.4% of women who had sex intercourse with bisexual males were infected.

W.A.P.87 EPIDEMIOLOGIC BENEFITS OF HEALTH DEPARTMENT NOTIFICATION OF HIV EXPOSURE

Wykoff, Randolph F.; Jones, J.L.; Longshore, S.I.; Hollis, S.I.; Quiller, C.B.; Gamble, W.B. The South Carolina Department of Health and Environmental Control, Greenwood, South Carolina, USA.

Objective: To determine if Health Department notification of HIV exposure (contact tracing) not only produces beneficial behavior changes, but also adds to the understanding of the epidemiology of AIDS in a given community.
Methods: Standard STD notification procedures were used, with an emphasis on targeting preventive education to the sex and needle-sharing contacts of HIV-infected individuals.
Results: 316 unique sex and needle-sharing partners of HIV-positive persons have been named in one Health District in the past 2 years. 107 (64%) were contacted, educated and offered testing. 202 (98%) agreed to be tested and 36 (18%) were HIV-positive. Only 6 (3%) of the 202 had been previously tested. 49% of the known HIV infections in our District have been identified by Health Department notification, 33% by private physicians and 18% by other sources. Of those exposed to HIV, 55 (27%) had only heterosexual exposure and 8 were infants. The age range of contacts was 14 to 74. We have been able to reclassify 3 HIV-positive men who denied major risk factors. Two dimensional mapping has lead to a clearer understanding of the transmission of HIV in our area.
Conclusions: Health department notification of HIV exposure significantly expands understanding of the extent of HIV infection and identifies HIV exposure among untested high-risk individuals and among people outside the risk group and age ranges usually associated with AIDS in the USA.

**Prévention de la transmission par contact sexuel et par consommation de drogue
Preventing Transmission by Sexual Contact and Drug Use**

W.A.P.88 EFFECTIVENESS OF EDUCATION IN INTRAVENOUS DRUG USERS TO PREVENT HIV SEXUAL TRANSMISSION.

Jean-François Delruey, A. Levy, A. Abellhauser, D. Penzo, A. Blanc, P. Bouz, J. Dubout, Hôpital Antoine-Béchère, 92141 Clamart, France.

Objective: To study the change in behaviour regarding the intravenous (IV) use of drugs, and the attitudes toward sexual preventive measure, in a group of HIV intravenous drug addicts (IVDA) in Paris Area.
Methods: Between January 1986 and June 1986, 264 HIV seropositive drug users were enrolled follow up in a 3 years prospective study. Patients initially agreed to attend counselling sessions twice a year. Clinically and immunological HIV status were performed, twice a year. In parallel the subject attitudes toward preventive measures concerning the IV use of drugs and sexual behaviour were recorded every 6th month.
Results: On 264 patients, only 206 were followed regularly during the 3 years study. They were 182 male and 64 female with a mean age of 24.3 ± 2.1 years. No significant data could be obtained on the proportion of patient which increased or decreased the frequency of injections neither the use of drugs at home or alone. At the second visit (6 months), 72 % regularly used unique needle or syringe, and 69 % used condoms during sexual intercourse. At the 6th visit (2 years 1/2), 61 % used unique injection material, but only 22 % always used condoms. These attitudes toward preventive measures were equally observed in male and female sub group.
Conclusion: In contrast with changes in sexual behaviour observed in homosexual population, there is a relative ineffectiveness of education and counselling in preventing the sexual transmission of HIV infection in IVDA on a 3 year period.

W.A.P.89

RISK BEHAVIORS OF IV COCAINE USERS: IMPLICATIONS FOR INTERVENTION

Chitwood, Dale, B.; McCoy, C.B.*; Cozart, M.*; Trapido, E.J.*. *University of Miami School of Medicine, Miami, FL, USA

Objective: Identify traits of intravenous cocaine use (IVCU) which are relevant for planning risk behavior reduction programs.
Method: Data from two tri-ethnic, male and female IVCU cohorts are presented. 1) To describe high risk traits of IVCU existing before AIDS was discovered, interview data collected in 1980-81 from 75 IVCUs are presented. 2) To describe current risk behaviors and attempted behavioral change to reduce HIV exposure, data collected in 1987-88 from 255 IVCUs are presented.
Results: Prior to knowledge that AIDS existed (1980-81), IVCUs reported several high risk traits-cocaine obsession (68%), use escalation (61%), no spending limits (72%), cocaine-related money problems (82%), always craved cocaine (72%), never refused cocaine (44%), prostitution (47%) or traded sex (5%) for cocaine. Current IVCUs were twice as likely (21%) as other IVCUs (10%) to test HIV-1Ab+. 70% reported risk reduction efforts, but a majority still injected daily, shared needles, had IV and non-IV sex partners (SPs), never used condoms. Attempts to stop sharing (20%) or share less often (22%) were reported by more IVCUs than shooting cessation (5%) or needle cleaning (13%). Reduction in number of SPs was reported more often (23%) than increased condom use (11%).
Conclusion: Many IVCUs engage in high risk behavior. Self-initiated attempts to change both needle use and sexual behavior often are unsuccessful. Implications for intervention programs are discussed.

W.A.P.90 THINGS OF RISK REDUCTION AMONG INITIATES INTO INTRAVENOUS DRUG USE 1982-1987

Wahney David, Anthony, J.C. Celentano, D.L. Solomon, L. Choudhury, M., Mandell, W. The ALIVE Study. Johns Hopkins School of Hygiene and Public Health, Baltimore, Md, USA.

Objectives: The purpose of this study is to identify and compare initial injection practices of IVUOs by year first used to determine if initiation practices were changed during the course of the epidemic.
Methods: As part of the baseline questionnaire for a natural history of HIV infection (ALIVE) active IVUOs recruited from the community were asked to report year first injected, drug first used, and the frequency of injection, using sterile needles, sharing needles and cookers during their first three months of use. The distribution of responses were dichotomized and grouped by year first used. The chi square test for trends was performed.
Results: Of the first 1840 participants, 421 reported initiation between 1982 and 1987. Over these years, heroin as the first drug decreased (p < .01), while cocaine increased (p < .05). The proportion who never used sterile needles decreased (p < .05) as did the proportion who always used needles after another person (p < .05). The proportion who had > 3 needles sharing partner decreased (p < .01).
Conclusion: Although these data are from a cross-sectional study they suggest a shift from heroin to cocaine and a shift toward lower risk practices among new IVUOs between 1982 and 1987.

W.A.P.92 SEXUAL BEHAVIORS AND CHARACTERISTICS OF 627 GAY AND BISEXUAL MALE PARTICIPANTS OF THE DALLAS SEX PROFILES STUDY

EDUCATIONAL INTERVENTIONS FOR THE PREVENTION OF AIDS.
Toddler, Fred** Myers, T.** Korta, R.*****, Jackson, M.* Orr, F.* Row, C.**
AIDS Committee of New York, **University of Toronto, Toronto, Ont., Canada, ***Humberbrook Medical Centre, Toronto, Ont., Canada.

Objectives: To describe demographics, knowledge, attitudes and sexual behaviors of the 627 participants at time of recruitment into the study.
Methods: A non-interventive study was recruited from the community by a variety of methods. Subjects completed questionnaires prior to random assignment to control or 3 educational intervention groups.
Results: The mean age was 37.4 years (range 14 - 72); 564 had completed college or university, 45.6 had been HIV antibody tested; 13.0% were seropositive and 4.8% reported AIDS or AIDS related illness. Sexual practices reported for the prior 5 years and 3 months are:
Sexual practices Control 3 Years 3 Months
Anal intercourse - Receptive 69.8 36.24 69.14 14.53
Anal intercourse - Insertive 55.4 41.6 71.5 18.9
Oral-Genital - Insertive 98.48 54.18
Oral-Genital - Receptive (with cum in mouth) 79.2 26.6
Mutual Masturbation 98.9 91.3
Conclusion: Although there may be problems with recall bias and the methods used, there appears to be a decrease in unsafe sex practices in the study population over the course of the past 5 years.

W.A.P.94 ONGOING IMPACT EVALUATION OF THE COMMON USE PROMOTION/USER-INITIATION PROGRAM FOR PREVENTING AIDS IN THE DOMINICAN REPUBLIC

Cherchez, Ernesto De Nova, E.A.; Rosario, S.
PROGRES, Ministry of Public Health, Santo Domingo, Dominican Republic.

Objective: To evaluate the Dominican Republic Condom Use Promotion/Initiation Program (1987-1989) and to analyze its main impact on population.
Methods: Condom use adoption before and after program implementation has been assessed through: 1. A series of CAP studies with female sex workers and their clients, transsexual, gay and bisexual men, jail inmates, Haitian migrant workers and the general population; and 2. Periodic descriptive surveillance of hotel and motel rooms where condoms are made universally available.
Results: Positive attitudes toward condom use have increased from 55% in 1985 to 73% in 1988. Condom use in 1988 was less than 2% in the generally active male population and less than 1% in female sex workers (FSW). By 1988, condom use in hotels and motels was 18%. FSW carrying condoms in their purses has grown to 94%.
Conclusion: Creating and maintaining a permanent state of awareness of AIDS and aggressively enhancing the perceived value of condom use has significantly increased condom use in the Dominican Republic.

W.A.P.91 SELF EFFICACY AND COMMUNITY NORMS PREDICT AIDS RISK REDUCTION AMONG GAY AND BISEXUAL MEN IN SAN FRANCISCO: THE AIDS BEHAVIORAL RESEARCH PROJECT

Neilands, Larry Coates, T.P. Morris, S.*
University of California, San Francisco, CA, U.S.A.

Objectives: To describe correlates and predictors of reductions in high risk sexual behavior among gay men in San Francisco.
Methods: Subjects were 440 men in the AIDS Behavioral research Project responding to annual surveys since 1984. Subjects responded to mailed surveys regarding sexual behaviors, relationship status, antibody testing experience, and variables from our AIDS Risk Reduction Model (ARRM). Variables measured in 1984 to predict risk behavior in 1987 included serostatus, AIDS professional symptoms, AIDS loss, relationship status, perceived social norms, and health beliefs (self-efficacy, threat, knowledge). Multiple logistic regression was used to derive adjusted odds ratios for each variable.
Results: 60% of the men practiced high risk sexual behavior in 1984 (50% practiced unprotected anal intercourse). Only 30% practiced high risk behavior in 1987 (12% practiced unprotected anal intercourse). Individuals who practiced high risk behavior in 1984 and 1987 were more likely to perceive that peers continued to practice high risk behavior (adjusted odds ratio = 1.11, p<.05). Those high in personal efficacy (adjusted odds ratio = .95, p<.05)and who tested positive for antibodies to HIV (adjusted odds ratio = .42, p<.05) were less likely to continue the practice of high risk behaviors in 1987. **Conclusions:** AIDS risk reduction campaigns may benefit from methods for increasing personal efficacy through skill training.

W.A.P.93 PRELIMINARY ANALYSIS OF FACTORS ASSOCIATED WITH COMPLIANCE WITH GUIDELINES FOR PREVENTION OF SEXUAL TRANSMISSION OF HIV IN HETEROSEXUAL COUPLES

Nichols, Margaret Peroni F., Sampson G., Leibel J., Kennedy M.J. - Woodhull Medical and Mental Health Center, Brooklyn, NY, USA.

Objective: To present a preliminary analysis of factors associated with compliance with practices for prevention of sexual transmission of HIV in a cohort of monogamous couples.
Methods: The Northern Brooklyn Partner Study, began in September 1982 with funding from the CDC. It is a three year longitudinal study of monogamous heterosexual couples in which one partner has a high/very high risk factor (sexual contact with the other partner). The sample is drawn from a community based primary health care facility which serves a population that is 93% black or Hispanic and 86% IVUO's and their sexual partners. Data gathered are retrospective as well as prospective, and include sexual and drug use behavior, psychological measures, and medical parameters (stage of disease, partner, p-24 status, HIV culture, concurrent VD, etc). All subjects are reinterviewed and examined at 3 month intervals.
Results: Preliminary data presented here will be a comparison between couples who are following "safer sex guidelines versus couples who are not. The dimensions used for comparison include knowledge of HIV transmission, perceived threat of infection, perceived self-efficacy (the feeling that one can control one's own health), self-esteem, depression, perceived distance from AIDS, partner/peer support, and quality of the relationship.
Conclusions: These results indicate that some of the variables that are relevant in AIDS prevention for gay men are not relevant in the setting of heterosexual transmission in an impoverished minority community.

W.A.P.95 AN EVALUATION OF THE EFFECTS OF VARIOUS LUBRICANTS ON LATEX CONDOMS

Pugh, Bradley Engstler, M.
Aerial Incorporated, Tusculum AL, U.S.A.

Objective: To determine if short-term exposure to lubricants adjacently applied to latex condoms can cause sufficient deterioration to warrant concern about condom failure during use in one experiment and in six subjects at body temperature and in another experiment for one hour at room temperature and then tested for tensile strength according to ASTM Standard test methods. A control group, without lubricant exposure to any lubrication, was subjected to the same testing.
Results:
Tensile (MPa) Tensile (MPa)
Lubricant (Body Temp.) (Room Temp.)
No lubricant (control) 22.6 22.4 ASTM Std.
Vegetable oil 18.1 6.4 Tensile
Petroleum jelly 15.9 11.6 mtn. = 17 MPa
Personal lubricant 11.2 2.2
Conclusion: Some personal lubricants used in sex shops and other household items (petroleum jelly, vegetable shortening) have a significant deleterious effect on the strength of condoms. This deterioration is severe enough and occurs rapidly enough that their addition to latex condoms as adjunct lubricants is likely to cause the product to fail during use. Only water-based or silicone-based lubricants or others that have been tested and recommended by the condom manufacturer should be used.

Épidémiologie et santé publique Epidemiology and Public Health

W.A.P.96 EVALUATION OF CONDOM UTILIZATION AND ACCEPTABILITY OF SPERMICIDES AMONG PROSTITUTES IN KINSHASA, ZAIRE

Mills, B.J., Ryder, A., Saez, R., Project SIDA, Kinshasa, Zaïre, *CDC, Atlanta, GA, *Institute of Tropical Medicine, Antwerp, Belgium.

Objective. To evaluate the effectiveness of a condom intervention program and to evaluate acceptability of spermicides in Kinshasa prostitutes.

Methods. From June-December 1988, 801 prostitutes were interviewed about knowledge, attitudes and practices of condoms at entry of an STD/HIV survey, and again 3 months later. 1000 women were interviewed, counseled and free condom distribution. 210 HIV-1+ women were interviewed, counseled and given 3 months of free condom supply. 1004 women were interviewed. In a pilot demonstration project, 52 women were offered spermicides.

Results. 70% of women actively reported "regular" condom use (27%, 37% and 32% respectively (p<0.1). After 3 months, 33% of women reported using condoms use (50% always, and 50% inconsistently) independently of HIV sero-status. Safety of spermicide use was not attributable to condom use. The reported condom use of 140 women followed up prospectively was validated with incidence of STD, presence of spermicide on vaginal smear and incident pregnancies out of 8 women who seroconverted, was a consistent condom user (2/10) and 7 were inconsistent condom users (1/7) (p<0.05).

Incidence of:			
N. gonorrhoeae	0.7	1.6	0.02
T. vaginalis	1.4	1.7	NS
Syphilis seroconversion	4.5	5.2	NS
No. of new pregnancies (3.7/2%)	8	8.7(2%)	NS

(% expressed as episode per woman year of observation)

Spermicides (Benzalkonium oxides) were used in 92% of client encounters, were well accepted and were associated with high reported effects.

Conclusions. Condom use increased considerably after intervention but STD transmission persisted despite high reported condom use. Spermicides are highly acceptable among prostitutes.

W.A.P.98 THE SUPPLY OF, AND DEMAND FOR, CONDOMS TO PREVENT HIV TRANSMISSION IN DEVELOPING COUNTRIES

Kanana-Lemba, W., Harris, J.R., and Shelton, J.D.
U.S. Agency for International Development, Washington, D.C., U.S.A.

Objective. To assess the supply of, and demand for, condoms in preventing HIV transmission in developing countries.

Methods. U.S. Agency for International Development (A.I.D.) funding and shipping data were reviewed for Fiscal Years 1987-1989 worldwide condom prevalence was analyzed.

Results. Since 1987, A.I.D. has been the leading provider of condoms for developing country AIDS control programs. A.I.D. funds have bought 172 mil. condoms and over 120 mil. have been shipped to 56 countries. 48% of all condoms have gone to Africa, 27% to Asia, and 24% to Latin America and the Caribbean. Demand is increasing and half of all shipments were in the past six months. Shipping condoms can play a vital role in preventing HIV transmission. Current supply and demand are too low to significantly impact on the pandemic if all 120 mil. condoms shipped had gone to Nigeria, less than 4% of Nigeria's 22 mil. males ages 15 to 49 years would have condoms for one year. To make enough condoms available, other donor resources are needed. Increasing the demand for condoms requires urgent attention in developing countries, only 3% of reproductive age couples use condoms in Africa, 0.5% do. Social marketing and private sector distribution must complement government efforts. Given the absence of vaccines and curative treatments, condoms are the world's most promising technology to prevent transmission of HIV.

W.A.P.100 INCREASING CONDOM ACCESSIBILITY: WHAT ARE THE BARRIERS?

Spencer, Brenda, Spiers, A., Job-Spiers N.
US22 INSERM, Paris, France.

In both research and promotional campaigns, condom promotion is usually characterized as a problem of attitude and behaviour change at the level of the individual i.e. as a question of acceptability. Far less attention has been paid to the question of accessibility. Yet, applying the experience of previous campaigns and simple marketing principles, the accessibility of France condoms may be obtained in pharmacies and large supermarkets. The range of other outlets is negligible, nonetheless, companies attempting to install vending machines report having met with great difficulties. Given the high rate of HIV positivity in France and the traditionally low rate of condom use, this situation appears paradoxical. Our research programme therefore aims to identify the barriers to achieving a wider availability of condoms - at the level of the general public, including machines. We report here on installation in a questionnaire in a high distribution TV magazine, and a national representative sample with a polling organisation. Results show overall acceptance of wider distribution to be high among all ages and all socio-economic groups. There was no preference for stalls in toilets. The two proposed stalls with an acceptability markedly lower than the rest (around 50%) were the workplaces and public buildings. Other sites, including universities, highschools, bars, stations, leisure centres, health centres and the street, had acceptance levels between 70-90%. We infer that the major barriers lie elsewhere than with the general public.

W.A.P.97 AIDS AND CONDOM-USE IN THE NETHERLANDS

Ernst M.M. de Vroom*, Th.G.N. Sandfort*, M. Paalman**, K.A.P. Tielman*
* University of Utrecht, ** STD Foundation, Utrecht, Netherlands.

Objective. Since May '87 a number of campaigns directed at the general public were undertaken. The levels of knowledge, attitude and behavior among heterosexuals before and after the campaigns are assessed.

Methods. Data were collected by semi-annually interviewing approximately 1000 respondents (age 15-45). Interviews were done by telephone, respondents were randomly solicited in each of the four surveys.

Results. From May '87 to October '88 (figures from the fifth survey (April '89) will be presented as well), people associating "safe sex" with condoms (as intended by the campaigns) rose from 43% to 82% (p<0.001). It was confirmed that condoms protect against AIDS by 98% in Oct. '88 compared to 74% in April '87 (p<0.001). The overall attitude regarding condoms became more positive: the number of people saying the advantages of condoms prevail, increased from 52% to 78% (p<0.001). Among people having non-steady sexual relationships, condom-use increased from 30% to 77% (p<0.001), although not all these users used condoms consistently.

Conclusion. A number of changes have occurred, presumably supported by the conducted campaigns. Condom-use has become relatively more acceptable and more people associate the prevention of HIV-infection with the use of condoms. People with non-steady sexual relationships now use condoms more often, although more than 10% of the occasions used. Further interview attempts to ascertain a cause for such high breakage.

W.A.P.99 PERSISTENT CONDOM BREAKAGE

Vogler, Bruce*
*Haripoo Foundation, Topanga, CA, U.S.A.

Objective. To assess why males well informed in condom usage repeatedly broke condoms during post-penetration coitus.

Methods. Several hundred males who had condoms break during coital use were screened. 25 (a) correctly answered all questions about proper use of condoms, but (b) reported breaking condoms more than 10% of the occasions used. Further interview attempted to ascertain a cause for such high breakage.

Results. About one third of the men practiced vaginal intercourse; the remainder anal intercourse. All 25 men claimed only to use "water-based" lubricants; never using "oil-based" ones. Yet 23 identified their usual coital lubricant as Vaseline Intensive Care hand lotion, Johnson's Baby Oil, or Nivea Hand Creme. Each of the 25 men believed these lubricants were "water-based" because they were readily washed away in tap water, in contrast to lubricants such as Vaseline Petroleum Jelly, Crisco or butter. All 25 men were U.S. college graduates.

Conclusion. These data suggest that differences in frictional stress between anal and vaginal intercourse may not suffice to account for breakage. Coupled with the reported rapid deterioration of condoms caused by mineral-oil wax lubricants, the data suggest that some portion of coital breakage of condoms may be based in the conscientious users' misconception that baby oil and emulsified oil lubricants are "water-based." Better choice in language may be important for condom use brochures.

W.A.P.101 A SIMULATED PHYSIOLOGIC TEST OF LATEX CONDOMS

Ernst, M.A., Betts, S.M., Rinaldi, J.E., Herman, Bruce A., Carey, R.F., and Athey, T.W.
Division of Physical Sciences, Center for Devices and Radiological Health, FDA, Rockville MD 20857 USA.

Objective. To test latex condoms for the passage of HIV-size microspheres under simulated physiologic conditions.

Methods. HIV is simulated by uniform polystyrene, fluorescent microspheres with mean diameter of 0.11 µm. These microspheres are suspended in physiologic phosphate buffered saline with surfactant. The condom is inflated to form and inserted into a fabric mesh which limits the expansion of the condom to physiologic dimensions. The form with the condom and fabric mesh is secured in a test chamber and the condom filled with the suspension of microspheres under a static pressure of 60 mm Hg, which was found to be the maximum pressure difference across a condom in modelling experiments performed in our laboratory. The chamber is filled with the same solution less the fluorescent microspheres. The test system is maintained at a temperature of 37°C and a pH of 7.0, while the chamber's fluid is continuously monitored for the presence of the fluorescent marker.

Results. The test system has quantitatively identified latex-induced holes as small as 8 µm in diameter and is capable of detecting holes as small as 3 µm. Tests of 69 condoms from 2 manufacturers found 6 condoms which had holes. The leak rates corresponded to hole diameters in the range 4 µm to 7 µm.

Conclusion. This test is sufficiently sensitive to determine whether condoms provide an effective barrier to HIV-size microspheres under (static) physiologic conditions.

Section d'affichage Poster Session

W.A.P.108 CHANGES IN HIV RISK BEHAVIOUR IN DRUG INJECTORS ATTENDING SYRINGE-EXCHANGE PROJECTS IN ENGLAND AND SCOTLAND
Stansby, Gerry K., Jackson, A.C. and Dolan, K.
Monitoring Research Group, Oldfields¹ College, London, UK.

Objective: To assess the impact of syringe-exchange projects on the injecting and sexual behaviour of injecting drug users. The study was part of the evaluation of government sponsored syringe-exchange projects.
Methods: Injectors attending 4 syringe-exchange projects were provided with information about HIV risks, given needles and syringes on an exchange basis, and condoms. Self-reported risk-behaviour was assessed with a prospective interview administered at two points in time with 142 clients who attended up to March 1989.

Results: Syringe-sharing in the previous 4 weeks dropped from 34% to 27%; sexual risk (transmission) dropped from 77% to 69%; those with two or more partners dropped from 26% to 21%. Surveys of two comparison groups of injectors not attending syringe-exchanges showed higher levels of syringe-sharing in the first survey (n = 220) 42% shared, in the second survey 31% 4 months later (n = 174) 52% shared.
Conclusion: The evidence indicates that many syringe-exchange clients maintain low risk behaviour and others adopt them. There are some who resist change. The changes over three months are small, but support the argument that injectors can be helped to change their HIV risk behaviour. Comparison groups of non-attenders showed higher levels of risk behaviour.

Prévention : politiques et évaluation des programmes Prevention: Policy Issues, Program Evaluation

W.A.P.110 CARA - A TOOL FOR AIDS PREVENTION
Belachew, Wifried.
University of Oldenburg, Oldenburg, Federal Republic of Germany

Objective: CARA is the abbreviation for computer assisted risk management with a dialogue for the prevention of HIV infection. The prevention of the HIV-infection in a dialogue with the computer. Target groups are students and young adults. It consists of 2 parts: Part 1: With this program the participants acquire the knowledge one should have about AIDS.

Part 2: The participants get the opportunity to assess the risks of their particular lifestyles in the fields job, leisure/sports, traffic and sexuality. The participants receive a feedback on the riskiness of their lifestyles, especially on the risky behaviors with regard to a HIV-infection.
Results: The program has widely proved its usefulness and efficiency in German schools. It is highly attractive to students. Teachers and AIDS counsellors use it for the introduction of lectures on AIDS and the preparation of personal communication.

W.A.P.112 TRAINING THE HEALTH CARE PROFESSIONAL: THE AIDS REGIONAL EDUCATION AND TRAINING CENTERS PROGRAM OF THE HEALTH SERVICES ADMINISTRATION (HSKA)
Hornor, Anne, Haffner, Martell, Moore, D. and Mocher, A.
Division of Health Services Administration, HSKA, United States Public Health Service, Rockville, Maryland, USA.

Objective: To establish regional education centers that will provide multidisciplinary training for health care professionals.
Methods: With a projected cumulative total of more than 300,000 AIDS cases by 1992, it is essential that health care providers be trained in the diagnosis, management and treatment of HIV-infected patients. The insufficient number of providers active in the care of AIDS patients presents a major gap in the health care delivery system. In recognition of this problem, the United States Congress appropriated funds to establish the AIDS Regional Education and Training Centers Program.
Results and Conclusions: To date, thirteen centers have been created. These regional education and training centers provide multidisciplinary HIV/AIDS training for health care personnel within the framework of the following three goals: 1) training community primary care providers to incorporate strategies for HIV prevention into clinical priorities as well as to diagnose, manage, and counsel patients and their families; 2) training individuals to serve as educators in their local area; and 3) educating health care professionals in providing sensitive and integrated care of AIDS patients through the improvement of their understanding of the complexity of the disease.

W.A.P.109 DRUG TREATMENT CENTERS AS THE MEDIUM FOR A COMPREHENSIVE APPROACH TO AIDS PREVENTION FOR INTRAVENOUS DRUG USERS
Gardner, Jessica, Jones, T., Korman, G., Fearn, E., Mendenhall, J., P.O., Bowen, M.S., Centers for Disease Control, Atlanta, Ga., U.S.A.

Objective: To describe a model plan for prevention of HIV infection, sexually transmitted diseases (STD), and hepatitis B virus (HBV) in drug intravenous users. The model was by states who are recipients of Centers for Disease Control (CDC) funding. The model includes: 1) Cooperative Prevention: Drug Treatment Centers (DTC) are under-utilized settings for providing health care for people who are at high risk for HIV, HBV, and STD through CDC funded state health departments to prevent these diseases. 2) Comprehensive Approach: DTCs are under-utilized settings for prevention activities in these settings was lacking. Consequently, CDC staff designed a model plan to facilitate staff planning activities. 3) Implementation: The model plan includes: a) Staffing: DTCs should be staffed with the essential components of this model practice in order to provide comprehensive care. b) Services: DTCs should provide HIV and STD testing, directly observed TB preventive therapy, referral and expanded care of intravenous drug users (IVDU) for medical, psychiatric, and/or referral for contraband services, and personal medication of intravenous drug users. c) Funding: Funding mechanisms and a detailed evaluation of impact will be described. d) Evaluation: Impact of this model includes analysis of injection number of clients enrolled, number of consultations, and the number of referrals. e) Management: Systems for IVDU who are at risk for TB and who may be infected with HIV.

W.A.P.111 SHORT AND LONG TERM RESULTS OF AN AIDS PREVENTION PROGRAM
Miller, Tim; Broome, C.*; Flowers, J.**; and Iversen, J.***
*AIDS Response Project, Garden Grove, CA; **University of California, College of Medicine, Irvine; ***Chapman College, Orange, CA, U.S.A.

Objective: While there has been a growing number of AIDS prevention programs reported to the literature, few have contained outcome results and none have reported follow-up data.
Methods: Employing a 21 Item AIDS Prevention Test (APT) designed by the authors, which has previously demonstrated both reliability and Form A, B equivalence, 102 St in 10 successive Stop AIDS Workshops were invited to participate in a 3 month follow-up program. All St took Form A of the test prior to the workshop and Form B after. 50 agreed to retake Form B 3 months, 27 actually returned the follow-up test. 25 of the follow-up St also returned a Form B evaluating them, filled out by their significant partner.
Results: The 27 St demonstrated increased knowledge (70.0 to 81.6) correct (1.90 to 1.2), p < 0.05), a positive change in AIDS related attitudes (27.56 to 29.89, t(26)=2.84, p < 0.004 (25 possible)), and a positive change in intended sexual behavior (18.00 to 22.56, t(26)=3.12, p < 0.001 (23 possible)) from pre to post workshop. At 3 months, the St showed increased positive change in attitudes (11.56, t(26)=4.91, p < 0.001) a slight reduction in actual behavior from pre-workshop to follow-up was still significantly positive (16.00 to 19.66, t(26)=3.94, p < 0.001). The 13 tests filled out by partners verified the St self reported attitudes (33.00) and behavior (19.50). There were no significant correlations between knowledge, attitudes and behavior per se, but correlations between changes in these three were significant.

W.A.P.113 OUTCOME OF HIV PREVENTION AND COUNSELING AT COOK COUNTY HOSPITAL, ILLINOIS: A TWO YEAR FOLLOW-UP
Belcher, E., Gales, E., Wita, E., Heller, L., Shyne, B., et al.
The Cook County Hospital, 1201 North Dearborn, Chicago, Illinois, U.S.A.

Objective: To evaluate the 1983 experience of a public hospital-based AIDS education and risk reduction program, and determine the year trends in client demographic data and counseling outcomes.
Methods: Between November, 1981, and December 31, 1982, 1188 persons at risk of HIV infection received HIV prevention counseling. In 1981, 2384 people were counseled. Of these, 1,311 (55%) were 19-29 years old (18.1%) were female (18.1%), were employed (19.1%), were African American (18.1%), Hispanic (1.84%), Asian (1.38%), American Indian, or 18 (1.84%) were of other ethnicity. By risk behavior, 201 (17.8%) were gay/bisexual men, 21 (1.8%) were prostitutes, 801 (67.8%) were heterosexual men, 27 (2.3%) were female prostitutes, 17 (1.4%) were partners of abuse, 19 (1.6%) were partners with multiple partners, and 11 (0.9%) other.

Results: Needs in 1982 are shown by table and were from 1981-1982 in table II.

TABLE I. QUARTER OF 1982		TABLE II. 1981 - 1982	
SEX	AGE	1981	1981-1982 %
MALE	18-29	72	100
FEMALE	18-29	32	47.2
EMPLOYED	18-29	32	47.2
AFRICAN AMERICAN	18-29	32	47.2
PROSTITUTE	18-29	32	47.2
MULTIPLE PARTNERS	18-29	32	47.2
OTHER	18-29	32	47.2

In 1981, 1,311 (55%) of those counseled received HIV prevention counseling. In 1982, 1,188 persons at risk of HIV infection received HIV prevention counseling, reaching 2,499 clients at risk of HIV infection at Cook County Hospital, of whom 84.4% were HIV negative and 15.6% were HIV positive. A majority of clients reported significant behavior change resulting from the interventions at health follow-up.

W.A.P.114 APPLICATION OF METHODS/RESULTS FROM FAMILY PLANNING OPERATIONS RESEARCH TO AIDS PREVENTION IN AFRICA
Hamer, Maria L., Columbia University, N.Y., USA.

OBJECTIVES: To apply operations research (OR) methods derived from family planning to develop effective processes for prevention of sexual transmission of HIV in Africa.
METHODS: Family planning OR has developed and tested culturally appropriate, cost-effective strategies to increase access to and acceptability of contraception, including condoms, in Africa. To collect data for program development and monitoring, OR uses methods from epidemiology, demography, anthropology, and market research. **RESULTS:** OR projects identified unexpectedly high levels of contraceptive knowledge among males and females in African countries (knowledge levels above 80% in urban Niger and Burkina Faso, over 40% in rural Côte d'Ivoire and Senegal) and increasing use of methods, including condoms. Data have been used to develop innovative educational and contraceptive delivery systems such as distribution in Lagos markets and by traditional midwives in Sudan, where contraceptive prevalence rose from 9% to 26% in rural areas. OR is currently being applied to an AIDS education program in Rakai, Uganda, and elsewhere. **CONCLUSIONS:** OR is effective in the field of reproductive education and contraceptive delivery in Africa. Like AIDS prevention, family planning touches on controversial and sensitive issues, including changes in sexual practices and condom use. OR will be useful in promoting behavior change and condom use for AIDS prevention.

W.A.P.116 SEXUAL BEHAVIOUR OF YOUNG ADULTS AND THE EFFECTS OF AIDS PREVENTION CAMPAIGNS IN SWITZERLAND

Ziegler P., Dubois-Arber F., Lehmann Ph., Institut Universitaire de Médecine sociale et préventive, Lausanne, Suisse, ** IPSO, Zurich, Suisse.

This study is part of the overall evaluation of the Swiss prevention campaign. **Objectives:** To measure the effects of the prevention program within the 17 to 30 years old resident population in Switzerland. To identify indicators measuring efficacy of prevention campaigns. **Methods:** Interviews by phone on the basis of a standardized questionnaire. Interviews are designed to obtain valid responses regarding questioning within the intimate sphere despite others standing by. The quota sampling design is stratified by place of residence (N = 3 times 1200). Data have been collected at three points in time: February 1987 (t0) before the launching of the first STOP-AIDS campaign, October 1987 (t1) nine months thereafter and October 1988 (t2) eighteen months thereafter. **Results:** The proportion of people having had occasional sexual contacts out of a monogamous relationship within the previous six months remains stable (86% at t0, 14% at t1, 15% at t2). However, the use of condoms during occasional sexual relationship has increased significantly: the proportion of people saying that they never use condoms declines (67% at t0, 56% at t1, 13% at t2). At the same time occasional usage increases (25% at t0, 45% at t1 and 58% at t2), so does consistent usage (9% at t0, 17% at t1 and 29% at t2). Beyond this observations other aspects of sexual behaviour confirm the tendency towards safer sex. **Conclusions:** Young adults in Switzerland are the more and more numerous to protect themselves against AIDS in situations carrying a potential risk of HIV contamination.

W.A.P.118 MORE THAN ONE TYPE OF HIV EDUCATION AND TESTING PROGRAM IS NECESSARY TO REACH SELECTED TARGET POPULATIONS IN LARGE CITIES

Duetsch, A., Flynn, M., Hesse, P., Jain, S., Webb, D., Adams, G., ** University of California Davis, Sacramento County Health Department, ** AIDS-STOP Task Force, Sacramento, CA, U.S.A.

OBJECTIVE: To compare the populations being tested for HIV-1 in a hospital setting, an Alternative Test Site (ATS) and Drug Treatment Program (DTP). **METHODS:** Demographic information was recorded from medical records of patients tested in the hospital, exclusive of AIDS Clinic, from 1/86 - 8/87. Records of IV drug users were reviewed in detail. Information regarding ATS and DTP outlets was obtained from the County Health Department (CHD) and our education/prevention program for IVUO (EPP). **RESULTS:**

	Hospital	ATS	DTP
Total	1169	9.5%	88.1%
Male	48	84.0%	2927
Female	31	5.7%	253
MSP/Prostitutes**	16	12.5%	2754
Transfusion Recipients	17	7.4%	127
Sex Partner of the above	1648
Undiagnosed	480
Others	120	24.0%	2

CONCLUSIONS: Different populations are tested at different test sites. Access to all test sites is essential to reach different risk groups in large numbers with education and testing programs. They are complementary.

W.A.P.115 DETERMINANTS OF AIDS POLICY PREFERENCES OF THE GENERAL PUBLIC
Gomez-Danig and Trigueros, M.*

*University of Michigan, and **University of Murcia, Spain.

Objective: To analyze factors associated with preferences for alternative public policy options related to the behavioral control of AIDS.
Methods: Responses were from 1540 adults interviewed by telephone in the 1987 Chicago sex General Population Survey for AIDS in International Conferences on AIDS, October 16-20, 1987. Determinants of responses to the 16 questions relating to endorsement of specific policy alternatives included demographic variables, self-assessment of AIDS risk status, and attitudes toward homosexuality.
Results: Factor analysis revealed three clusters of policy options preference: employment-based testing program, government-sponsored education and service program, and compulsory public health measures. A unique combination of sociodemographic and attitudinal characteristics predicted each set of preferences. In all three cases, the level of educational attainment was the strongest predictor of policy preferences.
Conclusions: Public information programs should consider the role of attitudes toward homosexuality as they strongly influences the formulation and use of new information about AIDS. Furthermore, public policy makers need to be aware of the power of attitudinal components of public support for various AIDS policy options.

W.A.P.117 EFFECTIVENESS OF THE SWISS AIDS PREVENTION CAMPAIGNS IN 1987

Hamer, Dominique; Dubois-Arber F., Lehmann Ph., Ostypeller F., Institut de Médecine sociale et préventive, Université de Lausanne, FPM, Zurich, Suisse.

Under the slogan STOP-AIDS, a national multimedia campaign is continuously conducted by the Federal Office for Public Health since 1986. Equivalent efforts are made stimulating multipliers to develop specific or local preventive actions. This program also includes a continuous and independent evaluation which has - to measure behaviour changes, to identify factors which have positive or negative influences on changes, - to propose corrections or adaptations which could improve campaigns. Conclusions are based on 20 intercomparative studies conducted in 1988 involving nearly 4000 persons of various parts of the population: **Knowledge on AIDS (HIV transmission and protection) are good.** There is still doubts on what is not dangerous (risk with saliva or blood transfusion in Switzerland). **Health professionals generally overestimate their professional risk.** This creates fear and further suspicious attitudes to some patients. **There is no stigmatization.** Despite an apparent social consensus of non discrimination, casting out of persons are unfortunately observed occasionally. **Adoption of protective behaviour is in progress but still difficult.** It's often related with emotional dimension of relationship. Condoms sale slowly increase (less than in 1987). **Messages are clear,** range general population and target groups. Number of peripheral preventive actions have been developed, but still few efforts have been done for IVUDs. Social and health professionals have played very little preventive role.

W.A.P.119 HIV CAN SEROPREVALENCE SURVEY DATA BE USED TO MANAGE HIV PREVENTION PROGRAMS?

ONATEL, Lima; Jones, T.S.; and Forrester, W.* AIDS Program and Center for Prevention Services**, Center for Disease Control (CDC), Atlanta, GA, USA.

Objective: To guide health departments in utilization and limitations of CDC Family of Surveys (FOS) data in managing HIV prevention programs. **Methods:** We analyzed survey methodology and procedures to assess potential biases in each type of survey data. Considering these limitations, we suggested appropriate use of different types of public health programs. A communication system for dissemination of data is proposed. **Results:** No single seroprevalence survey is representative of the entire population. Biases were identified in each type of survey. Characterization of the population surveyed and adherence to standard CDC protocols will minimize biases. In prevention programs, CDC FOS data may be used in allocating resources and in determining the types of education, counseling and testing services offered. Over time, data will be useful in following trends in HIV infection and in evaluating the impact of prevention activities. Success in reaching infected persons may be measured by comparing seroprevalence rates in unlinked surveys with voluntary testing in the same population. Consultants in health departments and at CDC form a network for disseminating data to health care providers and program managers. **Conclusion:** FOS seroprevalence data will be a valuable tool in the surveillance and prevention of HIV infection. Awareness of the survey biases and in interpreting data is essential. Dissemination services is needed so prevention programs can access and utilize data effectively.

Autres rétrovirus : HTLV-I et HTLV-II Other Retroviruses: HTLV-I and HTLV-II

Th.A.P.1 PREVALENCE OF HTLV-I/II INFECTION AMONG MALE INTRAVENOUS DRUGUSERS AND THEIR SEXUAL PARTNERS IN OSLO, NORWAY. Joseph R. Puckett, C.T. Schaaf, R. Schaefer, M. J. Schroer, D. J. Berens, W.T. Hines Veterans Administration Hospital, Hines, Ill., *Oslo Diagnostic Services, N.O., *U.S.A.

Objective: To determine the prevalence of HTLV-I and HTLV-II infection in 150 HIV-1 and 19 of their sexual partners. **Methods:** HTLV-I and HTLV-II were detected by repetitively reactive ELISA was confirmed by Western Blot, demonstrating antibody to 22 antigens. Results: The prevalence of antibody to HTLV-I was 8.6651(7/150) for the patients and 5.2651(1/19) among the sexual partners. Only 10 patients (6.66%) had antibody to HTLV-II. Only 1 couple of 19 was noted to be antibody positive for HTLV-II by repetitively reactive ELISA. However, on Western Blot assay, the patient's sera reacted with only 1 antigen, while his non-drug abusing spouse was confirmed positive. There were no statistical differences in the incidence of sexually transmitted diseases (STD) among the HTLV-I positive patients as compared to either the HIV-1 positive patients or to serologically negative control group drawn from the same population. Only one patient was positive for both HTLV-I and HIV-1 as confirmed by Western Blot. CD4/CD8 lymphocyte ratios in HIV-1 infected patients (0.46±0.15) were significantly lower than ratios for HTLV-I infected patients (1.74±0.17) (p=0.006) for non-infected control patients (1.36±0.13) (p<0.001). Absolute CD4 lymphocyte counts were significantly lower among HIV-1 infected patients (802±225) as compared to HTLV-I (888±23) (p<0.02) and control patients (1659±274) (p<0.001).

Conclusion: Prevalence of HTLV-I in our non-endemic geographic area was greater than that of HIV-1 in our cohort of patients. Infection with HTLV-I was independent of HIV-1 infection or STD's.

Th.A.P.3 HTLV-III EN FRANCE METROPOLITAINE
Lemire, Jean-Marie*, Costa, J.P., Courouce A.M.**, et le
Groupe Rétrovirus de la Société Nationale de Transfusion
Sanguine.

*CHTS - 34010 Montpellier, France. **CHTS - 75015 Paris, France

Objectif: Estimer la diffusion de l'HTLV-III en France métropolitaine.
Méthode: 4797 échantillons sériques (2319 donneurs de sang et 2478 sujets à risque ont été collectés en France métropolitaine. Les dépistages ont été réalisés par un test d'agglutination ou des tests immunoenzymatiques. Les sérums positifs étaient confirmés par immunofluorescence indirecte et Western Blot.

Résultats:

Sujets	Nombre	Anti HTLV-III positifs
I. Donneurs de sang		
- Caucasiens	1274	0
- Originaires de zones endémiques	1045	7
II. Sujets à risque		
- Polytendus	307	0
- Consultants pour MST	401	0
- Toxicomanes	1690	0

Conclusion: Les sujets contaminés par HTLV-III ont été retrouvés chez les toxicomanes (79/1000) et les donateurs originaires de zones endémiques (79/1000). La diffusion en France est donc rare, mais une surveillance régulière s'impose.

Th.A.P.5 HTLV-I SEROPREVALENCE IN PARTNERS WITH HIV AND SEROLOGIC DISEASE, OTHER RISK GROUPS, AND BLOOD DONORS IN JAPAN.
*Houston, Texas, **Houston, C., **Memphis, J., **Smith, H., *Leif
A. *University of Illinois and **Blood Transfusion Service, Newark, Zimbabwe.

Objective: HTLV-I is associated with T-cell tumours and tropical Spastic Paraparesis (TSP). Relatively high prevalence are reported from several African countries. Little data has been published in Zimbabwe. **Methods:** Commercial ELISA kits were used for HTLV-I and HIV testing. Only strongly reactive specimens are reported here.

RESULTS

	No.	%pos.	%
Normal blood donors, several regions of Zimbabwe	931	1	0.1
Leukemia patients	6	0	0
Macrophilia (multi-transfused)	23	0	0
HIV-negative patients with serology from the WHO clinical AIDS criteria.	88	0	0
HIV-seropositive patients with neurologic disease	11	2	16.2
HIV-seropositive patients with neurologic disease	21	1	4.8
Of which 2 were typical TSP, both HTLV-I neg	1050	4	0.4

Of these patients with HTLV-I and neurologic disease:

- 1) 53 y.o. HIV-positive man with myelopathy progressing over 3 months.
- 2) 21 y.o. HIV-positive woman with probable nonster transverse myelitis and subsequent progression of neurologic deficits.
- 3) 38 y.o. HIV-negative woman with a 3 year history of spastic paraparesis. Other causes were not fully excluded in this patient.

CONCLUSIONS: HTLV-I appears less common in Zimbabwe than other African countries. It is strongly associated with neurologic disease. Possible association with leukemia or HIV infection requires further study.

Th.A.P.2 SCREENING FOR HTLV-I ANTIBODIES AMONG FINNISH BLOOD DONORS, HEMOPHILIACS AND HIV-SUSCEPTIBLE PATIENTS. P. Leinikki, E. Miettinen, J. Kallioinen, J. Leinola, H. Brunner-Korenkovic and M.-L. Kantanen. National Public Health Institute, and the Finnish Red Cross Blood Transfusion Service, Helsinki, Finland.

Objective: To evaluate HTLV-I screening among blood donors. **Methods:** Serum samples from blood donors (N=1803), hemophiliacs (N=196), patients of health care centers (N=676), AIDS information and support centers (N=446), i.v. drug abusers and inmates were tested using HTLV-I ELISA test (Du Pont, USA). Confirmatory tests were done by WB (Du Pont, USA). Indirect immunofluorescence and passive agglutination of gelatin particles coated with viral antigen (K. Okochi, Kyushu University Hospital, Fukuoka, Japan). **Results:** No true positive cases were found. Nine sera were repeatedly reactive in the ELISA test. None of them gave a characteristically positive reaction pattern in WB but showed reactivity against individual components of the virion. The reactive sera came from hemophiliacs (1), healthy blood donors (4), health care center patients (4) and AIDS information and support centers (1). The final result was confirmed by immunofluorescence and passive agglutination. **Conclusion:** HTLV-I screening is not warranted among blood donors in Finland at the moment. The atypical reactivity, sometimes interpreted as an indication of a HTLV-I related retrovirus and earlier reported from patients with lymphomas or leukemias was also found among healthy blood donors.

Th.A.P.4 PREVALENCE OF HTLV-I ANTIBODIES IN HIV-1 INFECTED PATIENTS IN A MEMORIAL COMMITTEE IN THE BROOKLYN, NY. Bauer, Stanley* Amari, L. and Ernst, J. The Bronx-Lebanon Hospital Center, Bronx, NY, USA.

Objective: To determine the prevalence of HTLV-I infection in an HIV-1 infected inner-city population. **Methods:** Anonymous sera (classified by age, sex, and race) and positive by HIV-1 ELISA and WB were tested by HTLV-I ELISA and WB. HIV-1 ELISA negative control sera were tested by HTLV-I ELISA. HIV-1 positive sera were from clinic outpatients, emergency room patients, and inpatients with no factors which met exclusion criteria of the CDC Sentinel Hosp. Program. HIV-1 negative sera from the hospital population served as controls. **Results**

SOURCE PATIENTS	HIV-1 POS	% HTLV-1 POS
Sentinel Hosp.	394	28%
Clinic	58	21%
Emergency Room	24	50%
Control (HIV-1 NEG)	172	8%

Conclusion: HTLV-I infection has spread more widely in inner-city minority groups than has been previously documented. Study partially supported by the CDC Sentinel Hospital Program.

Épidémiologie et santé publique Epidemiology and Public Health

Th.A.P.7 **HELIX-I ANTIBODIES IN THE SOLOMON ISLANDS.**
Murray, Daniel B., Koolman, St. View, Jr., and Mahalingam MK.
University of California, Davis Medical Center, Sacramento, CA, USA and
Oswego University School of Medicine, New Haven, CT, USA.

Objective: To determine the extent of HELIX-I infection in the Solomon Islands.

Methods: We tested 1,317 random individuals over the age of 5 using ELISA (Cellular Products, Buffalo, NY and Dupont, Wilmington, DE) as a screening test. We used enzyme from Hillwood Biologicals (Cupertino, CA) to prepare Western Blots (WB) as a confirmatory test.

Results: The prevalence of antibody interactive with HELIX-I by ELISA was 12.9% (96/716) in the North Solomons Province (Papa New Guinea) and 14.6% (89/601) in Malaita Province (Solomon Islands). However, in the North Solomons Province samples of 51 of 90 samples positive by ELISA were positive by WB. Thirty four were negative and 51 were indeterminate, usually showing faint p19 or p24 cross-reactivity.

Conclusion: Although there is a high prevalence of antibody interactive with HELIX-I by ELISA in the Solomon Islands, few HELIX-positive samples were also positive by WB. These puzzling results may reflect problems with HELIX-WB testing, cross-reactivity with immune complexes, or the existence of an antigenic variant of HELIX-I or a novel serotype in this area of the South Pacific.

Th.A.P.8 **LACK OF HTLV-IV INFECTION IN NON-IV DRUG USING HIV SEROPOSITIVE MEN IN LOS ANGELES**
Aboukhalil, Elmad, Miyazaki, T., Shimo, D.J.,
Division of Hematology, UCLA Department of Medicine, Los Angeles, California.

Objective: To determine the seroprevalence of HTLV-IV infection among HIV seropositive men.

Method: 634 sera obtained from Western blot confirmed HIV seropositive men seen at the UCLA AIDS Center between 1984 and 1988, were subjected to radioimmunoassay (RIA) using an HTLV-IV-infected human T-cell line (2B-1). Sera obtained from known Japanese adult T-cell leukemia patients and unaffected healthy individuals served as positive and negative controls. Groups studied: 1) Asymptomatic (N=13); 2) AIDS Related Complex (N=15); 3) Kaposi's Sarcoma (N=300); 4) AIDS defining opportunistic infections (N=76); and 5) high grade lymphoma (N=12). Only 2 patients were known I.V. drug users. Results: None of the tested sera were positive for antibodies to HTLV-IV. In common, using identical methods, we previously reported that 3.1% of sera collected from a group of 1000 (N=107) in Los Angeles harbor antibodies to HTLV-IV(1). Seropositive females used I.V. drugs or were found to have frequent sexual contact with I.V. drug using men.

Conclusion: By using a sensitive and specific assays that we have employed extensively in HTLV-I endemic areas, we find, in opposition to previous studies, that HTLV-IV infection is undetectable among selected seropositive homosexuals who do not engage in I.V. drug usage (2). Furthermore, no cross reactivity between HTLV-IV and HIV p24 gag gene products was seen using RIA analysis. Additional studies looking at the seroprevalence and significance of HTLV-IV infection in broader based populations at risk for seroreactive status are in progress.

References: (1) *Blood* Vol. 72, No. 5, Suppl. 1, 1988. (2) *Virology* Vol. 150, 1986.

Th.A.P.9 **HIV-1 AND HTLV-I SEROPREVALENCE IN CRITICALLY ILL RESUSCITATED EMERGENCY DEPARTMENT PATIENTS.**
Lewin, A.; O'Ryan, A.; Rivers, J.; Pohod, D.; Belan, B.; and Saravolatz, Louis D., Henry Ford Hospital, Detroit, Michigan, USA.

Objective: To determine the HIV-1 and HTLV-I seroprevalence and demographic features among critically ill emergency department (ED) resuscitated patients in a low HIV-1 seroprevalence area.

Methods: Patients who required resuscitation had an anonymous questionnaire completed by their physician. Sera was obtained and tested by ELISA. Repeatedly reactive samples were confirmed by IFA for HIV-1 and both Western Blot and RIPA for HTLV-I.

Results: Between 9/24/88 and 1/15/89 there were 25,378 ED visits. Patients SIGMET reflected the demographics of a Detroit inner city hospital ED. Seventy-nine percent (257/325) of eligible candidates were enrolled with a mortality of 25.3% (65/257).

	n	HIV-1	HTLV-I
Trauma (blunt or penetrating)	144	4.3% (7/144)	1.4% (2/144)
Medical Resuscitation	113	4.4% (5/113)	2.7% (3/113)
Total	257	4.7% (12/257)	1.9% (5/257)

Intravenous drug use was determined by history in 7/17 and by physical examination in 8/17 retroviral infection patients.

Conclusion: Health Care workers in a low HIV-1 seroprevalence area are at risk for HIV-1 and HTLV-I exposure during the resuscitation of the critically ill ED patient. Identification of known high risk groups occurs in approximately one-half of patients, emphasizing the need for strict adherence to universal precautions.

Th.A.P.10 **HIV-1 AND HTLV-I INFECTIONS IN INTRAVENOUS DRUG USERS (IUDUS) IN DETROIT 1985-1989.**
Lewin, A.; Mironov, S.; Pohod, D.; Lee, H.; Saravolatz, Louis D.; et al., Henry Ford Hospital, Detroit, Michigan, USA, and AIDS Laboratories, W. Chicago, Illinois, USA.

Objective: To monitor the seroprevalence of HIV-1 and HTLV-I and examine the HIV-1 infection free survival time in IUDUS who were followed from 1985-89.

Methods: Consecutive serologically unknown IUDUS seeking medical care for conditions unrelated to HIV were eligible to participate. After informed consent an anonymous questionnaire was completed and sera obtained. Serum specimens were tested by ELISA and repeatedly reactive samples were confirmed by IFA for HIV-1 and Western Blot and RIPA for HTLV-I.

Results:

Year	n	HIV-1	HTLV-I	HIV-1 and HTLV-I	HIV-1 or HTLV-I
1985-1986	86	12.3% (12/86)	9.3% (7/74)	3.2% (2/70)	22.5% (16/70)
1988-1989	71	15.7% (11/71)	10.0% (7/70)	4.2% (3/71)	18.3% (13/71)

Seropositivity was not associated with risk reduction practices, prostitute contact, or duration of drug use. IUDUS who traveled to metropolitan New York were more likely to be HIV-1(+) than those who did not (p<0.05). The HTLV-I attack rate was higher in HIV-1(+) or HIV-1(-) drug users (p<0.05).

Conclusion: During 1985-89, the prevalence of antibody to HIV-1 and HTLV-I was relatively stable among Detroit IUDUS. Travel to an endemic area increased the risk of acquisition of HIV-1. Since coinfection exceeded the expected frequency, HIV-1 and HTLV-I transmission may not be exclusively independent.

Th.A.P.11 **PREVALENCE OF HELIX-I ANTIBODY IN SELECTED MEN IN LOS ANGELES AREA**
Murray, Daniel B., Koolman, St. View, Jr., and Mahalingam MK.
University of California, Davis Medical Center, Sacramento, CA, USA and
Oswego University School of Medicine, New Haven, CT, USA.

Objective: To determine the seroprevalence of HELIX-I in men with high risk behavior.

Methods: Sera were collected from men with the history of multiple male sexual partners and analyzed for HELIX-I and HIV antibodies. Medical history and other data were obtained from the questionnaire forms completed at the time blood was drawn for testing.

Results: We have previously reported that 8% of men with multiple male sexual partners were positive for antibodies to HIV (1). Now we report that 14% (14/100) of men with multiple male sexual partners were positive for antibodies to HELIX-I. In addition, 14% (14/100) of men with multiple male sexual partners were positive for antibodies to HELIX-I. All sera that reacted in the HELIX-I-ELISA recognized specific HELIX-I proteins of p19, p24, p25 and p26 in the immediate. The ages of seropositive men ranged from 18 to 60 years and all had multiple male sexual partners for several years. Physical examination did not reveal lymphadenopathy or other symptoms. Use of the HELIX-I-positive men were black, one Hispanic and 6 Caucasian. None of the men had a history of blood transfusion or received any blood product.

Only 2 of 10 seropositive men admitted use of intravenous (IV) drugs.

Conclusion: We report a high prevalence of HELIX-I infection in men with multiple sexual partners. Since only 1 of the men had used IV drugs, it is evident that HIV was transmitted sexually. Although one of the men showed an HIV-1(+), close at the time their blood was tested, a prospective study would be important to relate HIV-1 infection with any disease that may develop in the future.

Th.A.P.12 **HTLV-III INFECTION IN AN INNER-CITY EMERGENCY DEPARTMENT**

Alan, Gilbert*, DiGirolamo T**, Lofy L*, Silvestro R*, Quinn T.**
*Johns Hopkins University, Baltimore MD, **AIDS, KEM, Bethesda, MD, USA.

Objective: To study the epidemiology of HTLV-III in a population known to have a high rate of HIV-1 infection.

Methods: Random serum samples drawn from 2944 consecutive adult patients presenting to an inner-city emergency department in Baltimore were tested for HTLV-III and HIV seropositivity by ELISA and confirmed by Western Blot (WB).

Results: We found 19 (1.3%) HTLV-III positive and 98 (3.3%) HIV positive. Of the 153 of the patients (6.8%) were 80 seropositive to HTLV-III, only 3 patients (all IV drug users) had concurrent infections. The age range among HTLV-III seropositive patients was 20 to 66 years old, with half the patients greater than 50 years old. The age distribution of HTLV-III infected individuals matched that of the patient population. In contrast, HIV was concentrated among those 25-44 years of age (p<0.05). Of the HTLV-III seropositive patients, 93% (28) were black, 48% (16) were male and only 77% of the patient population (p<0.05). Only black, African blacks made up 97% of the HTLV-III seropositive patients and 5 were transfusion recipients. One other patient's only potential known source of infection was associated exposure to an HIV infected partner. All but one of the HTLV-III infected patients lived in the surrounding neighborhood implying that HTLV-III was not likely imported from the Indian. The HTLV-III infection was not confirmed. Although the prevalence of HTLV-III in the United States has been estimated to be 0.04, HTLV-III may be more prevalent in certain areas of the U.S. than previously thought. Sexual transmission does seem to play a major role in HTLV-III infection. The data support the hypothesis that HTLV-III and HIV are relatively independently transmitted diseases.

Th.A.P.19 HIV-1 AND HIV-2 INFECTIONS IN IMPRISONED HIGH RISK GROUPS OF BARCELONA.

Theo Ramos, A. Clotet, F. Puig, H. Infectious Diseases Unit and Blood Bank Unit, Hospital de Infectious Diseases "German Trias i Pujol", Universitat Autònoma de Barcelona, Barcelona, Spain.

Objective. To evaluate the prevalence of HIV-1 infection among intravenous drug abusers (IDU) in an area where a high incidence of HIV-1 infection has been described previously in this risk group.

Methods. This serology protocol was for the first time between January 1989 and December 1989 in our hospital, were tested by ELISA for the presence of anti-HIV-1 and anti-HIV-2 antibodies. Western blot was used as confirmatory test in repeatedly reactive samples.

Results. During the study period, 473 IDU serum samples were screened and the overall HIV-1 and HIV-2 antibody prevalence was 70.0% and 0.4%, respectively. The seroprevalence rates were stable during the study period. Confirmation was detected in all cases with HIV-1 antibodies.

Conclusion. This in our case represents an important reservoir for HIV-1 infection, but a role dated to a low prevalence of HIV-2 antibodies. For both retroviruses the total figures did not change throughout the four-year period.

Th.A.P.20 HIV-1 ANTIBODIES AMONG PRISON INMATES IN NORLAND

Vilhoor, David*, Taylor, E.*; Wisniewski, C.*; Tanner, C.*; McFarley, M.*; Hillier, T.*; Nokes Hoodley, School of Hygiene and Public Health, Baltimore, MD, USA *Abbott Laboratories, North Chicago, IL, USA

Objective. To identify prevalence and risk groups for HIV-1 infection among inmates entering prison.

Methods. Specimens routinely obtained during intake evaluation of 1,000 consecutive male inmates, excluding repeat offenders, entering Maryland prisons during the same time period in 1987 and 1988 were assayed for antibodies to HIV-1 by EIA. Repeat reactive samples were confirmed by Western blot and HIVPA. Demographics were compared by serostatus using non-parametric statistics.

Results. Among 1933 inmates, 19 (1%) were repeatedly reactive by EIA.

GROUPS	NUMBER	M/FS	REPEATABLY REACTIVE	P VALUE
RACE: Black	1396	19/11(45)		<0.001
Non Black	537	0/0(0)		
AGE: <25	1070	18/1(1.7)		<0.001
25-35	863	1/0(1.1)		
YEAR: 1987	800	5/0(0.6)		
1988	1033	14/1(1.4)		0.06

Reactivity to HIV-1 did not vary significantly by HIV-1 serostatus, jurisdiction, offense category.

Conclusion. Unlike HIV infection in this population (7.0%), approximately 1% was infected with HIV-1, occurring most in blacks over 25 years of age. The seroprevalence rate of HIV-1 in prison inmates is 5-10 times higher than in normal U.S. populations.

Th.A.P.21 HIGH RISK OF CONFIRMED HIV-1 INFECTION

AMONG INTRAVENOUS DRUG ABUSERS (IVDA) FROM NEW ORLEANS

Leo Helms*, Swanson, P. J., Shorty, V.,*., Chack, J.***; Rosenblatt, J.***; and O'Connell, T.*** *Abbott Laboratories, W. Chicago, IL; **Oxoid Harcourt, Weybridge, New-Orleans, LA; ***CLA School of Medicine, Los Angeles, CA, U.S.A.

Objective. Determination of HIV-1/II infection in New Orleans IVDA.

Methods. (1) Serum from 121 IVDA were tested by EIA, Western blot and HIVPA for antibodies to HIV-1/II. (2) Lymphocytes from 27 of 121 IVDA were analyzed by PCR. HIV-1/II sequences were differentiated via restriction and sequence analysis. (3) Viral cocultures were done using lymphocytes from 9 EIA positive IVDA and 20 negative EIA low risk individuals. Reverse transcriptase (RT) and immunofluorescence (IF) with monoclonal anti-p24 and anti-p26 were used to monitor viral expression.

Results. (1) Serum samples from 54 of 121 IVDA were EIA positive, 33 of which were confirmed by Western blot and/or HIVPA.

(2) EIA WESTERN BLOT/HIVPA PCR: HIV-1 + HIV-1 + HIV-1 + HIV-1 +

23 Positive IVDA 16 Confirmed 2 16 0

4 Indeterminate 4 0 0 1

4 Negative IVDA 1 Negative 0 1 0

4 Negative 4 Negative 0 0 0

20 Negative Donors 20 Negative 0 0 20

(3) RT/IF COCULTURES of EIA and IVDA lymphocytes were positive by RT. At 6 weeks of culture, 8 of the 8 cocultures were also positive by RT.

Conclusion. A cohort of 21 HIV-1 positive individuals has been identified to New Orleans. This represents the largest HIV-1 cluster confirmed by a combination of virological and molecular genetic methods.

Th.A.P.22 HIV-1 INFECTION IN SPAIN

Soriano, J., Abella, I., Tor, J., Flores, A., Clotet, B., Ribera A. Infectious Diseases Unit and Service of Hospital de Badalona "German Trias i Pujol", Barcelona, Spain.

Objective. To evaluate the prevalence of antibodies against HIV-1 among people at risk for this viral infection.

Patients and methods. We studied serum samples of 682 intravenous drug abusers (IVDA), 53 hemodialysis polytransfused patients, 3 subjects diagnosed of Toxic Spastic Paraparesis (TSP) and 102 West Africans living in Barcelona since 1982. Antibodies to HIV-1 were investigated by ELISA and repeatedly reactive samples were studied by Western blot.

Results. See table.

	IVDA	Polytransfused	TSP	West Africans
*ELISA + (357/682)	27/682	3/53	0	5/102
**ELISA Clonatec, France; **WESTERN BLOT by Point, USA	2/27	0	0	1/5

Conclusion. Our results suggest that HIV-1 infection is present in Spain among IVDA and West African immigrants. A low prevalence is recognized.

Th.A.P.23 COINFECTION WITH HIV, HTLV-1 AND HBV IN TRINIDAD AND TOBAGO

Souriana, Barbilomae*, F. Cleghorn**, E. Waller**, K. Bhattar*, *The University of the West Indies;

** The Caribbean Epidemiology Centre, Port of Spain, Trinidad;

*** The National Cancer Institute, Maryland, U.S.A.

425 consecutive HIV antibody positive sera assayed in 1986-88 were tested for antibodies to HTLV-1 and confirmed by Western blot. 42 (10.1%) were HTLV-1 antibody positive. IVDA is not practised in Trinidad and Tobago and when adjusted for age this cohort had a 5 times higher seroprevalence than the general population. 17/60 (10.6%) of HIV antibody positive homosexual men were coinfecting with HTLV-1, 9/90 (10%) of heterosexual women, while 14/58 heterosexual men (24.1%) were HTLV-1 antibody positive. Of 382 patients singly infected with HIV, 205 (53.2%) had AIDS or developed AIDS in the period 1986-88 compared with 20/42 (45%) of coinfecting patients. The hepatitis virus (HBV) closely resembles retroviruses in its molecular structure including a reverse transcriptase mechanism in its replication.

HIV DNA has been found in T-lymphocytes of HIV infected people who are core and surface antibody positive and surface antibody negative. Significantly, out of 425 HIV positive patients, 7/6 (1.6%) had triple antibodies to HIV, HTLV-1 and HBV had AIDS in the period under study. In a prospective study of 34 homosexual men who were singly infected with HIV and followed for a period of 5 years, 10 (29.4%) had progressed to AIDS, while of 6 men who were doubly infected with HIV/HTLV-1, 3 (50%) had progressed to AIDS in the same time period. 2 cases of HBV were HIV antibody positive. Further studies are in progress to assess the role of HTLV-1 and HBV as co-factors in AIDS.

Th.A.P.24 HTLV-1 IN INTRAVENOUS DRUG ADDICTS (IVDA) AND GAY MEN IN SAN FRANCISCO

Beatty, Ellen C.*, Murphy, E. J., Drummond, J.**, Baccetti, P.**, Chalko, R.**, Greenstein, J.S.*** et al., *San Francisco General Hospital, University of California at San Francisco, San Francisco, CA; **Harvard Medical School, Boston, MA; ***University of Washington, Seattle, WA

***The National Cancer Institute, University of California at San Francisco, San Francisco, CA, U.S.A.

Objective. To describe the seroprevalence of HTLV-1 in IVDA's and gay men in San Francisco comparing a commercially available ELISA with Western Blot (WB) and CN 175 purified virus. Methods: Serum samples from 809 IVDA's in methadone programs and from 383 gay men were independently blindly tested for HTLV-1 in 2 independent laboratories. Most specimens were from cross-sectional participant samples between 1982 and 1987. Additionally, longitudinal paired specimens were available in 153 IVDA participants.

Radiolabelled WB and ELISA showed similar temporal trends although the WB consistently detected more positives: 1982 12% ELISA +, 16% WB +; 1987 12.5% ELISA +, 19% WB +. By ELISA WB seroprevalence correlated with age: age <40, 8.2% age 40-50, 13.7% age 50-60, 25.9% age 60-69, 39.3% age 70 and over. Whites had fewer positive results, 10.2% vs. 21.7% blacks, and 19.6% Hispanics. Men (7.5%) were more often positive than women (4.7%). The longitudinal paired samples demonstrate reproducibility of results over time. By ELISA 21 initial positives and 6 initial negatives remained so, however 8 other initial positives were later negative and 8 other initial negatives became positive by WB. By WB 25 initial positives remained so, 14 initial negatives and 2 negatives became positive on follow-up cases. Many of the discrepant results observed between WB and ELISA were categorized as borderline by WB and of the borderline qualitative value of the ELISA.

Conclusion: For the study populations the two methods provided comparable results: the prevalence of HTLV-1 in IVDA's in San Francisco is more common than HTV, particularly in older blacks and Hispanics. Further evaluation of discrepant results is in progress with WB with HTLV2 and radioimmunoassay.

Th.A.P.43 STATISTICAL CONSIDERATIONS OF MISCLASSIFICATION OF PATIENTS AT BASELINE IN TWO AIDS CLINICAL TRIALS

Alan J. Fisher, Ph.D., Elizabeth J. D'Arcy and Betsy, V. J.***
*Hiroak, Inc., Costa Mesa, California, USA; UCLA School of Medicine, Los Angeles, California, USA; **Heron Group, Los Angeles, California, USA.

Objective: To evaluate the impact of initial patient classification in 2 studies of oral zidovudine.

Methods: Data from LAS (N=166) and ABC (N=213) patient groups were combined after a statistical reclassification of patients. The reclassification was based on covariates measured at the time of enrollment in such a way as to define 2 new groups of patients maintaining the within strata homogeneity at baseline. This analysis examined the effects of possible misclassification of patients among the LAS and ABC trials. Statistical adjustment for prognostic variables was done on a Cox proportional hazards model. Sensitivity analysis to evaluate model assumptions and protocol deviation were performed to supplement the primary analysis.

Results: The data when stratified by original study designation, statistically stratified by baseline characteristics or treated as a large group were not statistically significant. Classification is not an important determinant to the conclusion that zidovudine was effective in delaying progression to AIDS among these patients.

Th.A.P.45 ZIDOVUDINE PROPHYLAXIS FOR PERSONS WITH ACCIDENTAL PERICUTANEOUS BLOOD EXPOSURE: A DECISION ANALYSIS

Ray, Douglas L., M.D., Robert Ross School of Medicine, New York, NY, USA.

Objective: We performed a decision analysis to determine the thresholds of safety and effectiveness which would justify short-term zidovudine (AZT) administration for persons with accidental percutaneous exposure to either HIV-positive blood or blood of unknown HIV serologic status.

Methods: We used a Markov model to accommodate the short-term risks of HIV infection and AZT effectiveness and toxicity after HIV-positive blood or blood of unknown HIV serologic status. The measure studied were life expectancy and lives saved per cohort. Published data were used to estimate seroconversion rate (0.8%), rate of HIV-induced development AIDS (0.8%/year), and AIDS survival (0.06%/year). No information is available on AZT effectiveness and little is known about AZT effectiveness toxicity. Wide variations in all assumptions were made in the sensitivity analysis.

Results: For those with exposure to blood known to be HIV seropositive, the benefits of AZT outweigh the risks under all but a combination of the most skeptical assumptions of AZT safety and effectiveness. Using moderate assumptions (AZT effectiveness 30% safety 2 deaths per 30,000 AZT recipients), AZT use exceeds life expectancy by 7 weeks and averts 1% deaths per 10,000 persons exposed.

Under more optimistic assumptions (90% effectiveness and 1 AZT death per 30,000), life expectancy is extended by 6 weeks and 500 deaths averted per 10,000. However, under pessimistic assumptions (AZT effectiveness and 8 AZT deaths per 30,000), the risks of AZT minimally outweigh the benefits. Wide variations in the assumptions have little effect on the thresholds, with the exception of seroconversion in a function of the blood prevalence of HIV infection; the AZT benefits do not clearly outweigh the risks when the prevalence is below 10-20%.

Conclusions: Until the results of clinical trials are known, the decision must be based on strength of belief regarding AZT effectiveness and toxicity. Unless studies show AZT to be both highly effective and toxic, the benefits of short-term AZT outweigh risks after exposure to HIV-positive blood. AZT benefits do not clearly outweigh risks after exposure to blood of unknown serologic status.

Th.A.P.47 BLOOD EXPOSURE DURING SURGICAL PROCEDURES.

Franklin, C.***, Parfitt, C.***, Poy, D.***, Lowry, P.***, Ball, D.***, Centers for Disease Control, Atlanta, Georgia, USA; ***Grady Memorial Hospital, Atlanta, Georgia, USA.

Objective: To describe the nature and frequency of occupational exposure to blood among operating room personnel during surgical procedures in a large public hospital.

Methods: Trained observers sampled operations and recorded the type and duration of procedure, emergency nature, estimated blood loss by the patient, occupations of personnel, infection control precautions used, and number and type of exposures.

Results: One or more persons had skin, mucous membrane, or percutaneous exposures to blood during 49 (33%) of 151 operations, including 9/19 (47%) in trauma, 12/32 (38%) in orthopedic, 12/39 (31%) in gynecology, 8/35 (23%) in general surgery, 2/18 (11%) in plastic surgery, and 3/7 (43%) in burn procedures. Of 1392 personnel observed, 88 (6.3%) experienced 116 blood exposures, including 49 contacts with exposed skin (42%), 40 episodes of clothing soiling (35%), 23 exposures due to possibly defective gloves (13%), 10 needlesticks or cuts with sharp objects (9%), and 4 exposures (3%). Risk factors for exposure (relative risk, 95% confidence interval) included being a nurse (1.8), participating in an emergency procedure (3.4), 2.0-5.1, patient blood loss > 250 ml (3.6; 2.5-5.4), and duration of time in the OR (1.1; 1.0-1.2).

Conclusions: The risk of blood exposure for operating room personnel is substantial. Studies are needed to quantify this risk, identify risk factors for exposure, determine the risk of HIV infection due to these exposures, and to design and evaluate preventive measures.

Infection par le VIH chez les travailleurs de la santé HIV Infection among Health Care Workers

Th.A.P.44

GUIDELINES FOR PREVENTION OF TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS AND HEPATITIS B VIRUS TO HEALTH CARE AND PUBLIC UTILITY WORKERS
Mullen JB, Baker, Edward L, Scahy MJ, Stites PV
National Institute for Occupational Safety and Health
Centers for Disease Control
Atlanta, Georgia, U.S.A.

In response to recently enacted United States legislation (Public Law 100-607, The Health Care Workers Protection Act of 1988, "AIDS" Amendments of 1987), guidelines have been developed for all health-care and public safety workers (including emergency medical workers, fire-fighters, police, and correctional facility workers) in the United States.

The document provides an overview of the modes of occupational transmission of HIV and hepatitis B virus (HBV), an assessment of the risk of transmission under various circumstances, and a discussion of the control of risk, and specific risk control recommendations for employers and workers. Also included in this document is information relating to medical management of workers who have sustained an occupational exposure to these viruses. A separate model curriculum based on the principles and practices discussed in this document has been developed concurrently for use in training workers.

An overview of the guidelines and curriculum will be presented, with specific recommendations for preventing transmission of these bloodborne viruses to emergency medical service workers, fire-fighters, police, and correctional facility officers.

Th.A.P.46 NATIONAL SURVEILLANCE PROGRAM: OCCUPATIONAL EXPOSURE TO HUMAN IMMUNODEFICIENCY VIRUS (HIV-1) INFECTION IN CANADA Emin, Elizabeth, Hollings, J. J., Federal Centre for AIDS, Health Protection Branch, Ottawa, Ontario, Canada.

Objective: To assess the risk of HIV infection among health-care workers (HCWs) exposed to blood or body fluids from an HIV-infected person.

Methods: Eligibility criteria require a documented parenteral, mucous membrane, or skin contact exposure to blood or body fluids from an HIV-infected person. HCWs are followed for one year post-exposure and 10 blood specimens are taken at 6 week intervals for six months post-exposure and at 9, 12, and 18 months. Standard information collected include demographic, risk factors and exposure circumstances.

Results: As of January 6, 1989, 234 HCWs had enrolled in the study, 80% of which were health-care providers, 14 laboratory technicians and 44 other workers. 47% of exposures were needlestick, 44 scalded wounds, 12% eye-splash, 16% open-wound contact, and 21% skin contact. 50 (23%) of the 234 exposures were likely preventable, had standard infection control procedures been used. Excluding HCWs for whom a baseline serology (within 30 days of exposure) was not available, there have been no seroconversions.

Conclusions: These data are consistent with other studies and support a very low risk of transmission of HIV infection after routine testing and parenteral, mucous membrane, or non-irect skin exposures in the occupational setting.

Th.A.P.48 REPORT OF A POSSIBLE LABORATORY ACQUIRED HIV INFECTION.

Raley, Christine L., Reif M, Murphy P**
Dallas County Health Dept, 907 Eaststowers Bend Cr, Dallas, Texas, USA.

Objective: Case report of possible occupationally acquired AIDS.

Case Report: In 1987, a 28 year old woman was referred to evaluate for a possible HIV infection. She had donated blood in 8/82 and was HIV negative, but a donation in 5/86 was HIV positive. She was black and western birth possibly but asymptomatic until 6/78 when she developed pseudomonas pneumonia. On interview, she claimed two lifetime sexual contacts: one, before 1981, who was not tested, but thought to be healthy in 1987; and a current partner, who had no serologic evidence for HIV infection in 6/87. The woman was a technologist who worked in a clinical laboratory that was known to handle HIV positive specimens. She denied other risks including transfusions, drug abuse, and other sexual contacts. She experienced a scratch from a blood contaminated needle in 9/84 and adults to occasionally contaminating her hands with blood. She washed her hands frequently and was being treated for severe atopic dermatitis of her hands. An examination found no abnormalities except dermatitis and vesicles/lesions on her palms.

Conclusion: No discrete exposure was found in the interval between the blood donation. This woman possibly had been infected by direct inoculation in the vesicles/lesions on her hands with HIV contaminated blood in the laboratory.

Th.A.P.49 THE RISK OF EXPOSURE TO HUMAN IMMUNODEFICIENCY VIRUS AMONG HEALTH CARE WORKERS (HCW) IN A SOUTHERN U.S. JUDGE HOSPITAL - RIAL, GEORGIA: Gaumer, R*¹; Weeks, S*²; Leste, J*³; Sanders, C*⁴

¹Louisiana State University Medical Center, New Orleans, La, USA, ²Abbott Laboratories, North Chicago, IL, USA.

Objective: To assess the risk of exposure to HIV among HCW's at an Urban Hospital in the Southern United States (Charity Hospital of New Orleans).
Methods: Plasma remaining from CBC analysis of a cohort of patients presenting to the acute medical (n=246), the acute surgical (n=67) and obstetrical unit (n=221) were subjected to ELISA screening for HIV, with confirmation by Western Blot. Demographic information obtained on all patients included age, race, sex, risk factors for HIV, and type of problem. All HCW interventions with the possibility of exposure to blood or body fluids were recorded. All patients' identifiers were removed.
Results: Of 534 specimens, 11 (2.1%) were positive overall (5 men and 2 women). Rates were similar among black and white patients. Seven patients could be placed into a known risk group after interview, but only one was known to be at risk prior to some HCW intervention. None of the obstetrical patients were seropositive. Of 100 percent of trauma patients and 2.5% of medical patients were seropositive. Among men, there were similar rates of seropositivity among several age groups. At least two procedures with the potential to transmit HIV were performed per patient.
Conclusion: A substantial risk of exposure to HIV exists in the trauma and medical emergency areas. Thus, all HCW's in this region need to practice universal barrier precautions.

Th.A.P.51 SEMI-DYNAMIC BASED MODELING OF THE SPREAD OF HIV FROM BROWNSVILLE, University of Hawaii at Manoa, Honolulu, Hawaii, USA.

Objective: Describe a new approach to computer modeling of HIV and other sexually transmitted diseases spread in heterogeneous populations.
Methods: A sample of individuals closely matching the demographic and risk behavioral characteristics of a population is generated by computer and all HIV transmitting activities are simulated using distributed discrete event simulation techniques. Due to the computational intensity of this approach, these simulations are executed on parallel computers, machines with more than one processor. The result is a computerized laboratory for the evaluation of geographic, demographic, and behavioral factors.
Results: Early model simulations have been completed on a Smallbit Systems 2010 microcomputer, with more sophisticated versions in preparation. A description of the program components and input requirements is given; preliminary experiments with the models and their use in modeling HIV spread in Hawaii and Thailand are described.
Conclusions: Behavioral simulation provides a means of incorporating both geographic and demographic factors and the effects of behavioral intervention efforts into the modeling of HIV propagation.

Th.A.P.53 HIV CARRIERS: Increasing Infectivity with Progression to AIDS has Important Implications for the AIDS Epidemic among Heterosexuals. Gonzalez, Jose J*¹; Davidson, P*²; and Koch, M*³

¹ASA, N-4800 Arendal, ²ADN, N-4601 Kristiansand, ³HHU, Hergen, Bergen, N-5000 Bergen, Norway, ⁴VAC, S-546 06 Karlaborg, Sweden.

Recent evidence suggests that the degree of infectiousness increases with the duration and progress of the HIV infection. We have developed mathematical models taking into account increasing infectivity along with progression to AIDS, heterogeneous sexual behavior, import and export of persons and infections, and variable patterns of infectiousness.

The duration of both the seroconversion latency state and the interval of slight infectivity associated with it probably depends on the method of transmission and the infective dose. If this is so, then heterosexual HIV transmission is likely to be followed by a relatively long latency period, which in turn suggests that the rate currently observed for heterosexual transmission of the HIV will probably change accordingly. With the passage of time, new HIV carriers will necessarily enter the stages of increased infectiousness and thus accelerate the further spread of the HIV in a predictable way.

Th.A.P.50 CENSUS DATA AND FORECASTING OF S. AIDIS CASES FICKLING, J.G.; ROBBIN, J.S.; ZIEGL, J.S.*

¹Department of Entomology, University of Arkansas, Fayetteville, AR, USA. AIDS cases are unevenly distributed geographically. Nearly half of U. S. cases have been reported by New York and California that have less than 1/5th of the total U. S. population. Within California, over 2/3rds of cases have been reported from Los Angeles and San Francisco counties that have only 1/3rd of California's total population. Long-term epidemic forecasts should consider local differences in population size, life-style and onset of transmission. The Public-Use Microdata Samples of the U. S. census provide data on demographic and life-style variables. The A-sample is a 5% sample of the U. S. population. It has information on age, sex, marital status and relationship of individuals within households in 1154 areas that together make up the United States. Based on these data, we have estimated the relative size of populations at risk to AIDS through homosexual transmission. Using the population estimates, local AIDS incidence data, and an epidemic model, we forecast AIDS incidence from the local through national level. Although sensitive to parameter values and our assumptions, these forecasts give insight into the geographic distribution of AIDS. For example, while the incidence rate of AIDS in San Francisco and Los Angeles have been similar to date, we project that there will be ultimately 2-6 times more cases in Los Angeles than San Francisco.

Th.A.P.52 A DYNAMIC MODEL OF HIV TRANSMISSION AND AIDS IN SAN FRANCISCO

Hahnke, Herbert W., University of Iowa, Iowa City, IA, U.S.A.
Objective: To forecast HIV prevalence and AIDS incidence in the homosexual population in San Francisco using a transmission dynamics model.
Methods: The compartments in the model are seronegative and stages in the phases: HIV incubation, asymptomatic, pre-AIDS, AIDS and death. The homosexual population is also subdivided into the active and very active sexual categories with immigration, emigration and transfer between categories. The computer simulation model is a system of nonlinear difference equations with a time step of one month. The fit criteria require that the model be consistent with the a priori parameter estimates, with the reported fully-adjusted AIDS incidence from 1980 to 1987 and with the estimated HIV prevalence from 1979 to 1987. Projections are made assuming that decreases in sexual activity continue and also assuming no changes in sexual behavior after 1987.
Results: The pattern in the simulation model is that the HIV prevalence peaked at about 20,000 in 1985 (out of 56,000 homosexuals in San Francisco) and that the yearly AIDS incidence peaks at about 1000 in 1989 and decreases to less than 1000 by 1996. Although there is some saturation in the very active group, adequate fits are not obtained without changes in behavior. In the simulation the average number of new partners per month decreases by a factor of about 0.6 each year from 1982 to 1987.
Conclusion: The distribution of the AIDS incubation period with 7 stages gives the best fit in the simulation model. The simulations predict that the AIDS incidence peaked in 1989 and will decrease in the future. This pattern is primarily due to changes in behavior.

Th.A.P.54 A MULTIPLE RISK GROUP MODEL TO ESTIMATE AND PROJECT THE SPREAD OF HIV

Phillip, C. Conley*, Christopher, S*¹; Heall, D. R.* and van der Grinte, C.
¹Research Triangle Institute, Research Triangle Park; ²University of North Carolina at Chapel Hill, Chapel Hill, N.C., USA.

Objective: To describe an HIV transmission model and results of the model.
Methods: The model exhibits the following characteristics:
- all major (sexual and nonsexual) transmission routes are included.
- different transmission routes are accommodated simultaneously.
- parameters that are difficult to estimate (e.g., number and types of sexual or needle sharing contacts) are endogenous to the model, and
- results from the model can be used to evaluate intervention strategies.

The essential model features are described in four sections: estimation of initial population sizes, the algebraic representation of the dynamics of HIV, estimation of within and between risk group infection rates, and projection of the spread of HIV.

Results: National U.S. data is used to estimate model parameters and to provide 10-year projections of the course of the HIV and AIDS epidemics.

Th.A.P.55 HIV DYNAMICS IN LINKED RISK GROUPS, A MULTIGROUP TRANSMISSION MODEL. **
 Hans Gilman, M. S. Ruzhansky, M. J. C. Fox, R. A. Coutinho, ***,
 J. Buitrago,
 University of Michigan, The Netherlands, ** National Institute of Public Health and Environmental Protection (INPEM), Biltzowen; *** Municipal Health Service, Amsterdam, The Netherlands.

The HIV/AIDS epidemic is a composite of many overlapping and linked epidemics in several risk groups, each with its own dynamics and time course. The simultaneous spread of the infection is described by a multigroup transmission model. Six risk groups are distinguished: the homosexual community (two levels of promiscuity), the intravenous drug users (men and women), and the heterosexual, heterosexual men and women. Three modes of transmission are considered: anal and vaginal intercourse and needle sharing. The model helps to clarify why more data are needed to disentangle the relative contribution of the within and between group transmission routes. Given a specification of a baseline, the potential use of the model is illustrated by simulations describing effects of: a) blocking the transmission between the main risk groups and b) blocking the transmission between the main risk groups and the homosexual/epidemic runs its own course and that blocking the transmission between the main risk groups may substantially reduce the spread into the heterosexual population.

Th.A.P.57 IMPACT OF SERIAL BEHAVIOUR CHANGE ON THE AIDS EPIDEMIC
 Erling Bjørn,
 Helsebyrå, University of Glasgow, Glasgow, Scotland.

Objective: To investigate the effects of changes in sexual behaviour on HIV transmission and the AIDS epidemic.

Method: A new modelling technique is developed that permits the fast numerical solution of a HIV transmission model with multiple sexual activity levels, where the mean and variance of the number of partners per year is imposed on an arbitrary function of time. Using this, the timing and magnitude of an epidemic can be investigated under different patterns of sexual activity change.

Results: The details of the timing and magnitude of behaviour change (including the number of sexual partners each individual will on average take) dictate its value as a control measure. Although an early change is better than a later one of the same magnitude, eradication requires prolonged reduction and long-term low levels, if the disease is not to re-appear in a second epidemic.

Conclusions: Observed behaviour changes in certain sections of the community may be sufficient to cause HIV to die out locally, but unless change is made on a large scale, and on an lasting basis, further epidemics could occur.

Th.A.P.59 THE POTENTIAL FOR SPREAD OF HIV IN THE HETEROSEXUAL POPULATION IN NORWAY IN A SITUATION MORE STABLE
 Håkan Stenius, J. K. Grenvold, P. Magnus, L. M. Sande, L. Bakkeberg
 Dept. of Epidemiology, National Institute of Public Health, Norway.

To assess the potential for spread of HIV in the heterosexual population in Norway, based on sexual behaviour data, with and without input of infection from other groups.

Method: A simulation model is used. The model population is the heterosexual population (excluding IV-drug users) in Norway aged 15 to 60 years. The population is divided by age, sex and marital status. In each group the number of HIV infected subjects is calculated based on group specific values for the frequency of intercourse, the partner turnover, the pattern of partner choice, the proportion of married/cohabiting subjects eligible as sexual partners, prevalence of infection and transmission probability. The transmission probability and the AIDS hazard rate varies with time since infection. Behaviour is taken from the Norwegian study on sexual health. (random sample = 10,000, response rate 63% (J.M. Sande, this conference)).

Results: The epidemic is not self-sustained in the heterosexual population where the average transmission probability is below 1% per intercourse, and there is no input of infection from other groups. This result is insensitive towards changes in the initial conditions. It is sensitive towards changes in sexual behavior and in particular towards changes in the form of the transmission probability distribution. The simulated number of discordant couples is compared with empirical studies indicating that 1% transmission is too high. When input of infection from other groups is considered, the prevalence level is found to depend both on the influx of infection, and on the distribution of the contacts with the heterosexual population. Different source groups with different fun and contact distributions are discussed.

Conclusions: With current behavior the Norwegian heterosexual population is not likely to sustain the HIV-epidemic in isolation. Import of infection will be important in determining the prevalence level.

Th.A.P.56 ENHANCED COMPUTER MODEL OF HIV TRANSMISSION VIA NEEDLE SHARING
 Abigail David, P. Sains A.C., Lewis B **
 Trinity College, Hartford, CT ** Spectrum House Inc., Westboro MA U.S.A.

Objectives: To 1) develop quantitative descriptions of intervention measures for needle users; 2) incorporate these descriptions in a model simulating HIV transmission on the street and in jail; 3) evaluate effects of increased short- and long-term treatment center capacity and rehabilitation success rate; 4) evaluate effects of expanded testing before jail; 5) evaluate needle cleaning in jail. Parameters are to be estimated from survey data describing needle use in Worcester, MA.

Methods: Descriptions of the intervention measures are added to a preliminary model presented at the IV International Conference on AIDS. Parameters are estimated based on 1) survey data collected in treatment centers by the Worcester AIDS Consortium (6672 subjects); and 2) entry testing data for 450 inmates. We assess scenarios describing 1) improved drug treatment; and 2) increased testing and needle-cleaning, especially in jail.

Results: We establish a base run simulation which matches observed seroprevalence during 1982-89. For 1989 and beyond the base run assumes moderately high rates (30%/year) of both testing for HIV antibodies and adoption of clean needles by persons found seropositive. Relative to this base run, interventions begun in 1989 provide the following reductions in the cumulative number of AIDS cases through the year 2006: 1) doubled short- and long-term treatment center capacity and rehabilitation success—12% (2); 2) 100% testing and 100% needle cleaning by persons found seropositive—2% (3); 3) 100% needle cleaning in jail—22% (4); combination of 2) and 3) above—26%.

Conclusions: Combined intervention approaches can significantly reduce the number of projected AIDS cases in a population currently 18% seropositive. Simulation confirms that jails are reservoirs of HIV. To supplement aggressive testing and needle cleaning programs, provision of bleach in jails may be the most effective single intervention.

Th.A.P.58 MODELLING OF IMMUNE SYSTEM DYNAMICS IN HIV PATHOGENESIS: ISSUES IN IMMUNOMODULATION.

Rupert E.D. Whittier, Boston University/Tufts New England Medical Center Hospital, Boston, MA, USA.

Objective: To describe a modelling approach to the pathogenesis of HIV infection and the effects of immune-modulatory factors (e.g. stress, drug abuse, pharmacotherapy) on the dynamics of infection and the development of disease.

Methods: STELLA for the Apple Macintosh - system dynamics modelling software.

Results: System dynamics (SD) modelling exemplifies a flexible approach to understanding the pathogenesis of HIV infection, using a complex, non-linear, multi-loop, feedback simulation of the immune response to revivify infection. The approach shows itself to be of value in generating and testing causal hypotheses of pathogenesis and the effects of policy intervention based on the model's premises, even in the absence of precise data. It focuses on immune response dynamics as a consequence of the structure of the immune system rather than of the one-way effects of extraneous variables (such as HIV infection) and allows a more sophisticated approach to understanding the role of immunomodulation and co-factors in the development and prevention of disease.

Conclusions: System dynamics modelling of HIV pathogenesis affords a more thorough approach to understanding the essential details in disease development and may be useful for developing policy in the implementation of therapeutic immunomodulators and antivirals. The use of non-linear approaches to understanding pathogenesis are necessary for effective intervention development.

Th.A.P.60 EVIDENCE FOR A 16-18 YEAR MEAN TIME BETWEEN HIV VIRAL INFECTION AND AIDS ONSET
 Gretchen Wilson, and Holmes W.***
 * State University of New York at Buffalo;
 ** State University College at Buffalo, Buffalo, NY, U.S.A.

Past estimates of incubation time of AIDS have relied on estimates of time-of-infection that may have been questionable. We present 1077 cases of transfusion-related AIDS, as reported to The Communicable Disease Center, Atlanta GA, U.S.A. (CDC) which we have examined for the pattern between HIV viral infection and AIDS onset. This is probably the only class of AIDS patients for whom the precise time of infection is reasonably ascertainable. We conclude that a Weibull distribution with a mean time of 18 years and a shape factor of 0.23 represents a reasonable fit, and that a 1 year mean does not. It appears that the fitted curve represents only a lower limit, and that the true mean is somewhere between 16 and 20 years. However the most recent data update (July 1988) suggests that the data will converge at a mean incubation time approximating 18 years, with a Weibull shape factor of 0.23. We recognize that this suggests a much longer incubation time than previous estimates but may be explainable. From the work of Waldshly et al reported at the last conference in Stockholm, which suggested a dormant period between infection and expression of antibodies of as much as four years. From our curves we estimate that a minimum of 20,500 and perhaps a maximum of 30,200 transfusion-related cases of HIV remain undetected.

Session d'affichage Poster Session

Th.A.P.61 INCUBATION TIME FOR AIDS IN TRANSMISSION-ASSOCIATED CASES: AN ESTIMATION FROM THE FRENCH DATASET

Castellan, Dominique*, Laporte, A.T.M., Valléon, A.J.*

*INSERM U 253, Université Paris VII, Paris, France, *Direction Générale de la Santé, Paris, France.

Objective: To calculate estimates for mean and median incubation times for AIDS, and to give confidence intervals for these two parameters using the French dataset.

Methods: The method described by Lu et al. was selected and as in several previous works, a Weibull or a gamma distribution for incubation time were postulated. The Likelihood Ratio Statistic (LRS) was used to derive 90% confidence intervals. The French dataset where each case was individually reviewed, was used. Ninety two (92) cases with multiple transfusion, single transfusion without knowledge of the time of transfusion, association of another possible major risk factors were eliminated, leading to a final dataset of 167 subjects. Due to the age dependence of incubation time, the analysis was restricted to the 149 subjects under the age of 50 years.

Statistics	Weibull	Gamma
Mean (Years)	5.3	6.9
90% CI	4.4 - 8.9	1.9
Median (Years)	5.3	6.4
90% CI	4.4 - 8.8	4.7 - 11.4
Log Likelihood	-509.2	-508.6

Conclusion: Similar fits were observed with both distributions. Confidence intervals, under the Weibull assumption in particular, are narrower than those previously published. This indicates that an accurate estimate for mean incubation time in transfusion-associated cases will probably be obtainable in the near future.

Th.A.P.63 MODELLING PROGRESSION OF HIV INFECTION

De Smedt, Victor*, Lamy, Nicholas*

*Harvard Univ., Boston, MA, *Brown Univ., Providence, RI

Statistical modeling of progression of HIV infection is made complicated by two problems: 1) follow-up of infected patients is generally much shorter than the average time to die and 2) the times of infection are generally unknown. As a consequence, it is difficult to distinguish between different models for progression of markers of HIV infection, such as T-helper cell count. Some investigators have proposed that decline is gradual until shortly before onset of AIDS, but available data do not permit rejection of models with fairly constant decline over the entire latency period. The ability to discriminate among models can be enhanced by incorporating information about the distribution of infection-time among HIV seropositive people and of markers among the seropositive. This can be achieved through use of growth curve methods that treat the time of infection as a random effect whose distribution is estimable, either from the data on progression itself, or from external controls. This methodology was applied to data on progression of T-helper cell count in 426 HIV-1 infected men from the Men's Health Study in San Francisco, using a estimate of the infection-time distribution for the whole city. Based on our preliminary analysis, it is difficult to reject the hypothesis of a slow, steady decline in this marker. Assuming a constant rate of decline, roughly two-thirds of infected men would be expected to have annual drops in T-helper count between 88 and 140. When the model was expanded to include a quadratic term, there was slight evidence of a slowing of the rate of decline, but after 5 years, the slope was reduced by less than 10%.

Th.A.P.65

SIMULATING THE EPIDEMIC DYNAMICS OF HIV-INFECTION USING STOCHASTIC PROCESSES OVER RANDOM GRAPHS

Cheng F. Bih, P. Bhattach, T. Kéger
Fakhr El Fikri, University of Montreal, Canada, Boudif M., FRG

Objective: To develop and apply to the epidemic dynamics of HIV-infection a mathematical model and simulation procedure which incorporates the structure of sexual contacts inside a society and reflects the inherent stochasticity of the transmission dynamics. This model is implemented on a computer program and can be used as a decision tool for possible prevention strategies.

Methods: The model consists of a set of equations, modeling the social contact structure of a society, specified by social parameters, on which a discrete time stochastic process evolves, representing the spread of infection, spread by medical and social parameters. This is computer simulation, a well defined description of the underlying process as well as of the dynamic to be simulated, including a parameter defining the distribution function, social preferences in partner selection, regional structure, time dependent infectivity. The use of observable alleles for a close look at the fine structure of the transmission process. Hence, not only the overall outcomes on the course of the epidemic are improved, but typical infection paths are followed and investigated, and effects of prevention strategies can be modeled at the scale of the individual.

Results: In comparison with different epidemic models, the most remarkable feature of the model are: transport from the highly progressive part of the heterosexual population into the heterosexual population with low partner numbers is slowed down by the force of the infection, i.e. the group acting as mediator; inside the majority of the heterosexual population, the epidemic grows but never reaches that exponentially due to low partner numbers and low rate of partner change. A second, where direct transmission is induced individually and their presence in turn prevents other specific risk behaviors, is simulated. The effect of these behaviors is analyzed. **Conclusion:** Incorporating the social contact structure into an AIDS model is essential. The spread of infection is strongly determined by the graph structure. The model indicates that, if the actual growth inside the heterosexual population is slower than expected from the early growth pattern, enough heterosexuals may reach the low rate to slow transmission into this class which may not necessarily be taken as a sign of significantly lower transmission rate or of low penetration depth of HIV-infection into the heterosexual population.

Th.A.P.62

HETEROGENEITY IN THE INCUBATION TIME OF AIDS: A STOCHASTIC SERIAL COMPARTMENT MODEL

YIZHAK BARTIL*, BAULELEKE R.N., PLUMMER F.A., Kenya Medical Research Institute, University of Nairobi, Nairobi, Kenya**.

OBJECTIVE: To determine if stochastic processes could account for the observed heterogeneity in the development of AIDS. **METHODS:** We hypothesize that prior to developing AIDS (S₁) individuals must pass through a series of intermediate stages (S₂, S₃, ..., S_n). The transition to AIDS is irreversible if the transition probability between S_i and S_{i+1} is stochastic with an exponential distribution the probability of developing AIDS after time t is $F(t) = 1 - \exp(-\lambda t) = 1 - \exp(-\lambda t) = 1 - \exp(-\lambda t)$ where F(t) is the fraction of HIV infected individuals ultimately developing AIDS at time t. **RESULTS:** Taking $\lambda = 3$ and S₁ as stochastic with an exponential distribution the probability of developing AIDS after time t is $F(t) = 1 - \exp(-\lambda t) = 1 - \exp(-\lambda t) = 1 - \exp(-\lambda t)$ where F(t) is the fraction of HIV infected individuals ultimately developing AIDS at time t. **CONCLUSION:** Stochastic processes can account for the observed heterogeneity in the incubation of AIDS.

Th.A.P.64

"STRUCTURED" AND "SELECTIVE MIXING" FORMULATIONS ON HETEROGENEOUS CONTACT TO STUDY HIV TRANSMISSION

Cooperman, James*, Jacques, Colin*, Simon, Carl, University of Michigan, Dept. of Epidemiology, 3919 Observatory, Ann Arbor, MI.

Objective: Provide a mathematical and theoretical context as well as quantitative suggestions for the study of sexual and needle contact patterns affecting the course of the AIDS epidemic. **Methods:** We have developed a mathematical theory and model of contact structure which proceeds from the assumption that there are two forces creating heterogeneous sexual and needle contact patterns in a population. The first is the choice of social contexts for meeting potential sexual partners. We model this with a formulation called "structured mixing". The second is the degree of selectivity exercised in choosing partners among those who are encountered in these social contexts. We model this with a formulation called "selective mixing". **Results:** The two formulations combine into one overall theory in different ways depending upon how information is collected on the social contexts of sexual or needle sharing partnerships. Information may be collected on the social contexts where actual partnerships were made, on where sexual attraction was felt or the opportunity to share needles presented itself, or on more general social patterns. For each of these approaches, there are different approaches required to collect information on the selection of partners. We discuss how predictions of the future course of the epidemic and estimates of the relative risk of oral and sex are very sensitive to coarse structure information. We also discuss how to collect such information. **Conclusion:** Epidemiologists have tended to disregard questions about who has sex or shares needles with whom in their investigations because they lack an overall theory to guide the collection and analysis of such information. This deficiency could be causing us to double the risk associated with different behaviors (especially to underestimate the risk associated with oral sex). It is also resulting the analysis of where we might expect the epidemic to spread next. Our structured and selective mixing model provides a basis to overcome this deficiency.

Th.A.P.66

A RISK BASED HETEROGENEOUS MODEL OF THE SPREAD OF HIV

Stanley, K.A., Hagan, James H., Colgate, S.A. and Layton, S.P., Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA.

Objective: To understand how social behavior influence the spread of HIV and the difference between spread in heterosexual and homosexual populations. **Setting:** We extend a model for the heterosexual spread of HIV to include heterosexual and homosexual populations. The population is divided into two groups, which is assumed to be the primary social variable determining mixing patterns. Variation in infectivity and progression to AIDS are accounted for. Mixing between groups with different risk behaviors is determined by an acceptance function, which can bias partnerships to form between individuals with similar risk behaviors, or can allow mixing to be determined by availability. We can use our model to study the effect of a different female to male than male to female transmissibility. We also can examine the spread of the infection from the homosexual to the heterosexual community via bisexual contacts. **Results:** Models can help us understand better how the AIDS epidemic is spreading and which intervention strategies might be most effective. The mixing function largely determines the growth of the model epidemic. If individuals select partners with similar behavior, the epidemic progresses as the risk group at the front of the wave. If individuals are less discriminating in partner choice, the epidemic changes, the mixing function is determined by the "most likely" partner; group. Initially growth is slower, but it quickly surpasses the behaviorally discriminating case. The epidemic is significantly different from women to men than from men to women, less strategies for stopping the epidemic are very different than if they are the same.

Th.A.P.67 CHALLENGES IN MODELING HIV INFECTION IN LOW SEROPREVALENCE POPULATIONS

Watters, John F.
University of California, San Francisco, California, U.S.A., Utah Health Study, San Francisco, California, U.S.A.

Objective: To explore the difficulties in developing predictive models of HIV infection in populations with low prevalence of rates of infection.
Methods: Data from a cross-sectional study of intravenous drug users (IVDU) collected in all waves since 1986 are examined (N=3700). Results of various regression equations that examine the predictive power of known risk factors are contrasted. These models are also compared to models developed in high prevalence populations.

Results: In San Francisco, HIV-1 seroprevalence in intravenous (IVDU) has remained relatively stable at less than 10% between 1987 and 1989. However, distribution of virus is heterogeneous with significant variation between ethnic groups and neighborhoods of residence. Black heterosexual IVDUs (n=87), for example, were more likely to be HIV-1 positive than their white counterparts (n=740) over the period 1987-1 to 1989-1 (O.R. 1.8, 95% C.I.=1.2, 2.1). In one San Francisco neighborhood the frequency (rate) of HIV-1 infection among heterosexual (HET) (n=188) was twice that of Males residing elsewhere in the city (n=478) in 1989-1 (O.R.=2.2, 95% C.I.= 1.3, 3.7). Nevertheless, risk factors predictive of HIV infection in other studies of IVDUs (eg. frequency of injection, use of shooting galleries, and numbers of sharing partners), failed to consistently predict HIV infection.

Conclusions: Predictive models that identify independent risk factors contributing to HIV infection among high seroprevalence populations are independent of virus is relatively homogeneous may not apply to the large number of cities with relatively low HIV infection rates among heterosexual IVDUs. This is likely due to heterogeneity in distribution of infection markers in low prevalence populations. This tends to erode the predictive power of independent variables that appear to predict infection in populations with more homogeneous distribution of markers. Model construction in low prevalence, heterogeneous populations must examine the separate risk ecologies that may differ widely among cultural groups and from neighborhood to neighborhood.

Th.A.P.68 ESTIMATING INTRAVENOUS DRUG USER (IVDU) POPULATION FROM AIDS STATISTICS IN SAN FRANCISCO

Birnbaum, Patrick; Aldrich, M.; Mandel, J.
Youth Environment Study, Inc., San Francisco, CA, U.S.A.

Objective: To present a method by which to estimate the size and demographic makeup of populations at high risk for AIDS, with an example of IVDUs as an example.

Method: Back-calculating the number of HIV-infected IVDUs from infection to AIDS, applying seropositivity levels to determine IVDU population size.

Results: A single-page computer spreadsheet illustrates how the number of IVDUs at risk for AIDS can be back-calculated from reported variables. In San Francisco this further split by ethnicity, age, sex and neighborhood.

Conclusions: Population size can be estimated using reported AIDS and HIV seropositivity measures. AIDS surveillance accuracy and HIV-related non-AIDS diseases must be considered in making such estimates.

Th.A.P.69 AIDS IN THE MORDIC COUNTRIES - FORECASTS

Kalishman, B.
Medical School of Public Health
Göteborgs, Sweden.

The numbers of new AIDS cases per year in the Nordic countries are given below.

Year	Before 1983	1983	1984	1985	1986	1987	1988
Cases	7	20	34	83	145	204	267

A demographic model where birth corresponds to becoming HIV-infected and death to developing AIDS was used to summarize the series and to produce forecasts. Through trials and using a least squares criterion, a model with 270 HIV-infected in 1982 and a yearly incidence of 0.05 among the infected was adopted. The rate of virus transmission used to fit the model was 1, i.e. every infected person infects one other person during each year. Data fit well to this model up to an including 1986. The model gives 271 cases in 1987 and 522 in 1988. Thus, a certain reduction of transmission seems to have occurred from about 1986. A 60% yearly reduction was estimated. Under these assumptions, the epidemic is now close to its peak (275 cases). The number of new cases per year will start slowly to decrease to about 170 by the year 2000. A substantial number of new cases per year will appear, however, for a long time in spite HIV-transmission will be very small from about 1995, which is an optimistic prospect.

Similar calculations have been made for the two Nordic countries with the highest numbers of cases, Denmark and Sweden, the results pointing in the same direction.

Th.A.P.70 EFFECTS OF MODELING HETEROGENEITY OF DRUG USE BEHAVIOR

Stegel, J., Weinman M., Shepard D., Watters J., Finberg M., Harvard Sch. of Public Health, Boston MA.

*University of California at San Francisco, San Francisco, CA

Objective: Investigate how Drug Use (DU) risk behaviors vary widely. Heterogeneity of behavior may affect predictions of the spread of HIV obtained in epidemic models. This research examines effects of heterogeneity in a model to assess the effectiveness of intervention programs targeted to IVUDs.

Methods: Data are from a survey of 603 IVUDs in San Francisco (Urban Health Study 1989). Measures of injection frequency, needle sharing, and medication effectiveness, and medical case history. Heterogeneity is modeled in ways consistent with the original San Francisco data.

Results: Results obtained from all models considering heterogeneity of risk behaviors show higher life expectancy than baseline results obtained using the overall parameter means.

Model	IE (years)	SE (IE)
Homogeneous Risk Groups	12.0	1.4
Heterogeneity of Injection Freq (Modelled in 3 Groups)	14.4	1.7
Heterogeneity of Injection Freq (Modelled in 27 Gps)	14.8	1.6
Modeling of Increases of Inj Freq (Upper, Lower 10%)	14.0	1.5
Heterogeneity of 3 Parameters Simultaneously (Index)	16.4	1.8

Conclusion: Simulations suggest that in modeling the spread of HIV among IVUDs, an assumption of homogeneity of risk behaviors is likely to result in an overestimate of epidemic spread. It will be important to attend to both qualitative and quantitative evidence of heterogeneity in addressing AIDS among IVUDs.

Th.A.P.71 A RETROSPECTIVE MODEL OF THE SPREAD OF HIV AND THE DEMOGRAPHIC EPIDEMIC

Stanley E. Ann*, Seitz, S.T.***, May, P.O.**, Johnson, P.D.**, Hyman, J.H.**, Curry, T.T.***, et al.

*Los Alamos National Laboratory, Los Alamos, NM 87545 USA, **U.S. Bureau of the Census, Washington, DC, USA, ***University of Illinois, Champaign, IL, USA, ****Air Force Academy, Colorado Springs, CO, USA

Objective: To model the spread and demographic impact of HIV and AIDS.

Methods: We have developed a model of the spread of HIV to study the impact of the epidemic on nations where the primary mode of transmission is heterosexual. This model is based on the work of Bagnacchi. It divides the population into promiscuous—characterized by inter-time sexual contact—and nonpromiscuous groups. We model the flow of infection between urban and rural areas through migration. Modes for transmission of HIV perinatally and by blood transfusion, for marriage formation and dissolution, fertility, and non-AIDS mortality are included.

Results: The results are available through a window-based interface. The age-specific mortality and infected populations, by time since infection; the number of new HIV infections and AIDS cases; deaths from AIDS and from all other causes; the impact of AIDS on the population age structure; and the spread of HIV from urban areas to rural areas are shown.

Conclusions: A comprehensive model of the heterosexual spread of HIV infection and AIDS has been developed to analyze the possible future course of the epidemic. Continuing changes and enhancements to this model in the future will include the provision for the homosexual spread of the virus.

Th.A.P.72

ESTIMATION OF THE EFFECT OF AGE ON TIME TO AIDS IN HIV-INFECTED SUBJECTS FROM OBSERVATIONAL DATA

Robins, James, Harvard School of Public Health, Boston, MA, USA.

The NIH has recently put an RSP for community-based non-randomized studies of the effect of treatments such as AZT on time to AIDS among HIV-infected subjects. In such observational studies, the count history may be simultaneously a confounder and an intermediate variable. To history is a confounder since subjects with low TC counts are at an increased risk of developing AIDS and more likely to receive treatment with AZT. TC count history will be an intermediate variable if AZT delays time to AIDS by increasing viral destruction of TC cells. When a time-dependent risk factor like TC count is both a confounder and intermediate variable, all standard statistical methods (such as Cox's proportional hazard model) may result in a biased estimate of the AZT effect on time to AIDS whether or not one adjusts for the confounder TC count history in analysis.

In this paper new statistical methods will be described that allow for proper control of confounding by intermediate variables such as TC count history. These methods estimate the partial hazard, a new class of additive, the nested structural failure-time models, using a class of instrumental variable estimators. Relationships between the partial hazard and (a) non-inferior 3-stage least-squares estimators and (b) Robins' (1986) G-computation algorithm and G-mart test are discussed. User-friendly software available for analysis is described.

Th.A.P.73 SIMULATION OF HIV TRANSMISSION IN A STRUCTURED COMMUNITY OF INTRAVENOUS DRUG USERS

Deegan Peterson, Keith Willard and Michael Altmann University of Minnesota and VA Medical Center, Minneapolis, Minnesota, USA.

An Intravenous (IV) Drug Community/HIV Transmission model has been developed to help evaluate public health intervention programs. The model uses Monte Carlo simulation to determine when an IV drug user contracts HIV and how the HIV infection progresses. The HIV progression model reproduces the stages of HIV infection: virus contact, asymptomatic stage, beginning symptoms, ARC, AIDS, and death. The population model of an intravenous drug community simulates dynamics: 3 types of addicts, differentiated by amount of drug use, a process of recruitment to addiction and to heavy addiction; withdrawal during incarceration and treatment programs; recovery from addiction and death from non-HIV-associated causes. The IV drug community is structured into a social network based on literature reports. Users are exposed to HIV through sharing syringes and acquaintances in their social networks, strangers in the general population and in "shooting galleries." The probability of HIV transmission given contact with contaminated needles is estimated from reports of sero-positive rates in health care workers exposed to HIV needle sticks. The model is flexibly structured and has been adapted to populations representing different geographic areas having unique social structures, exposure characteristics, and underlying HIV prevalence. Simulations of a needle-exchange program and increased treatment indicate the importance of prevention in determining the long-term success of intervention.

(Supported in part by NIH RR-1632 and the Veterans Administration)

Th.A.P.76 THE PREDICTION OF THE NUMBERS OF AIDS CASES IN THE UK, AND THE ESTIMATION OF THE INCUBATION PERIOD OF AIDS.

Medley, Graham and Anderson, R.M.

Department of Biology, Imperial College, London SW72BZ, UK.

Objective: To use available data to forecast the future numbers of diagnosed AIDS cases in the UK.

Methods: Mathematical models are described that use (a) the numbers of reported cases in the UK to predict future cases, and (b) data available for estimating the incubation period of AIDS.

Results: Previous estimates of future UK AIDS cases (*Short-term Prediction of HIV Infection and AIDS in England and Wales*, HMSO, London, December 1988) and the incubation period of AIDS (Medley et al., *Nature* 1987, 338, 719-721; Anderson & Medley, *Epidemiology of HIV Infection and AIDS: Incubation and Infectious Periods, Survival and Vertical Transmission*, AIDS 1988, in press) are updated.

Conclusions: The results are discussed in terms of their implications for the AIDS epidemic in the UK and other industrialized countries.

Th.A.P.77 RELIABILITY OF ESTIMATES BASED ON BACKCALCULATION.

Mitchell, G. Hall, P.S. Rosenberg, B. Riggs, J.J. Goedert, M.C. Beckwith, M.D., R. Broome, Johns Hopkins, Maryland, USA

OBJECTIVE: To assess random and systematic uncertainties in estimates from backcalculation of the cumulative numbers of HIV-infected persons up to 1985 and through the present, the differences between average infection rates over previous time intervals, and projections of future AIDS incidence.

METHODS: Using flexible models of the previous HIV infection rate, we evaluated the effects on estimates above of uncertainties in the AIDS incubation distribution, the form of the infection rate curve, delay corrections, and changes in the surveillance definition. Our method yielded variances for random errors as well as an assessment of the systematic error, such as from misspecification of the incubation distribution.

RESULTS: We studied persons with hemophilia and non-IV drug using homosexual men using a Weibull AIDS incubation distribution $F(t) = \exp[-0.0027 \cdot t^{2.516}]$ derived from persons with hemophilia. We find evidence for an earlier peak in infection rates in these two test cases. In line with independent epidemiologic evidence, these results suggest that valid inferences may be made for other risk groups. Sensitivity analyses indicated that near-term projections of AIDS incidence were relatively stable with respect to perturbations of the underlying model. However, estimates of the cumulative number of infections occurring after 1985 and estimates of changes in the infection rate have large random and systematic components of error.

CONCLUSIONS: Our results help us to assess the strength of substantive inferences made using the method of backcalculation.

Th.A.P.74 REVERSE EXTRAPOLATION AS A METHOD FOR ESTIMATING HIV SEROPREVALENCE

Scakelton, Colin L.; McGregor, J.R. and Jaroni, A.N.

University of Alberta, Edmonton, Alberta, Canada.

Objective: To provide a method for estimating HIV prevalence.

Methods: Reverse extrapolation is applied to 8 and 10 year AIDS projection estimates. Current infection prevalence then is calculated based first on one assumption which states that approximately three times as many people presently are infected as will actually develop AIDS 8 years hence; a second assumption used is that twice the number of those who will develop AIDS 10 years hence already are infected.

Results: Reverse extrapolation can be estimated for regionally defined groups for whom AIDS projections can be determined. For example, from AIDS projections for the province of Alberta through July 1985, determined by the Polson, polynomial, logistic, and doubling time models, a direct estimate of 3.46% and an upper estimate of 4.97% were obtained. The then current provincial AIDS total of 137 case reports. Equivalent estimates for Canada, at a time when the cumulative total number of AIDS cases was 1,941, were in the range 20.7%-18.8%, with a more liberal value around 100,000.

Conclusion: The method appears reliable since it produces findings consistent with those of others. It is both robust and cost-effective. However, it is no substitute for valid data gathered directly through seroprevalence surveys of defined groups. Actual reliability will be established when results from seroprevalence surveys are available for comparison.

Th.A.P.76 PROTECTING LOCAL AIDS INCIDENCE USING BOTH SURVEILLANCE AND SEROPREVALENCE MEASURES

Boyer, J., Engel, J., Lichtenfeld, J., Hall, S., and Anderson, J.

The Mexico Health and Environment Department, Santa Fe, New Mexico, U.S.A.

OBJECTIVE: To protect AIDS incidence through 1992 for the State of New Mexico by two different methods: one which extrapolates from past seroprevalence data, and one which projects future cases based on current HIV seroprevalence estimates.

RESULTS: The surveillance-based projections were derived directly from recent US national projections. The future proportions of all US cases expected to occur in New Mexico over the next four years were projected as a linear extrapolation from those proportions observed in the last four years' data in local AIDS surveillance data. The HIV seroprevalence-based projection method uses the most recent local seroprevalence surveys to estimate the projected rate of new infections currently reported, as well as for those expected to be infected by future transmission to existing seroprevalence for each year from about their infection of HIV infection and expect future AIDS incidence.

RESULTS: Both projection methods produced similar estimates through 1992. 824 cumulative cases were predicted by the surveillance method and 1033 were predicted by the seroprevalence method. Back-calculation of the number of "expected" cases for 1985 based on the assumption used in the seroprevalence-based method produced a number of cases which was only slightly higher than that actually observed. Thus, the seroprevalence-based estimates are **OVERESTIMATES**. Some methods' predictions that both surveillance and seroprevalence measures can be useful in determining local AIDS control.

Th.A.P.78 A REVIEW OF SOME TECHNIQUES FOR BACKWARD ESTIMATING THE PREVALENCE OF HIV FROM AIDS CASE INCIDENCE

Phillips, G. Cooke, J., Beach, S., Fisher, S., Small, D., and van der Boven, C.

Research Triangle Institute, Research Triangle Park, North Carolina, USA
University of North Carolina at Chapel Hill, Chapel Hill, N.C., USA.

Objective: Some methods for estimating HIV prevalence from AIDS case data are examined. Featured in this examination is the Brookmeyer-Gall method. The validity of the method is assessed by performing sensitivity analysis of the HIV prevalence estimate by year for different incubation distributions.

Results: An estimate of U.S. HIV prevalence is produced. **Conclusion:** The Brookmeyer-Gall method is an objective procedure for estimating past HIV prevalence but a proper representation of the incubation distribution is critical in providing reliable estimates.

Th.A.P.79 PROJECTING PROPORTIONS OF AIDS CASES OVER TIME
KARON, John M.; Devine, GJ
AIDS Program, Centers for Disease Control, Atlanta, GA, USA

Objective: To model time trends in the proportions of AIDS cases in groups, in order to make short-term projections of future proportions.
Methods: Let $f_i(t)$ be the proportion of cases in group i , $i=1,2,\dots,C$, at time t . Model the generalized logit: $\log(p_i(t)/p_0(t)) = f_i(t) + \text{error}$, where $f_i(t)$ is a polynomial in time (estimated using weighted regression) and group G is the reference group ($f_G(t) = 0$). Predicted proportions are: $\hat{p}_i(t) = \exp(f_i(t)) / \sum \exp(f_i(t))$.
Results: Predictions are nearly independent of the choice of the reference group. We modeled quarterly incidence of U.S. cases for Jan 1984 through June 1988 group geographically into metropolitan statistical areas: New York City, San Francisco, Houston, and others (reference group). Linear polynomials give good fits to observed proportions and predict decreases in each area, with the following observed and predicted percent of U.S. cases: New York City San Francisco Houston
Quarter Obs. Pred. Obs. Pred. Obs. Pred.
1987/1 18.6 18.3 6.4 6.6 3.1 3.3
1988/1 17.4 17.5 5.9 5.4 2.9 2.8
1989/4 12.1 12.1 3.9 3.9 2.6 2.6
Conclusion: Modeling proportions can give useful short-term projections even with relatively few cases in some groups. Proportions in risk groups can be modeled after the effects of the new case definition on trends are understood. Estimates of uncertainty and prediction intervals can be obtained from a multinomial likelihood incorporating similar models.

Th.A.P.81 MODELING OF THE AIDS EPIDEMIC IN MEXICO
JOSHILLA, Angeles, A. Sanberg, T. Awbich, A. Mohar, J.J. Valdespino, J. Sepulveda, T. et al.

*Harvard University, Boston, MA, USA; **Direccion General de Epidemiologia, Mexico DF, Mexico.
Objective: To forecast new AIDS cases among different risk groups in Mexico, and estimate the impact of preventive measure on the spread of the epidemic.
Methods: We used a closed compartmental model to forecast new AIDS cases among homosexual and bisexual males, and heterosexual males and females. For each group 1000 individuals were defined: uninfected persons, infected but asymptomatic persons, and diagnosed AIDS cases. It is assumed that the AIDS risk is a function of the proportion of infected persons in each risk; where spread of infection is proportional to the product of the number of healthy persons in free healthy to infected, and from infected to asymptomatic, and asymptomatic people do not spread the disease. discrete non-linear regression was used to estimate the parameters of the model so that the prediction would fit the number of reported AIDS cases in Mexico. The impact of preventive measure was determined by the probability of transmission of HIV.
Results: By August 1988, 1811 cases had been diagnosed in Mexico, 748 were homosexual males, 353 bisexual males, and 118 heterosexual males and females. The model predicts that the AIDS incidence will continue to rise in Mexico for at least the next 8 years and will spread among the heterosexual population. By means of education programs, decreasing the transmission probability by 10% in all groups will result in a decrease of 24% in the number of cases accumulated over an 8 year period. A 10% decrease would prevent more than 400 of the cases.
Conclusion: Simple models can be valuable to predict the evolution of the AIDS epidemic and the impact of behavioral change.

Natural History of HIV Infection**

Th.A.P.83 GENETIC EPIDEMIOLOGY OF AIDS (Liu, S, Desmond, K Gilles, B Newman, and P-C King, University of California, Berkeley, CA 94720, USA). We are currently addressing two crucial questions about the epidemiology of AIDS: 1) Does host genotype influence susceptibility to HIV infection? 2) Does host genotype influence the rate of disease progression once a person is infected with HIV. Our first study results from the San Francisco Men's Health Study (SFMS), consists of 80 Caucasian men in 4 clinical groups: 1) HIV- despite high risk behaviors; 2) HIV+ with no symptoms for at least 2 years; 3) HIV+ with at least 2 clinical findings but without AIDS; and 4) AIDS. Our second study sample consists of 40 Caucasian AIDS patients from the AIDS Clinical Research Center (ACRC) in San Francisco and 70 healthy Caucasian controls. In both samples, we are comparing sequences of genes involved in immune response by analysis of DNA polymorphisms.
Our first results are for T cell receptor-beta chain (TCRB), which is detected by the cDNA probe PT10 after digestion of genomic DNA with Bgl II. All alleles have fragment lengths 10.0 and 9.2 kb. In the SFMS sample, allele frequencies did not differ between the HIV- group or the three HIV+ groups ($P > .155, p > .20$). Among HIV+ men, asymptomatic subjects did not differ from symptomatic and AIDS patients ($P > .842, p > .89$). We are continuing to screen other candidate sequences involved in immune response and will present these results at the meeting.

GROUP	Clinical Status	TCRB Allele		N
		10.0 (K)	9.2 (L)	
SFMS	HIV-	28 (48)	30 (52)	29
	HIV+, asymptomatic	18 (36)	32 (64)	25
	HIV+, symptomatic	21 (48)	31 (60)	26
ACRC	AIDS	4 (29)	10 (71)	7
	AIDS	51 (55)	41 (45)	46
Controls	Healthy	89 (56)	69 (44)	79

Th.A.P.80 THE AIDS EPIDEMIC IN MEXICO
GARCIA, Mohar, V. De Grutola, J.L. Valdespino, H. L. Alcázar, H. and J. Sepulveda, S. et al.
Harvard University, School of Public Health, Boston, MA
General Directorate of Epidemiology, Ministry of Health, Mexico City, Mexico.

Objective: To predict the short term course of the acquired immunodeficiency syndrome (AIDS) epidemic in Mexico.
Methods: By the method of back calculation using cumulative number of AIDS cases reported until October 1988 and adjusting for report delay for right-truncated data in chronological time, we estimate the future number of AIDS cases in Mexico. The analysis comprises the results of the National Serum Survey (NSS) which is intended to provide a reliable estimate of the current HIV seroprevalence in the entire country of Mexico.
Results: Initial analysis adjusted for the report delay demonstrates that there are significant differences in AIDS reports by risk factor (homosexuality vs. others) and by region (Mexico city vs. others). The results of the "working backwards" modelling, with consolidated results of the NSS, will be presented.
Conclusion: The authors considered that the method of back calculation with adjustment for report delay in conjunction with a reliable estimate of seroprevalence will substantially improve the accuracy of their projections. This analysis will give better insight into the future course of the AIDS epidemic.

Th.A.P.82 LIMITATIONS OF OFFICIAL FORECASTS USED IN PLANNING URUGUAY AIDS SERVICE NEEDS
GARCIA, Luis M.; Winfield, N.
New York University Medical Center, New York, New York, USA.

Objective: To compare official and semi-official projections of AIDS prevalence and associated medical/social service needs among city, state, and federal agencies for New York, San Francisco, Los Angeles, and other U.S. cities. To explain how assumptions and choice of methodology affect these projections.
Methods: Critical review of published forecasts.
Results: There are significant differences in projecting prevalence and service needs had shifted from the federal to state and local levels in the last few years. The forecasts used in the planning of AIDS services in the Centers for Disease Control (CDC) in 1986 for San Francisco, New York City, and Los Angeles, the Institute of Medicine's estimates of hospital bed need through 1991 were based on these CDC projections. Major official strategic plans had recently been developed for San Francisco, Los Angeles, and New York State which include case projections broken down by risk group and forecasts of need for hospital, long term care, and other services. The forecasts used in the CDC's official forecasts using computer methods often differ sharply from those of the local, state, and federal agencies. The forecasts result from the choice of assumptions (e.g., history of HIV infection, seroprevalence rates, future infection rates, disease progression rates, and reporting lags) and projection method (linear or polynomial extrapolation).
Conclusions: The choice of assumptions and methods affect official forecasts for various cities and require alternatives.

Th.A.P.84 EVALUATION OF THE IMMUNOLOGICAL STAGING SYSTEM IN A POPULATION BASED COHORT
ROYCE, Rachel*, Winkelstein J Jr*, Anderson RM*, Lang WM*
*University of California at Berkeley, **IRK Inc., San Francisco, CA, USA.

Objective: To apply the immunological staging system, ISS, (Colla-Panzer, 1987) to a sample of HIV infected men. To determine risk of AIDS by ISS stage after 42 months of observation, and pattern of change in stage.
Methods: ISS Stages 1-3 are composed of an additive combination of immunological abnormalities: CD4/CD8 T cell ratio of <1.0 , CD4 T cell count of <500 cells/ μ l, and lymphopenia of <1500 cells/ μ l. Lack of abnormalities defines Stage 0. The 368 HIV infected men, initially AIDS-free, of the San Francisco Men's Health Study probability sample were staged at visit 1 by the ISS and re-classified every 6 months at follow-up visits 2-8. Risk of AIDS by initial stage was determined after 42 months follow-up.
Results: At visit 1, 2 men were unclassifiable by the ISS. The remaining 366 men were distributed among Stages 0-3 as follows: 161, 368, 211, and 3K. The risks of AIDS and 95% confidence limits after 42 months were .02 (.003-.09), .14 (.10-.19), .43 (.32-.54) and .18 (.06-.41) for Stages 0-3.
All but 10 men were classifiable on visits 2-8. By visit 8, 627 had changed to a higher stage relative to visit 1. Of classifiable men with at least 2 follow-up visits (414/222) regression in stage at 1 or more visits.
The relatively low risk of AIDS in Stage 3 on visit 1 may be artifactual because men in Stage 3 on visit 2 and visit 3 had higher risks of AIDS at 30 months follow-up.
Conclusion: ISS is easily applied and predicts progression to AIDS. Men do not appear to move uniformly through the stages. Stage 3 which is based on lymphopenia, may not describe a risk of AIDS distinct from the other stages.

Th.A.P.85 TIME FROM FIRST HIV INFECTION TO PERSISTENT ANTIGENEMIA
 CHMEL, P. H., MURPHY, R. M., PHILLIPS, J. M., COOPER, R. G., CARU, V. J., and Ising, L. *Northwestern University Medical School, Chicago, IL
 *The Johns Hopkins University School of Public Health, Baltimore, MD, USA.

Objective. HIV antigenemia is an important predictor, independent of CD4 cell number, for the development of AIDS. The objective of this study was to assess the usefulness of HIV antigenemia as an indicator of time since first HIV infection.
Methods. For each of 439 HIV antibody positive (Ab+) men in the Chicago MACS infection was established using IgG and platelet count (Munoz et al. IV International AIDS Conference). Mean and ranges of the mean times since first infection for each of 184 men who were not seroconverters (SC) were compared. Development of antigenemia in 47 HIV antibody seroconverters (SC) was examined to assess the validity of our estimates.
Results. 386 CD4+ T-lymphocyte counts were HIV Ab+, Ag+ at entry had an estimated mean time from first HIV infection to study entry of 12.0 mo. (range 17-1251), compared to 28.1 mo. (range 18-717) for the 73 Ab+ men with Ag detected at entry (p<0.02). Approximately 75% of this latter group were not seroconverters for at least 2 consecutive 6 mo. to 6 mo. polymerase chain reaction (PCR) and range of detectable antigenemia at entry were from 3 to 30 mos. (7 men). 8 SC developed Ag that did not persist.
Conclusion. Persistent antigenemia in a seropositive cohort is informative about the time since initial HIV infection. Estimation of this time may be useful for describing progression of HIV disease when CD4, platelet count, and antigen status are known.

Th.A.P.87 DEFINING THE INTERVAL BETWEEN HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION AND THE APPEARANCE OF HIV ANTIBODY
 BARON, R. A., ROBERTS, R. D., DE, C. J., JAMES, J. W.,
 BALSBERG, S. W., LONG, R. M., AND PETERSON, R. A. at al.
 *AIDS Program and *Division of Sex Factors, CDC;
 *Emory University, Atlanta, GA, USA.

Objective. Persons infected with HIV who have not developed antibody detectable by currently used tests may be at risk through blood donation or sexual contact. This study was done to estimate the duration of this virus-positive, antibody-negative period.
Methods. We investigated 27 homosexual and 12 hemophilic men for whom stored peripheral blood mononuclear cells (PBMC) were available before and after seroconversion. PBMC were assayed for HIV RNA by the polymerase chain reaction technique using gag and gag region primers; serum was tested for p24 antigen by enzyme-linked immunosorbent assay (ELISA).
Results. Four persons had HIV RNA detected before seroconversion; all had HIV RNA detected only on the seronegative date closest to the time of seroconversion. Three persons had antigen detected before seroconversion; in each case HIV RNA was also detected. Using a Markov model, we estimated the median time from infection with HIV (as assessed by detection of HIV RNA) to first detection of HIV antibody to be 5.6-6.1 (S.E.M. 0.3) months. Modeling of reported cases of HIV infection with known exposure gave an estimate of a median of 2.6-3.0 months from exposure to antibody detection, and 50% of cases would be expected in 5.6-6.0 months.
Conclusion. Prolonged periods of unrecognised HIV infection in persons who do not have detectable antibody appear unlikely.

Th.A.P.89 INTERNATIONAL SEROCONVERSION: ELISA, Robert's Goddard, J., Blattner, W. (National Institute, Bethesda, MD), and the Seroconverters Working Group.

Objective. To expand an ongoing registry of persons with documented HIV seroconversion in order to determine the natural history of HIV infection and compare the course of HIV in persons infected by different routes, in different geographic areas and at different times.
Background. The natural history of HIV infection has not been understood when the time of infection can be reliably established. Most investigators doing prospective studies use seroprevalent subjects and enroll cohorts of subjects of only one risk group. Thus, the ability of single cohorts to define critical natural history issues is limited.
Methods. We have established a registry of seroconverters by providing simple data forms to investigators engaged in seroprevalent studies of groups at risk of AIDS. Essential data are identifying number (names not accepted in order to assure confidentiality), age, sex, risk group, dates HIV antibody tests were less negative and first positive, dates and types of antiretroviral treatments (if any), last follow-up date, AIDS outcome (if any). Summary reports will be prepared at ICI and shared with all participants.
Results. Results are presented elsewhere (See Time-to-AIDS among HIV Seroconverters, by the Seroconverters Working Group [Bisgaard]). So far 315 seroconverters (through 1988) have been registered by 38 groups in 11 countries, including the United States, Canada, Europe and Australia. Risk groups include homosexual men, hemophiliacs, i.v. drug users, blood donors, and heterosexuals. This work suggests that HIV seroconversion and HIV CONTRIBUTIONS WILL BE WELCOME. We would be pleased to answer questions and provide forms and guidance for investigators willing to participate.

Th.A.P.86 LONG-TERM HIV INFECTION WITHOUT CLINICAL ILLNESS OR IMMUNODEFICIENCY. HORNBERGER, M.B. AND HAY, M.T. *PROGRESSIVE Lymph, Alan R. *Buchholder, S.S. *Sheppard, M.M. *Wilber, J. *Hersel, M. *Mandel, J. *HPT, C. *Tilley, M. *Sutherland, G. *Dept Public Health, San Francisco, CA. *ACA Public Health Foundation, and *Pathology Inst., Berkeley, CA. **CDC, Atlanta, GA, USA.

Objective: To evaluate the immunologic and virologic profile of persons with long-term HIV infection who have not developed HIV-disease.
Methods: From a cohort of homosexual/bisexual men, 184 HIV-antibody (Ab) positive men evaluated in 1988 had well defined seroconversion (SC) dates. We compared 37 men who were Ab positive for > 5 y (mean=8.0 y) without clinical evidence of immunodeficiency and who had < 400 T4 lymphocytes (non-progressors [NP]) to 81 men with AIDS or ARC (progressors [P]).
Results: 14 count of all 184 men was not statistically associated with year of SC. Compared to P, NP had a higher T4 count, T8 count, and hemoglobin and a lower beta2-microglobulin. Of those NP tested, 25/37 were negative for HIV antigen. 11 NP did not significantly differ on assays for natural killer activity or Ab-dependent cellular cytotoxicity. When tested by ELISA for Ab to 6 gag polymerase chain reaction (PCR) and range of detectable antigenemia at entry were from 3 to 30 mos. (7 men). 8 SC developed Ag that did not persist.
Conclusion: V4 count is not a marker for duration of infection. NP do not have evidence of replicating virus, but do have evidence of latent HIV infection. Although similar to PMA for some immunologic parameters, NP differed in strength of Ab response to certain core and envelope antigens.

Th.A.P.88 OCCURRENCE OF INDETERMINATE WESTERN BLOT (WB) TESTS AND LACK OF TRANSMISSION OF THE HIV INFECTION AT LOW RISK FOR HIV INFECTION. HUNTINGTON, WY, USA, 1986-1988
 MALABO, ROBERT; HINDLANDS, A. W. and the WAHD AIDS Vaccine Program*
 *Marshall University School of Medicine, Huntington, WV. **Bethesda, MD, USA.

Background: During screening of prospective volunteers for an AIDS vaccine study (G160 Microcosm), we noted the frequent occurrence of WB in our low risk population. WB was the most common reason for eliminating volunteers from participating in the study.
Objective: The present study was undertaken to examine the epidemiology of WB in low risk persons.
Methods: Sera were obtained from three groups: paired sera obtained 1 month before and tested for antibodies by ELISA (Abbott) and WB (Dupont); p-24 antigen (Abbott) was also tested.
Results: No HIV infections were found in our population. Repeat WB occurred in 11 members of 10 different families. Nine WB were among male children in the families (p<0.1). WB was caused by weakly reactive p-24 bands in 9/11 family members. 2/24 cord sera exhibited WB; neither child had WB 36 months later; one child seroconverted WB that was not present in cord serum. WB occurred in 23% of low-risk adults in Huntington, WV.
Conclusion: WB is common among persons at low risk for HIV in our city. There was no evidence of horizontal transmission of WB in families or vertical transmission for mothers to children.

Th.A.P.90 LACK OF CORRELATION BETWEEN NEUTRALIZING ANTIBODY TITERS AND CD4+ DECLINE IN THE SAN FRANCISCO HIVERS HEALTHY STUDY.
 SHARON, R. M., HANSEN, C. W., MILLS, L. W., MOYER, K. W.,
 *California Public Health Foundation, *WVRI and *Richardson Davis Laboratory, Department of Health Services, University of California, Berkeley, CA, USA.

Objective: To determine the relationship between neutralizing antibody titer and the decline in CD4+ cells in the San Francisco HIVers Healthy Study.
Methods: A novel fluorescent micro-plate reduction assay was used to measure early neutralizing antibody titer for IgM and IgG and bisexual men 30 months after entry into the San Francisco Health Study. The assay employed a monoclonal cell line derived by centrifugation through molten agarose in 96 well trays. The study population was composed of 120 seropositive homosexual individuals with <500 CD4+ cells at entry (1984) and 34 seropositive asymptomatic CD4+ controls. 54 continued to have <500 CD4+ cells after 30 months while 66 showed a decline in CD4+ cells. The relative neutralizing capacity is expressed as the reciprocal of the serum dilution at which 50% of the input tubes forming units are inhibited.
Results: All sera which were antibody negative by ELISA showed no neutralizing capacity at the lowest serum dilution (1:3). All positive sera had mean capacity to neutralize prototype HIV-1 III with a titer of 12-31. The geometric mean titer for the group without CD4+ decline was 432. The geometric mean titer for the group with declining CD4+ cell numbers was 484. There was no correlation between the distribution of titers within the two groups.
Conclusion: This work suggests that there is little or no correlation between CD4+ cell decline and the capacity to neutralize the prototype strain of HIV-1.

Th.A.P.91 THE EFFECT OF HEPATITIS B VIRUS VACCINATION ON T-CELL SUBSETS IN HIV-1 SEROPOSITIVE MEN IN THE BALTIMORE MACS
Oshaka Nancy, Margolick J, Fox R, Muñoz A. The Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.

Objective: To compare the effect of hepatitis B virus vaccination (HBV) on T-cell subsets in HIV-1 seropositive (+) and seronegative (-) homosexual men. Methods: Previously HIV seronegative HIV-1 + and - homosexual men in the Baltimore MACS either did or did not receive HBV. Blood was drawn immediately prior to enrollment in the study (baseline) and every six months thereafter for analysis of T-cell subsets (CD4, CD8). Change(Δ) was defined as the difference between the baseline value and the most recent evaluation, with followup(fu)/pp ranging from 6 to 36 months.

Results	CD4			CD8			
	Mean	Baseline	Mean Δ	Baseline	Mean Δ	per Δ mo	
Group HIV-1	Mean	Mean ± SD	Mean ± SD	Mean	Mean ± SD	per Δ mo	
1	4	32.7	-0.4	27	7.6	0.1	
2	+	162	32.7	47 ± 6.6	-0.2	29 ± 6.1	-0.6
3	+	23	33.8	32 ± 6.7	-1.6a	44 ± 11.0	1.6a
4	+	21	31.3	30 ± 11.2	-3.3a,b	37 ± 10.4	4.3a,c

a: p < 0.05 compared to group 1; b: p=0.063 compared to group 3; c: p=0.007 compared to group 3. The differences between groups 3 and 4 persisted after adjusting for baseline CD4 and CD8.
Conclusion: These data suggest that HBV may influence T-cell subset proportions in HIV-1 + individuals over time. Further followup of this and other populations is needed to confirm this conclusion.

Th.A.P.93 INCREASED "TYPICAL THERAPY" IN LATE STAGES OF HIV INFECTION.
Bartus, D.D.,* Medfield, R.R.*; Fowler, A.*; Oster, C.*; and the Walter Reed Retrovirus Research Group *Walter Reed Army Inst. Med., ** SRA Technologies, Inc., Washington, D.C., U.S.A.

Objective: To compare results of HIV isolation attempts from peripheral blood mononuclear cells (PBMC's) of early versus late stage patients. Methods: PBMC's from 91 staged HIV seropositive patients were obtained from heparinized blood specimens by density gradient fractionation. 2x10⁶ and 2x10⁵ cells from each patient were inoculated into cultures of PHA and TI-2 stimulated normal donor target PBMC's. Culture fluids were monitored weekly for HIV p24 antigen.

Results	Positive		
	# Total	< 2.5x10 ⁵	> 2.5x10 ⁵
Stage			
Controls	0	0	19 (100%)
WR 1 - 2	41	11 (27%)	16 (39%)
WR 3 - 5	40	27 (68%)	8 (20%)
WR 6	10	10 (100%)	5 (50%)

90% of HIV seropositive patients with decreased CD4 cell counts (less than 400 per μl, stages 3 - 6) were culture positive, compared to 66% of early stage patients with normal CD4 counts. Cultures became positive more rapidly in patients with late stage disease.
Conclusion: HIV can be more frequently and more rapidly recovered from blood in the later stages of illness.

Th.A.P.95 SEROLOGIC EVIDENCE OF EPSTEIN-BARR VIRUS (EBV) REACTIVATION BEFORE AND AFTER HIV-1 SEROCONVERSION.
Rahman, Ahd., Kingley, L., Rinaldo, C., Atchison, R., Ho, M., Brinig, M., University of Pittsburgh, Graduate School of Medical, Pittsburgh, Pennsylvania, USA.

Objective: To evaluate the relationship between early HIV-1 infection and active/reactivated EBV infection based on serologic markers of EBV infection. Methods: This nested case-control study included a group of homosexual/bisexual men who seroconverted to HIV-1 (n=49) referred to matched controls (n=49) who remained seronegative to HIV-1 for 2 1/2 years. HIV-1 infection was documented by ELISA and confirmed by Western-blot assay. Immuno-fluorescence assays were used to determine IgG antibody titers to EBV-VCA, EBV-EA and EBNA. Results: All 49 HIV seroconverters were seropositive to EBV (titer ≥ 1:5) while 47/49 (96%) of controls were seropositive to EBV. Antibody titers to EBV-VCA and EBNA did not differ significantly between cases and controls 6 months prior to the time of HIV-1 seroconversion for cases. Antibody titers to EBV-EA were significantly elevated (p < .001) among cases (Geometric mean titer GMT = 30) prior to HIV-1 seroconversion compared to controls (GMT = 7) and remained significantly elevated for 1 1/2 years post HIV-1 seroconversion. Four-fold or greater rises in VCA-IgG titers were strongly associated with HIV-1 seroconversion (odds ratio = 3.4; p = .004), indicating probable reactivation of EBV. Negative correlations were observed between the antibody titers to EBV-VCA and EBV-EA to CD4+ lymphocytes, while mean number of CD8+ lymphocytes were elevated in cases pre and post HIV seroconversion. Conclusions: These results suggest that EBV reactivation is correlated with HIV-1 seroconversion and that evidence of a ≥ 4 fold rise in VCA-IgG is detected in a majority of HIV-1 seroconverters within 18 months. This may have implications regarding the role of EBV in the future pathogenesis of HIV-1 infection.

Th.A.P.92 INCREASED RATE OF HIV-1 ISOLATION AMONG HIGHLY HOMOSEXUALS WITH LOW CD4 COUNT
HOMANOW, FAYZAGGAR, K. GATSHA, M. HARDY, D. INAGUNA, M. LEE, C. GROVIT, P. GUNJA. A Report from the Multicenter AIDS Cohort Study (MACS), NIH, Bethesda, MD, U.S.A.

OBJECTIVE: To correlate variation in HIV-1 isolation with changes in immune status as determined by CD4 count among HIV-1 seroconverters. **METHOD:** One hundred and ninety-four seroconverted homo/bisexual men participating in a prospective study of the natural history of HIV-1 infection were studied for HIV-1 isolation and cellular immune status in three (MACS) Centers. Coincubation with normal PHA-P stimulated PBMC's were monitored four weeks for HIV-1 replication utilizing P24 antigen capture. **RESULTS:**

CD4/mm ³	%/Total	n	CD4/mm ³	%/Total	n
0 - 199	24/28	26	600 - 799	29/28	74
200 - 399	44/58	80	800 - 999	12/18	67
400 - 599	38/50	76	> 1000	13/27	48

The HIV isolation rate for participants with low CD4 (< 200) was greater than those with high CD4 (> 1000) count. The test for trend was statistically significant (Mantel-Haenszel chi square 9.4, P=0.002). **CONCLUSION:** Declining CD4 is associated with immune impairment. The association between lower CD4 count and increased HIV-1 recovery may suggest that progression of HIV-1 infection is associated with a higher percentage of infected T-cells and more effective viral replication. Low CD4 cell count is a significant predictor of HIV-1 isolation.

Th.A.P.94 GRAPHICAL DESCRIPTION OF HEMATOLOGICAL CHANGES AFTER HIV-1 SEROCONVERSION IN HOMOSEXUAL MEN. Huffes, Alvarez; Margolick J; Phair J; Giertz J; Rinaldo G, for the Multicenter AIDS Cohort Study (MACS), Bethesda, MD, USA.

Objective: Describe the multivariate distribution of hematological variables at different times from HIV-1 seroconversion. **Methods:** The 271 seroconverters observed in the MACS within 4 years of follow-up provided 1816 assessments of hematological values at different times from seroconversion from -1 to 3 yrs. Bivariate coordinates and contours of multivariate normal distributions estimated from the data were used to display the interactions between different variables. **Results:** The means and standard deviations of selected hematological variables according to the number of years from seroconversion were

	Tests from HIV-1 Seroconversion			
	1	2	3	20
Assessments (N)	192	445	517	2
ln(CD4/CD8)	0.4940,46	0.2440,57	-0.1340,58	-0.3740,69
CD3-(CD4+CD8)/μl	100120	172139	202100	462013
Hemoglobin(g/dl)	15.4423,10	15.3981,09	15.2321,20	15.0627,15
Platelets (in K)	270558	259460	246257	227255

The CD4:CD8 ratio was negatively correlated with double negative cells (CD3-(CD4+CD8)), positively correlated with hemoglobin and had a consistently small correlation with platelets. **Conclusion:** Strong downward trends after seroconversion are apparent in CD4/CD8 and in platelets. CD4/CD8 and platelets are weakly correlated and have different prognostic information for AIDS. Changes in double negative cells and hemoglobin are asymptomatic, but of small magnitude relative to their variability.

Th.A.P.96 CLINICAL PATTERN AND COURSE OF HIV INFECTION IN 29 PATIENTS WITH SEROCONVERSION
Rozak, M., Staszewski S., Kindervater G., Kamps B., Gottstein A., Helm E.B., Universitätsklinik Frankfurt, Zentrum der Inneren Medizin, Infektiologie, Th- Stern-Kai 7, 6000 Frankfurt/M, Federal Republic of Germany

Objective: To describe changes in immunological parameters and occurrence /course of clinical symptoms in patients (pts) with seroconversion (SC) of HIV infection. **Methods:** During routine check-ups of ca. 3000 pts with risk for HIV infection between 1/1986 and 12/1986 at Frankfurt University Clinic, SC could be proved in 29 pts. All serum samples, positive and negative ones, were re-tested by means of ELISA, IPT, or WB. All 29 pts were followed up (physical examination, routine lab. lymphocyte subtyping). **Results:** Mean interval from last negative to first positive test was 180 da (min. 10, max. 656) (Under the name of SC). Under the name of SC being up to the course of SC, of 29 pts, 1 had meningitis-encephalitis, 1 had generalized convulsions, 4 pts had exanthema, 10 symptoms of parainfluenza bouts. Physical & immunological follow-ups (6-9mo after SC; mean: 19mo) showed that only 19 pts (31%) had non-pathological results; after 6-12mo, already 16 pts (56%) had an increase in CD8+ cell count, 4 pts (14%) a decrease in CD4+ cell count. **Conclusion:** 2/3 of our patients presented with subclinical or manifest symptoms due to acute HIV infection. Further examinations will have to show whether different patterns of acute infection correlate with different long term courses.

Ramzi A. Sharrakhal and Averbach T.*
*The Hebrew University & Hadassah Faculty of Medicine, Jerusalem, Israel, **Harvard University, Cambridge, MA, U.S.A.

Utilizing equations which were developed for probabilities of HIV infection through sexual intercourse, we demonstrate the asymmetry of the probabilistic risks for a man and a woman engaging in sexual intercourse in a Western society. Two factors determine this asymmetry: 1. The prevalence of AIDS and HIV seropositivity varies widely between men and women of specific age groups, and 2. the infectivity of receptive vaginal intercourse is also asymmetric between the sexes, women being at higher risk. The equations for the two extreme possibilities of a monogamous relationship with many events of intercourse and for multiple partners with one contact with every partner are respectively:

$$P = \frac{1 - (1 - P)^N}{N} \quad \text{for } (1 - (1 - P)^N) \cdot N$$

P = probability of being infected in the situation described; P = probability that a partner is infected (the prevalence of HIV in the group from which the partner is assumed); 1 - P = probability that one contact with an infected partner will result in infection; N = the number of sexual encounters.

Solving these nonlinear functions for the ratios of P women/P men gave five relative risks for men and women to be infected in both types of encounters. As a situation where both the prevalence for men is higher and their risk is lower for vaginal intercourse the Women to men ratio is much higher.

The implications of these findings are profound when formulating the objectives and concepts of educational interventions among sexually active heterosexuals. While condoms are used by men, it is mainly by women that a more distant of women that one should use condoms. Thus it may be essential to introduce "cooperative" motives into educational interventions to supplement the "egoistic" one of "safe sex". The introduction of "responsible sex" and its implications are considered.

A.508 "GROUPS AT RISK" AND "RISK BEHAVIORS": THE NEED TO UTILIZE BOTH CONCEPTS IN DESIGNING TARGET POPULATIONS FOR EDUCATIONAL INTERVENTIONS AND DEFINING THEIR OBJECTIVES

Ramzi A. Sharrakhal
The Hebrew University & Hadassah Faculty of Medicine, Jerusalem, Israel.

The central claim of the paper is that the two concepts, "groups at risk" and "risk behaviors" are neither synonymous nor interchangeable, and that in order to describe target groups for educational or other interventions, both terms are needed. "Risk behavior" or its prevalence is only one component of the definition of a "group at risk"; in other components being the prevalence of HIV within that group. A comparison of two hypothetical groups, since the data of the actual behavior of actual sub-groups are only approximate, will clarify the distinction between the two concepts.

TYPE OF GROUP	PREVALENCE OF HIV IN THE GROUP	BEHAVIOR IN THE GROUP	CHARACTERIZATION OF THE GROUP
A	low	high	a group at low risk (vulnerable)
B	low	low	a group at low risk (vulnerable)
C	high	high	a group at low risk (vulnerable)
D	high	low	a group at high risk (resistant)

*"Risk behavior" in actual practice are multiple partners, low use of condoms in general and sexual intercourse with high experimentation and variation in sexual practices (including inserting intercourse and/or insertion).

**The prevalence may not be of behavior but of conditions, i.e., a homosexual meeting an isolated component.

*** A situation may arise in which the group at risk is no longer a "group at risk" because of changing conditions, but in such a case the group at risk is still a "group at risk" because of the characteristics of the group.

Group A and B represent homosexual/heterosexual and adolescents in Israel, respectively, while group C and D represent the sub-population of homosexuals after the introduction on modified forms. Group A is exposed from the point of view of public health, health planning, and the design of educational interventions, both concepts are essential, since educational interventions for a group at future risk should differ from those for a group at immediate risk not only because of the characteristics of the group but also because of the characteristics of the risk. "Groups at risk" is therefore a useful and meaningful term.

A.509 SURVEILLANCE OF HIV-1 INFECTIONS BY ELISA USING HIV-1 AND HIV-2 SPECIFIC SYNTHETIC PEPTIDES

P. Leikola, J. Mäkelinen, M.-J. Karkonen and H. Brummer-Korvenkontio, National Public Health Institute, Helsinki, Finland.

OBJECTIVE: To screen for HIV-1 and HIV-2 cases in Finland and to evaluate a new test employing HIV-1 and HIV-2 specific synthetic peptides as antigens.

Methods: Serum samples sent for routine HIV-testing from healthy individuals and HIV risk groups were tested by an ELISA with either a combination of, or individual HIV-1 or HIV-2 specific synthetic peptides representing the N-terminal regions of gp-41 (COMB-test, Pharmacia Inc. Uppsala, Sweden).

Results: Of the 5221 sera negative with other tests, 9 were repeatedly reactive in the COMB-test indicating a specificity of 99.84. Among the 25 true positive sera 23 gave no or very little activity with HIV-2 compatible with true HIV-1 infections. Two samples, originating from the same individual reacted with the HIV-2 specific peptide. They also showed gp-reactivity in HIV-2 western blots. The patients had worked in endemic areas of Africa before returning to Finland. One falsely reactive sera also showed high activity against HIV-2.

CONCLUSION: The result indicates that the test has good specificity and is able to reveal HIV-2 positive cases among samples thought to be HIV-1 positives by conventional techniques.

A.510 HIV-1 SEROPREVALENCE IN A GROUP OF HIV POSITIVE ITALIAN SUBJECTS (IN PARTICIPATING UNDER SURVEILLANCE) - PROGNOSTIC DATA

Laura Loggioni, F. Giacomoni, P. Lanza, A. Berretta, A. Rinaldi, S. Sabatani, Dipartimento di Biologia generale - Università di Milano, Milano; * Divisione di Malattie Infettive - Ospedale Maggiore Bologna, Bologna, Italy.

Aim: We detected the presence of specific HIV-1 antibodies in HIV positive subjects to evaluate (1) the percentage of double infection (2) if the subjects with double infection presented an evolutive pattern.

Methods: The presence of specific HIV-1 antibodies was tested by ELISA method in 240 HIV positive subjects (212 were intravenous drug abusers). The HIV seropositive samples were investigated by Western blot assay.

Results: The presence of HIV-1 ELISA reactivity was found in 17 of the 240 HIV positive sera (7.08%). This reactivity was not confirmed by Western blot in 2 subjects, 6/17 subjects were AIDS. **Conclusions:** The data confirmed the presence in Italy of HIV-1 specific antibodies in HIV positive subjects also suggested in other epidemiological studies. We need a follow up of HIV-1 and HIV-2 positive subjects to evaluate a possible higher evolutive pattern towards AIDS.

A.511 INCIDENCE OF HIV MARKERS AND HIV ANTIBODIES IN BLOOD DONORS IN LISBONA AND FERREIRA, PEOPLE'S REPUBLIC OF ANGOLA

Luiz Carlos Martins, Cohen T. M., O'Brien F. A., Sousa-Ferreira, M. O. P., Mann-Almeida, M. J. A., Almeida Neves, J. K. V.

*Lab. Virology, Fac. Pharmacy, Univ. Lisbon, Portugal; **American Univ. Health Sciences, London, B. P. Africa; ***Vista, St. Maria, Lisbon, Portugal. JNICT GRANT 87-679

Objective: To determine the prevalence of HIV 1 and HIV 2 infections and hepatitis B markers among a cohort of blood donors in Lisbon and in Ferreira, People's Republic of Angola.

Methods: The incidence of HIV markers and HIV antibodies was evaluated in 124 blood donors living in Lisbon (74) and Douro (50). Serological tests for detection of HIV antibody, including the specific HIV 1 and HIV 2 ELISA kits, HLA, W. K. Comp-reactivity between HIV 1 and HIV 2 large glycoproteins were further tested against a synthetic peptide corresponding to the dominant epitope of transmembrane protein. Serological tests for detection of HIV markers were performed with ELISA kits.

Results: As shown on table.

Location	Distribution of HIV antibody and HLA Ag. HLA Ag. HLA Ag. HLA Ag. HLA Ag. HLA Ag.					
	Anti-HIV-1	Anti-HIV-2	HLA Ag. HLA Ag.			
Lisbon	74	17(41.1)	14(7.14)	28(74.13)	17(41.1)	17(41.1)
Douro	50	3(7.6)	1(2.0)	1(2.0)	1(2.0)	1(2.0)
TOTAL	124	31(24.1)	15(11.9)	29(23.1)	17(13.7)	18(14.1)

Discussion: The incidence of HLA Ag. in sera from Lisbon and Douro is high. HIV 1 and HIV 2 infection rates among blood donors. The highest percentage of positive cases in Douro, Portuguese region, border of Zaire. The social and economic consequences of these problems have to be considered.

A.512

ANALYSIS OF A SCREENING PROGRAM FOR HIV AND HIV INFECTION IN MEN OF REPRODUCTIVE AGE

H. H.***
Foundation of "San Giuseppe", Faculty of Medicine of Lisbon and Faculty of Pharmacy of Lisbon***
Av. Prof. Aguiar Rosa - 1600 LISBOA - PORTUGAL.

OBJECTIVE: 1 - To study the prevalence of antibodies to HIV and HIV in a population of men attending a Family Planning Clinic (FPC) and a men's clinic. 2 - To derive a protocol of a study which would include the following: a) a study of the prevalence of HIV and HIV in the population; b) a study of the prevalence of HIV and HIV in the population; c) a study of the prevalence of HIV and HIV in the population.

MATERIAL AND METHODS: All men attending the FPC and the AC from January 1987 to December 1988 were screened for HIV and HIV. A total of 1,000 men were screened. Blood was collected from each man and analyzed for HIV and HIV. The results of the serological tests were compared with the results of the clinical information related to HIV infection. Blood was collected from each man and analyzed for HIV and HIV. The results of the serological tests were compared with the results of the clinical information related to HIV infection.

RESULTS: Three out of 100 Portuguese men were positive for HIV-1. All had one out of 50 HIV-2 seropositive men. The prevalence of HIV-1 and HIV-2 in the samples collected at different times if the criteria for defining women as seropositive did not include tests on a second sample, the number of seropositives was 100. It is important to note that the results of the serological tests.

CONCLUSIONS: A representation of both HIV-1 and HIV-2 in this urban population was found and the prevalence of HIV-2 in a second sample as a means of reducing false positive is documented in this study, where a protocol to repeat serologically the blood tests was implemented, taking advantage of the special conditions in this health center.

- A.513** Stochastic Models Illustrate Vividly the Connection between Behavior and Risk for HIV Infection. Gonzales, Jorge J., Myrvet, M., Vavik, L., *ASA, Arendal, *Teachers College School, Rossmore, Norway.

Objective. To use the power of modern Personal Computers to display graphically the connection between behavior and risk for HIV infection.

Methods. A stochastic simulation model takes into account stochastic parameters in a hypothetical risk environment. The correlation between behavior patterns and risk for HIV infection is displayed by means of powerful graphics.

Results. We describe the application of our stochastic simulation model to train medical personnel and school teachers in Norway and West Germany.

- A.515** IS SEXUAL PROMISCUITY A RISK FACTOR FOR HIV IN EAST AFRICA? Ng'othia, G., Constantia, H., and Abacha, E., *U.S. Naval Medical Research Unit No. 3, Cairo, Egypt (A WHO collaborating center for AIDS), **Direction Technique de la Santé, Djibouti, Djibouti

Objective. To investigate if the 8-cell lymphocyte virus HIV-2 shares the sexual transmission route of HIV in East Africa.

Methods. 200 sera belonging to 2 groups of individuals from the East African city of Djibouti were tested for antibodies against HIV-2. Study groups comprised sexually promiscuous individuals at high risk for HIV, but HIV-2 western blot negative; 50 female prostitutes in Group 1 and 50 males with a sexually transmitted disease in Group 2. Group 3 comprised 50 female controls and Group 4, 50 male controls. All sera were screened at a 1:50 dilution using IFA (Immunofluorescence) incorporating HIV-2 infected and uninfected cells as substrates. Sera with positive reactions were titrated further.

Results. Despite the slightly higher percentage of positive sera (50%) at the screening dilution in the two study groups, these differences were not statistically significant. Moreover, median titers and geometric mean titers of positive sera were very similar in all 4 groups.

	Group 1	Group 2	Group 3	Group 4
SER:	66	74	70	70
Median titer:	40	40	40	40
Geometric mean titer:	39	37	38	39

Conclusions. Sero-epidemiological data indicate that HIV-2 infection was not more prevalent among sexually promiscuous subjects. Thus, HIV-2 does not seem to share the sexual transmission route of HIV in East Africa. Supported by DANMED/WHO/CDC, Bethesda, Md, work Unit No. 3663103B05.A0.333.

- A.517** ACCIDENTAL EXPOSURES TO HIV-POSITIVE BLOOD AMONG HEALTH-CARE WORKERS IN 2 SWEDISH HOSPITALS.

JÖRBERG, HANS. Marland, M., Sjöström, E., Danderyd Hospital, Danderyd, Sweden.

Objective. To document circumstances, frequency and outcome of accidental exposures to HIV-positive blood and body fluids among health-care workers.

Methods. This prospective study was started in January 1, 1983. It includes health-care workers in 2 Swedish hospitals giving medical care for HIV-infected patients. All reported cases of damage with exposure to HIV-positive blood or body fluids among more than 2 500 health-care workers have been registered. Blood samples (including an early blood sample) of the exposed workers have been regularly taken and examined (ELISA).

Results. Among 70 accidents have been reported, so far. Different kinds of personal exposures were dominating. So far, all anti-HIV antibodies have been negative.

Discussion and conclusions. Seronegativity after accidental exposure with blood has been estimated to 5 per 1 000 exposures. In our study no seroconversion in around 40 persons and 30 other HIV-accidents have yet been confirmed, which is to be expected. The majority of the seronegative HIV-accidents were caused by needle-sticks in combination with phlebotomy, blood-culturing and injections. To our judgment, around 1/3 of the accidents might have been prevented.

This study clearly shows that hazardous circumstances, among others, were manipulation with needles (recapping, disposal, "cleaning up"), laboratory work (tubes) and surgery (secure needles). To minimize the risk in the future we have to identify hazardous circumstances, work etc and do something about it (guarded needles, puncture proof boxes, safe work practices). Further, we have to educate and inform health care workers, as well as others, about the hazards and change their behavior if needed!

- A.514** HIV Screening Efforts in a Low-Risk Population. MARSHALL, CHARLES E., Sanchez, Jose L., *Buffalo, Pa; Lewis, Vasari M., Guterman, Frank L., *Wessex Army Community Hospital, Ft Belvoir, Ill; *Walsh Reed Army Institute of Research, Lexington, DC, USA.

Objective. To determine the prevalence of HIV antibody seropositivity in a low-risk population.

Methods. The U.S. Army requires HIV testing at least biannually for individuals on active duty. Blood donors are also routinely screened for HIV infection. During the past year, inpatients and some outpatients have received an HIV antibody test. These patient categories are listed below.

Results. High-risk patients, which include people with clinical evidence of HIV infection, individuals treated for substance abuse and contact referrals, have the highest HIV antibody prevalence rates. Patients treated at a sexually transmitted disease (STD) clinic had the next highest prevalence. Routine hospital admission and blood donor screening showed rates similar to or lower than that seen in active duty screening.

HIV SCREENING RESULTS

	N	Pos/Screened	Prevalence/1000	95% C.I.
High-risk group	24/278	14.3	58.8 (9.19-3)	
STD Clinic	31/327	10.4	32.9 (6.12-3)	
Med/Wurg Admissions	17/112	1.1	9.8 (0.11-1)	
OS/RT Admissions	1/2246	0.4	1.8 (0.16-4)	
Blood Donors	15/1513	0.6	4.2 (0.16-8)	
Active Duty Screening	81/3894	1.8	4.6 (0.81-3)	

Conclusions. Adjusted HIV screening of routine hospital admissions does not appear to be warranted.

- A.516** A PROSPECTIVE STUDY OF HIV INFECTION IN FORMER DRUG USERS: A 4-YEAR STUDY OF 114 PATIENTS. ALLENWOOD, GRINGIRI, R.G.H., M. Colombo, A.L. Zanetti, R. Romeo and P.S. Manonni. University of Milan, Milan, Italy.

Objective. To assess whether or not stopping drugs has any beneficial effect on the course of HIV infection, inactive drug users living in the community of San Patrignano (Italy) were prospectively followed. **Methods.** These patients voluntarily enrolled into a rehabilitation program based on agricultural, handicraft and industrial activities and were forcibly taken off drugs during residence. Except for married couples, they had no sexual contacts. Since 1985, 203 seropositive, western-blot confirmed, asymptomatic patients have been followed at 6-month intervals for 6-66 months (median 32). 179 patients (59%) were lost because they either reached the end-point of rehabilitation (12%) or left the community (32%). 114 patients (61 M, 33 F, 16-42 yrs of age, median drug abuse: 6 yrs) are currently being followed. 65 patients (21.9%, 6.4% annual incidence by 110-month analysis) deteriorated to stage IV (CD4), 5 developed full-blown AIDS (5.2%, 1.2% annual incidence). The annual deterioration rate for a control group of 110 active drug users who were followed as outpatients between 1985 and 1988 was 28.4% (1.6% vs 28.4% P<0.01).

Conclusions. Stopping illicit drugs may be beneficial to the outcome of HIV infection.

- A.518** RISK FACTORS FOR HIV INFECTION AMONG INDIVIDUALS SEEKING TESTING IN THE UNITED STATES.

WILSON, VICTOR. Zeffman, S., Frank, A., Brandenburg, R., Sivils, R., *State University of Pennsylvania, University of Colorado, Colorado, USA.

Objective. To characterize individuals seeking HIV antibody test and to evaluate the prevalence of anti-HIV sero test. **Methods.** Self-administered questionnaire distributed together with test results to individuals requesting HIV testing in all parts of the health care system in 4 states in 1987-1989 and April 1989. 2169 (55%) completed the questionnaire. **Results.** Seropositivity was 32% of sero tested sera. 26% in the age groups 15-29, 26% in 30-39 years of age. 70% of sero tested individuals were male. Risk factors and their association with seropositivity are listed in the table.

Risk Factor	No.	Sex	Anti-HIV sero. pos.	Anti-HIV sero. pos. %
Reported risk factor	8	(M)	8	(100)
IV drug abuse	182	(182)	182	(100)
High heterosexual behavior	182	(182)	182	(100)
Sex with IV drug abuser	28	(28)	28	(100)
Sex with person from Africa, overseas with bisexual male	89	(89)	100	(100)
Sex with heterosexual partner within the last 12 months	455	(444)	2	(.4)

Sex of above: 100 (28) M, 302 (100) F
1000 (200) M, 1000 (100) F
The overall prevalence of anti-HIV was 12%, highest among sex with heterosexual behavior. **Conclusions.** Many individuals seeking HIV testing are heterosexuals and have a very low prevalence of HIV. Being male to seek valid estimates of the prevalence of HIV infection in the general population requires prevalence studies may give valuable information about trends in infectious disease.

A.519 NATIONAL STUDY OF HIV SEROPREVALENCE IN NATIVE AMERICANS
Gentry, George A.,* Wooper F***, Malgoures SD***,
*Centers for Disease Control, Atlanta, Georgia; **Indian Health Service,
Phoenix, Arizona; ***Indian Health Service, Tucson, Arizona, U.S.A.

Objective. To assess existing levels and future trends of HIV infection among American Indians and Alaska Natives in the United States.

Methods. Following approval from tribal authorities, blinded seroprevalence testing will be conducted on men obtained for syphilis screening from pre-natal patients, patients undergoing initial evaluation for a sexually transmitted disease, and patients entering drug or alcohol treatment programs. The study will be conducted throughout the Indian Health Service (IHS) (case population of approximately 1,144,000 individuals). Approaches to sera collection will be tested for HIV antibodies during a one-year study interval starting in 1989. Results will be stratified by reason for sera being obtained and by rural or urban clinical setting. Sera will be segregated by clusters of $\geq 20,000$ service population to further protect confidentiality and ensure statistical reliability of results.

Results. The pilot phase will begin in January, 1989. By March, 1989, surveys are expected to be implemented in many of the IHS service areas.

Conclusions. These surveys will provide relatively unbiased estimates of seroprevalence for the clinic subpopulations of IHS service users. It should also serve as a baseline that may be followed through time for the assessment of the progress of the epidemic and preventive activities in this population.

A.521 SEROPREVALENCE OF HIV ANTIBODY IN A CITYWIDE SAMPLE OF EMERGENCY ROOM PATIENTS
Modest Deyan*, Jai J**, Stevens P**, Holman S*, Shriver J*,
*Delta Health Division, **Oregon Health Division, ***Oregon Health Sciences University, Portland, Oregon, U.S.A.

Objective. To determine prevalence of HIV antibody in a citywide population of patients seeking emergency room (ER) care.

Methods. Seven hospital-based emergency rooms providing 90% of Portland's emergency services collaborated to simultaneously measure HIV seroprevalence in their combined patient population. During two 48-hour periods in the summer of 1988, all blood drawn from patients for other purposes were tested for HIV antibody after personal identifiers had been removed. Specimens were also screened for hepatitis B surface antigen (HBsAg) and core antibody (HBeAb). Demographic and risk factor information as obtained by routine ER practice was linked with test results.

Results. Blood from 444 patients was tested. Patients' residences were evenly distributed throughout the metropolitan area. The largest proportion of patients were in the 20 to 30 year age group (24.9%/year age group (18%) and in the 40 and over group (18%). Twenty-one patients (4.7%) were identified as intravenous drug users. No males were identified as being homosexual. Seven percent of patients had experienced transfusion. Invasive procedures were performed on 34% of patients. Only 2 patients (0.45%, 95% CI ± 0.22) tested HIV positive. One of these patients was already known to be HIV positive. Three of 444 (0.68%, 95% CI ± 0.16) patients were HBsAg positive and 55 of 444 (12.4%) were HBeAb positive. Conclusions: The rate (0.45%) of HIV seroprevalence in this city-wide mixed low and high risk population is the rate of HBsAg seroprevalence (0.68%). In contrast, the prevalence of HBeAb (12.4%) indicates a substantial proportion of this population may be at risk for future HIV infection. This method of passive sampling may provide a simple way to estimate HIV infection rates in a general population.

A.523 ACCEPTANCE OF HIV-ANTIBODY SCREENING AND PREVALENCE OF ANTIBODIES AGAINST HIV AT A STD CLINIC

Hilitt B, Holmstedt and Mørch, HK**
*Statens Serum Institut, **Nilspejlegade 1, Copenhagen, Denmark.

During periods of three weeks repeated every third month from October 1987 to February 1989, all persons attending a STD clinic in Copenhagen for serodiagnosis were offered a blood test for HIV-antibodies. The test could be performed anonymously or not. Data concerning sexual orientation, prostitution, first abuse and sexual contacts with high risk groups were collected. During all four periods 1751 persons attended the clinic. HIV-antibody testing was not accepted by 11.0% of heterosexual men, 9.6% of homo-/bissexual men and 9.8% of the women. No major differences in acceptance of HIV-antibody testing during the four periods was seen. Four heterosexual men, 11 homo-/bissexual men and one woman were found HIV-antibody positive. The data support that a constant number of clients attending a STD clinic would even anonymously HIV-antibody testing and underline the necessity for blinded HIV-antibody testing in order to disclose the true prevalence in this group.

A.520 DETECTION OF HIV ANTIBODIES IN DENTAL SCHOOL AT THE UNIVERSITY OF BUENOS AIRES

Cespede JM, Sobaglia L, C*, Tricca A*, Brizuela J*, Benaglia M*, Macklin G, Guillemeo** et al.
*Curso de Microbiología, Facultad de Odontología, Universidad de Buenos Aires, **INIDMA, Academia Nacional de Medicina, Buenos Aires, Argentina.

Objective. To determine HIV-infection seroprevalence in dental professionals, as they represent an important group to study HIV-infectious occupational risk.

Methods. A total of 617 subjects was included in this study: 400 first-course students at the School of Dentistry, 112 predoctoral students and 105 dental professionals. Serum samples were tested for HIV antibodies by means of ELISA (Abbott recombinant HTLV III ELISA). Samples reacting positive by ELISA were confirmed by Immunodiffusion or Western Blot.

Results. Only 10 (1.6%) males out of the 400 first-course students had HIV antibodies. Risk-factor analysis in the seropositive cases showed that 1 subject was homosexual and intravenous drug abuser and 2 were intravenous drug abusers.

Conclusions. Though dental professionals are likely to be repeatedly exposed to HIV-infected persons, we did not find infection in any of the 112 predoctoral students, nor in the 105 dental professionals, assuming a low risk for the studied group.

A.522 SEXUAL MIXING MODELS WITH LIKE-WITH-LIKE PREFERENCE

Stultz, Peter* and Castillo-Chavez, Carlos**
*Strathclyde University, Glasgow, Scotland, **Cornell University, Ithaca, New York, USA.

Objective. To develop an alternative to proportionate mixing in sexually transmitted disease models.

Methods. Starting from the three fundamental constraints on a mixing function (it must be positive, normalized, and conserve the number of partnerships), a new mixing model can be constructed by finding an appropriate transformation of a suitable function (describing mixing between individuals of similar activity).

Results. A new mixing model is derived, based on a transformation of a local mixing function ("like-with-like") which has the property $f(x) = f(y)$. Different choices of f provide different degrees of localized mixing in the population, and affect the dynamics of an STD epidemic.

Conclusions. Predictions of epidemics of STDs are very sensitive to the nature of like-with-like mixing in the population.

A.524 THE INFLUENCE OF CHANGES IN SEXUAL BEHAVIOUR ON THE TRANSMISSION DYNAMICS OF HIV-1 IN THE UK

Opina, Santos; Blythe, S.; Anderson, R.M.
Imperial College, London, UK; *Strathclyde University, Glasgow, Scotland.

Objective: To assess the consequences of changes in sexual behaviour on the transmission dynamics of HIV-1 with reference to the male homosexual community in the United Kingdom.

Methods: The distribution of sexual activity (rate of acquiring new partners) and transmission probabilities (involving the adoption of "safe sex") are altered in a simple model of the transmission dynamics of HIV-1. The model incorporates distributed infectious and incubation periods.

Results: The future course of the HIV-1 epidemic is highly sensitive to the timing and the magnitude of changes in sexual behaviour. The effects of changes in sexual behaviour are not linearly proportional to either the magnitude of the change or the time of its initiation. Conclusions: The timing of a change in sexual behaviour is crucial in reducing the numbers of future AIDS cases. Great benefit is obtained by changing sexual behaviour as soon as possible, and any delays drastically reduce the impact of a change.

IMPACT OF REVISED CASE DEFINITION ON AIDS SURVEILLANCE IN EUROPE

Rocheleux Park, Bessy, Couturier, L.*, Brunet, A.S.* and national surveillance coordinators of 21 countries. WHO Collaborating Center on AIDS, Paris, France.

Objective: To determine the modalities of application and impact of the revised WHO AIDS case definition on surveillance in Europe.

Methods: A survey was carried out among the 32 countries of the WHO European region investigating modalities of surveillance of AIDS and application of revised case definition.

Results: Of 20 countries having answered by end of January 1989, 15 have set up a surveillance system for HIV-1 individuals. 20 countries have an AIDS surveillance system which is mandatory and 6 voluntary. Under-reporting has been assessed by few countries 9/20 mostly by matching AIDS cases with death certificates. Revised case definition was applied in all 20 countries by 01/01/89. Six countries have actively carried out a retrospective investigation on cases previously reported with AIDS and 3 have also investigated HIV patients not previously diagnosed with AIDS. 156 AIDS patients fitting the revised case definition have been reported representing an increase of 4%. This is much lower than figures reported in literature.

Conclusion: Most of the 20 countries having answered by end of January 1989 had applied the case definition by first of January 1989. Impact of new cases is extremely low and will be assessed when complete set of answers are received.

A.538

THE INCIDENCE OF GLOVE PRACTICE DURING GONORRHOEA TREATMENT AND VARIATION

PROTECTIVE EFFECTIVENESS

J. J. BENTON, J. M. BART, Departments of Obstetrics, St Mary's Hospital, London, and The Wellcome Women's Hospital, Langenbeck, West Kingston.

A study was performed to ascertain the incidence of glove practice at lower urinate suggest. The increasing incidence of hepatitis B and HIV infection in women make this of increasing importance to surgeons. The following results were obtained:

Total Gonorrhoea patients	200
Total where gloves practiced	107 (53%)
Nonurine control - during emergency Gonorrhoea section	6/116 (5%)
- during elective Gonorrhoea section	30/120 (25%)
- Urine control	5/128 (6%)
- Urine not controlled	50/110 (45%)
- during closure of urterine canal	3/90 (3%)

*We stated whether emergency or elective section in 10 cases. **We stated whether controlled or not in 5 cases. This trial shows the highest rate of glove practice yet reported during a surgical procedure. By its currently undergoing a controlled trial of a new form designed to grip both urterine muscle and meatus more effectively. The use of double gloving, white latex gloves, new gloves (Elastogel) on the fingers and the increasing use of staples for skin closure should also reduce this unacceptably high rate of practice.

A.539

MODIFICATIONS ET VARIATIONS GÉOGRAPHIQUES DES GROUPEMENTS DE TRANSMISSION DE L'INFECTION VIH EN FRANCE

Leclerc, M., Christine, Ligue Française pour la Prévention des Maladies Infectieuses, France.

Objectif: Préciser la répartition actuelle des groupes de transmission sur l'ensemble des sujets infectés par le VIH quelle que soit la stade, en France.

Méthodes: Recensement de tous les sujets séro-positifs hospitalisés ou vus en consultation dans 20 Services de Maladies Infectieuses du 1er juillet 1987 au 1er juillet 1988.

Résultats: Sur 3873 sujets recensés, dont 80 % non atteints de SIDA, la répartition des groupes de transmission était la suivante: homosexualité 37 %, toxicomanie 41 %, transfusion et hémosuccès 7,8 %, transfusion et hémosuccès 6,9 %, autres et indéterminés 5,1 %. Le pourcentage de toxicomanie y était le plus élevé dans le Sud, à Marseille, 80 % et à Nice 66,6 %, et le plus faible dans le Nord, à Lille, 12 %.

Conclusion: Le groupe de transmission toxicomanie y est pour l'ensemble des sujets séropositifs nettement plus important que pour le seul groupe des SIDA déclarés (20 % des SIDA en 1988). Ce groupe est surtout important dans les zones méditerranéennes, comme pour l'Italie et l'Espagne. Il représentera le groupe le plus important des malades atteints de SIDA dans les prochaines années en France.

HIV SEROPOSITIVE MEN INFECTED WITH MULTIPLE CMV STRAINS: A LONGITUDINAL STUDY OF THE RELATIONSHIP TO T-CELL SUBSETS

Leach, Charles*, Daniels, R.; Visccher, B.**; Giorgi, J. and Cherry, J.* UCLA - Sch. of Medicine and **Public Health, Los Angeles, CA, USA.**

Objective: To investigate the relationship between serial infection with multiple CMV strains and T-cell subsets.

Methods: We identified 56 asymptomatic HIV-1 seropositive homosexual men participating in a study of HIV-1 infection who acquired CMV from semen at two visits 5 to 8 months apart. CMV DNA was isolated from paired isolates in six men, cut with restriction enzymes and then subjected to junctional hybridization. Lymphocyte subsets were determined by flow cytometry.

Results: Paired isolates from each of 2 men gave identical banding patterns (Group 1). Four men were found to acquire a non-identical strain at the second visit (Group 2). Both groups had lower CD4 and CD8 counts at the second visit (mean decrease in CD4: 27% (Group 1), 35% (Group 2); mean decrease in CD8: 14% (Group 1), 33% (Group 2)).

Conclusion: Serial acquisition of multiple CMV strains occurs in asymptomatic HIV infected homosexuals. All 6 subjects persistently shedding CMV had decreases in CD4 and CD8 cell counts. Evaluation of the remaining CMV isolates (in progress) is necessary in order to determine whether men with multiple strains have different changes in T-cell subsets than men with identical strains.

A.541

SEXED HIV RISK BEHAVIOR REDUCTION IN PUBLIC WORKERS

Leiro, M., Fumason, A., Valenzuela, J., Baker, Charles E. Dallas County Health Department, Dallas, Texas, USA.

Objective: Reinforce safer sex behaviors among sexually active gay men.

Methods: Health department staff of the High Occupancy of contact for sexual partners among gay and bisexual men, particularly at one public employees prepared package for distribution in the park. Each package contained condom packages coded with a red stripe, safer sex brochures, and a list of services available at the health department, including anonymous HIV antibody testing and counseling. The packages were distributed to park patrons who appeared to be in the park for the purpose of arranging sexual partners who appeared to be in the park for non-threatening behavior. The park patrons were offered the plain white packages and were told the packages were "house product samples." Anecdotal information was collected about the manner of the patrons, the frequency of entering and leaving the park, the park hours for patron contact in the park. Demographic information was collected.

Results: Condom packages were found in the park after the health department began the package distribution. Patrons accept the packages, are not threatened, appear interested in the material and appreciate our effort in coming to them. Patrons are called the health department and ordered laundry approach used by health department staff promotes a sensitive image of the health department, as it also facilitates safer sex behavior reinforcement.

A.542

PREVENTION OF PERINATAL TRANSMISSION OF HIV

Berman, Stuart; Centers for Disease Control, Atlanta, GA U.S.A.

Objective: In report projects to date by projects to prevent perinatal HIV transmission.

Methods: Home demonstration projects evaluate and facilitate the use of contraception and encourage risk reduction among women HIV-infected or at highest risk for infection.

Results: The project, funded for \$6.5 million per yr, are a major way for CDC to develop perinatal HIV prevention interventions for implementation by State government and provide additional resources targeting minority and inner-city populations. Projects will address 2 factors determining HIV seroprevalence among newborns: HIV prevalence among women (15-44) and birth rates among those HIV+. Efforts have focused on limiting spread and increases in prevalence of HIV among women. However, effective program development requires data about contraceptive practices and attitudes and about reproductive decision-making among women such as female intravenous drug users (IVDs) and sex partners of drug users—the mothers of 75% of pediatric perinatally-acquired AIDS cases. In 10 cities women who are crack users, IVUs, sex partners of IVUs, prostitutes, or HIV+ will be assessed in public clinics, obstetric units, drug treatment, through referral by community organizations, and by outreach among AODC, efficacy of referral, use of contraception, and risk reduction will be evaluated and facilitated. Among them, pregnancy rates, breastfeeding attitudes, and determinants concerning use of contraception will be assessed.

Conclusions: These projects should provide information to direct efforts to prevent perinatal HIV transmission.

VIRUS, SYMPTÔMES ET TOXICOLOGIE.
ESPÉRANZA FERRAZ, LOUVERNE J. L., RICHMOND R. C., ROCHARD J.
 = Établissement d'Hygiène Publique Nationale, France, France.
 Alle des Thuys 94251 PIRENES CEDEX FRANCE.
INTRODUCTION: L'échage de seringue chez les toxicomanes expose au risque de contamination VIH. Les tests de seropositivité sont élevés (>50%) chez les drogués en région parisienne. Les risques de transmission sexuelle sont peu documentés chez cette population.
OBJECTIFS - MÉTHODES: Préciser et comparer le mode de vie sexuel, les taux de seropositivité VIH, les marqueurs de l'apoptose chez les toxicomanes IV et les toxicomanes aveugles. Conditions : consentement, confidentialité, anonyme.
RÉSULTATS: Population : toxicomanes de sexe masculin, incarcérés en Juin 87 : 183. 18 infirmeries (sans d'injection) Pas de différence statistique pour l'âge (27 ans), la réponse de 2 usages de drogue (1/soir) la durée de la toxicomanie (5ans), les caractéristiques de vie sexuelle : 72 statut conjugal, 2 homosexuels, 5 bisexuels, 23 rapports 2 cas 21 avaient des rapports uniquement avec leur conjoint et 5 (15%) avec des prostituées. Parmi les partenaires sexuels féminins 40% utilisaient des drogues IV. Une différence statistiquement significative est retrouvée pour les facteurs suivants :

	VIH	WBL (vs) TP/TH	Nouveaux partenaires(1)
IV n = 63	30 (45%)	17 (27%)	14
Non IV n = 120	53 (44%)	31 (26%)	14

CONCLUSION: L'incarcération VIH est liée à la toxicomanie IV. La fréquence de la syphilis chez les IV et aveugles fait craindre des risques de transmission hétérosexuelle de VIH.

A.545

EARLY COURSE OF HIV INFECTION IN 40 SEROCONVERTERS
Alessi, E., Muratori, Simoni, Martoni, S., Guini, N., Cervinatti, G. and Marzoni, M.
 Inst Clinic of Neurology, University of Milan, Milan, Italy.

OBJECTIVE: To study the natural history of HIV infection.
METHOD: Forty homosexual, who became seropositive from December 1985 to January 1986, were followed from 11 to 36 months (mean 23 months). The mean time between the last negative and first positive tests was considered to be the time of infection. Clinical, immunological and virological parameters were assessed at enrollment and every 4 months.
RESULTS: Generalized lymphadenopathy developed in 15 patients from 3 to 15 months, mainly insidious in 1 (after 4,15,17 and 22 months) had constitutional symptoms in 3 (after 31, 21, and 29 months). The development of constitutional symptoms was accompanied by HIV antigenemia, but symptoms and antigenemia spontaneously regressed in 2 of 3 patients after few months. No statistically significant modification of immunological parameters was observed in about 50% of patients. Only one patient developed profound immunosuppression.
CONCLUSION: Our follow up study demonstrated the variability of the course of HIV infection. Some of the laboratory parameters analyzed seemed of value in predicting the disease progression.

A.547

PROFIL ÉPIDÉMIOLOGIQUE DES INJECTIONS SEXUELLES AU VIRUS D'IMMUNODÉFICIENCE HUMAINE (VIH) EN SUISSE.
Duressat, J.-M., Baccini, J., Marouzzi, J., Lépigne, M., SAAD, M.P., Université de Sherbrooke, Sherbrooke, Québec, Canada.

OBJECTIF: Décrire la population infectée par le VIH dans un milieu plutôt rural. Afin d'en souligner les différences par rapport au milieu urbain.
Méthodes: Étude rétrospective de tous les cas de SIDA (S), para-SIDA (P.S.) et infections, asymptomatiques (I1) diagnostiqués au CHU et dans ses hôpitaux affiliés entre octobre 1984 et octobre 1986.
Résultats: 85 personnes infectées ont été diagnostiquées dont 30 S, 20 P.S. et 35 I1. Les facteurs de risque pour cette population se lisent comme suit: homo-bisexuel 60%, drogues IV 23%, sang et dérivés 17.6% et contact hétérosexuel 14.1%. Le nombre de cas de S est passé de 3 par an en 1984 à 1 par an en 1986. 40% des S étaient des hétérosexuels (H), dont 20% de femmes. Le contact avec une personne infectée (21%), le prostitué (13.3%) par sexe en 1986, 40% des S étaient contactés (33.3%) étaient les P.S. le plus souvent identifiés chez les H. L'âge moyen des S est de 48.3 pour les hommes et 39.75 ans pour les femmes. 86% des cas de S ont été diagnostiqués en Suisse, mais 37% seulement se sont infectés en Suisse.
Conclusion: L'infection par le VIH est en progression constante en Suisse. Ce S s'explique la part plus importante que dans le reste du Canada (40% vs 18%). L'âge moyen des personnes les atteintes, est relativement élevée (56%). Le contact avec un S (23% vs 9%) et sanguin (13% vs 4.6%) sont plus élevés que dans le reste du pays. Une proportion importante des S diagnostiqués en Suisse s'est contaminée hors Suisse. Ces particularités diagnostiques de l'infection par le VIH doivent être prises en considération dans les campagnes d'information et de prévention.

A.544

DETECTION OF COLLISION VS LEAK IN CONDOM BIOLOGICAL TEST.
Torres, José, Amador, María, H., Muñoz, J., Navarro, J.,
 Comité Anti-SIDA, Barcelona, Spain.

Objective: The condom is recommended and used as an efficient barrier against HIV and other infections. In practice, the use of a condom may present irregularities or leaks. This has been resolved efficiently with rigorous sampling plans for leak-detection tests, realized in all standards by conductometric or electrochemical test (ET). But, as the test is made on a condom in repose and without mechanical tension, eventually existing micro-occlusions or micro-chaps would not be detected as leak. Given that a condom in use in sexual relations is subjected to forces and stress, deformations, there could appear leaks, invisible in condom without tension, and the protection is lost. To evaluate this loss of protection by HIV due to appearance of leaks while using (stretching) condom, it is proposed to test, with Rheological test (Rheo.) Methods, a condom tested with usual leak ET and Rheological test 2 homogeneous lots of 2 different manufacturers, considering the presence of leak at the indication of 50m/ISO 4074, (UNE 53625) and Rheological test 2 homogeneous lots of 2 different manufacturers (condom in repose). There was no leak found for the Rheological Test detected 1 and 14 leaks in the two manufacturers respectively. **Conclusion:** 1) Condom can prevent micro-occlusions or micro-chaps which will be transformed into leaks and holes and they will loose their protection effect against HIV when submitting them to forces and deformations. 2) The leak detection tests for condoms with the Rheological Test permit to reject non-safe condoms with micro-occlusions or micro-chaps which would not be detected by usual test (ET).

A.546

NATURAL HISTORY OF HIV INFECTION IN STRAITS SETTLES
 AT THE MEDICAL COLLEGE OF SINGAPORE
Rafiq, Alihan, Farner, G., Bhatia, G.,
 Singapore, S. Medical College of Virginia,
 Singapore, S. S. S.

OBJECTIVE: To describe the natural history of HIV infection in females seen at MCV.
METHOD: This study retrospectively compared the clinical course of 46 HIV infected women with 412 HIV infected men followed at MCV from 1/88 to 1/89.
RESULTS: Females comprised 10% of the HIV infected population seen at MCV; 36 (77%) were black, 14 (30%) were white, and 19 (41%) were Chinese. Their racial risk factor for acquiring HIV was 19 (41%) for 31 (47%), sexual contact 24 (48%), blood products 6 (12%) and 18 sexual exposures. During this time 35% of the women had AIDS compared to 33% of the men. Although a similar proportion of men and women were taking zidovudine the mortality rate for females was only 14% compared to 33% of the male HIV infected population ($p < 0.05$). The percent of men and women took zidovudine and T-cell counts were higher in women (40-35% of patients avail. alive survival time (date of HIV diagnosis to present) was longer in men than women (19-35%). **CONCLUSION:** The natural course of HIV infection in women is less well known than in HIV infected men. The lower mortality rate for women in this study may reflect later infection. Further investigation is required concerning the natural history of HIV infection in women.

A.548

LONG TERM FOLLOW-UP OF HOMOSEXUAL MEN WITH PERSISTENT LYMPHADENOPATHY: ATTACK RATE FOR AIDS.
Sankovitz, E., Gold, J.W.N., Campbell, S.W.,

Armstrong, D.
 Memorial Sloan-Kettering Cancer Center (MSKCC),
 New York, N.Y., U.S.A.

Objective: To determine the attack rate for AIDS in a cohort of homosexual men identified with lymphadenopathy between 1981-1983.
Methods: Cases of AIDS occurring in a previously described cohort (Medicine 1985; 64: 203-213.) followed at MSKCC were documented. Patients lost to follow-up (LF) were traced. **RESULTS:** The natural course of HIV infection in women is less well known than in HIV infected men. The lower mortality rate for women in this study may reflect later infection. Further investigation is required concerning the natural history of HIV infection in women.
Results: 25/41 LF were traced. 52 patients had been continuously followed. 3 HIV negative patients were excluded. 40 patients developed AIDS, 1 died without LF, 30 were alive without AIDS and 19 were LF. The attack rate for AIDS was 58.4% at 7 years.
Conclusion: The average annual attack rate for AIDS has been 8.3%/year in this population.

LACK OF ASSOCIATION BETWEEN FREQUENCY OF BLOOD DONATION AND SEROPOSITIVITY FOR HIV AND OTHER INFECTIONS: AN UNEXPECTED FINDING IN RIO DE JANEIRO - BRAZIL.

Marcia Filipe, C. F., Pereira, M. A., Osório, R. J., Martins, F. V. T., Jansen, W. C. M.* and Martins, C. M.*

* Federal University of Rio de Janeiro, Rio de Janeiro (RJ) Brazil.

Objective: Due to the importance of blood transmission in the diffusion of infectious disease in RD we have performed this study in order to better understand blood transmitted disease and frequency of blood donation.

Methods: 2,658 (non-paid) blood donors (16 to 60 years old) from the hemotransfusion center of our hospital, between January and June 1987 were submitted to VDRL, ELISA-ABOIT (HIV), Complement Fixation (Chagas) and RIA (HBsAg). An extensive questionnaire was submitted by a trained nurse in order to determine possible risk factors. Chi Square tests and confidence Limits were used for statistical analysis.

Results: The prevalence among blood donors (95% confidence interval) was found to be 4.4% for Lues (3.69-5.21); 0.56% for Chagas (0.29-0.83); 0.76 for HBsAg (0.39-1.12); 0.7% for HIV (0.41-1.01). There was no statistical significance between these infections was 5.6% (4.82-6.50).

Conclusions: The association between frequency of blood donation and frequency of HIV, Chagas and HBsAg, statistically significant results were found for Lues and blood donation frequency ($X^2=7.75$ p<0.001). We have also tested for possible association among these infections, in whom Chagas and HBsAg were statistically significant ($X^2=45.46$ p<0.001).

Conclusion: Our results show that the association between frequency of blood donation and reaction to most of the disease studied was very poor as it was for HIV, Chagas and blood transmitted disease. Findings about Chagas and HBsAg were

A.550

SEROEPIDEMIOLOGY OF HUMAN IMMUNODEFICIENCY VIRUS TYPE-1 AND VIRAL HEPATITIS INFECTIONS IN NEW YORK CITY INTERVIEWED DRUG USERS (IVDU)

Brown, Laurence B. M.*; Kreek, M. J.†; Trepo, C. M.†; Chu, A.†; Hagan, D.†; Phillips, L. M.†; Johnson, F. V.†; Institute for Research and Treatment Corporation, Brooklyn, *Marlin Hospital Center, †Rochester University, New York

NY, USA; ††Faculté Alexis Carrel, Lyons, France.

Objective: To examine the behaviors associated with HIV-1 and viral hepatitis infection in IVDU enrolled in drug treatment. **Methods:** As a part of a larger HIV seroprevalence study in which a standardized questionnaire was administered, 50 subjects recruited from patients enrolled in drug treatment in NYC in 1987. Seru was obtained and analyzed for HIV-1 antibodies (using ELISA and Western blot assays) and for hepatitis B virus (HBV) and hepatitis delta virus (HDV) antibodies and antigens. **Results:** The HIV-1 infection rate was 54% and 86% of the subjects had at least one marker for HBV infection. Serological evidence of anti-HBc, anti-HBc, anti-HBc, HBsAg, and HBeAg was found in 86%, 70%, 38%, 25, and 0%, respectively of the sample. No evidence had serological evidence of HDV infection and HIV-1 was associated with anti-HBc (p=0.073) serostatus.

Conclusions: These findings are consistent with similar mechanisms of transmission between HIV-1 and HBV and suggest that a HBV vaccination program among IVDU enrolled in drug treatment would have significant public health benefits.

A.551

TRENDS IN AIDS INCIDENCE BASED ON ACTIVE SURVEILLANCE IN 12 MEDICAL SCHOOL AFFILIATED HOSPITALS

Lawrence Mervin A. and Schneider, D. J.

UMDNJ - New Jersey Medical School, New Jersey, U.S.A.

Objective: To demonstrate how trends in AIDS incidence can be assessed utilizing data obtained through active surveillance in 12 hospitals affiliated with the New Jersey Medical School.

Methods: Analyses will focus on descriptive methods for presenting data in tabular or graphic form. Survival analysis (with co-factors) will be used for comparing survival following diagnosis among population subgroups.

Results: Some of the major findings to be presented include:

1. Since 1981, 2218 confirmed adult cases of AIDS have been reported, including 738 males, 888 Black, 202 White, and 178 Hispanic.
2. After annual increases from 1981 to 1987, new cases declined in 1988.
3. The primary modes of transmission were: a) IV drug use (66%), b) homosexual/bisexual contact (16%), and c) (51) heterosexual contact (8%).
4. AIDS incidence among homosexual/bisexuals has decreased; heterosexually transmitted AIDS has increased, accounting for 1% of new cases in 1988.
5. Case fatality rates are highest among homosexual/bisexuals with AIDS.
6. Among homosexual/bisexuals with AIDS, the incidence of Cryptococcosis and Kaposi's sarcoma is increasing; HIV encephalopathy is increasing among heterosexuals with AIDS.

Conclusion: The application of descriptive methods to local surveillance data can be useful for projecting future treatment needs, targeting population subgroups for intervention, and identifying leads for further investigation.

A.552

CONVERSION FROM HIV TO HTLV

Patay, Olivier*, M'Go, M., Dolambert, A., Lafay, C.*

*Service des maladies infectieuses et tropicales, **Laboratoire de microbiologie, Villeneuve St Georges-France.

Objective: Rechercher la séroprévalence du HTLV chez des patients infectés par l'HIV.

Methods: 170 sérum positifs pour le VIH ont été testés pour le HTLV par ELISA. Les sérum appartenant à différents groupes à risque (hétérosexuels, homosexuels, post-transfusionnel, maternofœtal, et hétérosexuel). Les sérum positifs en ELISA ont été confirmés en Western Blot.

Results: 4 sérum ont été positifs en ELISA dont 2 confirmés par Western Blot.

Sexe	Age (ans)	Origine	Facteur	PI9	PI24	PI28	PI53
Patient 1	M	27	France	Touxonnisme	+	+	+
Patient 2	M	38	Senegal	Hétérosexuel	+	+	+
Patient 3	F	31	Congo	Hétérosexuel	+	+	+
Patient 4	F	31	Haïti	Hétérosexuel	+	+	+

Un seul patient toxiconome était positif et présentait par ailleurs une cirrhose post-hépatite B. Le conjoint de la patiente 4 est VIH+ mais HTLV-.

Conclusion: la séroprévalence ELISA HTLV apparait faible (2,4%) et survenant essentiellement chez des patients venant de zones de forte prévalence (Afrique, Caraïbes). Ces résultats apparaissent identiques à ceux d'autres études effectuées en région parisienne.

A.553

Human Immunodeficiency Infection in the Elderly: A Retrospective Analysis of 20 Patients

J. Thompson, M.D., J. Vetter, M.D.,

New Jersey Medical School and VA Hospital East Orange N.J., U.S.A.

Objective: To describe the clinical course of the 20 elderly patients who were diagnosed with HIV infection/seroconversion according to CDC criteria group 1-2. Their ages ranged from 65 to 82 years. The risk factors for the group included 10 men and 10 women. The risk factors for the men were 10 homosexual contacts, 10 heterosexual contacts.

Results: The mean age was 72 years. The mean duration of illness was 1.5 years.

Conclusions: The clinical course of HIV infection in the elderly is similar to that in the young. The clinical course of HIV infection in the elderly is similar to that in the young. The clinical course of HIV infection in the elderly is similar to that in the young. The clinical course of HIV infection in the elderly is similar to that in the young. FIRST CASE OF HIV/HIV2 INFECTION IN CAMEROON

KAPFLE, L., ZEING, L., NGU, A.*, DUATINA, A.**,
 MONY-LORE, M.***, NALA, J.***, NDI, J.***, NDI,
 *NATIONAL AIDS CONTROL YAOUCHE, CAMEROON ** UNIVERSITY TEACHING HOSPITAL
 YAOUCHE, CAMEROON *** CENTRAL HOSPITAL, ABINDJO, COTE D'IVOIRE
 *** CENTRAL HOSPITAL, YAOUCHE, CAMEROON.

Objective: To report the first case of HIV1 and HIV2 infection diagnosed in a Cameroonian patient. 30 till June 1989, 5 000 sera were screened for HIV2 antibodies and all were found negative.

Methods: Systematic screening of patients referred to the university teaching hospital, using Elisa test (Detecting HIV1 and HIV2) and Western Blot (Upstart and Diagnostic Pasteur) for confirmation.

Results: A 28 years old patient referred for prolong fever, weight loss and oral candidiasis was recently found HIV1 and HIV2 positive. Looking at the past medical history, the patient had frequent West African.

Conclusion: In this case study, we should start thinking about the presence of HIV2 in Cameroon, considering the frequent movement of people between neighbouring countries.

A.574

HIV SPREAD IN PROSTITUTE POPULATION IN TOULOUSE (FRANCE)

Raye-Bengeali C., Paul, G., CLINICAL FINDINGS OF SEROPositives.
 *Laboratoire de Virologie, CHU Purpan;
 **Service de Dermatologie, CH Le Drapeau, Toulouse, FRANCE.

Objective: To assess the risk of contamination through prostitution (male or female) to our city.
Methods: We systematically screened anti HIV-1 antibodies in 97 female prostitutes (50 coming from Ghana) and 16 transvestites or transsexuals, regularly coming at the Venereal Disease Centre since May 1989, to January 1990. Screenings were realized using 2 immunoenzymatic techniques (Abbott and Wellcome). All positive sera were confirmed by the Western-blot assay (Du Pont De Nemours).
Results: 5 of the 97 prostitutes were seropositive: we screened the first one in 1985, two others in 1986, one in 1987, and one who seroconverted in 1989. But 2 of these intravenous drug abusers, so it was not possible to incriminate to sexual transmission with certainty. None of the Ghanese was seropositive. Among the transvestites and transsexuals, one patient seroconverted in 1989, and 3 patients were seropositive (2 in 1986 and 1 in 1987). For these patients drug addiction is unknown.

Conclusion: The prostitute population of Toulouse seems to be relatively free of HIV-1 contamination. But these results do not entirely reflect the true situation as a marginal prostitution also exists with people who are generally not subject to any control. Although these results are relatively reassuring, educational programs must be undertaken to prevent the spread of the disease, since contamination through prostitution has been shown to be a real risk.

A.575

THE NEW CASE DEFINITION CRITERIA, ITS IMPACT ON EPIDEMIOLOGICAL SURVEILLANCE IN SPAIN. Dr. Andrés Balboa*, Tello, Odorico**, Navarro, M. José**.

* Instituto General de Estadística y Demografía, Madrid, Spain.

** Instituto General de Estadística y Demografía, Madrid, Spain.

Cumulative AIDS cases in Spain in 1988 or 1989 were 2168. Modification of case definition criteria for reporting AIDS were undertaken in August 1987 by CDC, accepted by WHO in September and applied by the European countries since January 1st 1989. We have studied the impact of these new criteria of case definition among cases diagnosed in Spain since 1981. Since January 1st 1989 a 70.29% case increase has been detected applying the new criteria of case definition in respect to the old ones. By the new criteria the retrospective revision of cases diagnosed before this last date classified as no AIDS by the old criteria seems a 12.15% increase in 1984, 10.76% in 1985, 13.98% in 1986 and 30.13% in 1987. This impact is clearly higher among YVD (47,38%) and still 20.13% in 1987. This impact is also different by pathological and transmission categories. Equal serones in increased 1.05% in the heterosexual transmission category and 4.76% among the YVD. Nevertheless, a 22.56% increase associated to opportunistic infections is detected in the heterosexual transmission (500% increase associated to extrapulmonary tuberculosis), 20.29% among YVD (7,000% increase associated to tuberculosis extrapulmonary), a 10.00% in the heterosexual transmission category and 47.22% among children born from mothers at risk.

Conclusions: 1) Different impact is observed in different country areas in respect to pathological background and epidemiological pattern. 2) The relevance of these results is important for epidemiological analysis, trends and predictions. 3) This different impact should be considered by Public Health strategies and policies on people's perception about the case number increase.

A.576

PREVALENCE OF DIFFERENT RETROVIRUS IN SPANISH INTRAVENOUS DRUG

USERS. CONTRERAS C., GARCÍA SÁIZ A., VILHOTTST R., VARELA J.M., PEREZ ALVAREZ L., NESTER N., Instituto de Salud Carlos III, Madrid, Spain.

OBJECTIVE: To analyse the seroprevalence of HIV-2 and HIV-1 in Spanish intravenous drug users (IVDA) and the clinical findings in seropositive to HIV-2 and HIV-1 infections. We determine as well the incidence of coinfection with other infectious agents.

METHODS: - Sera collected from 2,269 IVDA's were tested (1,088 in 1987 and 1,181 in 1988). The presence of anti-HIV-1, -HIV-2, -HIV-1/2 antibodies was results by ELISA. IFA and WB was used as a confirmatory test. - Antigen ELISA test was used for HCV anti-HCV antigen detection.

RESULTS: - The prevalence of HIV-1 was 64.7% in 1987 and 61.8% in 1988. Data collection are ongoing and analysis suggests us to date that a 70% of seropositives still asymptomatic and a 30% shows some pathology related with HIV infection. We are currently performing the seroprevalence of anti-HIV-2 and HIV-1 in a group of IVDA's with statistic significance. A 8% show HBsAg and a 2.5% active syphilis.

CONCLUSIONS: - The prevalence rate, about 60% during 1987 and 1,988 and similar to previous years, is high enough to indicate a serious problem of HIV infection among the Spanish drug users. Very preliminary results indicate no incidence of HIV-2 and HIV-1 in this IVDA population.

A.577

CONTROL OF HIV TRANSMISSION IN THE NATIONAL BLOOD BANK IN MALI

M. K. Malin, A. Traore, A. Guindo, O. Fafara, Comité de lutte scientifique et technique contre le SIDA, Bamako, Mali.

Since the beginning of the national AIDS program in Mali in 1987, the national blood bank was one of the strategic points for detection, prevention of the transmission of the human retrovirus and the follow-up of the prevalence of HIV infection among blood donors. Blood donation was performed from pregnant women, young military recruits and students. Consecutively in 1987 a total of 1140 blood samples and in 1988 a number of 1841 were tested using "Rapid Elisa test" to detect HIV1 and HIV2.

The positive samples were then confirmed by Western Blot.

Results: A steady increase in the seroprevalence of HIV infection was observed. Among 1140 sera in 1987, sixteen (1.9 + 1.6%) and 1988 out of 1841 sera, seventy six (7% + 4.1%) were found positive. This represent a total increase of 256.25 in 100 sera.

Conclusion: In both years the studied cohort was not randomized and is not representative of the Malian population. Although in the country the infection rate is generally low, an evidence of rapid expansion of the epidemic is demonstrated in this study. Health dispositions undertaken for transfusion of safe blood only, a large restructuration program has started which intend to improve the basis and conservation of blood.

Thus the efforts of the national AIDS committee to prevent the transmission of the retrovirus should be actively reinforced.

A.578

THE NEW CASE DEFINITION CRITERIA, ITS IMPACT ON EPIDEMIOLOGICAL SURVEILLANCE

IN SPAIN. Dr. Andrés Balboa*, Tello, Odorico**, Navarro, M. José**.

* Instituto General de Estadística y Demografía, Madrid, Spain.

** Instituto General de Estadística y Demografía, Madrid, Spain.

Cumulative AIDS cases in Spain in 1988 or 1989 were 2168. Modification of case definition criteria for reporting AIDS were undertaken in August 1987 by CDC, accepted by WHO in September and applied by the European countries since January 1st 1989. We have studied the impact of these new criteria of case definition among cases diagnosed in Spain since 1981. Since January 1st 1989 a 70.29% case increase has been detected applying the new criteria of case definition in respect to the old ones. By the new criteria the retrospective revision of cases diagnosed before this last date classified as no AIDS by the old criteria seems a 12.15% increase in 1984, 10.76% in 1985, 13.98% in 1986 and 30.13% in 1987. This impact is also higher among YVD (47,38%) and still 20.13% in 1987. This impact is also different by pathological and transmission categories. Equal serones in increased 1.05% in the heterosexual transmission category and 4.76% among the YVD. Nevertheless, a 22.56% increase associated to opportunistic infections is detected in the heterosexual transmission (500% increase associated to extrapulmonary tuberculosis), 20.29% among YVD (7,000% increase associated to tuberculosis extrapulmonary), a 10.00% in the heterosexual transmission category and 47.22% among children born from mothers at risk.

Conclusions: 1) Different impact is observed in different country areas in respect to pathological background and epidemiological pattern. 2) The relevance of these results is important for epidemiological analysis, trends and predictions. 3) This different impact should be considered by Public Health strategies and policies on people's perception about the case number increase.

AIDS IN THE NORDIC COUNTRIES - PREVENTION AND CONTROL.
Kastholm-Christensen, B.*; Bjferner, J.**; Eriksson, S.***;
Kramm, A.***

*Danish Institute for Health and Nursing Research, Copenhagen, Denmark, **Institute of Social Medicine, Copenhagen, Denmark, ***Nordic School of Public Health, Gteborg, Sweden.

Psychological, social, administrative and political aspects of AIDS in the Nordic countries have been reviewed by the Nordic School of Public Health. As expected, the countries appear quite similar. Specified AIDS-commissions have been established, closely linked to governments. Specific target groups like homosexuals have been involved in preventive activities. Health education has been depicted the most important issue to combat AIDS. Large campaigns have been launched directed to the general public and towards groups like school children and health personnel. Knowledge about AIDS has been seen to be generally good and improving. Systematic knowledge about sexual behaviour, however, is virtually nonexistent. Donated blood and organs are completely tested. Anyone person who has a test and remain anonymous except in Iceland where the person has to identify himself at the test site, but is reported by code.

Treatment and care is similar in the Nordic countries basically handled by the health authorities. Voluntary and private organizations are, however, more important than generally in the health sector. Differences exist: Legislation. In Sweden and Iceland STD-infection is under the law for sexually transmitted diseases. In Finland, it is a notifiable disease while there are no specific legislation concerning HIV-infection in Denmark and Norway.

A.581

Evaluation of a multidisciplinary HIV diagnosis and management centre. Bywater, Australia.
Muriel, A.†; Stewart, Burditt, F.,†; Magier, L.; Osis, J.
Alton Street AIDS Centre, Spence Hospital, Sydney, Australia.

Objective: To provide a multidisciplinary diagnosis, consultancy care and early intervention service for persons infected with HIV. Method: The Alton Street AIDS Centre, established in March 1985, is staffed by 45 full time professionals and support staff including doctors, nurses, counsellors and research officers. The Centre provides free and confidential case and post-test counselling, HIV antibody testing, medical management of HIV related signs and symptoms, referral and nutritional support groups. A computer based medical record system was developed and implementation of HIV related signs and symptoms, referral and nutritional support risk education programmes and early intervention drug trials.

Results: To the end of December 1986 a total of 1730 clients had been listed at the Centre, 859 male, 2259 female, 28 heterosexual or unknown, 1119 intravenous drug users and 401 prostitutes. Of the total 1440 (83%) were diagnosed as HIV antibody positive, 1385 (96%) were homosexual or bisexual, 36 (5.6%) of the heterosexual intravenous drug users and 7 (1.5%) of blood transfusion recipients tested were infected. Over 70% of cases initially diagnosed by private physicians.

Conclusion: The comprehensive and specialised services provided by the Centre have resulted in it becoming the major referral clinic for management of early HIV infection. The Centre provides an early diagnosis and management model that facilitates effective implementation and evaluation of intervention strategies aimed at slowing disease progression.

A.583

LYMPHADENOPATHY IS A WEAK PREDICTOR OF CLINICAL OUTCOME IN HIV INFECTION
Muller, S.†; Spert, Anderson, R.***; Boyce, R.***; Shihashi, S.***
*Children's Hospital, Francisco, CA, USA; **PWRIC, Inc., San Francisco, CA, USA; ***University of California, Berkeley, CA, USA.

Objective: To determine the relationship of lymphadenopathy to clinical outcome in HIV infection. Methods: Lymphadenopathy was measured by trained examiners in a population-based sample of 385 men from the San Francisco Men's Health Study who were seropositive at entry (1982-1983). The incidence of symptoms of progressive HIV infection and of AIDS were determined at 42 month's follow-up.

Results: The presence of ≥ 2 serological nodes ≥ 1 cm and the presence of total peripheral lymphoid mass ≥ 10 g were both associated with slight but not statistically significant increased risk of developing both HIV-related symptoms and AIDS.

Conclusion: Lymphadenopathy measured in two ways predicts future development of clinical illness or AIDS only weakly in HIV infection.

Risk of Symptoms	Odds Ratio (95% CI)	Odds Ratio (95% CI)
< 2 nodes	11/232 (31%)	14/78 (14%)
≥ 2 nodes	11/232 (5%)	6/285 (2%)
≥ 10 g	38/159 (49%)	38/152 (25%)
≥ 10 cm	31/47 (66%)	18/64 (28%)

In a multiple regression analysis controlling for CD4+, beta-2 microglobulin and symptoms, lymphadenopathy was not independently related to AIDS (p=0.7).

Conclusion: Lymphadenopathy measured in two ways predicts future development of clinical illness or AIDS only weakly in HIV infection.

A.580

RISK PROFILE FOR HIV INFECTION AT A SEXUALLY TRANSMITTED DISEASE CLINIC.
Bridson, Gary J.*; LaCombe, D.***; Byrnes, D.***; Saint Michael's Medical Center, **East Orange Health Department, Newark, N.J., USA.

Objective: To determine HIV risk profile of HIV infected individuals in an STD clinic population, and comparing STDs at time of diagnosis.

Methods: One hundred and forty patients were counselled and tested for HIV antibody, at an inner city STD clinic over a 7 month period. Thirteen (9.3%) patients tested positive for HIV antibody by ELISA and Western blot. Due to anonymous testing only 6 patients could be identified for post testing counselling and follow up.

Results: All 6 patients were males, mean age 29.2 (±4.5SD) years. Risk factors identified were: Intravenous Drug User, 5 (83.3%) patients; Homosexuals, 4 (31.5%) patients; Sex with prostitute, 2 (15.4%) patients; Intravenous Drug User and Homosexual, 1 (7.7%) patient; Bisection, 1 (7.7%). Four homosexuals had syphilis with an RPR titer ranging between 1: 8-4096, 1 patient had a rising RPR titer despite treatment with 1.8 Penicillin (total 7.2 million units), 3/6 patients had evidence of an ulcer or skin breakdown at the time of diagnosis.

Conclusion: The above data suggest that the majority of patients identified with HIV infection in an STD setting are still within a recognized high risk group. However sexual behaviour patterns need to be modified in order to limit heterosexual transmission. Patients with genital area skin breakdown appear to particularly be at increased risk for acquiring syphilis and HIV infection.

A.582

VIRAL HEPATITIS B(OR)AND AIDS IN RISK COMMUNITIES IN THE NORTH-EAST OF ARGENTINA(NEA)
Pérez, Oscar**†; Biglione, J.***; Fernández, I.†; Galindez, M.***; Jannini, I.***

*Centro de Estudios en Salud Pública, UNRA**Comité Prevención SIDA, Rosario, Santa Fe, Argentina.

Objective: To study the attack rate of HBV and HIV in drug addicts (IVDA) and homosexuals (HS), compared with the general population as per samples collected from voluntary blood donors (VBD). Methods: Studies were made on samples from communities seeking medical advice in response to CPDMS appeal. HBV-carriers were differentiated thru ELISA/HBsg and previously infected ones, thru ELISA anti-HBc. All sera were searched for HIV thru ELISA and confirmed thru immunoelectrotransference (WB).

Results: Community HIV (%) HBsAg(%) δ Anti-HBc(%)
 IVDA (+) (25%) 32 (8.6) 251 (62)
 VBD (-) 37 46 (16.6) 211 60
 HS (+) (43) 3 (7) 32 (75)
 VBD (-) 4 (108) 28 (7) 306 (75)
 TOTAL 451 31 (7) 338 (75)

Conclusion: HBV-infection is 1 to 8 times more frequent in the above risk populations than among VBD in the NEA. HBV attack rate is higher among HS than among IVDA. HBV-chronic carriers were found more often among IVDA than among HS. There are more HBV-chronic carriers among HIV-IVDA than among HIV-HS. If IVDA samples are received in blood banks as VBD ones, HBV transmission risk will grow accordingly, unless adequate controls are implemented. HIV presence is not statistically significant to determine HBV presence in each population.

A.584

DIAGNOSIS AND MORTALITY TRENDS IN AN OUTPATIENT AIDS CLINIC
Kings, Craig; Kelly, J.; Martz, C.

*New York Hospital Center/Community Health Project NY, NY, USA.

Objective: To review trends in diseases of diagnosis and death in a community based primary care AIDS clinic population as a basis for improved management. Methods: All cases (163) of AIDS diagnosed from 1/1/86 to 1/1/89 in a primary care out-patient AIDS clinic were reviewed for index diagnosis, year of diagnosis and diagnosis of death and diagnosis of death.

Results: Trends in diseases of diagnosis and diseases of death over three years are as follows:

Disease of Diagnosis		Disease of Death	
1986	1987	1986	1987
PCP	21(41%)	21(40%)	15(46%)
KS	22(43%)	17(32%)	13(27%)
Other	81(85%)	15(28%)	16(32%)

Conclusion: With the advent of PCP prophylaxis and improved management, mortality from PCP has decreased while the incidence of PCP has not changed significantly in our clinic population. Early aggressive PCP prophylaxis may reduce the incidence of PCP as an index diagnosis. Mortality from pulmonary KS has increased, although KS has been less frequently diagnosed overall in these patients. The increasing number of AIDS deaths attributed to pulmonary disease suggests that one should be alert to subgroups who benefit from earlier diagnosis and treatment. Of special concern are the increasing deaths from unknown causes. Perhaps more aggressive work-up might have elicited a definite diagnosis amenable to treatment, e.g. extrapulmonary pneumocystis.

A.591 ELECTRONIC REPORTING SYSTEM FOR AIDS SURVEILLANCE IN CANADA
 Hault, Peggy; Klemis, K. Federal Centre for AIDS, Health Protection Branch, Ottawa, Ontario, Canada.

Objectif: To describe the development of an electronic system for national reporting of AIDS surveillance data.

Methods: AIDS is a reportable condition in all provinces and territories in Canada. Through collaborative efforts between the provincial/territorial Ministries of Health and National Health and Welfare, a systematic method of reporting AIDS cases was established using a standardized case report form.

Results: The case report form was developed to collect demographic information, behavioural risk factors, clinical, and laboratory data. Completed forms are sent to the provincial/territorial Ministries of Health for evaluation and are then forwarded to the Federal Centre for AIDS. In 1986 the provinces/territories were introduced to an electronic bulletin board system, designed to facilitate data collection and dissemination. They were provided with custom computer software, and hardware where needed, to standardize the method of reporting cases electronically. Training workshops were provided to familiarize key groups with software and the process of transmitting data electronically.

Conclusions: This standardized method of reporting provides rapid collection of data and dissemination of reports. Effective communication between key groups plays an integral part in the success of this and other surveillance systems.

A.592

A.593 AN UPDATE ON HIV-SEROPREVALENCE STUDIES
 IN THE NETHERLANDS.
 Conyn, L.H.; Nieuwling B.; Jager, J.C.
 Natl Inst Publ Hlth Rivm (1991), Bilthoven, the Netherlands.

Currently available data on HIV seroprevalence among selected groups in the Netherlands are inadequate to assess the spread of the epidemic among homosexual men, intravenous drug users or the population-at-large. So far, only volunteer studies have been conducted. Additional surveys are required: 1) to establish a base-line of infection levels in selected groups; 2) for public health management and policy; and 3) for serological and prediction of the course of the epidemic.

Various options for conducting such surveys are discussed, and mixing blood collections and hospital samples are identified. Anonymous testing of some of these blood samples is proposed to minimize the self-selection bias which renders studies comprised of voluntary participants uninterpretable. Some legal and ethical objections have been raised that so far have prevented anonymous testing in the Netherlands. There is no general agreement yet that anonymous testing is needed to collect information that otherwise would not be available, and that such testing is justifiable if anonymity of the data is assured. In the serologic surveillance studies with informed consent will be considered in pre-selected institutions, to document whether compliance is high enough for valid information to be made from such studies.

A.595 LA DEMANDE D'EXAMEN SEROLOGIQUE HIV
 CHEZ LE MÉDECIN GÉNÉRALISTE
 V. VAN CASTRIEN, A. STROOBANT
 INSTITUT D'HYGIENE ET D'ÉPIDÉMIOLOGIE, BRUXELLES, BELGIQUE

Depuis le mois de mai 1988, la demande pour un test HIV a été introduite dans le programme d'enregistrement de morbidité de 150 médecins généralistes sensationnels constituant un réseau représentatif des médecins généralistes de Belgique. L'objectif est d'évaluer dans quelle mesure le médecin généraliste est confronté avec le problème du SIDA, de surveiller l'évolution de la demande au cours des années et de caractériser les situations dans lesquelles cette demande est formulée.

L'enregistrement est anonyme et comprend les données suivantes : Age et sexe, motif de la demande, comportement à risque éventuel, test HIV effectué ou non.

Les résultats des premiers mois de l'enregistrement montrent que moins d'une demande par mois et par médecin (0,8) est actuellement rencontrée. Près de 70% des femmes qui demandent un test ne présentent aucun facteur de risque alors que la proportion n'est que de 44% chez les hommes. Le taux de positivité des tests demandés est de l'ordre de 1,8%. Les résultats sont comparés avec ceux qui ont été enregistrés en France et en Suisse par des réseaux comparables.

A.594 PREVALENCE OF HIV-1 ANTIBODY AMONG GAY MEN IN THE U.K.: DIFFERENCES BETWEEN CLINIC ATTENDERS AND NON-ATTENDERS.
 Dallas, Robert; Cowan, J.F.S.; Bohannon, T.J.;*** and Suberland, S.*** Project SIDA, South West Polytechnic, London, U.K.; **University of Wales, Cardiff, U.K.; ***King's College Hospital, London, U.K.; ****Ulrich Hill, London, U.K.

Objectif: To estimate the prevalence of HIV-1 antibody in the homosexual active male population of England and Wales and, bearing in mind that current estimates of prevalence and possible spread are based on those attending STD clinics, to estimate the differences between clinic attenders and non-attenders.

Methods: 525 gay and bisexual men in two centres in the U.K., London and South Wales, were recruited using a variety of methods and interviewed in a non-clinic setting. Blood samples were reinterviewed from 346 (66%) of these and tested for HIV-1 antibody using the Wallace competitive assay. Positives were confirmed in the first instance with the Abbott recombinant assay.

Results: In London, 19 (9.4%) of the bloods tested positive to HIV-1 antibody, and in South Wales, 5 (1.4%). When allowance is made for verifiable test results from those who did not provide blood samples, these rates rise to 13.4% and 3.9% respectively. The proportion of positive results among those attending clinics was 13.4% in London and 7.4% in South Wales while the proportions among non-clinic attenders were 5.7% and 1.8% in the two sites. The higher rates among the clinic attenders are comparable with those obtained in clinic studies in comparable areas of the U.K.

Conclusions: Rates of seroprevalence of HIV-1 among gay and bisexual men based on bloods collected at clinics appear to be overestimates.

EPIDEMIOLOGICAL, POLICY AND PLANNING ISSUES IN HIV

DECADE IN A BRITISH HEALTH REGION: A REVIEW
 Zeki, Ambrose* and Kearns, William. North East Thames Regional Health Authority and *Department of Community Medicine, University College and Middlesex School of Medicine, London, England.

Objective: To describe the epidemiological, policy and health services planning issues in relation to HIV disease within a region of the British National Health Service. **Methods:** Data on the regional epidemiology of HIV disease and the distribution of services were reviewed and the strategic policy and planning issues identified.

Results: The North East Thames is the British health region second most affected by AIDS and has consistently contributed approximately 18% of all cases of AIDS diagnosed in the United Kingdom. Analysis of the geographic distribution of people with AIDS by where they received medical care and where the ill reveals that a few central London districts have attracted a disproportionate number of people with AIDS. These central London districts would be unable to provide care for the vast majority of people with AIDS in the region. The Regional Health Authority has developed a policy for service development based upon the available epidemiological information. The strategy includes upgrading geriatric medicine and problem drug services throughout the region, providing care as close as possible to where people live and establishing an appropriate balance between hospital, home and non-home non-hospital services. All districts have been funded to undertake educational, training, counselling and health promotion activities. Limitations within this approach to planning services are identified.

Conclusion: The British National Health Service provides the potential for developing coordinated services of a high standard on a regional basis.

A.599

DECONTAMINATION OF AN HIV CONTAMINATED CUP MARKER:

COLEMAN, JANE, LISKAY, J., BOCHNER, R.L., JR., SULLIVAN, R.L., LANGFOLD, A.J., MINKOFF, L.*
 *University of Maryland, Baltimore, Maryland; *Biophysics Institute, Research Triangle Park, N.C.; **Duke University, Durham, N.C.

OBJECTIVE: Markants are used widely for cardiopulmonary resuscitation (CPR) training. Simulating a "miss scenario", a markant was contaminated in different experiments with either cell-free or cell associated HIV-1. Recommended decontamination procedures were compared by maintaining a wet surface for 10 or 5 sec rather than the recommended 30 sec. The experiment also addressed the relative contributions of chemical disinfection and the mechanical action of wiping.

METHOD: The markant was contaminated with either a virus saturated swab containing cell-free HIV-1 (10^{7.0} infectious unit/ml) or with a pipette containing cell associated HIV-1 (10^{6.0} infectious unit/ml). The decontamination procedure consisted of 70% isopropyl alcohol sponge or spray or dry 4x4 sponge for 10 or 5 sec, drying time of 30 sec and 5 sec of wiping the surface. After each maneuver a sample from the markant surface was obtained, cultured in AIDS or CEM cells and the presence of virus determined by reverse transcriptase assay and by quantitative p24 antigen detection (Eitest). **RESULTS:** HIV-1 was detected after markant contamination but not after disinfection with alcohol for 10 or 5 sec. HIV-1 was detected both after initial contamination and after wiping with a dry 4x4 sterile sponge.

CONCLUSIONS: Decontamination of an HIV-1 cell free or cell associated contaminated cup markant was achieved in 5 sec with either a 70% isopropyl alcohol sponge or spray, but not using only a dry 4x4 sponge demonstrating the importance of chemical disinfection.

A.601

RESISTANCE OF HIV IMMUNODIFFUSION VIRUS TO DISINFECTANTS AND UV RADIATION

Patel, Hassan*, D. Gu*, H.J. Jeffrey**, J.V. Collins*.
 *Brompton, **St. Stephen's and **St. Mary's, H. Hospitals, London.

Previous reports that HIV is susceptible to disinfectants are based on suspension tests. We tested 70% alcohol (100% Alcohol: 100% Final concentration ethanol 63.8%, methanol 3.5%, water 28.55 v/v), acetone, 1% and 2% alkaline glutaraldehyde (Gidec, burgundy lid) against HIV dried on a surface. The following inocula were dried in triplicate on to sterile coverslips and immersed in disinfectant: 1) Cell-free HIV in 10% serum at 10^{7.0} TCID₅₀ (TCID₅₀ = the highest dilution of virus infective tissue culture viruses with 7 days); 2) 10^{7.0} HIV-infected T-lymphocytes; 3) Cell-free HIV (10^{7.0} TCID₅₀) in neat serum. At timed intervals disinfectant was rinsed off with PBS-A. Cover slips were cultured for 23 days in RPMI with CD366 cells and examined for viraemia and HIV antigens; positive cultures were passaged into fresh cultures to confirm infectivity. Disinfectant-free and toxicity controls were performed.

Results: 70% alcohol failed to inactivate cell-free or cell-associated HIV within 20 minutes. Acetone, tested only against cell-associated inocula, failed to inactivate HIV within 40 minutes. 2% and 1% alkaline glutaraldehyde inactivated cell-free HIV within 2 minutes. 2% and 1% alkaline glutaraldehyde presence of neat serum 2% glutaraldehyde remained effective; it failed to inactivate HIV within 15 minutes. **Conclusion:** Acetone and 2% and 1% alcohol failed to kill HIV surfaces within 40 and 20 minutes respectively; serum greatly reduced the efficacy of 1% glutaraldehyde.

A.598

OUTREACH TO IV DRUG USERS AND SEX PARTNERS:

SATISFACTION AND DISSATISFACTION OF OUTREACH WORKERS
 Bull, C., Dema, S., Green, F., Saffer, M., Friedman, S.R., Tross, S., et al.
 National Drug Research Inc., New York, New York, U.S.A.

Objective: To assess workers who widely used for AIDS outreach to IV drug users and their partners. Our objective is to describe the characteristics of outreach workers and to provide AIDS prevention and education information to increase their use and their partners in New York City, and to detail areas of the satisfaction and dissatisfaction they encounter as employees.

Methods: A total of 60 outreach workers were employed by National Drug Research Inc. during 1986-1988 to provide AIDS risk reduction information to IV drug users and their sex partners. Information was available through interviews with the 27 outreach workers currently employed by the agency and a review of agency records for all outreach workers.
Results: Of the 60 workers, approximately 60% were male and their ethnic composition was 50% Black, 39% Hispanic and 1% White. Most outreach workers were ex-addicts, recruited from various treatment modalities. Staff turnover at the end of one year of employment was 20%. 1% of the 27 workers hired in 1986 and 1987, more than half were no longer employed by the organization within one year after their hiring date. Information on the satisfactions and dissatisfactions encountered by these employees is being collected and the data are being analyzed focusing on organizations (i.e., career path available) and individual issues (e.g., burnout).

Conclusion: The relatively high turnover rate of these employees indicates that further study of the satisfactions and dissatisfactions experienced by these workers is needed, so that measures to address the dissatisfactions can be incorporated in employee policies.

A.600

RESISTANCE OF HIV-1 BY A NEW ALGAEKAT MODEL

Geiger, Edgar*, Tenford V. Linn*, Hirsch R.S.,*
 R.T.C.* Infectious Disease Unit, *Department of Orthopedic Surgery and Rehabilitation Medicine, Massachusetts General Hospital, Boston, MA, USA

Objective: To study the feasibility of inactivating HIV-1 in bone graft material by gamma irradiation.

Methods: Serial dilutions of HIV-1 (10^{7.0}-10^{8.0} TCID₅₀/ml) were subjected to gamma irradiation under conditions simulating those within a bone allograft. Irradiated and control specimens were cultured on 89 cells which were subsequently evaluated for cytopathic effect and p24 antigen production. **Results:** High titers of virus (10^{7.0} TCID₅₀/ml) were not inactivated by gamma irradiation up to 0.5 Mrad. p24 antigen values (cpm/ml) for lower titers irradiated (B) and control (C) virus exposed to 0.4 Mrad is shown:

10 ⁶ TCID ₅₀ /ml	(B/C)	Mrad	Mrad	Mrad	Mrad
10 ⁶	0/0	0/0	0/0	0/0	0/0
10 ⁷	0/0	0/0	0/36	0/36	0/500
10 ⁸	0/0	0/0	0/3	11/1.6	362/500
10 ⁹	-	0/0	11/43	4,3/42.1	>500/500
10 ¹⁰	-	0/0	21/0.5	4,3/350	>500/500

Cytopathic effect was observed in all cultures in which p24 antigen production was detected.

Conclusion: Doses of gamma irradiation previously recommended to inactivate many viruses including HIV-1 appear inadequate in this model. Higher doses or alternate methods of ensuring allograft sterility with respect to HIV-1 may be required.

A.602

POTENTIAL FOR HIV TRANSMISSION VIA BLOOD GLUCOSE MONITORING DEVICES

Realt, P., Brennan, Constance*, Murphy, V., Norton, T.
 University of Washington, Harborview Medical Center, Seattle, Washington, USA

We are following a 43 year old HIV-positive insulin-dependent diabetic woman whose only known exposure to HIV was from vaginal intercourse with her HIV-positive bisexual husband. The woman indicated to us that since 1981 she has screened family members, friends, and relatives for diabetes by performing fingerstick glucose determinations on them. She would routinely use a single disposable lancet to draw blood from several individuals in rapid succession, after pricking herself, without wiping the lancet. Four family members who had shared a lancet with our patient during the past year have been screened and are HIV-negative.

We found that packaging material of the lancets used by our patient contain no warning labels against sharing lancets. A local survey of 3 brands of lancets and 3 brands of lancet holders indicated that only 1 brand had labels warning about potential transmission of diseases with the device. We also found no warning labels on some brands of insulin syringes. Diabetic equipment such as lancets and syringes represent a potential route of transmission for HIV and other blood-borne pathogens. We speculate that the practice of sharing used lancets as demonstrated by our patient, a well-educated middle socio-economic class woman, may be more common among diabetics than is generally recognized. Physicians and diabetic educators should educate their diabetic patients about the proper use of lancets and syringes and appropriate warning labels should be required on these products.

A.627

A COMMUNITY-BASED HIV ASSESSMENT UNIT:
HOW DOES IT WORK?

Mozsan, Alizah, Davis L, Irani P., Ramis C.M., Norris B., Burzewski M, et al. - Woodhull Medical & Menal Health Center, Brooklyn, NY, USA

Objective: To describe how patients at high-risk for HIV infection are evaluated and treated by an interdisciplinary team providing a community-based HIV assessment unit.

Methods & Results: Woodhull Medical & Menal Health Center, a division of NYC Health and Hospitals Corporation, is a large municipal hospital serving an impoverished, medically underserved, black and latino community. Woodhull Family Health Center has been designated by Woodhull as the community-based facility for outreach, screening, evaluation and treatment of HIV-related diseases. The majority of high-risk patients are IV drug users and their sexual partners. An interdisciplinary team of providers, including clerks, administrators, nurses, physicians, physician assistants, psychologists, and social workers, has been trained to meet the needs of this community. The roles of Team members and their interactions with patients will be discussed. An approach to the medical and psychosocial interventions provided to high-risk and HIV-infected patients will be presented. Emphasis will be placed on the medical protocols designed for a community-based setting. The process will be illustrated by following theoretical at-risk patients from initial referral to staff involvement and treatment.

Conclusion: A community-based approach provides an ideal setting for an interdisciplinary team approach to the care of patients with HIV-related diseases or who are at high risk. This is particularly effective in an impoverished black and latino community.

A.629

PREVALENCE OF ANTIBODIES AGAINST HIV-1 AND HTLV-1 IN AFRICAN SERA SAMPLES COLLECTED DURING THE 1960'S

Frankl, Tatjana, McShee, B., Lewinski, C., Longjumeau, M., Nair, R.N.M., and Poljakoff, R., et al. - Roche Diagnostic Sytes, Inc., Nutley, New Jersey, U.S.A., and University of Michigan, Ann Arbor, Michigan, U.S.A.

Objective: To study the prevalence of HIV-1 and HTLV-1 infections during the 1960's in Ghana among the Akan, Ewe, Ashanti, and Ewe tribes.

Methods: 408 archived sera samples from Ghana collected as early as 1960 were used in this study. Sera was screened for the presence of antibodies against HIV-1 and HTLV-1 using Roche recombinant HIV-1/HTLV-1 antigen combination screening EIA. This assay has been shown to have high specificity and sensitivity. Samples which showed reactivity in the HIV-1/HTLV-1 using specific recombinant antigen.

Results: Thirty-five out of 408 (8.7%) samples showed reactivity with HIV-1/HTLV-1 combination fusion proteins. Fourteen of the samples (3.5%) showed presence of antibodies against HIV-1 (gp120/gp41). Fifteen out of 35 positive immuno-reacted only with HTLV-1 recombinant antigen (3.7%). Six samples had antibodies against both HIV-1 and HTLV-1 (1.5%).

Conclusion: HIV-1 and HTLV-1 infections may be more prevalent than estimated during the 1960's in Africa.

A.631

INCREASED SUSCEPTIBILITY OF UNDIFFERENTIATED PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) AND CD8+ CELL-DEPLETED PBMC TO IN VITRO INFECTION WITH HIV AFTER INGESTION OF 2 TO 4 BEERS

Reasars, Omer*, Linschler, Bora*, Rajasekya-Balla, A.M.M., *M.D., of Med. & Dent. of New Jersey, Camden, NJ; *M.D., of St. Christopher's Hosp. for Children, Philadelphia, PA; **M.D., of Oklahoma, Oklahoma City, OK, USA.

Objective: To determine the duration of the previously described effects of acute ethanol ingestion on HIV infection of PBMC *in vitro* (PARDJ J 2:483), 1988) and the influence of removal of CD8+ cells on these phenomena.

Methods: PBMC isolated from 7 healthy non-alcoholic volunteers before and 1 hour, 2 days after consumption of 0, 1-1.3 (mean 1.1) liters of beer, and PBMC depleted of CD8+ cells by panming 2 times on anti-CD8 cells, were cultured for 3 days. HIV replication was estimated by: a) counting the syncytia appearing after overnight incubation with 80%², cells, and b) assay of HIV-p24 by antigen capture enzyme immunoassay (EIA) by supernatant (depleted PBMC only).

Results: HIV infection of PBMC was detectable only if CD8+ cells were removed *in vitro* or if the PBMC were obtained 1 to 3 days after ethanol ingestion. The latter was associated with a 3-fold rise in syncytium formation when CD8+ cell-depleted PBMC were used. Means of 4 syncytia per well were found before beer ingestion, 12 syncytia after ingestion of 4, 5 and 2 per well (1), 2) and 4) days, respectively, after ingestion of beer.

Conclusions: CD8+ cells prevent HIV infection of normal undifferentiated PBMC. Prior ingestion of beer increased the susceptibility of PBMC to HIV infection *in vitro* for at least 11 days. Alcohol-associated enhancement of HIV replication occurred after removal of CD8+ cells. The same was not seen in the case of loss of CD8+ cell function previously ascribed to alcohol ingestion.

A.628

EVALUATION OF COMPLIANCE RATE IN A CLINIC SERVING MINORITY AND LOW INCOME COMMUNITIES

Davis, Iida, Leibell, J., Patrick, J., Langner, P., et al. - Woodhull Medical and Menal Health Center, Brooklyn, NY, USA

Objective: To determine compliance rates for HIV-seropositive persons in a socioculturally sensitive clinic (SSC) setting from communities that are considered "traditionally noncompliant".

Method: Missed appointments rates were compared between the SSC and the ambulatory care network (ACN). The overall broken appointment rate was determined as a proportion of total appointments. Retrospective chart review explored factors contributing to missed appointments taking into account race, sex, age, risk behavior, treatment regimen and protocol. Patient specific missed and scheduled visits, and explanations of missed visits were documented.

Results: The average broken appointment rate in the SSC is 15%, and 4% in the ACN. When rescheduled appointments were included, the noncompliance rate falls below 10%. Factors contributing to missed appointments were: lack of contact with work schedules, lack of child care, lack of adequate transportation, family illness, and hospitalization.

Conclusion: The overall compliance rate in the SSC is significantly higher than the ACN documenting (1) the importance of accounting for SSC variables in traditionally noncompliant communities (2) given the vital role of ambulatory care services for HIV diseases, clinic structures must be modified for communities with these variables, to increase participation in ambulatory and research protocols (3) the social role of women as caretakers, regardless of their health status, is undervalued as a contributing factor to noncompliance in HIV disease treatment in these communities.

TRAINING THE HEALTH CARE PROFESSIONAL: THE AIDS REGIONAL EDUCATION AND TRAINING CENTERS PROGRAM OF THE HEALTH RESOURCES AND SERVICES ADMINISTRATION (HSA)

Norman, James; Jefferson, P.; Marrelli, B.; Moore, D.; Macher, A. - Division of Medicine, Bureau of Health Professions, HSA, United States Public Health Service, Rockville, MD, USA.

Objective: To establish regional AIDS education centers that will provide multidisciplinary training for health care professionals.

Methods: With a projected cumulative total of more than 500,000 AIDS cases by 1997, it is essential that health care providers be trained in the diagnosis, management and treatment of HIV-infected patients. The insufficient number of providers active in the care of AIDS patients presents a major gap in the health care delivery system. In recognition of this problem, the United States Congress appropriated funds to establish the AIDS Regional Education and Training Centers Program.

Results and Conclusions: To date, thirteen centers have been created. These regional education and training centers provide multidisciplinary HIV/AIDS training for health care personnel within the framework of the following three goals: 1) Training community primary care providers to incorporate strategies for HIV prevention into clinical priorities as well as to diagnose, manage, and counsel patients and their families; 2) Training individuals to serve as instructors in their local areas; and 3) Educating health care professionals in providing sensitive and integrated care of AIDS patients through the improvement of their understanding of the complexities of the disease.

A.632

THE OPPORTUNITIES IN HUMAN AIDS (HOAIDS) ARE ZOOOTIC.

Jonas-Aas, Marcell L., Pineda, Robert H. - Univ. of Missouri, Columbia, MO, USA; Montgomery HS, Bethesda, MD, USA.

Objective: To explore animal diseases and animal products with respect to AIDS.

Methods: The opportunities associated to HAIDS were searched in the AIDSLINE database with GRATEFUL MED™ software and scrutinized *in-vitro* the concept of zoonoses (1). The number of publications mentioned to each were recorded in order to rank them in order of their relative importance. Most of them, as indicated with an asterisk (*), are also CNS infective.

Results: Cryptosporidiosis (894) and influenza (10) viruses are well spread in the animal kingdom. Pseudo-tuberculosis (630) is a parasite of swine, sheep, goats, and humans (2) as is leishmaniasis (686) to several other species. Cryptosporidiosis (141), histoplasmosis (50) and coccidioidomycosis (157) are zoonoses and candidiasis (167) is common in animals. The myxomatosis (137), including leishmaniasis, are infections of, or shared with, animals. Salmonellosis (30), campylobacteriosis (10) and listeriosis (107) are, frequently, although not always or only, associated to foods of animal origin. Cat scratch disease (2) and leish disease (2) are also involved in HAIDS.

Conclusion: Opportunistic, the major cause of death in AIDS, are zoonoses (1) and thus conceivably acquirable from animals and/or animal products. The epidemiology of this approach needs urgent evaluation. Used in conjunction with the animal AIDS models [simian (SIVS), feline (F AIDS), bovine (BAIDS), equine (EAIDS) rabids (RAIDS), murine (MAIDS), etc.] they could be useful in the pathobiological modeling of HAIDS. The HIV's themselves are infective both to closely related primates) as well as to far removed (non) animal species, whose common ancestors with the animal herbivores and thus are zoonotic. 1. M.B.O.7 AN INTERDISCIPLINARY APPROACH TO AIDS CARE: ST. PAUL'S HOSPITAL

Colleen, Irene, St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada.

Objective: To describe the coordinated, interdisciplinary management of patients with HIV infection at St. Paul's Hospital (SPH).

Since the early days of the AIDS epidemic it has been apparent that we are confronted with a biological and social challenge that does not fit a traditional model of patient care management. Recognizing this, and that AIDS care does not fall within the purview of a single medical specialty, SPH has developed an interdisciplinary model of patient care. This model relies on the full participation of the family practitioners, medical specialists, hospital and home care liaison nursing staff, AIDS dedicated social workers, pharmacists and other related disciplines. The primary focus is on the clinical care of patients, with a special emphasis on identifying and providing direction for the resolution of psychosocial problems. There is a high degree of commitment to research and education at all levels. There is an emphasis on quality of life and treatment through outpatient care which is greatly facilitated by a dedicated HIV Clinic and close liaison with community support services. These services have allowed the successful expansion of our AIDS program to 3,367 inpatient days (1986-89) and 10,000 outpatient visits (1988). This represents 75% of the AIDS related care in the province of British Columbia.

M.B.O.9 THE CHALLENGE FACING NURSING IN CENTRAL AFRICA
 Kopolo Olive, Department of Nursing, University Teaching Hospital, Lusaka, Zambia.

M.B.O.11 HOME NEEDS (CARE FOR AIDS PATIENTS)
 Maynard, Pat. St. Elizabeth Nursing Home, Don Mills, Ontario, Canada.

M.B.O.8 THE IMPACT OF AIDS ON FAMILIES OF HAEMOPHILIACS IN WALES
 Reese, Jacqueline, University of Wales College of Medicine, Cardiff, South Wales, U.K.

Objective: To describe the impact of AIDS on the families of affected Welsh haemophiliacs.

Anyone involved with haemophilia has to be impressed by their courage in getting on with the business of living in spite of the debilitating nature of the disease. Now over fifty individuals living in Wales are facing a new obstacle - HIV infection as a result of contaminated blood products; six have already died. The sex linked mode of inheritance means that more than one family member may be affected. **Method:** The data on which the study is based was collected over a period of twelve months from the families of adult males and children attending a haemophilia centre. The qualitative holistic approach of grounded theory is used to explain the subjective dimensions of their human experience. **Results:** At least one wife has seroconverted, others have not made love since their husbands were found to have contracted the AIDS virus, largely due to the fact that their husbands recoil from physical strain. Parents have a huge burden to bear, some have experienced publicity surrounding the death of a child, several having other affected children face stigma and social isolation, others live in fear of being identified. **Conclusion:** Marriages are under stress, there is evidence of poor communication between partners who frequently keep the knowledge to themselves, wondering how long they are going to be able to keep it quiet.

M.B.O.10 A COMPARISON OF THE PROJECTED NURSING CARE NEEDS OF HOSPITALIZED AIDS AND NON-AIDS PATIENTS
 Lydia Lewis, I. Corbett, S. Brewer, et al. Department of Nursing, Royal Victoria Hospital, Montreal, Québec, Canada.

Objective: To confirm the observation that the nursing care requirements of hospitalized AIDS patients (AP) are greater than those of hospitalized non-AIDS patients (NAP).

Method: Staff nurses used the patient classification system, Project of Research in Nursing (PRN) to quantify projected patient nursing care needs. This validated tool describes patient care needs by integrating workload measurement with the nursing process (assigning a value to each anticipated nursing intervention: debridement of wound = 5 points). The advantage of this approach is that it allows for the individualization of the measurement (time) of care required (not given) as scheduled for the patient. Daily PRN scores of 49 AP admitted in 1986 were retrospectively collected from nursing records. Two matched controls without AIDS, admitted concurrently to the same service, were sought for each AP resulting in 129 NAP on whom data could be found.

Results: The mean daily projected nursing care hours were: 16:10.5 for all hospitalized AP, and 10:54.4 for all hospitalized NAP. Patients requiring an intensive care section: 25:02:1.6 for AP and 24:24:10.1 for NAP. Patients admitted to a nursing unit: 14:56:2.2 for AP and 10:04:8 for NAP. The mean length of stay for all AP was 26:52:6.4 and 11:34:10.5 for NAP.

Conclusion: Nurses estimate that AP require 52% more nursing care than NAP. This information supports nursing judgment and intuition by providing an objective measure of workload which is valuable for resource management.

M.B.O.12 CHANGING PATTERNS OF PNEUMOCYSTIS CARINII INFECTIONS

Hopewell, Phillip C. San Francisco General Hospital, San Francisco, California, U.S.A.

M.B.O.13 ANIMAL MODELS OF PNEUMOCYSTIS CARINII PNEUMONIA

Quarles, Sherry F., Bartlett, R. S., Smith, J. W., Indiana Univ. School of Medicine, Indianapolis, Indiana.

Objective: To develop a model of *Pneumocystis carinii* pneumonia that would consistently produce a good yield of uniformly heavily infected animals suitable for drug testing or biochemical work.

Methods: Virus-free female Sprague-Dawley rats weighing 150 - 150 gm are immune suppressed by a) cortisone acetate 250 µg/kg twice weekly, b) dexamethasone 1.2 mg/kg in drinking water continuously, or c) methylprednisolone 40 mg/kg once weekly. Drinking water contains 0.5 gal/l tetracycline. Rats receive standard laboratory chow (CD# protein). Transurethral injection of 10^8 to 10^7 organisms is performed 4 to 7 days after the start of immune suppression.

Results: Virus-free rats used in these studies are also *Pneumocystis-free*. The rate at which they become infected naturally depends upon the level of exposure to already-infected animals. Transurethral inoculation of these rats speeds the development of heavy *Pneumocystis* infections so that rats may be harvested for biochemical work by 6 to 7 weeks. Rats are also more uniformly infected by this mechanism. Tests of drug for therapy may be started at 4 weeks and harvested at 6 to 7 weeks. For relapse studies a prophylaxis start at the time of inoculation and run 6 weeks.

Conclusions: Transurethral inoculation of *P. carinii* into immune suppressed rats produces consistently heavy infections and allows efficient drug testing in therapy, prophylaxis and relapse protocols. These heavily infected rats are also good sources of organisms for biochemical studies.

M.B.O.14 TREATMENT OF PNEUMOCYSTIS CARINII INFECTIONS: ANTIMICROBIALS

Tava, Felix. Hôpital-Dieu de Montréal and Université de Montréal, Québec, Canada.

The current treatment for *Pneumocystis carinii* (PC) infection are efficacious in more than 95% of cases. Different factors contributed to this progress: better educated physicians and patients; earlier diagnosis; better management; extended knowledge of pharmacokinetics of PC drugs; the effect (s) of AZT treatment, etc. However, the incidence of adverse reactions is high and the initial therapy should often be changed. Several therapeutic principles are now recognized, such as: do not treat empirically; make an early specific diagnosis; non-specific tests (except for blood gases at rest and exercise), are not cost-effective and delay the etiologic diagnosis; consider PC also in subtle or atypical cases; mild to moderate clinical forms could be treated orally; dosage modifications have few effects on adverse reactions or survival; in the presence of side effects better change the initial therapy, etc. For patients who are unable to tolerate "conventional" therapy 3 trials (investigational), approaches are available: eflopridine, trimetrexate/leucovorin and clindamycin/primequine; however their effectiveness, safety and recurrence rate are not appropriately assessed. New therapeutic regimens will be probably suggested and all these treatments should be evaluated in well-designed controlled clinical trials and not to be used indiscriminately.

M.B.O.15

NEW DEVELOPMENTS IN THE TREATMENT AND PREVENTION OF PCP
John S.G. Montaner, MD, FRCP(C), Director of AIDS Research Program
St. Paul's Hospital, University of British Columbia, Vancouver, BC, Canada

Despite a number of therapeutic advances, PCP remains the most common serious opportunistic infection in HIV-infected individuals. Two recent developments have shown promise in potentially altering morbidity and mortality associated with this condition. These are:

Adjunctive Corticosteroid Therapy: previous retrospective work suggested that adjunctive systemic corticosteroids could have a favourable effect by reducing respiratory failure, haemorrhagic decompensation and minimizing side effects to normally used antimicrobials. More recently, we have demonstrated in a placebo controlled trial that adjunctive oral corticosteroids (80 mg PO, QD for 7 days followed by a 14 day tapering course) can also prevent the development of clinical acute respiratory failure in patients with moderately severe PCP. This had a significant beneficial impact, not only decreasing morbidity but also improving quality of life. A welcome spin off of this trial has been the decrease in admissions to the Intensive Care Unit and earlier discharge of patients with AIDS-related PCP.

PCP Prophylaxis: the experience in indigent patients and more recently the report by Finkel et al focused our attention on the great potential value of PCP prophylaxis to AIDS. Unfortunately this was difficult to implement because of the generally poor tolerance among HIV-infected individuals of the commonly used prophylactic regimens. We have recently conducted a Canadian cooperative placebo controlled trial of the efficacy and safety of aerosolized pentamidine for the secondary prophylaxis of AIDS-related PCP. Patients were randomly allocated to receive pentamidine 60 mg/dose or placebo. The drug was delivered via a hand held nebulizer (PNEUMOPAC, MAID = 2.5-5.5 micron) over 15 to 20 minutes. Patients received an induction treatment consisting of 5 doses in 14 days followed by one dose bi-weekly thereafter. 102 patients were randomized at the time that the study was initiated. Of the 32 cases of PCP identified during the follow-up period, 27 of these occur among the 78 placebo treated patients while only 5 occur among the 84 patients receiving active therapy (p < .001, chi sq). Such groups were similar in terms of baseline data, median follow-up, side effects were uncommon and generally well tolerated. In contrast to previous reports, the tolerance of aerosolized pentamidine was extremely good and overall adverse events were rare. Our study conclusively demonstrates that aerosolized pentamidine is highly effective in the prevention of AIDS-related PCP.

M.B.O.30 TUBERCULOSIS (TB) AND ATYPICAL MYCOBACTERIA
IN PATIENTS WITH HIV INFECTION
Chaisson, Richard A.
Johns Hopkins University, Baltimore, MD USA
TB is common in HIV-seropositive populations with a high prevalence of *M. tuberculosis* infection. TB is often an early AIDS related opportunistic infection, occurring when CD4 cell counts are still relatively high (>250/ μ l). Clinical manifestations may be atypical, especially in extremely immunosuppressed patients, though 60-80% of patients have pulmonary disease. Common radiographic findings include diffuse infiltrates and adenopathy. Tuberculin reactivity is found in 40 to 80% of patients. Response to standard antituberculosis therapy is generally excellent; lifelong therapy may not be necessary. Prevention of tuberculosis with prophylactic treatment of tuberculin-reactive HIV-seropositive persons is an urgent public health priority.
Mycobacterium-complex (MAC) is a late complication of HIV-related immunosuppression. Most MAC disease is probably a result of recent infection, and all HIV risk groups are equally affected. Several distinct clinical syndromes are associated with MAC infection. While MAC causes considerable morbidity, its contribution to mortality is unclear. Treatment is difficult as most isolates are resistant to standard antituberculosis drugs. Studies in animal models and limited human data suggest that newer regimens may control MAC disease. Prevention of MAC infection may be possible with prophylactic therapy.

M.B.O.32 CRYPTOSPORIDIOSIS, ISOSPORIASIS AND MICROSPORIDIOSIS
Paul M., St. Vincent's Hospital & Medical Center of NY
Etiologic, chronic, fatal, nonbacterial diarrhea
with/without dissemination pose a very serious management problem in AIDS, especially those caused by *Cryptosporidium*, *Isospora*, *belli*, and *Microsporidia*. These protozoans are easily detected in stool specimens using acid-fast or immunofluorescent staining procedures, except *Microsporidia* which has not been demonstrated in stool and thus requires fluorescent biopsy. Transmission is mostly fecal-oral, sexual, water/food borne, animal contact and possibly inhalation. Risk factors include travel to tropical countries, homosexuality, immunosuppression, etc. Disseminated infection involves cholangitis, hepatitis, pulmonary infection, for *Cryptosporidium* and myositis hepatitis for *Microsporidia*. Although *Cryptosporidiosis* in nonimmunocompromised host is self-limited, in AIDS, it is resistant to multiple therapies. Spiramycin and transfer factor have limited success. Currently, the most promising treatment is hyperimmune bovine colostrum from cows vaccinated with *Cryptosporidia* antigen given to AIDS associated symptomatic patients resulting in long term remission. Isosporiasis with a much lower incidence than cryptosporidiosis is less devastating. Response to atabrin and sulfamethoxazole has been noted with/without recurrences in some earlier infections. Little is known of *Microsporidia*, the newly recognized pathogen in homosexual men with AIDS. Cases known so far are all fatal. In conclusion, drastic research is definitely needed to reduce high morbidity and mortality of these opportunistic infections in AIDS.

M.B.O.31 HUMAN CYTOMEGALOVIRUS (HCMV) INFECTIONS IN AIDS: DIAGNOSIS AND ANTIVIRAL TREATMENT.
Caru Giuseppe; Revello M.G.; Minoli L.; Grossi P.; Perinvalle E.; Parea W.
Institute of Infectious Diseases, University of Pavia, and IRCCS Policlinico San Matteo, 27100 Pavia, Italy.
Objective: To correlate HCMV antigenemia and viremia with symptoms and ganciclovir (GCV) treatment in AIDS patients with systemic HCMV infections.
Methods: Antigenemia was determined in peripheral blood polymorphonuclear leukocytes (PMNL) by IFA using a Mab to HCMV immediate early antigens (EA) (2n assay), and viremia by IFA staining of "shell vial" cell cultures (inoculated with a known number of PMNs) 24h p.i. using a Mab to HCMV EA.
Results: Overall, 13 of the 65 (20%) AIDS patients examined had reactivated HCMV infection, 14 of 55 (25.4%) had viremia and 7 of 30 (23.3%) both viremia and antigenemia. Of these, the 2 patients with a high number of positive PMNs had high fever and were thus treated with GCV, with final disappearance of fever and virus from blood. Of 89 blood samples tested, 76 (87.6%) gave concordant results for both viremia and antigenemia, 9 (all taken during GCV therapy) were positive for antigenemia only and 2 for viremia only.
Conclusion: By monitoring HCMV antigenemia and viremia it seems possible to anticipate onset of symptoms and to earlier initiate and carefully evaluate effectiveness of GCV treatment.

M.B.O.45

VALIDATION OF THE SURVIVAL EXPERIENCE AMONG A LARGE COHORT OF AIDS PATIENTS TREATED WITH ZIDOVUDINE
CROSS-KEY, TERRY, DILLI, P.; ANDREWS, R. and TILSON, H. Burroughs Wellcome Co., Research Triangle Park, North Carolina, U. S. A.

Objective: To validate and extend the original survival experience reported in a large cohort of AIDS patients who received zidovudine through a compassionate-release program.

Methods: Through a compassionate-release system, 4805 AIDS patients began treatment with zidovudine over a six-month period in late 1985 and early 1987. These patients were also closely monitored for an additional 5 months by means of a structured epidemiologic study and data from a limited drug distribution system. Survival experience up to 46 weeks after treatment initiation has been published. However, because the least-to-followup rate in the original population was high, an effort was made to validate actual survival in a subset of all patients treated in sites participating in another study where retrospective data collection provided nearly complete follow-up.

Results: The validation study confirmed the original survival experience reported and extended that experience beyond 12 months. Prognostic effects of baseline hemoglobin level and functional status at well as the elapsed time between diagnosis and treatment were examined. **Conclusion:** A validation study has confirmed previous findings and allowed assessment of survival beyond that reported previously for a subset of patients. The extent to which these data can be generalized to the original population will be discussed.

M.B.O.46

SURVIVAL PATTERNS OF ZIDOVUDINE TREATED AIDS PATIENTS COMPARED TO UNTREATED CONTROLS.

DELLA, I. In order to establish the influence of antiviral therapy on survival of AIDS patients, we compared the survival patterns of patients receiving zidovudine with survival patterns of a control group of patients who were contemporaneously not receiving ZDV.

Methods: All Italian adult AIDS cases reported between January '87 and March '88 were included in this study. Of these, 773 began ZDV therapy and 1000 were untreated. Age, gender and risk factors for AIDS were similar in the two groups. Survival was calculated for each patient from the date of diagnosis through July 31, '88. Kaplan-Meier method. Wilcoxon test was used to evaluate differences between groups.

Results: Survival at 12 months for treated patients was 90.9% (95%-94.9%) while survival of untreated patients was 44.4% (39%-48%). Survival pattern of patients who initiated therapy but voluntarily interrupted within 30 days approached the survival of untreated patients (55.3%).

Stratification for clinical presentation and semester of diagnosis, and differences in survival of the two groups of patients.

Conclusion: Data obtained clearly confirm that ZDV therapy is associated with increased survival of AIDS patients, also when comparisons is made with untreated controls and not simply with historical controls.

M.B.O.47

NATURE, TIME COURSE AND DOSE DEPENDENCY OF ZIDOVUDINE RELATED TOXIC EFFECTS. RESULTS FROM THE MULTICENTRIC NATURAL AZIDOTHYMININE TRIAL (MCAZT).

ROSE, JOHN; MONTGOMERY, GORD; GILMAN, K; PAMME, M; SMITH, R; PALM, J; THOMAS, C; COE, J; WELLS, G; O'NEILL, M and VAN DER BRUG, G. Amgen, San Diego, CA, USA

Objective: To characterize the nature, time course and dose dependency of zidovudine related side effects in early HIV-infected individuals.

Methods: 1000 HIV seropositive, drug naive, stage 2 patients in HIV positive (HIV+) and HIV negative (HIV-) groups were treated with zidovudine 600 mg/day for 2 weeks, 600 mg/day for 2 weeks and 1200 mg/day for 2 weeks followed by a washout period of 2 weeks after which they were treated on 600 mg/day or 1200 mg/day for the highest previously tolerated dose at 6th interval. Subjects were randomly assigned to 4 or 6 g regimens while CDC groups with initially taking 600 or 1200 mg/day. Clinical and laboratory evaluations were performed at 3 week intervals.

Results: Symptomatic adverse events were reported in 96% of subjects, most commonly nausea (64%), fatigue (57%) and headache (49%). These were generally self-limited, resolving briefly at each dose decrease. A decrease in hemoglobin counts occurred after initiation of therapy. This was not dose dependent and reversed rapidly upon discontinuation of treatment. A red blood cell count decrease, a mean cell volume increase and a granulocyte count decrease developed only in a dose independent fashion, resolving at least partially during the washout phase. The decrease in reticulocyte count was dose related between 600 and 1200 mg/day with no further change when the dose was escalated to 1200 mg/day. Bone marrow changes occurred equally as demonstrated by megakaryoblasts in 95% of 85 specimens at week 11. LHM remained unchanged through out the 60 weeks. These effects were not dependent on study site, CDC group or drug regimen (4th vs 6th).

Conclusions: Hematologic effects include a mild macrocytic megakaryoblast count with a decrease in reticulocyte count and granulocyte counts. These appear to be dose independent in the range 600 mg to 1200 mg/day and rapidly reversible upon discontinuation of the drug. The fact that these effects are minimal on the smallest dose employed (600 mg) supports the need for efficacy studies at lower doses than those currently recommended.

M.B.O.49

TOXICITY OF COMBINED AZT/GANCICLOVIR (DMC) THERAPY IN AIDS PATIENTS

REASHAM, JESSIE; ANTONIADIS, D; CANNON, D; LEEDON, JR. LA CO-DCD Medical Center, Los Angeles, California, USA.

Objective: To assess the incidence of various hematologic toxicity during combined AZT/DMC therapy. Methods: 48 patients (pts) were treated with combined DMC from Jan 1986 to Dec 1986. No cytokes were used. DMPC maintenance was 3mg/kg (q 12h) in 1/20 pts, 4mg/kg in 9/20. Toxicity management for H1H grade 1 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 2 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 3 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 4 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 5 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 6 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 7 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 8 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 9 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 10 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 11 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 12 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 13 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 14 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 15 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 16 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 17 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 18 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 19 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 20 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 21 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 22 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 23 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 24 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 25 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 26 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 27 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 28 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 29 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 30 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 31 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 32 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 33 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 34 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 35 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 36 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 37 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 38 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 39 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 40 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 41 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 42 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 43 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 44 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 45 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 46 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 47 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 48 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 49 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 50 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 51 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 52 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 53 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 54 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 55 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 56 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 57 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 58 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 59 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 60 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 61 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 62 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 63 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 64 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 65 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 66 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 67 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 68 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 69 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 70 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 71 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 72 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 73 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 74 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 75 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 76 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 77 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 78 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 79 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 80 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 81 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 82 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 83 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 84 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 85 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 86 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 87 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 88 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 89 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 90 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 91 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 92 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 93 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 94 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 95 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 96 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 97 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 98 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 99 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 100 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 101 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 102 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 103 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 104 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 105 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 106 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 107 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 108 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 109 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 110 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 111 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 112 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 113 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 114 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 115 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 116 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 117 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 118 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 119 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 120 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 121 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 122 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 123 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 124 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 125 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 126 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 127 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 128 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 129 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 130 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 131 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 132 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 133 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 134 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 135 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 136 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 137 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 138 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 139 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 140 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 141 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 142 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 143 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 144 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 145 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 146 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 147 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 148 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 149 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 150 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 151 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 152 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 153 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 154 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 155 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 156 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 157 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 158 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 159 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 160 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 161 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 162 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 163 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 164 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 165 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 166 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 167 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 168 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 169 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 170 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 171 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 172 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 173 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 174 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 175 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 176 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 177 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 178 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 179 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 180 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 181 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 182 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 183 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 184 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 185 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 186 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 187 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 188 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 189 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 190 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 191 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 192 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 193 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 194 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 195 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 196 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 197 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 198 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 199 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 200 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 201 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 202 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 203 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 204 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 205 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 206 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 207 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 208 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 209 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 210 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 211 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 212 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 213 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 214 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 215 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 216 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 217 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 218 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 219 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 220 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 221 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 222 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 223 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 224 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 225 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 226 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 227 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 228 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 229 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 230 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 231 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 232 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 233 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 234 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 235 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 236 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 237 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 238 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 239 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 240 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 241 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 242 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 243 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 244 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 245 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 246 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 247 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 248 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 249 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 250 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 251 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 252 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 253 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 254 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 255 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 256 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 257 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 258 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 259 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 260 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 261 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 262 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 263 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 264 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 265 (q 3h) in 1/20 pts, 2mg/kg in 9/20. Toxicity management for H1H grade 266 (q 3h

T.B.O.1

FOLLOW-UP STUDY OF PATIENTS RECEIVING PENTAMIDINE AEROSOL FOR PREVENTION OF PCP

SCHEIDT, Michael, M.D., Kennedy, P., Kahn, S.,** Nagao, T.,* and Beringer, J.*
*Los Angeles Oncologic Institute, St. Vincent Medical Center, Los Angeles, California 90057; **Chief, Pulmonary Medicine, St. Vincent Medical Center, Los Angeles, California 90057, U.S.A.

Objective: To evaluate the efficacy of inhaled pentamidine in prevention of PCP during a 6 to 18 month follow-up period.
Methods: 51 patients with HIV (AIDS/AIHS) have been maintained on pentamidine, 150 mg every two weeks by inhalation. Group 2: 17 patients with prior PCP and with mean 74 of 106 cells/mm. Group 3: 14 patients with AIDS/AIHS without history of PCP and mean 74 of 262 cells/mm. All patients received HIV and syphilis tests.
Results: Incidence of drug toxicity, PCP, and death was compared.

Patient Group	Toxicity	PCP or Reassess PCP	No. of Deaths
I (n=31)	0	2	6
II (n=34)	0	0	0

The 6 deaths in I were unrelated to PCP.
Conclusion: Aerosolized pentamidine is effective prophylaxis against pulmonary Pneumocystis carinii in HIV immunosuppressed patients.

T.B.O.2

EFFETS DES AEROSOLS PROPHYLACTIQUES DE PENTAMIDINE SUR LA FONCTION RESPIRATOIRE A COURT TERME

MAILLAT, Richard-Claude Bernard, Paris-France.
P.N.M., Françoise; de Pietriotto, C., Lepetère, A., Landman, R., Girard, P.M., Salami, A.G.

Objectif: Evaluer la tolérance pulmonaire des aerosols de Pentamidine (APM) par la mesure de la capacité de transfert à l'oxyde de carbone (TLCO) et du gradient alvéolo-arteriel en oxygène (A(a-a)O₂).
Groupes: 46 patients SIDA ont été suivis pendant un mois net mois à la suite d'un (n=2) épisode (n=6) de pneumonocystose (N₂).
Groupes contrôle (n=10): 3 groupes APM (n=36): APM 1 (n=12), APM 2 (n=12), APM 3 (n=12).
La TLCO à l'état stable (à la valeur théorique) et ΔA(a-a)O₂ (norm) ont été mesurés à M1 et M2 (15 et 30 jours après la pneumonocystose). Aucun des patients inclus dans cette étude n'a présenté de recrudescence de pneumonocystose avant M2.

Groupes	M1		M2	
	TLCO %	ΔA(a-a)O ₂ t	TLCO %	ΔA(a-a)O ₂ t
Groupes contrôle	51,0	47,1	52,8	47,2
Groupes APM	46,5	44,4	45,9	47,7
	± 15,6	± 11,7	± 16,5	± 11,9

La TLCO augmente de façon non significative des deux groupes.
Conclusion: Les aerosols de Pentamidine ne semblent pas entrainer de troubles fonctionnels respiratoires dans la liste de la durée de cette étude.

T.B.O.3

AEROSOL PENTAMIDINE FOR PNEUMOCYSTIS CARINI PNEUMONIA PROPHYLAXIS: A 3 ARM RANDOMIZED TRIAL

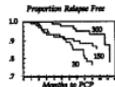

LANE, Douglas, M.D.,** Fogel, D.W.,* and the SF County Community Coronavirus Task Force.
*Department of Medicine, San Francisco General Hospital, Univ. of California, St. Francisco, CA; ** SUNY at Stony Brook, NY; ** Chief, Pulmonary Medical Center, SF.

Objective: To determine the efficacy of aerosol pentamidine for prophylaxis against Pneumocystis carinii pneumonia (PCP) in high risk HIV infected patients.

Methods: 408 patients were randomized to treatment with either 300 mg qtw, 150mg qtw or 300mg qtw of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=256), Kaposi's sarcoma (KS, n=88) or AIDS and other AIDS diagnoses (OAI, n=116). AP was delivered with a RespiRad Respirator II nebulizer (COPD/MMAAD-142 microns).

Results: Mean follow up in ongoing patients was 301 days (range 190-347). Intention to treat (ITT) analysis and analysis of PCP events of PCP on study (OS) in 28 days of eligibility and <60 days after last Rx showed 63 and 48 events (17% and 13%), respectively. Only 3 PCP events occurred in the KS or OAI strata; 75% of all PCP events were histologically confirmed.

The log-rank statistics comparing the three arms (ITT) were p=0.06 for 300 vs 150, p=0.15 for 300 vs 150, and p=0.17 for 300 vs 150. Cox regression models to adjust for number of prior PCP episodes, time since last PCP and zidovudine use. The reduction in relative hazard (300 vs 150) was 2.1 fold (p=0.1). **Conclusion:** There is a dose response showing 300mg qtw is best despite the longer interval between treatment. Since this is a dose response study, it underestimates the benefits of AP compared to no treatment.

T.B.O.5

LOW DOSE DAPSONE (D) PROPHYLAXIS (PX) OF PNEUMOCYSTIS CARINI PNEUMONIA (PCP)

LANE, Douglas, M.D., Kessinger, J.M., Tucker, R.K., Greene, S.I., Deresinski, S.C. and Stevens, D.A.
Santa Clara Valley Medical Center, San Jose, CA, U.S.A.

Objective: We evaluated the safety, efficacy and cost effectiveness of D as PX of PCP.

Methods: D (50-100 mg/d) was given as oral PX to 24 patients (PTS) with AIDS (21 PTS) or AIC (3 PTS). All PTS were male; mean age was 36.3 yrs; mean duration of disease was 9.7 mos. Three PTS received D as 1st PX and 21 as 2nd PX.

Results: Mean duration of PX is 106 d (range 21-430 d). There are 88 total patient mos. of PX: 71 on 50 mg/d, 17 on 100 mg/d; 17 PTS (71%) remain on PX, 4 are alive off PX and 3 have died (none of PCP). One PT relapsed with mild PCP on PX after 4 wks. Of D (50 mg/d), was treated successfully with D and trimethoprim and remains well at 160mg/d; 1 suspected toxicity occurred in 3 PTS (rash in 3); D was stopped in 4/5; none had serious sequelae. Monthly cost of PX per PT at our institution is \$1.10. For 21 pts treated with 100 mg/d and <\$400.00 for inhaled pentamidine (4mg/kg every 14d).

Conclusion: D (50-100 mg/d) is inexpensive and well tolerated. Our results suggest that even 50 mg/d is effective PX of PCP in AIDS. Comparative trials with alternative PX agents and dose finding studies of D for PX of PCP are in order.

T.B.O.4

SUCCESSFUL CHEMOPROPHYLAXIS FOR PNEUMOCYSTIS CARINI PNEUMONIA WITH DAPSONE OR BACTRIM

MICHA, Olga E.; Jacobs, D.L.; Lewis, N.S.;
St. Lukes-Roosevelt Hospital Center, New York, N.Y., USA; **Amocha Pharmaceutical, Princeton, N.J., USA

Objective: An open study of the efficacy and tolerance of dapsone or trimethoprim (TMP) for prophylaxis against Pneumocystis carinii pneumonia (PCP).

Methods: We studied 221 patients (pts) who were at high risk for PCP from AIDS and received prophylaxis. All pts had either <300 T4 cells/mm³ or had 2 or more PCP episodes in the prior 6 months.

Results: The mean T4 cells at the time of treatment initiation was 142 (range 0 to 373), 173 pts received dapsone (94 mg, range up to 43 mg) and 48 pts received bactrim (82 mg, range up to 57 mg), 2073 pts receiving dapsone 25 mg qtd and 674 pts receiving bactrim 615 mg bid developed PCP (n=631, 30%). In contrast, 26 episodes of PCP occurred in 23 pts who refused prophylaxis (9/6 mg, range up to 29 mg), 10% of pts receiving dapsone and 30% of pts receiving bactrim prophylaxis experienced an adverse reaction (p<0.0001). No hypersensitivity to X agents generally tolerated the other. 129 pts receiving both dapsone and AZT had no withdrawal from dapsone because of a sustained drop in hemoglobin. 125 pts receiving dapsone and 20 pts receiving bactrim developed other CI or malignancies. 10 pts on dapsone and 10 on bactrim have died.

Conclusions: Both dapsone and bactrim are equally effective in preventing PCP but a higher percentage of pts receiving bactrim experienced adverse reactions.

T.B.O.6

TRIMETHOPRIM-SULFAMETHOXAZOLE FOR SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINI PNEUMONIA IN AIDS

PIRANO, Gerald, M.D., J., Nicholas, P.,
St. Elizabeth Hospital Center, Elmhurst, N.Y., U.S.A.

Objective: In determine if maintenance therapy with trimethoprim-sulfamethoxazole (TS) prevents recurrent infection with Pneumocystis carinii pneumonia (PCP) in patients with the acquired immunodeficiency syndrome.

Methods: 100 patients were enrolled on all patients who had received at least 3 months of therapy with zidovudine (ZD) following an initial episode of PCP. Patients were randomized to receive either 12 of these patients also received TS in a dose of one double-strength tablet BID (Group 1). 11 patients were not treated with TS or any form of prophylaxis for PCP (Group 2).

Results: The two groups were comparable with regard to the severity of PCP (A-a gradient of 44.6 and 46.3 respectively) and time interval between diagnosis of PCP and initiation of TS (1.7 vs. 1.8 months respectively). None of the patients in group 1 developed PCP during 101 episodes of follow-up (mean 14.4 months). In group 2, there were eight relapses of PCP, three fatal, during 50 patient-months of follow-up (mean 8.2 months) (p<0.01). The one year mortality was 1/12 (8%) in group 1 and 4/11 (36%) in group 2 (p<0.05). 20 dapsone was reduced in 2/12 patients in group 1 because of neutropenia and 4/11 patients in group 2 secondary to anemia. There was no difference in mortality between the two groups.

Conclusion: TS is effective in the secondary prophylaxis of PCP in patients being treated with ZD, improves survival, and is not associated with increased bone marrow toxicity.

Redfield, Robert, Walter Reed Army Institute
 of Research, Rockville, MD, USA

T.B.O.23 CLINICAL DIAGNOSIS OF AIDS AND RELATED DISORDERS
MARSH, WENDY,
 Clinical Center, National Institutes of Health,
 Bethesda, Maryland, USA.

For individuals who are infected with HIV, morbidity and mortality are produced by three major processes: 1) opportunistic infections and tumors; 2) direct organ involvement by HIV; 3) immunologic processes such as antigen-antibody complex deposition. The quality and duration of patient survival can clearly be improved by prompt diagnosis of those processes that are treatable. Thus major emphasis must be directed at diagnosing the infectious complications that are responsible for causing 50% of deaths. Immunologic monitoring can predict when patients are most likely to be susceptible. Some diagnoses such as cerebral toxoplasmosis, cytomegalovirus retinitis, candida esophagitis, and perirectal herpes simplex can be made presumptively on clinical or radiologic grounds and response to therapy can be assessed. Other diagnoses such as pneumocystis pneumonia, cryptococcal meningitis, and the causes of diarrhea must be made specifically by microbiological or histologic criteria.

Traitement de la PCP PCP Treatment

T.B.0.26 AEROSOLIZED PENTAMIDINE VS. TRIMETHOPRIM-SULFAMETHOXAZOLE (TMP-SMX) FOR ACUTE PNEUMOCYSTIS CARINI PNEUMONIA (PCP): A RANDOMIZED DOUBLE BLIND TRIAL.

Montgomery, A. Ross, J. Edmon, J.L., Hopwood, M.J., Sattler, E.R., Fennberg, J.,*, Felger, D.W.,** and the U.S. National Cooperative Investigators.**
* State University of NY at Stony Brook; ** University of California, San Francisco; *** University of Southern California;**** National Institutes of Allergy and Infectious Diseases.
Objective: To evaluate the efficacy and safety of aerosolized pentamidine as treatment for acute PCP in AIDS patients.
Methods: Patients with suspected PCP are randomized at 24 centers pending confirmation of PCP and receive either aerosolized pentamidine (600 mg in 6 cc daily) or TMP-SMX (TMP-15 mg/kg/day + SMX-75 mg/kg/day) with either placebo aerosol or placebo IV. Standard treatment course is 21 days with an 8-month follow-up for recurrences and adverse events.
Results: 206 of the target 208 eligible patients have been studied (97 currently in treatment). Pooled data from the two treatment arms as of January 13, 1985:

	Rate
Eligible patients completing acute therapy	188
Randomized drug changing for poor efficacy	43
Optimal during acute treatment period	13
Major adverse event during acute treatment**	70
PCP recurrence months 0-4 follow-up (N=136)	8
PCP recurrence months 4-6 follow-up (N=74)	8
Extrapulmonary pneumocystosis	0
Pulmonary hemorrhage	0

Conclusions: Rates of toxicity, initial treatment failure and mortality are not excessive relative to other studied PCP treatments. PCP recurrence rates are also relatively low.

T.B.0.28 TRIMETHAZONE (TMX) SALVAGE THERAPY OF PCP IN AIDS PATIENTS WITHOUT ANY THERAPEUTIC OPTIONS: INTERIM RESULTS OF THE 1ST AIDS "TREATMENT TRIAL" PROTOCOL.

Feldner, Judith, Katz, D., Rubenstein, C., Myers, N. Beth, D. AIDS Program, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland, USA
Objective: To evaluate TMX salvage therapy of PCP in AIDS patients (pts) who cannot be treated with standard therapies (PCP, trimethoprim-sulfa and IV pentamidine). TMX is the first AIDS drug to be distributed under the FDA's new "treatment drug" mechanism, which permits access by licensed US physicians to a promising investigational drug with evidence of safety.
Methods: Pts with serologically-confirmed PCP, poly + bands > 1000, platelets < 20K who have experienced serious toxicity to both ST and/or have not responded to IV or aerosolized TMX 45 mg/kg* = 21 days and leucovorin 30 mg/kg* = 24 days. Successful completion of study therapy is defined as survival at 1 month follow-up.

Results:	Analgesics	Antibiotics	Intolerant/Infectious	Refractory
no treatment (n=12/788)	115	3	4	6
1st episode of PCP	32 (43)	33 (67)	5 (83)	
discontinued at entry	24 (31)	20 (59)	3 (50)	
days of ST at entry†	10 (8-28)	17.5 (11-24)	9.6 (7-13)	
inhab	34 (30)	27 (79)	3 (50)	
survived	34 (47)	2 (6)	3 (50)	
withdrew - adverse event	16 (14)	2 (6)	0 (0)	

Conclusions: TMX is an effective (39% survived) and well-tolerated salvage therapy for desperately ill AIDS patients. The "treatment drug" is a useful mechanism for providing wide access to promising investigational therapies.

T.B.0.30 EFLORITHINE IN PCP CASES RESISTANT TO CONVENTIONAL THERAPY.

SON, E. SMITH, S. OWEN, N. MELSON, B. G. GAZDAR, ST. BARTHOLOMEW HOSPITAL, TULHAR ROAD, LONDON, ENGLAND.

OBJECTIVE: To describe our experience with Eflorithine as a salvage treatment in HIV positive patients with Pneumocystis Carini Pneumonia (PCP) having failed to respond to Co-Trimoxazole or Pentamidine.
METHODS: 20 HIV positive patients with a microscopically confirmed episode of PCP received Eflorithine (400mg/kg) IV continuous infusion having failed to respond to either Co-trimoxazole or IV Pentamidine as assessed by worsening CXR, PaO₂ and failure of respiratory and respiratory rate to normalize.
RESULTS: 18 patients survived (64%) and 10 died during treatment with Eflorithine. There was no statistical difference between initial PaO₂ in survivors vs non survivors but there was a worse CXR in non survivors. No ventilated patients recovered. 30 adverse events in total were recorded: anaemia 11, thrombocytopenia 6, and phlebitis 15. All patients receiving greater than 10 days Eflorithine survived. Eflorithine was discontinued due to narrow spectrum in 3 patients.
CONCLUSION: Eflorithine is a salvage drug for salvage treatment of non responsive cases of PCP but does exhibit bone marrow toxicity.

T.B.0.27 THE IMPROVING SURVIVAL RATE AFTER INTENSIVE CARE FOR P. CARINI PNEUMONIA AND ESOPHAGITIS FAILURE

Yoshida, Robert M., Rossi, M.P., Hopwood, P.C., and Lusa, M.D.

*Robert Wood Johnson Clinical Research Program, Rutgers University, **The Franciscan General Hospital and the University of California, San Francisco.

OBJECTIVE: To determine the survival rate of patients with AIDS, P. carini pneumonia (PCP), and esophagitis failure who are admitted to the ICU, and to determine whether an improving survival rate (as compared to an earlier era) can be attributed to patient selection.
Methods: The study used a retrospective cohort design. Patients with AIDS and PCP who were intubated for respiratory failure at San Francisco General Hospital between January 1984 and December 1984 were studied. Hospital survival rates, long-term outcome, and severity of illness (including APACHE II scores) were measured, and compared to those of patients with PCP and respiratory failure hospitalized between 1981 and 1983.
Results: The hospital survival rate for the 50 patients in the 1984-85 cohort was 40%, compared to 14% for the 42 patients in the 1981-83 cohort (p<0.01). Age, episode of PCP, time since AIDS diagnosis, vital signs at hospital admission, respiratory, chemist, renal, and hepatic function, and APACHE II score did not differ significantly between the two cohorts. Anti-PCP therapy was similar in both cohorts. Although out-hospital survival was much more frequent in 1984-85 cohort than in the earlier era (77% vs. 26%), its use in individual patients was not associated with better outcome. There was no significant difference in 1 year survival rates between the 2 cohorts (7% vs. 24, by life table analysis).

Conclusions: The short-term outcome of patients with AIDS, PCP, and respiratory failure in 1984-85 has improved as compared to an earlier era. The improvement cannot be explained by patient selection, based on commonly measured prognostic variables, or by therapeutic advances. This improvement may result in a change in ICU utilization by patients with AIDS.

T.B.0.29 ORAL COBICISTATINS PREVENT ACUTE RESPIRATORY FAILURE IN AIDS-RELATED PNEUMOCYSTIS CARINI PNEUMONIA

Montagne, A.J., Lerman, L., Levin, N., Bullock, A., Schneider, M., and Ruddy, J.

AIDS Research Program, St. Paul Hospital, University of Alberta, Edmonton, Canada.

OBJECTIVE: To assess the role of adjunctive oral cobicistatins in the prevention of acute respiratory failure in patients with moderately severe AIDS-related Pneumocystis carini pneumonia (PCP).

METHODS: Randomized, double-blind, placebo controlled trial. A total of 60 patients are being studied. Inclusion criteria include:

1. First episode of PCP
2. PaO₂ 45 to 55 mm Hg (Fio₂ 21%)
3. No other active pulmonary pathology
4. No immunizations for pneumococcal pneumonia
5. Not on anti-PCP medications for more than 24 hours

Consenting subjects are randomized in blocks of 10 to placebo or prednisone 40 mg/kg PO bid for 7 days followed by 14 day tapering regimen. Acute respiratory failure (ARF) is defined as a 20% drop in oxygen saturation at day 3 as measured by pulse oximetry while breathing room air. Patients developing ARF are considered a failure of treatment and the code is broken.

RESULTS: To date, 30 subjects have been studied. Mid point interim analysis demonstrates that ARF developed in 4 out of 15 patients receiving placebo versus 1 out of 15 patients receiving adjunctive oral cobicistatins (p=0.05 Fisher exact test). All 8 patients developing ARF in the placebo treated group recovered rapidly after the initiation of conventional therapy. The single patient who developed ARF in the cobicistatins group went on to die on day 4. One further patient in the cobicistatins group died after resolution of his PCP from an unrelated cause (CNS lymphoma).

CONCLUSIONS: Oral cobicistatins prevent the development of acute respiratory failure in patients with moderately severe PCP. Furthermore, our results support the use of corticosteroids after respiratory failure develops in patients with AIDS-related PCP.

* Supported by a grant from the National AIDS Research Program (NIDDK), and St. Paul's Health, Canada.

T.B.0.31 CLINDAMYCIN/PRIMIDONE FOR P. CARINI PNEUMONIA IN AIDS.

Tombs, Gail; Fournier, S.; FGA4007, KJ, Leicester, U.K.; Pflanzl, U.J., Veiga, C.

Hôpital-Clouard de Montréal and Université de Montréal, Montréal, Québec, Canada.

Objective: To assess the tolerance, safety and the clinical outcome of clindamycin/primidone (Cln/Prm) in the treatment of P. carini pneumonia (PCP) in patients with AIDS.

Methods: This is an open clinical trial including patients with AIDS in whom "conventional" therapy for PCP failed or was not tolerated. The clinical outcome was assessed in patients with proven or highly probable PCP. The tolerance and safety was monitored in the above patients and in patients with possible PCP.
Results: So far 33 episodes of PCP (19 proven; 8 highly probable and 6 possible) were treated: 1st episode -21 cases and 2nd episode -12 cases. The Cln/Prm was given after 2-6 days of "conventional" therapy in 27 patients and as the initial treatment in 6 cases. Clinical response was defined as cure - 23 patients; improvement - 2 cases; failure - 2 patients. The cure rate of clinical response was less than 68 in 16 patients, 72 in 5 patients and 6 days in 2 patients. Adverse reactions were encountered in 15 out of 33 patients: neutrophilia rash in 10 patients (with fever, leukopenia or neutropa in 3, 2 and 1 of them respectively); mild diarrhea - 1 case. The duration of follow-up was 1 week (11 months); eight patients were followed for more than 7 months. In spite of no specific anti PCP prophylaxis only 3 patients had a relapse after 10, 10 and 9 months respectively.
Conclusion: Our results prove that a continued consecutive treatment with Cln/Prm in the therapy of PCP in patients is feasible and worthy.

T.B.O.32

LES ANTIGÈNES HIV-1 CIRCULANTS
Carpene R037211X
Hôpital Necker-Infirmerie Médecine, Paris, France.

La présence d'antigènes HIV-1 dans le sérum de sujets infectés est le reflet de la réplication persistante du virus dans l'organisme. Leur détection est réalisable par des techniques d'immunoanalyse qui sont commercialisées. Ces techniques sont fiables, faciles à réaliser, sensibles et reproductibles à condition de connaître les limites de leur utilisation et de l'interprétation des résultats obtenus :

- le dosage des protéines virales doit être exprimé en pg/ml pour obtenir une bonne reproductibilité ;

- l'évaluation de la valeur-seuil doit être faite dans une plus basse limite ;
- l'utilisation de dérivés capables de lier le virus est adéquate pour l'obtention d'une meilleure sensibilité et, en fait, permet l'évaluation de deux paramètres différents : les protéines virales solubles d'une part, et les particules virales complètes d'autre part. On démontre qu'il n'y a pas de proportionnalité directe entre ces deux paramètres, dont la valeur prédictive journalière fut différente.

Les antigènes HIV-1 circulants représentent un élément essentiel et indispensable pour le suivi biologique des patients et pour l'évaluation des thérapeutiques anti-virales. La présence d'antigènes HIV-1 circulants est le plus souvent corrélée à une évolution clinique défavorable. Cependant, l'absence d'antigènes circulants chez certains sujets atteints de SIDA pose le problème de l'interprétation des anticorps et des immuno-complexes et révèle un site et un stade non le reflet d'une réplication virale, mais aussi celui d'une équilibre antigènes/anticorps complexe.

T.B.O.36

HIV TECHNOLOGIES FOR THE DIAGNOSIS OF AIDS
Schuchman, Gerald AIDS Program, Centers for Disease Control, Atlanta, GA, USA

Specific testing for HIV antibodies and virus markers has permitted accurate diagnosis of AIDS and HIV infection. As the AIDS epidemic continues to spread, there will be a sustained need for more sensitive and quantitative assays. Higher sensitivity is needed to permit earlier diagnosis of infection which will become increasingly important as effective therapeutic interventions are developed to prevent the disease. Higher specificity is needed to decrease the number of false positives and to permit correct diagnosis of HIV infection in a larger spectrum of clinical situations where there is an incubate or indeterminate antibody profile. Quantitative tests for monitoring the virus burden and state of activity in an infected person are also needed to improve the ability to assess the clinical status of the patient and to evaluate the efficacy of new drugs and possibly vaccines.

The use of IgM-derived antigens has already shown great promise in the advancement of diagnostic testing. For developing countries, the availability of rapid, simple and inexpensive tests for HIV infection will offer the greatest hope for prevention of transmission of the virus particularly through screening of the blood supply. The application of this probe technology, particularly PCR, has already opened a new horizon for direct detection of the virus. This technology has proven useful for detecting infection in seronegative persons, for assessing virus expression and for finding and characterizing variant HIV.

Diagnostic testing for HIV will remain an important aspect of disease control even as prevention and therapy are developed for these infections. Fortunately, technology advancement for diagnosis of retroviral diseases has opened a very dynamic and an ambitious program can be expected in the development of novel diagnostic tests and test applications.

T.B.O.33

SEROLOGY TESTS FOR THE DIAGNOSIS OF AIDS
KIV, P. Shaughnessy, Tizard Centre for AIDS, Ottawa, Canada

The serological tests most commonly used for the diagnosis of HIV infection have been enzyme immunoassays using whole viral lysates to capture anti-HIV antibodies. These screen tests have been configured to have high sensitivity and are specifically, consequently, all positive results must be verified by a second procedure, such as immunoblot, immunofluorescence (IFA) or radioimmuno precipitation (RIP). In most settings, these tests are highly reliable and quality assurance programs have demonstrated this. In some countries, these assays have been modified to detect antibodies eluted from dried blood spots for use in large scale epidemiological studies. Newer HIV screen tests include those using recombinant proteins, synthetic peptides and antigens from both HIV-1 and HIV-2 as the capture antigens. Competitive EIA tests are particularly suitable for differentiating HIV-1 and HIV-2. Immunoblots utilizing recombinant proteins are available and have undergone preliminary evaluation. Simple, often rapid, HIV antibody detection assays have been developed for use in developing countries and emergency situations in developed nations. The performance characteristics of these tests can be quite good, but positive results must be verified by another method such as RIP, IFA or immunoblot. Antigen capture assays may be used to detect HIV p24 in serum. This procedure has been used both for monitoring the efficacy of drugs under clinical evaluation and providing a prognostic indicator of patient outcome. The efficacy of most of these commercially available reagents is excellent, but continued successful delivery of testing strategies requires adequate product and user quality assurance programs. International collaborations, for example, those sponsored by the World Health Organization and the Pan American Health Organization have been established to assist in the development and implementation of quality assurance programs.

T.B.O.35

Viral Culture as an Adjunct to Clinical Trials: Isolation of AZT-Resistant Variants of HIV-1.

Mark A. Waldinger, Booker, S.; Tremblay, M.; Souleyns, N.; Fanning, M.; Montaner, J.S.G.; O'Shaughnessy, M.; Gelson, K.; Palais, J.; Toukas, G.; Gill, J.; Bushy, J.
*Jewish General Hospital and McGill University, Montreal, Canada.
Our laboratory has participated in a Canadian AZT trial, designed to assess the efficacy of this drug on patients with Group II or III HIV-associated disease. Seventy two patients entered this trial received 600 mg AZT per day for 16 weeks, 900 mg for 8 weeks and 1200 mg for an additional 9 weeks. After 36 weeks, drug was withheld for 8 weeks and started again after 42 weeks at 1200 mg per day. Attempts to culture HIV were routinely carried out during this period. A significant increase in the percentage of cases from whom HIV could be successfully isolated was observed both at the end of the drug wash-out period, and during the period following (80% postwash-out vs 40% prewash-out). This corresponded to decreased time to culture positivity following the wash-out period (21 days vs 19 days).

We have also shown that HIV could be isolated under conditions in which AZT (10 µM) was included in the primary viral culture medium in each of two cases in which patients had received AZT for longer than 36 weeks. Assessment of frozen viral isolates, obtained from patients on long-term AZT therapy, has revealed the presence of AZT-resistant virus in each of 9 additional cases. This property of drug resistance appeared stable, and did not disappear when such viruses were replicated in the absence of drug. These AZT-resistant isolates were, however, susceptible to inhibition by each of four other nucleoside analogues. Supported by Health and Welfare Canada.

Quality of Care for Patients with AIDS**

W.B.O.13 **SIMPSON** - Quality of Care for Patients with AIDS
Dept. of Community Psychiatry
Kilpatrick, Brian G. St. Paul's Hospital, Vancouver,
British Columbia, Canada.

The community physician plays a pivotal role in provision of high quality care to persons with AIDS. The physician dealing with patients has the need to listen, to observe, to advise, and to console. In coping with AIDS, there is the additional need to advocate for our patients to provide quality care.

The physician plays different roles in each community in which he/she works. As a member of the global community, one is guided by the aims of the World Health Organization within the Global Programme for AIDS. These are information, education and communication to prevent further transmission of human immunodeficiency virus and to provide care to those already infected. With national and regional communities, one functions as educator, care-giver, and case reporter. Within the community of health care providers, one may be seen to be the coordinator of other care providers both institutional- and community-based, in addition to other roles.

Special roles may evolve in considering the community of patients of each physician. Physicians working within the general community have roles different from those of physicians whose patients' community encompasses primarily gay/bisexual men, hospital-in- or injection drug users.

W.B.O.14 **HOSPITAL CARE OF AIDS PATIENTS**

Clumbeu, Nathan
Free University of Brussels, St-Pierre University Hospital,
Brussels, Belgium.

Due to the medical, social, ethical and psychological backgrounds of AIDS patients, HIV infection has to be viewed globally. To face the enormous medical complexity of HIV infection, re-examination of established care structures has to be considered. In this respect, as demonstrated by the SFGS model, hospital care should be a part of a coordinated program including out-patient clinic (ambulatory care) and community based organizations. Depending available resources, commitment of health care providers, pre-existing structure such as infectious diseases department, and volume of patients enter hospital variability in care exists. Ideally, hospitalized AIDS patients should benefit from a dedicated in-patient unit or at least an integrated network of related sub-specialities. To provide coordinated care and treatment for the complex multiple problem which overwhelm the patients, AIDS team should comprise infectious diseases specialists, oncologists, generalists in internal medicine and family practice, psychiatrists and psychologists and social workers in liaison with consultant physicians (mainly pneumology, neurology, gastroenterology and dermatology). This multidisciplinary coordination should ensure optimal medical care and expert nursing and should reduce stress in AIDS care providers. In addition, psychological support for staff and volunteers as well as stress reduction program addressing education and information on infection control policy, ethical response and professional responsibility and psychological burden should be part of hospital policy.

W.B.O.15 **THE OUTPATIENT CLINIC IN AIDS CARE**

Yehlekin, Dan. University of California, San Francisco, San Francisco, CA, USA.

The most effective humane and efficient care for HIV disease requires well-coordinated care of the resources outside the acute hospital setting, particularly of the outpatient clinic. In San Francisco, dedicated AIDS clinics have allowed for the provision of comprehensive medical and psychosocial care that is oriented to the patient's common needs. In one model, physicians of varying professional/specialty backgrounds work as a team supplemented by experienced nurse practitioners and physician assistants. Social needs are provided by professional and volunteer counsellors, social workers and psychiatrists. Representatives of several community-based organizations are on the clinic staff and are able to provide effective referral to the services of these organizations. Also, clinic users are expert in HIV disease recognizing and resolving potential problems. This system combined with a model AIDS support unit, has enabled the continued reduction in the average length of hospital stay without compromising the quality of medical care delivered. Cases of HIV disease cure are lower in the San Francisco area than elsewhere in the United States.

The role of the outpatient clinic is central to the model of care in San Francisco. It serves as the home of the full-time provider staff and has provided a base for extensive studies of the cost of AIDS care as well as of new therapies. The opportunity to interact with a full range of HIV disease patients reinforces the commitment of the staff to maintain the best care possible in the community, further controlling overuse of in-patient services. This model works well in catering for a large population of patients most of whom are educated homosexual men in a city with a supportive attitude to AIDS issues. Clearly, stress would exist in many other settings that comprise HIV disease care. Many hospitals are reluctant to openly provide AIDS care and populations of drug users with HIV infection are burdened by other health and economic concerns. Nevertheless, dedicated AIDS clinics have been used in diverse situations with common success.

W.B.O.16 **HOME CARE THERAPY**

Walker-Martin, Jeanne. Visiting Nurse and

Hospice of San Francisco, San Francisco, California, USA.
In 1982, when Visiting Nurse and Hospice of San Francisco (VNH) began to receive referrals for people diagnosed with AIDS, Hospice professionals have sought a means to face organizational challenges regarding the provision of services for this population. Traditional family support systems were often insufficient, attendant care was often needed around the clock, and both private and public insurance were usually inadequate to cover the cost of care.

Since that time, VNH has provided support services to over 2000 persons with AIDS/HIV disease in the home setting or in the agency's residential care facility, Conita Home Hospice. This presentation will describe the development of the VNH AIDS Home Care and Hospice Program, and the special clinical features of the interdisciplinary team approach which combines the skills of physicians, social workers, trained paraprofessionals (attendants), and nurses, social workers, trained paraprofessionals (attendants), and volunteers with the support of family members or friends to provide home and hospice care to persons with AIDS.

- I. Overview of the AIDS Home Care and Hospice Program
 - A. Development from 1982-1989
 - B. Representation of the interdisciplinary team approach
- II. Management of the terminally-ill AIDS patient at home
 - A. Several important clinical considerations
 1. Pain and symptom management
 2. Mental status deterioration
 3. Substance abuse
 - B. Psychosocial Concerns
 1. Multiple loss issues
 2. Lack of traditional supports
 3. Minimal financial resources
- III. Reimbursement considerations

W.B.O.16.A **AIDS AND US VETERANS: A COOPERATIVE CARE APPROACH IN A**

MULTI-CENTRAL HEALTH CARE SYSTEM
Allen, Robert E.; Petersen, M. and Mather, S.B.
Department of Veterans Affairs, Washington, D.C., USA.

Objectives: To describe how the Department of Veterans Affairs (VA) national health care system responded to the needs of veterans with AIDS.
Methods: VA has one of the largest and most complex health care systems in the world, consisting of 173 medical centers, 133 outpatient clinics, 117 nursing homes, 27 domiciliarys and 134 Vet centers, employing approximately 230,000 individuals. VA has cared for approximately 7,000 AIDS patients using a comprehensive, multidisciplinary approach.
Results: Quality health care has been provided approximately 66 of all AIDS patients in the US to US differentiating centers. The comprehensive continuum of care includes voluntary testing with intensive pre- and post-test counseling, clinical evaluation and treatment, as well as hospital based home care, chronic placement and hospice care, including bereavement counseling for partners and family. Advanced research is conducted in many medical centers by the same clinicians caring for the patients and patients have opportunity to participate in clinical trials and other research studies. Health professional and other staff training programs in AIDS are ongoing in the VA.

Conclusions: Over 66 of all of the AIDS patients in the USA come to the VA for care. This large government run health care system has responded to the epidemic with clinical care, research and educational programs. These coordinated efforts have made it possible for any eligible veteran in the US to receive care for their AIDS related problems at any VA medical center.

Hémophilie : histoire clinique et études de cohortes Hemophilia: Natural History/Cohort Studies

W.B.O.23 SURVIVAL OF PATIENTS WITH HEMOPHILIA-ASSOCIATED AIDS IN THE UNITED STATES
 Stein-Dorson, Jeanette; Holmes, J.; Mahoney M. Centers for Disease Control, Atlanta, Georgia, USA

Objectives: To examine the survival of hemophilic patients after the diagnosis of AIDS.
Methods: Using national hemophilia-associated AIDS surveillance data and the life-table method of analysis, we calculated the median survival and the cumulative probability of survival for all and selected subgroups of U.S. hemophilic patients after the diagnosis of AIDS.

Results: The median length of survival was 11.7 months; the cumulative probability of survival was 49.2 ± 2.0% at one year and 28.9 ± 2.3% at two years. The length of survival varied by age at the time of AIDS diagnosis:

<13 years	13-32 years	32-52 years	>52 years
Median survival: 12.0 mo	16.4 mo	9.0 mo	3.0 mo

Patients diagnosed before 1986 had a median survival of 4.8 months compared with 15 months for those diagnosed in 1986 or later. Length of survival did not differ significantly by race, complication disorder, AIDS manifestation at the time of diagnosis, or region of residence. Seven patients survived longer than 36 months after AIDS was diagnosed. These patients were more likely to have received the 1987 revision of the CDC AIDS surveillance case definition than other patients.

Conclusions: Patients with hemophilia-associated AIDS patients are similar to those reported in other risk groups, excluding patients with Kaposi's sarcoma. Length of survival decreased with increasing age and improved over time. In contrast to other risk groups, no difference in survival was associated with race.

W.B.O.25 NATURAL HISTORY AND IMMUNORESPONSE OF HIV INFECTION IN INFECTED HEMOPHILIACS
 Sullivan, John L.,* Neap, R.,* Brewster, D.,** Levine, P.,** University of Massachusetts Medical School, ** Worcester Memorial Hospital, Worcester, Massachusetts, USA

Objectives: To evaluate the natural history of HIV infection and HIV specific immune response in patients with hemophilia.

Methods: A prospective study of 154 individuals with hemophilia was carried out over a 5 year period. Specific studies included HIV viral culture, serum p24 detection, lymphocyte surface marker analysis, neutralizing and AXC antibody studies, and detection of HIV specific CD4 activity.

Results: Over the first five years of observation 21 of 136 seropositive individuals (15%) developed AIDS. HIV was isolated from approximately 80% of infected individuals and 18% had detectable (>30 pg/ml) p24 core antigen in serum. Absolute numbers of CD4 T cells progressively declined in 80% of those infected while 16% had stable circulating CD4 cells. Activated (DR positive) CD8 T cells progressively increased from <2% to 21% of total CD8 T cells. Eighty percent of HIV seropositive individuals had detectable circulating cytotoxic T cells directed against HIV gag and envelope proteins. In addition HIV seroconversion was rapidly followed by the appearance of AXC antibodies (titers from 1:1000 to 1:1,000,000) directed against only HIV envelope proteins. Neutralizing antibodies were slow to appear and persist in extremely low titer (few <10 to 100).

Conclusions: These results suggest that persistence of active CD4 and AXC response in the absence of broad neutralizing antibody may result in progressive immune attrition with development of symptomatic disease.

W.B.O.27 CANADIAN NATURAL HISTORY STUDY (CNHS): HIV INFECTION IN HEMOPHILIA (HM) AND OTHER BLEEDING DISORDERS (1985-1989).

Prosser, M.,* Collins, A.L., S.K. Card, R., Garvey, S.,* Groom, G.,* Kobrin, N.,* L.J. Rubin, S.,* Sirovnick, R.,* and Lissak, C.,* Universities of Calgary, Memorial, Saskatchewan, Toronto, British Columbia, and McGill, Canada.

The CNHS Initiated in Jan 1985 enrolled 372 patients from 12 Canadian Hemophilia Centers. These included 285 Hem A, 48 Hem B, 37 von Willebrand disease (vWD) and 3 others. There were 86 children and 24 adults. 210 patients had severe, 72 moderate and 80 mild disease. In the 1988, 323 patients remained in the cohort, as 28 had withdrawn, and 28 had died. 16 of the deaths were due to AIDS. The latest observations are as follows: (1) The HIV seropositive (sp) rate was discordantly higher among Hem A (182 of 249) than Hem B (2 of 43), vWD (4 of 28) or others (1 of 3). The most important determinant for sp was the use of non-heated factor VIII concentrates as 81% of those severe Hem A receiving this product were positive of a sp vWD had received this product. One positivity is that before heated concentrates were supplied (Jul 1985), the Canadian volunteer plasma donation system was self sufficient for Factor IX concentrate, whereas 50% of the factor VIII had to be imported. (2) Progression of HIV disease was evident. At enrollment, of the 164 sp patients (44% of 372) CDC III, II, I & IV diseases were 72, 20, 10, and 10, respectively. In 1987, 170 patients were post (53% of 323). The CDC III, II, I & IV diseases were 47, 7 & 46. Including the 16 who died of AIDS, the number with CDC IV disease had increased from 10 to 61. (11) 6 patients seroconverted in 1987. This was traced to a factor VIII concentrate dry-heated at 60°C x 30 h.

W.B.O.24 OBSERVATION INDEX FOR AIDS AND OTHER HIV OUTCOMES IN A COHORT OF HEMOPHILIACS IN WESTERN PENNSYLVANIA
 Rosen, Lawrence, Y.,* Kirsney, L.A.,** University of Pittsburgh School of Medicine, Hemophilia Center of Western Pennsylvania; **Graduate School of Public Health, U.S.A.

Objective: To describe the distribution of AIDS and HIV-related outcomes following HIV seroconversion in a cohort of hemophilic patients.

Methods: A well-characterized cohort (n = 64) of HIV-infected hemophilic from Western Pennsylvania, on whom HIV seroconversion dates are known, have been followed prospectively for development of clinical manifestations of HIV infection including AIDS, AIDS-related complex (ARC), and CDC class IV infection. Kaplan-Meier estimates of cumulative risk for AIDS and other significant HIV outcomes by duration of infection were determined. **Results:** Of the 64 HIV-infected hemophilic, 27 (42%) have developed AIDS and 12 (14%) have developed ARC or CDC Class IV infection (through, herpes zoster). 80 cases of AIDS were observed in under two years' duration of infection. Using Kaplan-Meier product-limit method estimators, by 4, 6, and 7-1/2 years' duration of infection, the proportion developing AIDS is 12, 29, and 43%, respectively. The cumulative estimates for developing either AIDS or ARC/IV by 7-1/2 year duration is 60%. By age, for those > 30, 18-30, and < 18 years, the proportion developing AIDS by 6 years after infection is 50%, 25% and 5% (< .01).

Conclusions: Half of this cohort had developed AIDS or ARC/IV by 6 years' duration of infection. There appears to be a significantly shorter incubation to AIDS/HIV outcomes in those over 30 years of age at seroconversion.

W.B.O.26 NATURAL HISTORY OF HIV IN PATIENTS OF THE BOSTON HEMOPHILIC COHORT STUDY.
 Ames, Bernard, S.,* Miesse, P.,* Brackman, N.H.,** Maitin, C.,** van Loon, R.,** Kaarst, J.,** *Institut für experimentelle Haematologie, Bonn, FRG, **Massachusetts Institute of Technology, Boston, USA

Objective: To describe the natural history of HIV-infection in adult hemophilic patients.

Methods: 343 adult patients at Boston Hemophilia Center were tested positive for HIV in 1985. Since 1986, 313 patients have been regularly followed up, including clinical examination, routine laboratory, lymphocyte antibody, western blot and virus isolation.

Results: Six years after infection 18 (5%) of the entire cohort had developed AIDS. The most frequent manifestation of AIDS was PCP. HIV seroepidemiology: 12% toxoplasmosis, 7% HSI, 7% One 82 was observed. In 88% of patients 74 cell count decreased 50% or more over the observation period. Prognostic markers for progression to AIDS (other than decreased T4 cell count) were elevated 149, successful virus isolation and lines of anti-p24-antibodies.

In asymptomatic patients not treated with AZT (n=213), T4 cell count decreased 87 (41%) over Actual 74 cell distribution:

<100	101-200	201-300	301-400	401-500	>500
11	29	37	53	56	41

Conclusion: Our findings suggest that most HIV-infected hemophilic will eventually develop AIDS.

W.B.O.28 NINE YEAR FOLLOW-UP OF A COHORT OF 113 ANTI-HIV SERONEGATIVE HEMOPHILIACS

Lee, Christine A., Phillips AN, Elrod J, Jamesy G, Griffiths, PD, Kennell, PBA Royal Free Hospital and School of Medicine, London, England.

Objective: To assess the natural history of HIV disease in 113 infected hemophilic and 1 sexual contact.

Method: Patients were reviewed at frequent intervals from the time of seroconversion (established by retrospective testing in 69 (1983) patients) until November 1988. **Results:** The first seroconversion was November 1979 and the last July 1985. The median length of follow-up from the first positive anti-HIV test was 2 years 1 month. By 29 November 1988, 61/113 (54%) patients were symptomatic and 21/113 (19%) had developed AIDS.

SYMPTOMATIC	Thrombocytopenia	7 (6%)	AIDS	HIV wasting syndrome	2
	Herpes zoster	11 (9%)		Oesophageal candida	2
	Interstitial pneumonia	18 (16%)		PCP	1
	Oval candida	17 (15%)		Aspergillus pneumonia	1
	Schistosoma dermatitis	2 (20%)		KAL	1
				Cerebral toxoplasmosis	1
				Lymphoma	2
				Diagnosed mycobacteria	1
				with cerebral abscesses	1

Amongst 59 hemophilic with a known date of seroconversion, the clinical cumulative incidence of symptoms was 60% and of AIDS 70% after 9 years of seropositivity (Kaplan-Meier estimate). **Conclusions:** This nine year follow-up confirms that the majority of anti-HIV positive patients progress to symptoms and AIDS. This cohort may provide a control for future studies of therapy in asymptomatic patients.

SymposiumAspects cliniques
Clinical Aspects of AIDSInfection par le VIH : atteintes à certains organes
HIV Infection: Organ Specific InvolvementW.B.O.29 CLINICAL GASTROINTESTINAL (GI) DISEASES IN AIDS
Kotler Donald, St Luke's/Boos., Columbia PAS, NY

The GI tract is vulnerable to immune deficits, due to poor physical protection and a contaminated enteric environment. Multiple complications occur, based upon specific immune deficits in secretory immunity, impaired T-cell function, macrophage dysfunction and diminished immune surveillance against neoplasms. Oral and esophageal disorders usually are due to yeast infections, while aphthous ulcers also are common. Intestinal diseases can be grouped as primary infections of enterocytes, secondary involvement from systemic or otherwise disseminated disorders, and a syndrome of inflammatory bowel disease. Enterocyte infections are caused by protozoans such as cryptosporidium, microsporidium and isospora produce a clinical picture of 'short bowel syndrome'. Secondary involvement by viruses, such as CMV, fungal infections, mycobacterial infections, or tumors are prevalent. There is a prominent systemic reaction such as wasting, as variable focal symptoms based upon the precise site of disease expression. Many HIV-infected patients have an inflammatory bowel disease of uncertain etiology. Recent studies suggest that HIV may be a primary pathogen in the gut. Liver disease often is related to mycobacterial or viral causes but biliary tract diseases can cause major morbidity. The major sequelae of intestinal dysfunction are progressive malnutrition and dehydration, though other specific medical or surgical complications occur.

W.B.O.31 CLINICAL CENTRAL NERVOUS SYSTEM INVOLVEMENT

Pederson, Court, Department of Infectious Diseases, Hvidovre Hospital, Hvidovre, Denmark.

W.B.O.30

CLINICAL NON-MARROW INVOLVEMENT

Gelman, Karen, St. Paul's Hospital, London, United Kingdom

W.B.O.32

PATHOLOGY OF THE CENTRAL NERVOUS SYSTEM IN AIDS

Michaud, Jean, Department of Pathology, Ste-Justine Hospital and University of Montreal, Montreal, Canada

The neuropathological examination of the human central nervous system in AIDS discloses lesions in most cases and these are frequently a significant cause of morbidity and mortality. A wide variety of lesions are found and these may be classified in four groups:

- Direct Human Immunodeficiency Virus infection: the most characteristic process is a subacute encephalitis associated with multilacinated cells in 111-defined microglial nodules. White matter demyelination and vacuolar myelinolysis are frequently part of the picture. The pathogenetic issues mostly mediated by the microglia-macrophage complex but the pathophysiology is yet poorly understood.
- Opportunistic infections: toxoplasmosis, several types of viral encephalitis (cytomegalovirus and PML being the most frequent), mycoses and mycobacterial infections are the most frequent.
- Cerebral tumors: approximately 5% of AIDS patients will develop a primary intracerebral lymphoma which is usually of B-Cell type. The Epstein-Barr virus is presumed to play an important role in its etiology. Secondary CNS involvement by systemic lymphomas or Kaposi sarcomas is also found.
- Non-specific and non AIDS-related lesions.

In AIDS, two or several of the above mentioned groups of lesions or infectious organisms may be found in the same patient. Also, variations according to age groups, countries and patient subgroups as related to the etiology of the syndrome are now recognized.

W.B.O.33 THE LUNGS, THE CAUSE OF DEATH, AND BACTERIAL INFECTIONS IN AIDS: WHAT AUTOPSY STUDIES SHOW
Nichols, Larry, currently at Research Triangle Institute, Research Triangle Park, NC, USA

The lungs are the primary target of the most serious opportunistic infections of AIDS, the ones most frequently responsible for AIDS patients' deaths. Autopsy studies in the early years of the AIDS epidemic showed an extremely high rate of cytomegalovirus (CMV) infection at the time of death, with CMV pneumonia frequently playing an important role in the patients' deaths. Throughout the epidemic, most AIDS autopsy studies have corroborated the widespread clinical impression that *Pneumocystis carinii* pneumonia is the most common cause of death in AIDS patients. Recently, in a series of 40 AIDS autopsies at the New England Deaconess Hospital and Lasky Clinic in Boston, we found that bacterial (non-mycobacterial) infections were sole or contributing causes of death in 17 cases (42%). Eleven of these 17 bacterial infections were pneumoniae due to *Streptococcus pneumoniae*, generally superimposed on *Pneumocystis carinii* pneumonia, CMV pneumonia or lung injury from previous bouts of such processes. Given the particular propensity of *Streptococcus pneumoniae* to superinfect lungs injured by other infections, recognized in multiple secondary epidemics of *Streptococcus pneumoniae* following influenza epidemics, it is not surprising for *Streptococcus pneumoniae* to emerge as a secondary opportunist in AIDS patients with previous or underlying lung disease. These results confirm the importance of respiratory failure as a mode of death and show the importance of bacterial infections in general, and *Streptococcus pneumoniae* in particular, in patients with AIDS.

Clinical Trials: The "Actors' Perspective**

W.B.O.46 INVESTIGATORS' PERSPECTIVE
 Ronald, Allan B. Department of Internal Medicine,
 University of Manitoba, Winnipeg, Manitoba, Canada

W.B.O.47 Clinical Trials in AIDS: The Regulatory Perspective,
 ETHEL C. COOPER, DIRECTOR, DIVISION OF REGULATORY DRUG
 PRODUCTS, U.S. Food and Drug Administration,
 Rockville, Maryland, U.S.A.

FDA, in its regulatory role, is a major player in new drug development in the U.S.A. This role has become more intensive and extensive in AIDS drug development, as outlined in new interim regulations (21 CFR 312 Subpart E). From the scientific/regulatory perspective, three issues have been most problematic in the design and conduct of clinical trials in AIDS. The first issue stems from constraints on the choice of the most appropriate control group, whether placebo, no treatment, dose comparison, active, or historical control. A second major issue is selection of primary outcome measures on which decisions regarding efficacy should be made, particularly for new antiretroviral agents. A beneficial impact on important clinical endpoints is required to demonstrate efficacy of a new drug in most diseases. In the case of complex, chronic, life-threatening diseases such as AIDS, pressure builds rapidly to substitute near-term, "harder" clinical endpoints. The third major issue is timing of access to experimental drugs by patients with life-threatening diseases. The individual's "right" to try a new drug very early in development may conflict with society's need to determine systematically which drugs are safe and effective, and which are not. If appropriate and well-designed, randomized controlled trials (RCT) are not conducted during the "window of opportunity" following the demonstration of preliminary safety and activity, but before widespread use makes RCT difficult to perform because of the presumed but not proven efficacy of the drug, therapeutic advances in the treatment of AIDS will be delayed if not lost.

W.B.O.48 THE ROLE OF THE PHARMACEUTICAL INDUSTRY IN DRUG
 AND VACCINE DEVELOPMENT
 Patriciani, John C.

Pharmaceutical Manufacturers Association, Washington, DC, USA

The pharmaceutical industry has responded to the need for various strategies to intervene in the HIV global epidemic in a remarkably broad and rapid manner. Diagnostics became available within a year of the discovery of HIV as the etiologic agent, the first drug was approved only three years later, as was the first vaccine clinical trial. At the present time, there are over 50 companies involved in the development of over 60 medicines for the treatment or prevention of HIV infection.

Clinical trials remain the single most important means of assessing the actual safety and efficacy of new medicines, and the pharmaceutical industry has been working cooperatively with governmental organizations and others to evaluate potentially useful new agents. While there have been problems in the implementation of progress, the overall model of government/industry cooperation in the development of HIV-related medicines is one which PMA member companies support. Specific suggestions for improving the working relationship among industry, government, clinical research centers, and patients will be made.

PATIENTS' PERSPECTIVE

Paul Leblanc

W.B.O.50 THE CHALLENGE OF TESTING THERAPIES FOR HIV INFECTION

Roth, David, National Institute of Allergy and
 Infectious Diseases, Bethesda, MD, U.S.A.

W.B.O.51 ETHICS AND CLINICAL TRIALS

Robert A. Levine, Yale University School of
 Medicine, New Haven, CT, USA

The randomized clinical trial (RCT) is the gold standard for establishing the validity of medical therapies. RCTs must be conducted in accord with established ethical norms including: There should be a) sound scientific design, b) competent investigators, c) a reasonable balance of risks and benefits, d) informed consent, and e) equitable selection of subjects. This presentation is an overview of some of the more difficult ethical problems encountered by clinical trialists. Must subjects be informed that their therapy has been selected by chance? What should they be told about preliminary data and about alternatives to participation in the RCT? What is the role of the null hypothesis (or clinical equipoise) in the ethical justification of the RCT? Are placebo controls justified when subjects have lethal diseases? Is participation in a RCT a burden or a benefit? Should vulnerable populations be protected from the burdens of participation or assured access to the benefits of participation in RCTs? In what circumstances should alternative designs -- e.g., historical controls -- be considered? Satisfactory answers to such questions require careful consideration of the relevant facts about particular RCTs and prospective subject populations.

Th.B.0.1 PHASE I TRIAL OF ORAL RIBAVIRIN IN HIGH RISK PATIENTS FOR AIDS
 Richard B. **, Richard B. **, and Juriss K. **,
 *Cornell University Medical Center, New York, NY, USA
 **State University of New York, Albany, NY, USA

Objective: To determine tolerance and effect on virologic and immunologic parameters of oral ribavirin in high risk patients. **Methods:** Two groups of eight men each received either 1600 mg QID for 2 weeks (Group I) or 800 mg BID for 4 weeks (Group II). All patients also received zalcitabine, zidovudine, and zalcitabine. **Results:** All patients were well tolerated. Ribavirin was well tolerated. **Conclusion:** Oral ribavirin is well tolerated and may be useful in the treatment of HIV infection.

	8 week-treatment				12 week-treatment			
	CD4	CD8	CD8/CD4	CD4	CD8	CD8/CD4	CD4	CD8
Mean (SD)	441 (102)	441 (102)	1.00	441 (102)	441 (102)	1.00	441 (102)	441 (102)
SD (p value)	132 (0.03)	132 (0.03)	0.02	132 (0.03)	132 (0.03)	0.02	132 (0.03)	132 (0.03)
CD4/CD8 ratio	0.60	0.62	0.15	0.95	0.91	0.09		

Similar results were observed in Group B patients. **Conclusion:** Oral ribavirin is well tolerated and may be useful in the treatment of HIV infection. **Keywords:** ribavirin, AIDS, immunologic and virologic parameters.

Th.B.0.2 PHASE III TRIAL OF RIBAVIRIN + ZIDOVUDINE IN HIGH RISK PATIENTS FOR AIDS
 Richard B. **, Richard B. **, and Juriss K. **,
 *Cornell University Medical Center, New York, NY, USA
 **State University of New York, Albany, NY, USA

Objective: To assess the safety, toxicity, clinical immunologic and antiviral effects of oral 800 mg ribavirin administered daily for 4 months. **Methods:** 120 patients were randomized to receive either 800 mg BID for 4 weeks (Group I) or 1600 mg QID for 2 weeks (Group II). All patients also received zalcitabine, zidovudine, and zalcitabine. **Results:** All patients were well tolerated. Ribavirin was well tolerated. **Conclusion:** Oral ribavirin is well tolerated and may be useful in the treatment of HIV infection.

Th.B.0.3 2',3' DIDEHYDROCYTIDINE (DDC) IN THE TREATMENT OF PATIENTS WITH AIDS AND ARC
 Michael J. Galpin, J. * Thompson, J. *, Wilson, D. **, Donatucci, L. **, Soo, M. **,
 *Purton Research Group, Sherman Oaks, CA, USA **Huffmann-La Roche, Nutley, NJ, USA

Objective: To evaluate tolerance and antiviral activity of didoxycytidine (DDC) in a multiple dose study in patients with AIDS or ARC. **Methods:** Twenty-one patients with AIDS or ARC with p24 antigen > 70 ng/ml and CD4 < 400 cells/mm³ received DDC orally at a dose of either 0.03 mg/kg once a day or 0.01 mg/kg every 8 hours for 24 weeks. **Results:** At 0.03 mg/kg, mild peripheral neuropathy was reported in 3 of 11 patients between weeks 8 & 17. At 0.01 mg/kg, no cases of peripheral neuropathy were noted. Other adverse experiences included mild dyspepsia and nausea. **Conclusion:** DDC is well tolerated. Different dosing schedules and regimens demonstrated a different degree of antiviral activity. The 0.01 mg/kg regimen was most effective. Further study to evaluate DDC long-term safety and efficacy using clinical endpoints is warranted.

Th.B.0.4 ESCALATING DOSE PHASE I STUDY OF INTRAVENOUS AND ORAL 2',3'-DIDEHYDROCYTIDINE (DDC) IN PATIENTS WITH AIDS OR ARC
 Yachson, Robert; Thomas RV, Ph.D.; Kaji, H.; Hattman RH, M.D.; Kato H, Ph.D.
 Clinical Oncology Program, National Cancer Institute, NIH, Bethesda, MD, USA

Objective: Two pyrimidine drugs with activity against HIV, AZT and ddC, belong to the dideoxynucleoside (ddN) family. In this study, we report a Phase I trial of oral, a parenteral ddN analog. **Methods:** 20 patients with AIDS or ARC were given 2 weeks of ddI, IV, followed by 4 or more weeks of oral dosing (given with amoxicillin) at twice the IV dose. Six dosing regimens were tested, ranging from IV doses of 0.2 mg/kg every 12 hr to 1.6 mg/kg every 8 hr. **Results:** Oral bioavailability (given with amoxicillin) was 35%, and ddI penetrated into the CSF. Two pts dropped out at 1 wk (1 because of Cytosolic mononuclein gel for personal reasons); the other 18 completed 6 or more weeks of dosing. One pt (also on TMP/SMX) developed neutropenia after 20 wks, one pt developed a morbilliform rash, and one patient reported some difficulty sleeping or irritability; otherwise, toxicity was minimal. No macrocytosis was seen. No anti-HIV response was seen at the lowest dose; however, the 15 evaluable pts on the 8 higher doses showed evidence of an anti-HIV effect. In these pts, the T4 count increased from 141/55 at entry (mean/SD) to 228/43 at wk 2 (p<0.001) and 183/37 at wk 6 (p<0.01 or w/o entry). All 7 pts with detectable serum HIV p24 antigen (Ag) at entry had a decline by wk 2 (116/37 pgs at wk 2 vs. 119/43 at entry; p=0.02). Six of these 7 pts sustained the drop in p24 Ag at wk 6. Four single pts developed delayed type hypersensitivity reactions by wk 2. Six of 4 pts had increased in vitro proliferative responses to soluble Ag. The pts generally had increased energy and gained a mean of 2 kg wt. **Conclusion:** In short term testing, ddC appears to be an oral anti-retroviral agent with significant clinical activity but with minimal toxicity.

Th.B.0.5 PHARMACOKINETIC STUDIES OF RECOMBINANT SOLUBLE CD4 IN PATIENTS WITH AIDS AND AIDS RELATED COMPLEX
 John James **, Doris A. **, Giuseppe J. **, Robin L. **, Sherwin, S. **,
 *University of California San Francisco, San Francisco, CA, **New England Deaconess Hospital, Harvard Medical School, Boston, MA, USA ***Genetech Inc, South San Francisco, CA, USA

Objective: To describe the pharmacokinetics of intravenous human injection of recombinant soluble CD4 in patients with AIDS and ARC. **Methods:** Patients with AIDS and ARC, T-cells < 400 and normal hematologic and serum chemistries were enrolled in this study. One intravenous line was placed for pharmacokinetics; a second intravenous line was placed in each patient for drug administration. Soluble CD4 was administered over 3 to 5 minutes by slow intravenous push. Pharmacokinetic studies were done at 10, 20, 30, 40, 60 and 90 minutes as well as at 2, 4, 6, 8, 16, 36, and 76 hours post-injection. Pharmacokinetic studies were performed on days 1 and 6. The analysis for CD4 was performed using two monoclonal assay systems. **Results:**

Dose	T (minutes)	Duration (days)	Peak ng/ml
1 mg/kg	8	1-4	17-48
10 mg/kg	10	2-6	100-460
30 mg/kg	8	8-14	400-1350

Conclusions: Recombinant soluble CD4 given in intravenous bolus can be detected from 1.5 to 4 hours after administration at a dose of 1 mg/kg and the peak is 17-48 ng/ml. At 10 mg/kg the peak is 100-460 ng/ml. At 30 mg/kg the peak is 400-1350 ng/ml. Doses at 100 mg/kg and 300 mg/kg are being analyzed and IV administration and intravenous bolus have begun. Recombinant soluble CD4 can be detected in the serum in patients with AIDS and ARC. Increased dose of CD4 will increase the peak concentrations and the duration of CD4 detection.

Th.B.0.6 ESCALATING DOSE TOLERANCE TRIAL OF RECOMBINANT SOLUBLE CD4 IN HUMANS
 Schaller, Robert; De, Dae; Ganc, ***, Tierney, ***,
 Schneider, ***, Benochovitz, ***, et al. *Mass. Gen. Hosp., Boston, MA, USA, **Cedars-Sinai Medical Center, Los Angeles, CA, USA, **Wellington, Inc., Cambridge, MA, USA and ***NIH AIDS Program, Bethesda, MD, USA.

Objective: To study the safety and pharmacokinetics of recombinant soluble CD4 (rsCD4) when administered to humans by intramuscular or intravenous routes. **Methods:** We performed an escalating dose tolerance trial of rsCD4 (Beiggen) in which daily doses of 1 to 30mg rsCD4 were administered to a group of patients with AIDS or AIDS related complex who were preselected for the absence of antibodies to rsCD4. Tolerance was followed for adverse clinical and laboratory events during the 28 day dosing period. Pharmacokinetics of rsCD4 were determined after intravenous and intramuscular administration. Antiviral activity of rsCD4 was assessed by serum p24 antigen determination, and quantitative HIV-1 cultures obtained from peripheral blood mononuclear cells and plasma. **Results:** rsCD4 was well tolerated when administered by the intramuscular or intravenous routes. No significant changes in hematologic, hepatic, or renal function were observed. No antibodies to rsCD4 were detected following therapy. Pharmacokinetics of rsCD4 following intravenous and intramuscular administration, and immunologic and antiviral activity parameters will be presented. **Significance:** rsCD4 is well tolerated by humans receiving the drug for periods of up to 28 months.

Test de dépistage par réaction en chaîne des polymérasés PCR Diagnostic Test

Th.B.0.7 A METHOD FOR QUANTITATING RELATIVE AMOUNTS OF HIV PROTEIN GENES IN THE TOTAL AMOUNT OF HIV DNA IN SAMPLE. THE CHAIN REACTION (PCR) METHOD. **John S. Slesny**, Department of Infectious Diseases, Cetus Corporation, Emeryville, CA, USA

Objectif: To quantify by the polymerase chain reaction, the amount of HIV protein genes present in the total amount of HIV DNA in sample. The availability of such an assay will allow the monitoring of proviral load during the natural history of infection and during various therapeutic regimes.

Méthode: Human placental DNA was spiked with known copies of HIV molecules and coamplified in the presence of a primer pair that amplifies a 100 bp fragment of HIV-1 and a primer pair that amplifies a 262 bp control sequence, HLA-DQB1. Amplified products were detected by autoradiography following hybridization with HIV and HLA related probes and scanning by polyacrylamide gel electrophoresis. Because of differences in size, the amplified products can be differentiated. To quantify the amount of each product, the gels were scanned with a radioisotope system. Standard curves were generated by varying the amount of HIV and HLA products. Probes against known amounts of each target present prior to amplification. By extrapolating from the standard curves, the relative amount of HIV targets in a given sample was determined.

Résultats: By altering the ratio of HIV and HLA primers, we were able to simultaneously amplify both sequences. In comparing the HIV assays, we demonstrate that 10-800 molecules of HIV can be quantitated after 30 cycles of amplification, 200-2000 molecules with 25 cycles. HIV-1 and HIV-2 molecules with 50 copies of amplicon.

Conclusion: We demonstrate in model studies that HIV and HLA sequences can be quantitatively amplified. In addition, a quantitative method was obtained for both sequences. Results describing extension of these studies to AIDS and patients on antiviral therapies will be presented.

Th.B.0.9 EVALUATION OF THE POLYMERASE CHAIN REACTION (PCR) IN A WELL CHARACTERIZED COHORT OF HOMOSEXUAL AND BISEXUAL MEN. HIV-ANTIBODY NEGATIVE RESULTS ARE RARE. **Lifton Alan R., Stanley, M., O'Malley, P., Fane, J., Jeffrey, R., Miller, F., et al.** HIV-1 Antigen, HIV-1 Antibody, HIV-1 RNA, San Francisco, CA; *Pathology Institute, Berkeley, CA, USA

Objectif: To evaluate PCR for HIV DNA in a cohort of homosexual and bisexual men whose clinical and HIV-antibody (Ab) status is known.

Méthode: We conducted blinded PCR testing on frozen lymphocytes from 167 men participating in prospective studies of HIV infection. Thirty cycles of amplification were conducted, followed by detection with probes corresponding to the gag primers; each primer/probe assay was run in duplicate. A positive result was defined as repeat (2/2) detection of HIV DNA by at least one of the two primer/probe pairs; HIV-Ab testing was performed using ELISA and (if repeatedly reactive) IFA assays.

Résultats: PCR was negative for 101/102 (98%) HIV-Ab negative men. The one PCR-positive Ab-negative sample was PCR negative on repeat testing; a second specimen drawn from the same man 8 months later was also PCR and HIV-Ab negative, suggesting the first PCR result was a false positive. PCR was positive in 5/52 (10%) HIV-Ab positive men, including 7/7 patients with AIDS, 19/19 with AIDS-related conditions, 11/11 with asymptomatic generalized lymphadenopathy and 2/28 men without signs or symptoms of HIV-infection. Overall, the PCR and HIV-Ab were in agreement on 154/167 (96%) specimens.

Conclusion: The PCR assay, using this technique and in this population, has an excellent concordance with the HIV antibody test. Antibody-negative, PCR positive results for HIV were very uncommon.

Th.B.0.11 SEROLOGIOUS DETECTION OF HIV-1 OR HIV-2 IN AIDS PATIENTS. **De Ruess and Bruchmann, A.** Centers For Disease Control, Bethesda Research Branch, Bethesda, MD, USA

Objectif: To identify the nature of human T-cell lymphotropic virus (HTLV) DNA in AIDS patients which might be complicated by the presence of other opportunistic viruses such as Herpes, Hepatitis, etc.

Méthode: High resolution PCR was used to detect the cells derived from AIDS patients. Polymerase chain reaction was performed using specific sets of primers: HIV-1: pol primer pair at positions 3015-3026 sense strand and 3154-3136 antisense strand; probe at position 3050-3074; HIV-2: pol primer pair at positions 2989-3010 sense strand and 3111-3110 antisense strand and 3158-3136 antisense strand; probe at position 3000-3074; HTLV-1: pol primer pair at positions 1465-1638 antisense strand with probe at position gag 1395-1455). The amplified products were detected by Southern blot hybridization using specific viral probes.

Résultats: We have employed the polymerase chain reaction to distinguish HIV-1 and HIV-2. Cells derived from African AIDS patients had HIV-1 proviral sequences and cells from a homophilic from Africa showed HIV-2 proviral sequences in addition to HIV sequences.

Conclusion: Multiplexed PCR provides a sensitive, accurate and quicker method to distinguish the related T-lymphotropic retroviruses.

Th.B.0.8 COMPARISON OF PCR ANALYSIS AND CULTURE IN THE DETECTION OF HIV-1 INFECTION IN HEADPHILIC PATIENTS. **Madhoo, Ruzsa, Sanyal, A., & S. K. Sanyal, J., Hoopster, J., Balfour HR Jr.** *U of Minnesota, Mpls, Mn, *Cetus Corp, Emeryville, CA, USA

Objectif: To compare the sensitivity and specificity of an HIV-1 polymerase chain reaction (PCR) assay with an HIV-1 culture method in testing HIV-1 antibody-positive and antibody-negative hemophilia patients.

Méthode: PCR analysis was performed on the PBMC DNA from 59 HIV-1 antibody-positive and 20 antibody-negative hemophilia patients. A gag primer pair (EK 18 (151-157), SK39 (1637-1663)) and Tm polymerase was used to amplify a 115 base fragment over 30 cycles. Cycle time and temperature was as follows: denaturation 2x 95°C, reannealing 2x 55°C, chain elongation 60-72°C. The amplified HIV-1 sequence was then detected by autoradiography after hybridization with a ³²P-labeled probe (EK19 (1596-1633) and gel electrophoresis. HIV-1 cultures were performed using co-cultivating 1 X 10⁶ patient PBMC with 3 X 10⁶ PMA stimulated donor PBMC in the presence of RPMI-1640, 20% fetal calf serum and 1% 2-ME. PCR and assaying for the presence of HIV-1 p24 antigen every 3 days for up to 42 days.

Results	HIV-1 Ab Positive	HIV-1 Ab Negative
HIV CULTURE +	27/29 (93%)	0/20 (0%)
HIV PCR +	57/59 (97%)	0/20 (0%)

The results indicate that both PCR and culture were PCR positive and the two PCR negative antibody-positive subjects were culture positive. Therefore, all 66 HIV-1 antibody-positive subjects had direct evidence of HIV-1 infection by either PCR or HIV-1 culture or both.

Conclusion: Both HIV-1 culture and PCR analysis have comparable sensitivities (97% and excellent specificity (100%) in the detection of HIV-1 infection.

Th.B.0.10 DETECTION OF HIV-1 DNA IN PERIPHERAL BLOOD BY POLYMERASE CHAIN REACTION (PCR) AND NON-RADIOACTIVE OLIGONUCLEOTIDE PROBES. **Adge, E. L., Beckel, L., Govey, S., Kaplan, J., and Hirsch, M.** *Duke Medical Center, Billerica, MA, USA *Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA

Objectif: To detect HIV-1 DNA directly in peripheral blood mononuclear cells (PBMC) by PCR and hybridization with a non-radioactive probe.

Méthode: An oligonucleotide probe covalently linked to alkaline phosphatase has been used to detect HIV-1 sequences in DNA amplified by PCR. PBMC (3-5 x 10⁶) were isolated by Ficoll gradient sedimentation, lysed in a solution of 1.0M Tris-HCl, 100 mM NaCl, pH 7.5, 2.0 mM EDTA and boiled for 10 minutes. Two oligonucleotides flanking a conserved region of the HIV-1 pol gene (M80 isolate:1936-2112) were used as primers. Samples were subjected to 30-50 cycles of amplification. Products were detected by slot blot hybridization using the enzyme-linked probe.

Résultats: HIV-1 DNA was detected in PBMC from 20/21 (95%) seropositive individuals (CD4 Groups II-IV). Samples from 8/8 individuals negative for serum p24 antigen but positive following culture, were positive for HIV-1 DNA by this technique. DNA amplified from PBMC of seronegative individuals was negative for HIV-1 as were samples from cells infected with HIV-1, HIV-2, or CMV.

Conclusion: This sensitive non-radioactive method for detecting HIV-1 peripheral DNA, combined with improved sample processing, should be valuable in clinical and research settings.

Th.B.0.12 A MICROTITRATED DNA SANDWICH ASSAY FOR THE DETECTION OF HIV-1 IN CLINICAL SAMPLES. **Stamm, Kellin, D.P., Hung, L., Japanecki, C., Oweh, D., Pownall, and K. Maske.** Biotech Research Laboratories, Rockville, MD 20850 USA

Objectif: A microtitre based DNA sandwich hybridization assay was used to detect HIV-1 sequences in clinical samples following amplification with Polymerase Chain Reaction (PCR). HIV-1 DNA was obtained from peripheral blood lymphocytes from HIV-1 seropositive individuals and normal blood donors. It was then subjected to PCR amplification using specific primers in the HIV-1 gag region. The amplified product was hybridized in microtitre plates which contained covalently attached capture DNA sequences. A biotin labeled probe adjacent to the capture sequence was used to detect specific hybridization. Following incubation with a peroxidase-conjugated enzyme and a colorimetric substrate, the amount of hybridization was quantitated spectrophotometrically. All samples were also analyzed by Southern blotting using the labeled HIV-1 probe. Specific hybridization was quantified by cutting out the hybridized bands and counting in a scintillation counter.

Résultats: Using serial dilutions of HIV-1 infected cells with uninfected cells, the Optical Density (OD) hybridization was proportional to the amount of virus present in the sample. When the OD was off scale, dilutions of the amplified product could be performed to give a quantitative result. The test could detect 5-5 HIV-1 infected cells in 10⁶ uninfected cells, or about 10-11 molecules of HIV-1 DNA. DNA from a total of 164 clinical samples was amplified by PCR and the amplified product tested by the microtitre assay. The Southern Blot results were in complete agreement between the DNA sandwich and the ³²P Southern Blot results was observed.

Conclusion: The sandwich hybridization format provides a convenient, rapid and sensitive method for HIV-1 detection in a non-radioactive system. Using the microtitre wells, up to 96 samples can be analyzed at the same time. This format is compatible with existing plate handling equipment and will permit this assay to be automated for use in clinical laboratories.

Th.B.0.25 DIFFERENCES IN IMMUNE ACTIVATION PARAMETERS DURING AND AFTER HIV SEROCONVERSION: SERUM BILIRUBINOLIN, INTERFERON- γ AND SOLUBLE IL-2
B. HOFMANN, W. CUMBERLAND, P. DETELE, J. FARNEY, UCLA SCHOOLS OF MEDICINE AND PEDIATRICS, LOS ANGELES, CA, U.S.A.

Objective: To describe cellular immune activation during and after HIV seroconversion.
Methods: Serum Bilirubinolins and receptors are products and markers of cellular immune activation, whereas serum soluble Interleukin-2 receptor (IL-2R) reflects only T cell activation. **Results:** Pts subjects investigated for Bilirubinolins before, during, and after HIV seroconversion showed an increase of this marker. The increase of Bilirubinolins appeared to reflect two distinct events in the immune activation since the primary increase correlated to the simultaneous increase in CD4 T cells, whereas the Bilirubinolins serum concentration during the second and third year correlated inversely to the decrease in CD4 T cells. An analysis of serum receptors in 30 of these seroconverters showed similar changes. Analysis of three groups of HIV seroconverters with either stable high numbers of CD4 cells ($>1000/\mu\text{l}$), moderately decreasing CD4 numbers ($1000/100/\mu\text{l}$), or rapidly decreasing CD4 numbers ($200/100/\mu\text{l}$) showed a strong inverse correlation between the rate of CD4 T cell fall and the serum concentration of receptors and Bilirubinolins. The serum concentration of IL-2R increased after HIV seroconversion, but in contrast to serum Bilirubinolins and receptors, serum IL-2R was only slightly increased in those with fall declining CD4 cells but was markedly increased in those with stable CD4 numbers. **Conclusions:** Cells within the immune system, including HIV seroconverters, receptors, and IL-2R, differ in their responses to HIV infection and represent different aspects of AIDS pathogenesis.

Th.B.0.27 POWER OF SERUM BETA-2-MICROGLOBULIN AND SERUM NEOPTERIN IN DETECTING ADVANCED HIV-DISEASE

B. HOFMANN, W. CUMBERLAND, R. LEIDER, R. J. JONES, J. FARNEY, UCLA SCHOOLS OF MEDICINE AND PEDIATRICS, LOS ANGELES, CA, U.S.A.

Objective: To evaluate the discriminating power of serum beta-2-microglobulin (B2M) and serum Neopterin (NPT) between early and advanced disease.
Patients and Methods: In 497 HIV-positive patients (82% men, 18% women, 52% homo- or bisexual, 41% drug addiction and 7% other risk) were 50% asymptomatic (ASY), 50% had a persistent generalized lymphadenopathy (PGL), 9% ARC and 7% AIDS. The median age was 30 years (range 19-73). NPT in 1360 sera and B2M in 1366 were measured. After adjusting the variances of NPT and B2M by ANOVA, the clinical stages were pooled in a group with early disease (ASY and PGL, 84%) and one with advanced disease (ARC and AIDS, 16%). For these two groups sensitivity (SENS), specificity (SPEC), predictive value positive (PVP) and negative (PVN) were calculated for different cut-off values using Bayes' formula.
Results: NPT and B2M were significantly higher in advanced than in early stages. In advanced disease the variances were very large, especially for NPT. For ascending cut-off levels (reported as a ratio to the upper normal limit), SENS, PVP and PVN were raised as follows:

Ratio	cut-off	SENS	PVP	PVN	SENS	SPEC	PVP	PVN
1x	0.66	0.62	0.52	0.91	NPT	0.70	0.60	0.51
2x	0.19	0.96	0.48	0.85	B2M	0.25	0.94	0.43
3x	0.05	0.99	0.74	0.85		0.15	0.97	0.51
4x	0.03	1.00	1.00	0.84		0.10	0.99	0.63

Conclusions: High concentrations of B2M rather than NPT indicate advanced, low concentrations early disease. Due to a large variance, medium concentrations are not conclusive.

Th.B.0.29 HIGH INTERFERON LEVELS PREDICT SUBSEQUENT DEVELOPMENT OF AIDS

M. JOHNSON, R. HART, E. A. MERRITT, J. M. ***; HAMILTON, I. B. **, SHIBATA, S. **, WINKELSTEIN, V. ***, ***, THE OPIJHO COMPANY, KALAMAZOO, MI, U.S.A.; ***, SAN FRANCISCO, CA, ***, ***, THE OPIJHO COMPANY, KALAMAZOO, MI, U.S.A.; ***, UNIVERSITY OF CALIFORNIA, BERKELEY, CA, U.S.A.

Objective: To determine interferon levels in prevalent HIV seropositive men and examine the relationship of interferon to the subsequent progression to AIDS.
Methods: Interferon levels were measured in a blinded fashion by an AIDS-2 specific RIA and the viral plaque reduction assay on sera collected in 1985 from 86 HIV seropositive men in the San Francisco Men's Health Study.
Results: Development of AIDS by 30 months

Interferon Level	All HIV+	AIDS (+)
Undetectable	47	15 (31.9)
0.7 - 1.0 U/ml	16	6 (37.5)
1.1 - 2.6 U/ml	10	5 (50.0)
> 2.7 U/ml	13	13 (100.0)

In a Cox proportional hazards model including CD-4 and CD-8 lymphocyte counts, p24 antigen, and beta-2 microglobulin, the Interferon level is a significant predictor of AIDS and the viral plaque reduction assay is not. **Conclusions:** Elevated interferon levels occur in 45% percent of prevalent HIV seropositive men and high levels are associated with a poor disease prognosis.

Th.B.0.26 2'-5A Synthetase and Blastogenesis as Measures of Response to Azothymidine (AZT)

Reed, Stanley, Fanning, M., Casaccia, J., and Coates, R. University of Toronto, Toronto, Canada

Objective: To determine whether AZT given to CDC B, III and IVc HIV-infected men will be reflected in changes in levels of 2'-5A synthetase (2-SAS) and blastogenic response to mitogens.

Methods: We have previously shown, in a cohort of 22 men given escalating doses of AZT, that 60mg/d resulted in the greatest decrease in 2-SAS (50c pmoles) and increase in response to PHA. Further studies were done during a washout period of 13 weeks followed by 22 weeks at 1200mg.

Results: Persistent elevation of 2-SAS levels appears to be a bad prognostic sign in HIV infection. A significant drop in 2-SAS occurred on 60mg/d AZT (85.7 to 45.8 pmoles). Also, a significant increase in response to PHA was observed. During the washout period the 2-SAS rose (45.3 to 85.5) and the PHA response dropped to below prestudy levels. 12 weeks after resuming AZT at 1200 mg, 2-SAS levels fell again dropped and PHA response increased. However, by week 64, 2-SAS levels had risen to 74.3. PHA response remained unchanged. **Conclusions:** At 60 mg AZT, levels of 2-SAS and PHA responses normalize. Adverse changes in 2-SAS and PHA response occur with continued dose of 1200mg and when drug is discontinued.

Th.B.0.28 INTERFERON (IFN), BETA-2 MICROGLOBULIN (β_2 -M) AND NEOPTERIN (NPT) IN AIDS-ASSOCIATED KAPPA⁺ B LYMPHOMA (BL)

W. HALL, J. H. HANCOCK, J. D. SANDERSON, D. B. MERRILL, Sloan Kettering Cancer Center, NY, NY, USA

Objective: To study the relationship between endogenous IFN, β_2 -M and NPT and their values in predicting treatment response in patients with BL. **Methods:** Serum levels of IFN, β_2 -M and NPT were determined prior to treatment in 43 pts entered into a phase I trial of IFN- γ AZT. Pearson product moment correlation was computed to quantify the relationship between β_2 -M and NPT. Two-sample t-test was used to evaluate associations between endogenous IFN activity and levels of both β_2 -M and NPT. Fisher's exact test was used to evaluate associations between IFN, β_2 -M and NPT regression. **Results:** Median pretreatment β_2 -M was 3.4 (range 2.2-6.2) $\mu\text{g/L}$ (normal, 1.2-4.4), median NPT was 18 (range 8-64) fmol/L (normal, 2-10). 38% of pts had detectable serum IFN (normal, undetectable). β_2 -M and NPT were significantly correlated ($r=0.13$, $p=0.0003$). Pts with detectable serum IFN had significantly higher β_2 -M levels (4.21 \pm 2.7 vs. 3.14 \pm 1.1, $p=0.001$) and higher NPT levels (27.8 \pm 1.5 vs. 16.1 \pm 1.1, $p=0.005$) than those with undetectable IFN. Although individually, β_2 -M and NPT were not predictive of response, the tumor of pts with "low" levels of both (β_2 -M < 4 , NPT < 10) were more likely to regress (77% CR) than those with higher levels of β_2 -M, NPT, or both (37% CR, $p=0.01$). Pts with undetectable IFN showed a significantly higher response rate than those with endogenous IFN activity (77% vs. 20%, $p=0.028$). **Conclusions:** The responses of BL to IFN-containing regimens may be predicted by measurements of IFN, β_2 -M and NPT. The strong associations noted are likely due to IFN induction of β_2 -M and NPT. (Supported by NIAID-ACTC).

Th.B.0.30 TUMOR NECROSIS FACTOR (TNF) IN THE PLASMA OF AFRICANS INFECTED WITH HIV

SM. HOLLAND, R. L. COLEBURNER, FRANCIS, H. L. KHOOZI, KAPLAN, QUINN-TUGER, et al., Johns Hopkins Hospital, Baltimore, MD; Pirooz Shiba, Kazian, Zair, and NIAID, NIH, Bethesda, MD, U.S.A.

Objective: To determine the association of plasma TNF and clinical signs and symptoms of HIV infection and AIDS in African patients.

Methods: Physical examination, demographic information, and a health questionnaire were obtained from 52 outpatients and 52 inpatients referred to HIV Unit at the Makerere Medical College, Kampala, Zair, and 52 asymptomatic Zairian factory workers and their spouses. TNF levels (pg/ml) were measured using a radioimmunoassay (Cambridge, MA). HIV ELISA, western blot, and p24 antigen level were determined for each patient.

Results: 60% (66%) of 157 cases were seropositive for HIV. Mean TNF levels were 25 ± 8.1 pg/ml for all HIV+ compared to 39 ± 12.7 pg/ml for all HIV- (NS). Among asymptomatic factory workers and their spouses, HIV+ subjects had lower TNF levels (< 10 pg/ml) than HIV+ subjects (26.5 ± 10.5 pg/ml, $p=0.05$). HIV+ patients with AIDS had significantly lower TNF levels (12.5 ± 7.5 pg/ml) than HIV+ subjects (30 ± 12.7 pg/ml, $p=0.05$). In African subjects, mean TNF was lower in HIV+ (< 10 pg/ml) than HIV- (29 ± 13.7 pg/ml, $p=0.05$). This same relationship was seen in patients with clinical tuberculosis (NS) and HIV+ and 68 > 200 $\mu\text{g/ml}$ HIV- ($p=0.05$). **Conclusions:** TNF levels in both symptomatic and asymptomatic HIV infected Zairians are decreased compared to uninfected controls. These findings are in contrast to studies of North Americans and European patients, in which elevated TNF levels have been associated with advanced HIV disease. These data suggest that HIV infected Zairians have impaired or depressed TNF response.

Les problèmes associés au VIH en hémothélie : aujourd'hui et demain HIV Related Issues in Hemophilia: Today and Tomorrow

Th.B.O.31

THE FIRST AND SECOND EPIDEMICS
FVETL, Bruce M., * Centers for Disease Control, Atlanta,
GA, USA.

Objective. To determine the extent of AIDS in heterosexual partners of hemophilia patients.
Methods. Surveillance of heterosexual partners of hemophilia patients.
Results. By February 1989, more than 850 cases of hemophilia associated AIDS in the U.S. had been reported to the Centers for Disease Control. This represents an attack rate of about 5 to 7 per 100 of the 12,000-17,000 persons with hemophilia in the U.S. and approximately 1/5 of the HIV seropositive hemophilia patients. The accrual rate of AIDS in hemophilia patients has been constant for more than 3 years. Following the universal adoption of heat treated materials for therapy for hemophilia in 1984 and 1985, seroconversion of individuals receiving therapy essentially ceased. Recently an increase in transmission of HIV to heterosexual partners and to children born to women whose sexual partners are hemophilic have focused attention on this secondary epidemic. In 15 studies approximately 1/5 of heterosexual partners of hemophilic patients were seropositive but seroprevalence was as high as 21:41 in some studies. AIDS cases among these patients have been increasing and the epidemic curve of the heterosexual partner is similar to that of the primary epidemic that was recognized 4 years earlier in the hemophilia population. Risk reduction activities to date have had varying success at modifying behavior.
Conclusion. Risk reduction activities must be directed toward the hemophilia population and their sexual partners in order to stop this secondary epidemic.

Th.B.O.35

HEMOPHILIA: Special Management Issues.
Lee, Christine A.

Hemophilia and Haemostasis Unit, Royal Free Hospital, London, England.

The special management issues for haemophiliacs infected with HIV must reflect not only the underlying bleeding disorder but also the well-known interference of haemophilia. Almost all haemophiliacs infected with HIV have now been identified; education about treatment and discussion of dreaded issues can be started before the onset of symptoms. As a result the recruitment to, and compliance within, trials of treatment for asymptomatic haemophiliacs may be better than in other patient groups. The presence of an underlying bleeding disorder makes the investigative procedures required to diagnose many clinical problems more difficult. Operative procedures - for example, joint replacement - may encourage HIV-related complications. The double complexity of clotting factor deficiency and HIV-related thrombocytopenia raises additional clinical problems. Many haemophiliacs have multiple chronic virus infections - hepatitis B, C and D - which may respond to interferon. As haemophiliacs must continue to receive clotting factor concentrates, virus detection against B virus is mandatory, but the antibody response is not predictable. Adolescents have to declare both haemophilia and HIV early in their relationships; counselling this group is a delicate management issue. Couples may want to have children and the facts should be presented sympathetically for informed decisions to be made. Hemophilia, by the nature of its well-known inheritance, is a disorder of the whole family; the management of the individual patient inevitably involves other family members. Finally, litigation is an emergent special management issue which threatens the relationship between the haemophilic and his health care provider.

Th.B.O.32

VIROSTATIC METHODS FOR CLOTTING FACTOR CONCENTRATES: ARE THEY EFFECTIVE?

P.M. Mannucci

A. Rimondi, Hemophilia and Thrombosis Center and Institute of Internal Medicine, University of Milano, Italy

Although the widespread infection of hemophiliacs with the human immunodeficiency virus contaminating clotting factor concentrates is still a threatening and formidable shadow, the gloomy picture brought about by the AIDS epidemic is partially lightened by recent spectacular improvements in the safety of concentrates. An important step-forward towards the elimination of the risk of infection transmitted by large-pool concentrates is the development of virucidal methods that inactivate those blood-borne agents that have escaped the filter of donor screening. Since the human immunodeficiency virus appears very vulnerable to such methods, currently available concentrates can be considered substantially free from the risk of transmitting that virus. Even though the transmission of hepatitis viruses is much reduced but not totally abolished, virucidal methods are continuously being improved, so that it can be foreseen that concentrates will become safer and safer.

Th.B.O.34

RATES, MODELS AND COFACTORS OF HIV INFECTION AND AIDS IN

HEMOPHILIA James J. Goedert, HIV Epidemiology Section, National Cancer Institute, Bethesda MD 20892 USA.

Objective. To quantify the incidence of HIV (1977-89) and AIDS (after HIV seroconversion(s)) and to evaluate the effect of age on two phases: HIV-to-AIDS occurrence as an AIDS marker, then from marker to an AIDS diagnosis.
Methods. Annual hazard rates of HIV for a prospective multicenter cohort of 1278 subjects with hemophilia were modelled as piecewise constant with AIDS. For 319 subjects with HIV mid-point seroconversion dates we compared 1) the incidence of subjects in CD4 count, rise in interferon and p24 antigen (Abobot), and loss of p24 and gp120 antibodies (RIA) and 2) AIDS incidence overall and after each marker with actuarial methods and log-rank tests of significance. Results: AIDS incidence following seroconversion was 2.00/100 person-years and was directly related to age (from 0.62 for ages 1-11 to 4.24 for ages 35-70, p<0.0005). Type/severity of hemophilia, race, and factor concentrate dose had little effect (p=0.50). Annual incidence ranged from zero during the first year following seroconversion to 7% during the eighth year, with cumulative rates of 13.2% (p<0.001) for ages 1-17, 24.0% (p<0.001) for ages 18-34, and 43.7% (p<0.001) for ages 35-70. CD4 loss was high in older adults (p<0.005); anti-p24 was low in adolescents (p<0.005); and AIDS after loss of anti-p24 was low in children aged 1-17 (p<0.005).
Conclusion. Because several laboratory markers appear and predict AIDS risk at various rates as a function of age: 1) there are likely to be more HIV-infected children and adolescents than currently estimated; 2) prediction of AIDS in youngsters with available markers will be more difficult; and 3) drug efficacy trials will need 3-fold more children than adults.

Th.B.O.36

CONCENTRATES MEETING THE DEMAND

Abelardo Linares, M. Prof. of Medicine, New Puerto & Medical Affairs
The Mount Sinai Medical Center, New York, New York, U.S.A.

The adequacy of a nation's blood supply can be measured by whether or not it can meet the needs of its hemophiliacs. Prior to HIV infection, bleeding was the leading cause of death; transfusion was the only means of survival. For the hemophilic, survival and quality of life depend not only on safety and efficacy of product but on its availability. The United States, because of technology and liberal pharmaceutical regulations, is able to meet its own needs and to export 50 percent of the factor produced as well as a third of its plasma products. This is the result of a highly developed industry that has the capability for large scale production. Self-sufficiency as a country's policy is a laudable goal; however, we must ensure an adequate supply of product for those whose lives depend upon it. The European Community (EC) currently considering a directive that would ban importation of blood products derived from paid donors. In fact, most of the EC nations do not have adequate plasma supplies nor fractionation programs to meet their current needs. Indeed, since the very countries importing 80% of the materials exported by the U.S. 51 percent of all the product used in these nations is derived from paid donor plasma. In addition, few countries throughout the rest of the world can meet their current or future needs. Premature implementation of the EC directive could cause a devastating shortage for hemophiliacs. Because of limited resources, self-sufficiency may never be achieved. International interdependence has many advantages, economy of scale, rapid transfer of advanced technology, and potential cost savings for countries currently without fractionation programs. However, we need to go beyond the global issues to those of the individual patient. Many hemophiliacs are now HIV positive; they deserve an uninterrupted supply of affordable products.

Th.B.0.54 DETECTION OF HIV-2 ANTIBODIES BY A NOVEL HIV TRANSMEMBRANE SYNTHETIC PEPTIDE IN LINE-MEMBRANES

ERAGAKI, M. IMAI, F. POLET, D. J. HONORÉ, C. S. BRUN-VÉSTRET, F.***

Delormes, E. Van Heverbeke, R. P.

* Centre International de Recherches Médicales, BP 788, Francoville, Gabon;

** INNOVATIONS, Aachen, Belgium;

*** Hôpital Claude Bernard, Paris, France.

Objectives: The evaluation of a novel line-immunossay (LIA) with recombinant HIV1 and HIV2 proteins for screening of known HIV antibody positive sera.

Methods: The LIA-HIV assay (INNOVATIONS NV) uses only high purified synthetic HIV proteins in a line-immunossay technique for the detection of antibodies to HIV. The assay uses four purified synthetic HIV 1 antigens: the major core protein p24, an additional core protein p17, a polypeptide from the gag gene, the envelope gene and p1, a polypeptide derived from the endonuclease region of the polymerase gene. In order to detect HIV2 instead of HIV1 a synthetic transmembrane glycoprotein of this virus has been applied. A total of 15 known HIV2 antibody positive sera (prevalence of 90% and/or 100%-100) were screened.

Results: All the 15 HIV2 antibody positive sera reacted with the HIV2 transmembrane protein. The LIA test 87% of the sera reacted with the p24 and 83 protein, 10% reacted with the p24 only, 14% with p24 only, 4% with p17 and p24, and 2% with p17, 24, 24 and 7% of the sera did not react with any HIV1 peptide. Of the 65 HIV2 sera, none of them was reactive with the gag synthetic peptide. There was a good correlation between the results obtained with the LIA and the western blot patterns.

Conclusions: We have shown that the LIA system using synthetic HIV1 and HIV2 peptides allows the determination of HIV2 antibody positive sera.

Th.B.0.56 A NOVEL ENZYME IMMUNOSSAY TO DETECT ANTIBODIES TO BOTH HIV-1 AND HIV-2.

Backford, Ursula; Roberts, C. Duncan, R.J.S. and Pave, S. Wallace Diagnostics Research, Beckenham, Kent, SE3 3BS, U.K.

Objective: To develop an enzyme immunoassay capable of detecting antibodies to the known types of HIV with a sensitivity greater than commercially available at present.

Methods: Recombinant and peptide immunodominant epitopes constructed from HIV-1 and HIV-2 were labelled with alkaline phosphatase and used in an antigen-sandwich enzyme immunoassay. After the capture reaction, the enzyme was measured with an amplifying one-step substrate cycle.

Results: The assay had a sensitivity by end-point dilution up to 10-fold better than the anti-HIV-1 assays currently available in Europe, and had an excellent reactivity with sero-conversion samples. It detected all of the 289 anti-HIV-1 samples obtained world-wide, all of the 189 anti-HIV-2 samples obtained from West Africa and Europe, and had a low rate of false positivity. The assay was usable with serum, plasma or heat inactivated serum samples.

Conclusion: It is possible to improve on the sensitivity of the currently available commercial anti-HIV-1 assays and to detect anti-HIV-2 with an assay designed to be compatible with current blood bank procedures.

Th.B.0.58 SEROLOGIC EVIDENCE OF RETROVIRAL INFECTION IN ENTHAUSIAC DRUG ABUSERS (IVDA) (HIV-1, HIV-2, HTLV, HTLV-1, HTLV-2, HTLV-3, HTLV-4)

Stevan, S. and Lender, A. * Rush Medical Center, Chicago, Ill. and ** AIDS Project, University of Illinois at Chicago, School of Public Health, U.S.A.

Objective: To evaluate serologic evidence of HIV-1 and HIV-1 co-infection in IVDA.

Methods: Serum collected in 1988 from 1200 asymptomatic IVDA were screened for HIV antibody (anti-HIV-1) (EIA) (Abbott) confirmed by Western blot (WB). A subgroup of 94 IVDA were screened by EIA (Abbott) for HIV-1 (anti-HIV-1) and HIV-2 (anti-HIV-2) reactivities were reported in duplicate. Reactive HIV-1/2 samples were neutralized.

Results: The overall seroprevalence among the 1200 IVDA was 17% (per DuPont criteria): a subgroup of individuals was stratified by HIV-1b status. The HIV-1b seroprevalence was similar between the HIV-1b (2/0) and HIV-1b (1/40) individuals. The HIV-1b Ab positive rates among the 80 individuals was 33% and was identical in both groups. An additional seven HIV-1 seroconverters were identified during the 6-month study period. Two of these individuals were initially HIV-1b positive; 3/7 were consistently HIV-1b Ab reactive.

Conclusions: (1) among the HIV-1b and HIV-1b seroconverters, no difference in HIV-1b seropositivity was found. (2) HIV-1b has a low prevalence rate in this group. (3) Among the 7 HIV-1 seroconverters, there appears to be no change in HIV-1b seroreactivity.

Th.B.0.55 COMPARISON DES PERFORMANCES D'UN REACTIF ELISA UTILISANT UN PEPTIDE RECOMBINANT POUR LA DETECTION DES INFECTIONS A HIV 2. (L. ERAGAKI, A. IMAI, M. IMAI, F. POLET, D. J. HONORÉ, C. S. BRUN-VÉSTRET, F. VAN HEVERBEKE, R. P.)

* Centre International de Recherches Médicales - Francoville - Gabon;

** Institut Pasteur de Paris;

*** Service des Maladies Infectieuses - CRU de Toulouse - Allages - Clin. Clin. Clin.

Objectifs: Un nouveau test ELISA utilisant un peptide recombinant de HIV 2 (Château - France) fut sur un support solide (plaque de polystyrène), et fut appliqué à la détection des anticorps dirigés contre le virus de l'immunodéficience humaine (HIV 2) en milieu sérique.

Méthodes: Une population d'individus de 541 sérum a été soumise à la sérologie à 80 comparés au test ELISA classique (Orpax, Dupont de Nemours) pour HIV 1 ainsi qu'ELISA 2 et 3 au test ELISA HIV 1 recombinant (Château - France) et à un sérotype de multitést (Orpax) dans le sérum de référence (97.7-8). La spécificité est exprimée en pourcentage, comparée aux sérum non sérum (NS).

Résultats: Au cours de l'examen de sérologie, 1.54 % des sérum tests ont été trouvés séropositifs par les sérologies ELISA classiques, alors que seulement 2.9 % l'ont été avec le réactif Château pour Château, mais les résultats ont été confirmés dans le sérum. 21 sérum sur 30 sur les panels positifs ELISA (Sera positifs) alors que ceux positifs à ce test ont été confirmés.

Conclusions: Les tests ont été effectués au Western blot (WB) (245 5) et 2 (11.7 %) au HIV 2 (11.7 %).

Conclusions: Le test de la sérologie d'emploi est approprié (245 5), peut être à 80 fois appliqué dans le sérum de sérologie au test de l'usage sérum sérum, en milieu sérique, sur 8 en milieu sérum de sérum de sérum.

Th.B.0.57 COMPARISON OF SEROLOGIC ASSAYS FOR TRANSMISSIBLE RETROVIRUSES (HIV-1, HIV-2, HTLV-1, HTLV-2, HTLV-3, HTLV-4, HTLV-5, HTLV-6, HTLV-7, HTLV-8, HTLV-9, HTLV-10, HTLV-11, HTLV-12, HTLV-13, HTLV-14, HTLV-15, HTLV-16, HTLV-17, HTLV-18, HTLV-19, HTLV-20, HTLV-21, HTLV-22, HTLV-23, HTLV-24, HTLV-25, HTLV-26, HTLV-27, HTLV-28, HTLV-29, HTLV-30, HTLV-31, HTLV-32, HTLV-33, HTLV-34, HTLV-35, HTLV-36, HTLV-37, HTLV-38, HTLV-39, HTLV-40, HTLV-41, HTLV-42, HTLV-43, HTLV-44, HTLV-45, HTLV-46, HTLV-47, HTLV-48, HTLV-49, HTLV-50, HTLV-51, HTLV-52, HTLV-53, HTLV-54, HTLV-55, HTLV-56, HTLV-57, HTLV-58, HTLV-59, HTLV-60, HTLV-61, HTLV-62, HTLV-63, HTLV-64, HTLV-65, HTLV-66, HTLV-67, HTLV-68, HTLV-69, HTLV-70, HTLV-71, HTLV-72, HTLV-73, HTLV-74, HTLV-75, HTLV-76, HTLV-77, HTLV-78, HTLV-79, HTLV-80, HTLV-81, HTLV-82, HTLV-83, HTLV-84, HTLV-85, HTLV-86, HTLV-87, HTLV-88, HTLV-89, HTLV-90, HTLV-91, HTLV-92, HTLV-93, HTLV-94, HTLV-95, HTLV-96, HTLV-97, HTLV-98, HTLV-99, HTLV-100)

Int. of Imm. Washington, D.C.

Objectives: To compare different methodologies for the serologic diagnosis of human transmissible retrovirus infection.

Methods: Sera were obtained from civilian applicants for the armed services of the United States and initially screened with a qualitative HIV-1 enzyme-linked immunosorbent assay (ELISA). Reactive samples were then tested with a recombinant envelope based EIA and a Western blot method.

Results: Of 3,995 samples screened by the ELISA, 66 (1.65%) were scored as either repeat reactive (24-49%) or as questionable reactivities (32-84). Western blot analysis revealed that 3 (4.2%) showed banding patterns suggestive of HIV-1 infection. No bands were apparent on 55(83%) of the original 66 samples. These samples were also analyzed by a recombinant envelope based ELISA resulting in 18 (27.2%) scored as positive including 6 of that were Western blot positive. Of the other seven scored as positive by the recombinant ELISA, 7 were reactive by Western blot while 6 showed p19 bands, 1 showed p19 and p24 bands and 1 showed p19, p24, and p32 bands.

46 sera samples scored as negative by the recombinant ELISA were also scored as negative by Western blot. Of the original 3,995 samples tested, 3 (0.07%) can be considered positive for a transmissible retrovirus by two different EIA methods and by a Western blot method.

Conclusions: A recombinant envelope based ELISA can be used as a second level test prior to Western blot analysis to reduce screening false positives.

Th.B.0.59 RELATIVE SPECIFICITY OF TWO EIAs FOR ANTIBODIES TO HIV-1, HIV-2, HTLV-1, HTLV-2, HTLV-3, HTLV-4, HTLV-5, HTLV-6, HTLV-7, HTLV-8, HTLV-9, HTLV-10, HTLV-11, HTLV-12, HTLV-13, HTLV-14, HTLV-15, HTLV-16, HTLV-17, HTLV-18, HTLV-19, HTLV-20, HTLV-21, HTLV-22, HTLV-23, HTLV-24, HTLV-25, HTLV-26, HTLV-27, HTLV-28, HTLV-29, HTLV-30, HTLV-31, HTLV-32, HTLV-33, HTLV-34, HTLV-35, HTLV-36, HTLV-37, HTLV-38, HTLV-39, HTLV-40, HTLV-41, HTLV-42, HTLV-43, HTLV-44, HTLV-45, HTLV-46, HTLV-47, HTLV-48, HTLV-49, HTLV-50, HTLV-51, HTLV-52, HTLV-53, HTLV-54, HTLV-55, HTLV-56, HTLV-57, HTLV-58, HTLV-59, HTLV-60, HTLV-61, HTLV-62, HTLV-63, HTLV-64, HTLV-65, HTLV-66, HTLV-67, HTLV-68, HTLV-69, HTLV-70, HTLV-71, HTLV-72, HTLV-73, HTLV-74, HTLV-75, HTLV-76, HTLV-77, HTLV-78, HTLV-79, HTLV-80, HTLV-81, HTLV-82, HTLV-83, HTLV-84, HTLV-85, HTLV-86, HTLV-87, HTLV-88, HTLV-89, HTLV-90, HTLV-91, HTLV-92, HTLV-93, HTLV-94, HTLV-95, HTLV-96, HTLV-97, HTLV-98, HTLV-99, HTLV-100)

* American Red Cross, Washington, DC; ** Abbott Laboratories, Abbott Park, Ill.

Objective: Using Western blot (WB) and radioimmunoassay (RIA) to compare the relative specificity of 2 EIAs for antibodies to HIV-1.

Methods: Donor sera originally found repeatedly reactive (RR), 171 (Group I) by Abbott EIA and 25 (Group II) by Du Pont EIA in 40 different laboratories were retested by 2 EIAs and by WB.

Group I:	WB bands	No. Samples		No. Reactive	
		Abbott	Du Pont	Abbott	Du Pont
Group I:	None	29	24	16	12
	p19 only	26	33	22	28
	p24 only	36	33	33	33
	p19/p24	19	19	19	19
	p19/p24/gp46	5	5	5	5
Group II:	None	6	0	5	0
	p19 only	0	0	0	0
	p24 only	3	0	0	0

Six of 19 initially selected samples from Group I and none of the 9 with WB p19 or p24 from Group II showed gp46 reactivity by EIA.

Conclusions: Abbott EIA was more specific; 70% of samples showed all bands on WB and 33% showed a gp46 band by Western blot. Du Pont EIA was more reproducible; 89% of originally RR samples were still reactive as compared to 44% of Du Pont EIA RR samples.

M.B.P.1 IN UTERO HIV TRANSMISSION IDENTIFIED THROUGH PCR.

Vladic, Courant¹, Lours, F. +, Marin, F. +, Goudeau, A. +, Bricot, C. + and The Paris-Tours Collaborative group perinatal HIV transmission**.

INSERM U275, CHU de Tours, **Laboratoire de Virologie Tours (CNRS UA.271), *Centre d'immunobiologie périnatale, Paris, ****Diagnostique Pasteur, Marnes la Coquette, France.

Objective: To investigate the possibility of in utero HIV transmission.

Material: 33 fetuses obtained from HIV positive mothers at 16 to 24 weeks of gestation. 3 fetuses were obtained at 16-18 weeks by hysterotomy. Thymus and spleen were dissected and analyzed separately. PBL of 30 mothers were available. Methods: PCR for HIV DNA detection with 40 cycles and 3 sets of primers (9a) and (E) gene.

Results: HIV DNA sequences were detected in 19/31 thymus and 22/33 spleen fetuses samples. Positive results were obtained in fetuses from 16 to 22 weeks. HIV DNA unambiguously scored positive in 2/3 thymus and spleens obtained by hysterotomy at 16-18 weeks. By using primers specific for the highly polymorphic cytochrome b locus, we have concurrently identified informative mothers comparison of the results obtained with these primers between mothers' and fetal tissues DNA did not show evidence of contamination of fetal tissue samples by infected mother cells.

Conclusions: This study indicates in utero HIV transmission, occurring even at an early stage of gestation. The likely high rate of transmission must be taken in account for strategies aiming to prevent perinatal infection.

M.B.P.3 DISEASE PROGRESSION FOLLOWING PREGNANCY IN HIV SEROPOSITIVE WOMEN

McNelis LP, Wong JM, Whitlaw J, Shorne JM, Stewart EP, WDI, Virology; City Hospital; Immunology, Royal Infirmary, Edinburgh, Scotland.

OBJECTIVE: To assess disease progression following pregnancy in HIV seropositive women.

METHOD: Of 107 HIV seropositive women infected between 1983 and 1985, 31 have had a pregnancy post seroconversion. Follow up has included monitoring clinical status, CD4 lymphocyte count, IgG, IgA and HIV antigen at 6 monthly intervals.

RESULTS: Patients have been followed-up from 6 to 54 months with 18 having been followed for longer than 24 months. One has progressed to AIDS at 3 years post delivery and one has developed persistent oral thrush 2 years after delivery, the rest remain asymptomatic. CD4 lymphocyte depletion to less than 200 was occurred in 2 (6%) patients, 1 with AIDS and one other who is currently asymptomatic. IgG and IgA levels show no significant trend. 2 (6%) patients have become antipsychotic but remain asymptomatic. There is no evidence of increased disease progression in this group compared with the milliparusous women or those who had pregnancies prior to seroconversion. In fact the milliparusous group are clinically worse possibly as a consequence of continued infection they were.

CONCLUSION: Unlike others we have not observed an excess of post pregnancy disease progression. However, these are first pregnancies and none of the children have developed AIDS.

M.B.P.5 Failure of Targeted Screening to Identify HIV+ Pregnant Women.

Richard, Margaret; Quinn T; Kline, K; Remba, J; Chanson, R. The Johns Hopkins University Baltimore, Maryland, U.S.A.

Objective: To assess a targeted HIV screening program for women attending an inner city prenatal clinic.

Methods: All women attending the Johns Hopkins Hospital prenatal clinic between 2/87 and 1/89 completed a questionnaire to assess HIV risk behavior. HIV testing was offered to women with acknowledged risk factors. Testing was available to women without acknowledged risk factors, but was not encouraged. Ser. from rubella specimens were obtained from women not voluntarily tested for HIV, and tested anonymously for HIV antibodies.

Results: 1416 women were enrolled in the clinic and evaluated. The median age was 31 years (range 16-41). 80% were black and 80% single. HIV risk behaviors were reported by 241 (17%) women; 54% were partners of intravenous drug users (IVDU), 30% were IVDU, 10% had received transfusions before 1983, 4% were partners of bisexual men and 2% reported prostitution. 146/241 (60%) women with risk factors consented to HIV testing. 19 (14.3%) were HIV+. 18 women denying risk factors requested testing; 9 (49%) were HIV+. 473 specimens were available for anonymous testing; 136 (28.7%) from women with acknowledged risk factors. Six specimens from this group were HIV+. 473 specimens were available for routine testing. Overall, 34 (4.1%) of 824 pregnant women tested positive for HIV. 15 (44%) of the seropositive women had no acknowledged risk factors for HIV. In 15 (44%) of the 34 specimens from this group, HIV testing following HIV screening to pregnant women who acknowledge risk factors will fail to identify a substantial number of infected women in urban settings. HIV screening, counseling and education should be made available to all patients as part of routine prenatal care.

M.B.P.2 ANTIGENEMIA p24 AND CD4 CELLS COUNTS IN HIV PREGNANT WOMEN.

Jean-François Malinvaud, B. Sévénal, J.C. Pons, D. Meyer, V. Chabrier, Ph. Kieffer, A. Fautsch, A. Bourcier, HIV Pregnancy study group, Paris, France.

Objective: To investigate the effects of pregnancy on virological and immunological parameters in HIV pregnant women, we studied the evolution of antigens (Ag p24), anti p24 antibodies (Ac anti p24) and CD4 cells count during and after pregnancy.

Methods: 40 seroconverted 3rd trimester group 1: group 1 HIV pregnant women (n = 97), group 2 HIV aborted women (n = 114), group 3 : non HIV pregnant women. **Results:** CD4 cells are initially (first trimester) lower in group 1 (455 ± 71) and group 2 (502 ± 53), in comparison with group 3 (886 ± 72). A slight decrease is observed during the pregnancy (third trimester) in group 1 (400 ± 50) and group 2 (377 ± 68). The mainfact is the lack of increase of CD4 observed at the 3th month of post partum in group 1 (332 ± 66) and group 2 (338 ± 72) contrasting with group 3 (933 ± 65). In group 1 (HIV pregnant women) HIV antigenemia are found in 8/26 at the first trimester, 24/78 at the 2nd trimester, 14/72 at the 3th trimester. In the group 2 (women with induced abortion) HIV antigenemia is positive in 12/13 during the first 3 months. After the pregnancy antigenemia is respectively positive in 6/57 in group 1 and 8/102 in group 2. No modification of antibodies anti p24 was observed.

Conclusion: In HIV pregnant women, CD4 decrease is longer persistent in post partum. HIV Ag p24 appears frequently during the 2nd trimester but is reversible. The role of these immunological and virological abnormalities in disease progression, and in the subsequent evolution of HIV infection in pregnant women, are under investigation.

M.B.P.4 PREGNANCY ARISING IN HIV INFECTED WOMEN WHILE BEING SEROPOSITIVELY CHANGING ABOUT "SAFE SEX"

Seaman, Mark L., Purser, B., Hall, S., McCallow C, O'Meara C, Harpac R. North Shore University Hospital, Cornell University Medical College, Newburgh, N.Y.

Objective: To study the epidemiologic features of women who became pregnant after learning their HIV status.

Methods: 151 women who were of child bearing age have been followed after they were found to be antibody + to HIV-1. A registry has been maintained of women who became pregnant after knowledge of their antibody status and after discussions about "safe sex".

Results: Of 40 surviving women from 88 IVU's, 4 became pregnant one time and 1 2x. Of 43 surviving women from 44 women who acquired disease heterosexually, 7 became pregnant 3 times. No women of 11 surviving women from 17 who acquired disease from other means (6 transfusional, 3 Caribbean, 8 unknown male) became pregnant. 4/11 of women became pregnant even though they were taking AZIDUAPRINE and were counseled several times about "safe sex". One patient's pregnancy was ectopic, 3 delivered full term children, one is carrying the pregnancy to term, 7 had termination of pregnancy. Pregnancy occurred even with low helper cells (<200 cells/mm³) in 5. **Conclusions:** Pregnancy continues to occur frequently (11/134) even after women learn about their HIV status. Improved techniques about "safe sex" must be developed.

M.B.P.6 PREGNANCY AND ACCELERATION OF HIV-RELATED ILLNESS

Deuchars, Marie-Joselle¹, Page, J.W.², Madhavan, S.², **Cornell University Medical School, NY, NY, U.S.A.

Objective: To study the effect of pregnancy on the development of HIV-related illness in seropositive asymptomatic women in Port-au-Prince, Haiti.

Methods: A prospective study of 178 HIV-seropositive asymptomatic women of child bearing age was undertaken from 1983 to 1988. During the study period, 34 women were pregnant — 15 at time of study entry and 19 conceived during the follow-up period. There were 31 live births. Despite the 34 pregnant women (19% compared with the 144 non-pregnant women (81%)) with regard to the development of HIV-related illness. For the entire cohort, mean age was 29 years, gravidity 2.4, parity 2.1 and follow-up a mean of 21.4 ± 14.3 mo. (M and F) were comparable in these parameters and in their socioeconomic status. During the study period, 16/174 (47%) M and 27/144 (18%) F women developed AIDS or HIV-related illness (26/63, p<0.05) The illness rate for M (28%/1000 person-years) was not significantly higher than that of M (18%/1000 person-years). Illness developed in 5/16 M during pregnancy (mean, 5th month) and in 11/16 a mean of 6 months postpartum. The cumulative proportion of M women becoming pregnant increased from 10 to 28% over years 1 to 5 (logrank, p=0.01). Similar analysis showed the cumulative annual percentages of M developing symptoms at years 1 to 5: 22% of follow-up 1, 25, 35, 46, and 53% and for F at 23, 33, 53, 53, and 84%.

Conclusion: Pregnancy in asymptomatic HIV-seropositive women is associated with an accelerated development of AIDS or HIV-related illness during pregnancy and in the postpartum period.

M.B.P.7

FACTORS INFLUENCING MATERNAL DECISION-MAKING REGARDING PREGNANT OUTCOME IN HIV INFECTED WOMEN

Winters, A.; Weidner, B.; Burti, C.; Douglas, S.; Cabanot, T. and
Albert Einstein College of Medicine, Bronx, N.Y., U.S.A.

Objective: To determine the factors which influence HIV infected pregnant women to complete or terminate their pregnancy.
Methods: Thirty three HIV infected pregnant women were evaluated for factors involved in decision making regarding their pregnancy outcome. An elective termination of pregnancy (TOP) was medically available for the 22 (67%) women who were identified prior to 24 weeks of gestation. All women were aware of their HIV status and received comprehensive obstetrical and medical care as well as family counseling.

Results: Six of 22 women (27%) who were eligible for TOP chose to terminate their pregnancy electively. Of 11 women who developed HIV associated symptoms before 24 weeks of gestation, 4 elected TOP (36%). Seven of 33 (21%) had previously mothered HIV infected children. Six of 7 (87%) of these women chose to complete the current pregnancy. There was no difference in the number of previous abortions, maternal health, socioeconomic conditions, marital status, mother's presence of an HIV infected older child or HIV associated diseases between those women who pregnancies resulted in an elective TOP or those who chose to continue their pregnancy.
Conclusion: Neither the presence of an HIV infected older child nor HIV associated symptoms in HIV infected pregnant women appear to influence decision making concerning continuation of pregnancy.

M.B.P.8

THE IMPACT OF FREQUENCY OF INCREASES IN HIV-RELATED CD4+ COUNTS ON THE PROGNOSIS OF HIV-RELATED DISEASE

Schroeder RE, Doolittle JM, Nelson RA, Metcalz D, Rogers MM,
NYC HIV Perinatal Transmission Collaborative Study et al.,
Cornell/Albert Einstein College of Medicine, Bronx, NY, USA,
New York City Department of Health, New York, NY and CDC, Atlanta, Georgia, USA.

Objective: To study the effect of pregnancy on progression of HIV infection.
Methods: Since 1/85 341 HIV infected childbearing-aged women from a network program enrolled in an HIV natural history study had serial P-cell counts, physical exams and intravenous abuse, serology, sexual, medical/obstetrical history since 1978; the number of pregnancies since 1978 ending in livebirths (LB), miscarriages (CM) and (CM/CM), onset and duration with HIV-associated constitutional symptoms (CS) prior to oral thrush, (CM/CM) were compared relative to the development of (CM/CM) during pregnancy (P).
Results: Of 341 (304 black, 568 white) women 568 were P/2 with 2.6 yrs. HIV developed AIDS during pregnancy. Development of HIV related illness was by a 2x2 table.

	LB	CM	CM/CM (NONP-2)
Asymptomatic	25 (26%)	20 (26%)	20 (41%)
HIV Assoc. Ill.	13 (23%)	14 (39%)	17 (38%)
CM/CM	18 (32%)	20 (53%)	22 (48%)

There was no difference in the mean duration of CS for women with LB (2.6 yrs.) and those with CM (2.4 yrs) (p=0.05). On regression analysis, (CM/CM) was predicted by the mean CS onset and duration of CS (p<0.001) controlling on CM (0.001) and (CM/CM) and CS, and was not predicted by LB (p=0.59).
Conclusion: These data suggest progression of HIV disease to oral thrush or AIDS is not associated with pregnancy.

M.B.P.9

PHARMACOKINETICS/PHARMA OF ZIDOVUDINE(ZDV) IN HIV+ PREGNANT WOMEN

Burchett, S. et al. University of Wisconsin, WA, United States

Objective: To evaluate ZDV PK in pregnancy and postpartum.
Methods: In an ongoing study, ZDV PK were studied several times during the second and third trimester and postpartum in 13 women taking ZDV 200mg every four hours (10-15mg/kg/day). Multiple blood samples were obtained and ZDV conc. were measured by HPLC. PK were analyzed using noncompartmental analysis. CBC with red cell indices, T lymphocyte subsets, plasma and lymphocyte HIV cultures, and renal and liver function studies were done monthly.

Results:

	1st/2nd	2nd/3rd	3rd/4th	Postpartum
T _{1/2} (hr)	1.1 ± 0.1	1.1 ± 0.1	1.1 ± 0.1	0.9
C _{max} (ng/ml)	0.6 ± 0.10	1.4 ± 0.10	1.5 ± 0.07	1.1
AUC _{0-12hr} (hr*ng/ml)	1.1 ± 0.06	1.3 ± 0.04	1.1 ± 0.03	1.0
RTIC _{0-12hr} (ng/hr)	3.2 ± 0.2	2.4 ± 0.1	2.5 ± 0.2	1.2
FV _{0-12hr} (ng) %	4.5 ± 0.3	3.2 ± 0.4	3.5 ± 0.2	1.7

Cardiac Output (L/min) ranged from 24 to 127% of the maternal level. The T_{1/2} of ZDV in the neonates ranged from 9 to 23.3 hours. No symptoms or lab abnormalities required a reduction of dose. None of the babies manifested clinical or laboratory abnormalities in the neonatal period, although one baby was delivered at 36 weeks gestation by cesarean section for oligohydramnios and fetal distress.
Conclusions: ZDV PK in pregnant women were similar to other adults except V_d was increased. No unexpected toxicities were observed in mothers and neonates. Significant transplacental passage of ZDV was observed.

M.B.P.10

KNOWLEDGE OF HIV SEROSTATUS AND PREGNANCY DECISIONS

Reichman, R., Baruch, M., Margolis, C., Chalmers, R., Anderson, J., Hertz, J. Johns Hopkins University, Baltimore, Maryland, USA.

Objective: To describe pregnancy decisions among 89 HIV + women attending clinics at the Johns Hopkins Hospital.
Methods: Retrospective review of pregnancy decisions from records of 89 HIV + women: 34 women seeking prenatal care and 55 women attending an HIV infection clinic for women.
Results: Mean age of women 24.3 years (range 19-38 years). 80% black, 18% white, 2% other. Risk factors for HIV infection: 40% intravenous drug use (IVDU), 23% IVDU, 15% sexual partner, 11% transfusion, 4% blood or HIV + partner, 2% prostitution. 74/89 (83%) had previously been pregnant with 60% having 2-3 living children. Seronegativity was observed in 36/89 women during pregnancy, 10% of whom were identified as 50 week gestation. Two women had elective abortions (14 and 18 weeks), one had a spontaneous abortion at 17 weeks gestation, and 17 women opted to continue their pregnancies, 6/7 delivering term infants. 14 women (16%) became pregnant after hearing they were HIV+. None of these women was using contraception. One woman who delivered a term infant had an elective abortion at 10 weeks of a subsequent pregnancy. The remaining 13 women continued their pregnancies with 12/13 delivering term infants.

Conclusions: Knowledge of HIV infection was not associated with pregnancy termination or prevention of subsequent pregnancy. In light of risk of perinatal transmission and possible acceleration of HIV infection during pregnancy, education, counseling and specialized obstetrical and medical services for women with HIV infection are needed.

M.B.P.11

IMMUNOHISTOCHEMICAL DETECTION OF HIV-ASSOCIATED ANTIBODIES IN FORMALIN-FIXED PERINATAL PLACENTAS

Wagner, G. J., Schiller, R., Fagan, S., Linn, L., Huang, S. L., Unger, N. C., *Institute of Pathology, Department of Pediatric Pathology and *Laboratory of Immunology, Albert Einstein College of Medicine, *New York City Department of Health, *Freie Universität, *Klinikum Rudolf Virchow, Berlin, Federal Republic of Germany

Objective: Detection of intrauterine HIV-infection in fetal placenta of HIV-exposed pregnancies.
Methods: 1. 31 formalin-fixed neonatal placentas (22 of them with additional frozen tissue) of HIV-positive mothers. 2. Application of a: monoclonal anti-HIV antibodies (Dr. Pant anti-HIV-III p24, product 5281/7053; Mabser anti-p24, anti-p17); b: various capture markers for the typification of the antigen profile of Hofbauer cells (placental macrophages).

Results: 1. Detection of HIV antigens in Hofbauer cells of 21 formalin-fixed placentas. 2. Positive reaction of Hofbauer cells (HC) with anti-p24, p180/95, MAC 387; a subgroup of HC reacting with anti-CD1 and anti-MLA-28. No demonstration of CD8, Pan B and Bc.

Conclusions: 1. HIV antigens can be localized in Hofbauer cells of formalin-fixed placentas. The antigen profile of HC corresponds to that of epifurcal lamprophage cells. 2. Positive reaction of HC correlates to clinical signs of infection in the child, but up to now placental infection is more frequent than the latter. 3. Therefore, placental infection indicates an increased state of risk of the newborn not proven infection.

M.B.P.12

HIV SEROPREVALENCE IN AN INNER CITY OBSTETRIC POPULATION.

Johnson, John P., Watkins, Jr., Sims, F., Richardson, B., and Alpert, L., University of Maryland School of Medicine, Baltimore, Maryland.

Objective: To determine the seroprevalence of HIV infection in an inner city maternity population.
Methods: All women presenting to obstetric clinic were provided a questionnaire regarding HIV risk factors. The type and duration of risk factor was recorded and HIV testing was performed after informed consent.

Results: Four percent of the population indicated either sexual and/or drug use risk factors. Of this 41, 26% were seropositive. Women indicating drug use had a seroprevalence rate of 24%, those with sex partners who were drug users had a 7% seroprevalence rate, those women who admitted to both risk factors had a 33% seroprevalence rate. Women whose risk factor occurred strictly before pregnancy had a 9% seroprevalence rate. Those whose risk factor only during pregnancy had a 13% seroprevalence rate and those who had risk factors occurred both before and during pregnancy had a 40% seroprevalence rate.

Conclusion: A program of self-identification in inner city maternity population yielded an overall 1% seroprevalence rate. A drug use history was greater risk for HIV infection than sexual history. Duration of risk behavior and recovery of risk behavior appeared to increase risk for HIV infection. Screening for type and timing of risk factor may help to identify a particularly high risk population for HIV infection.

M.B.P.19

Seroprevalence of HIV-1 and HIV-2 among pregnant women in Newark, NJ.
Carter, E. M., ~~Deane, Thomas, J.~~ O'Connell, L., * Newman, P., * O'Leary, R., * Kline, R. C. et al.
*RHO-RT Medical School, Children's Hospital of New Jersey, Newark, NJ and
CC, NJMS, Camden, NJ.

Objective: To determine the seroprevalence of HIV-1 and HIV-2 in pregnant women delivering at a University Hospital in Newark, NJ, which serves primarily a local, inner city minority population (60% black, 38% Hispanic and 2% white).
Method: Between 9/87 and 9/88 samples of serum were obtained at the time of delivery from maternal, cord, or infant blood. Samples were serologically tested for the presence of antibodies to HIV-1 and HIV-2 by using ELISA (Abbott) and Western Blot (Bio-Rad).
Results: A total of 2,619 deliveries occurred and 2,000 samples were available for HIV-1 (94%) and 2,000 for HIV-2 testing. HIV-1 ELISA was reactive in 6.2% (136) and Western blot was reactive in 99/136 (73%) yielding a confirmed seroprevalence of 4.4% for HIV-1. HIV-2 ELISA was reactive in 2.1% (44) and Western blot was reactive in 7/44 (16%) yielding a confirmed seroprevalence of 1.3% for HIV-2. In conclusion, 10.5% (216) were also HIV-2 positive. Mean delivery at the institutions studied are at risk of 1/22 for HIV-1, 1/77 for HIV-2 and 1/260 for co-infection. These data suggest that vertical transmission to newborns of HIV-1 and HIV-2 are important risks in our community.

M.B.P.21

DIFFERENCES IN IMMUNOSUPPRESSION DURING PREGNANCY IN HIV-INFECTED WOMEN

Kohler, A.M., Friedmann, W. M. and Schwartz, S. **
*Dept. of Obstetrics, Universitat de Maric, P.R.
**AIDS-Center, Bundesgesundheitsamt, Berlin, F.R.G.

Objective: To evaluate the natural course of HIV-infection during pregnancy.
Methods: In a comparative study 54 HIV-infected and 50 HIV-negative pregnant women were investigated every 2 - 4 weeks on clinical status and the following immunological parameters: T-cell counts; CD4, CD8; Immunoglobulins: IgG, IgM, IgA, IgE; Circulating antibodies: IgG, IgM.
Results (median): On the basis of the immunological parameters the investigated collective of HIV-infected pregnant women was divided into 4 groups: Group 1: no abnormal immunological findings; Group 2: CD4/CD8 ratio < 0.8; CD4-cells > 400; Group 3: CD4-cells 250 - 400; Group 4: CD4-cells < 250.
Controls: Group 1: n=25 Group 2: n=13 Group 3: n=16
 n=50 n=11 n=13 n=5
CD4 decr. >10% 27 9 23 12 5
CD8 decr. >10% 0 2 12 9 2
CD4 decr. >40% 0 2 9 8 5

Discussion: The greatest extent of immunosuppression during pregnancy in HIV-infected women was seen in group 2 (3 decrease of CD4-cells > 40%) and group 4 (decrease of CD4-cells < 40%). The majority of women showed a postpartal regeneration; 6 women had a continuous loss of CD4-cells after delivery.

M.B.P.23

SEROPREVALENCE IN A HIGH MULTIRACIAL POPULATION
C. Miller, M. J., Fajardo, R., Ferns, P., Elin, J., Sosa, C.
Duke, N. University of Miami, Miami, Florida, United States of America.

Objective: To determine HIV-1 seroprevalence by antibody status in women delivered at a medical center serving the multi-ethnic population of Miami, Florida, U.S.A.
Methods: From 7/78 to 12/88, patients admitted to the labor suite had sero, blood tests, and history of STD or less. They were interviewed, consented, and offered HIV antibody testing after delivery. The samples of those who refused or were discharged before interview were banded. Inactive obtained directly from patients included seroprevalence and the following risk factors: drug (cocaine, crack, IV), sexual partners, sexually transmitted, blood transfusion.
Results: Of the 7,400 offered testing, 52.7% gave consent, of whom 2.1% were seropositive. Of the 1,774 refusing testing, 1.8% were HIV-positive (Chi square analysis p < 0.01), exposing a bias. Of the 1,000 who refused, 2.2% were seropositive. The age distribution of the seropositive matched the statistical population. Tests were 18.3% of the seropositive (12.5 - 65 years old). Seropositive Hispanics predominated (87%); 52.1% were 25 years of age, compared to Haitians (38.3%), 57.8% were 35 years old or > 50 years. Seropositivity also correlated with drug use, multiple partners, and risk status, p < 0.005 each. However, 45.4% of the seropositives had no admitted correctly accepted risk factors.
Conclusions: Screening would be offered to all pregnant women, certainly in our population. Sexually active teenagers are at risk of infection, especially the Black American. While asymptomatic risk factors are associated with seropositivity, no apparent risk factors account for almost half these infected patients, implying heterosexual transmission as the largest identifiable factor. Education for prevention should begin before sexual saturation.

M.B.P.20

PATHOLOGY AND HIV EXPOSURE IN TERN PLACENTAS FROM SEROPROTECTIVE WOMEN. Chandra, B., Blotnick, G., H. J., Kitzler, J., Kresnowski, J., Kormanik, J., New York University Medical Center & Bellevue Hospital Center, New York, N.Y., U.S.A.

Objective: To compare the pathology of tern placenta from seroprotective HIV infected and seroprotective women using routine histologic, immunohistochemical, and in situ nucleic acid hybridization techniques.
Methods: Tern placenta of seroprotective and seroprotective women were evaluated by hematoxylin and eosin (H & E) staining for evidence of vasculitis (VA), villitis (V), chorionitis (CH), and chorioamnionitis (CA). They were also examined by immunoperoxidase (IP) staining using monoclonal anti-p24 antibody, lactin (L), cytokeratin (CK), amniotic (AM), and uterine glands (UG) were evaluated. Some of these were tested using IP and in situ nucleic acid hybridization (ISH) techniques using an RNA probe complementary to the 3'LTR and envelope region of HIV-1.
Results:

Seroprotective	Histology			Immunoperoxidase			IP/ISH	
	VA	CH	CA	IP	CK	AM		
Seroprotective	1/45	0/45	2/45	1/24	1/24	0/14	0/17	1/17
Seroprotective	0/21	0/21	9/21	0/17	0/17	0/17	0/14	0/14

Conclusions: HIV infection does not appear to cause significant pathologic abnormalities in the tern placenta. HIV antigens can be identified rarely in placental trophoblastic tissue. HIV nucleic acid can be found in those trophoblastic cells also containing HIV antigen. Examination of the tern placenta from HIV infected women has failed to clarify the mechanism of transmission of this virus from mother to fetus. Conceivably, tissue from earlier gestational placentas may be more informative.

M.B.P.22

EFFECT OF PREGNANCY ON THE PHARMACOKINETICS OF ZIDOVUDINE
Urbán, J., Muñoz, D., López-Ariza, A. and Schumann, R.
School of Pharmacy, University of Washington, Seattle, WA, U.S.A.

Objective: The incidence of HIV infection in pregnant women is increasing. Thus, administration of zidovudine (ZDV) to pregnant women may be of benefit to both mother and fetus. To determine the effect of pregnancy on the pharmacokinetics of ZDV, experiments were conducted in macaques (Macaca nemestrana) in term and after delivery.

Methods: ZDV was administered as a single IV bolus dose (10mg/kg) to two macaques at term and 1 week after delivery. Blood samples were collected frequently over the next 4h. Urine was collected over 24h. ZDV and its active metabolite (ZDV) in both plasma and urine were assayed by HPLC (1).

Results: The total plasma clearance (CL), steady-state volume of distribution (Vss) and the terminal half-life of ZDV were assessed. At term, these parameters for the two animals studied, were estimated as 24.6, 27.6 min/l, 903, 1314 ml/kg, and 37.4, 45.5 min respectively. In the non-pregnant state, these parameters were 27.8, 30.1 min/l, 727, 1256 ml/kg, and 39.9, 74.8 min respectively.

Conclusions: The pharmacokinetics of ZDV do not appear to be altered by pregnancy. Similar experiments in further animals are in progress.

1. Good S. et al. Chromatog. 1981; 41: 123-133, 1988.

M.B.P.24

A PROSPECTIVE STUDY OF THE MENTAL AND MOTOR DEVELOPMENT OF INFANTS BORN TO HIV INFECTED INTRAVENOUS DRUG USING MOTHERS

Blattner, Ron; Jeremy, R. J.; Rusey, C. M.; Vetrucio, P. M.; and Cowan, M. M., *MATTER-FACET, San Francisco, **University of California, San Francisco, U.S.A.

Objective: To describe prospectively the mental and motor development of infants born to IV drug-using mothers exposed in utero to HIV.
Methods: Quarterly screenings on the Bayley Scales of Infant Development (BSID-II) using a standardized Bayley Index (BSID-II) and a Psychomotor Development Index (PDI) (1). Three groups of infants: CONTROL (HIV-negative mother, n=15); INFECTED (HIV-positive mother, HIV-negative child, n=10), and UNINFECTED (HIV-negative mother, HIV-negative child, n=10).
Analysis: Comparison of BSID and PDI scores of the three groups at ages 3, 6, 9, 12, and 15 months: a) group means, and b) individual developmental curves.
Results: INFECTED infants showed lower BSID and PDI means with age than the CONTROL and UNINFECTED groups. In contrast to both non-infected groups which did not continue to decline. However, while the CONTROL group performed around normal BSID and PDI, the UNINFECTED group hovered about 1 standard deviation lower. Individual developmental curves showed that among the best developing infants were 5/6 of the CONTROL, 1/6 of the INFECTED, and 2/3 of the UNINFECTED. Among the poorest, 7/8 were CONTROL, 7/8 were INFECTED, and 4/5 were UNINFECTED.
Conclusions: The mental and motor development of HIV infected children declines over the first 15 months of life. The mental and motor development of infants exposed prenatally to HIV but not infected is poorer than that of CONTROL. Children not so exposed.

M.B.P.25 INFLUENCE OF GESTATION ON HIV INFECTION.

REVELLE, A.L., PUEL, J., THIRICRE, J., BENOIST, H., FORTIN, J.-C.
*Service de Gynécologie-Obstétrique, Hôpital La Grange; *Service de Virologie, Hôpital Purpan; **Service de Pédiatrie B, Hôpital Purpan, Toulouse; ***Association "Le Patriarche", Saint-Cesair, France.

Objective. In order to compare the influence of time alone to the influence of time plus pregnancy on infection with HIV, we report results of a three year follow-up of two groups of women. (A) 60 HIV antibody positive, asymptomatic pregnant patients (34 live births, 26 medically indicated abortions) (B) 68 age and sex matched HIV antibody positive, asymptomatic patients without gestation.

Methods. In these two populations, the following parameters were compared: clinical stage, sedimentation rate, white cell count; relative lymphocyte count, relative and absolute T4 lymphocyte count, the T4/T8 ratio, the serum level of IgA, and the presence of the P24 HIV antigens. These parameters were measured during pregnancy, at termination of pregnancy, and one, two, and three years thereafter.

Results. No statistically significant differences between the two groups were found. In 20 % of the pregnant population, we found a transient appearance of the HIV P24 antigens during pregnancy.

Conclusion. Over a period of three years, no difference in the progression of HIV disease was observed between a population with and one without pregnancy. The transient appearance of HIV P24 antigens during pregnancy, does not seem to be a poor prognostic marker for progression of HIV disease.

M.B.P.27 PREGNANCY OUTCOME IN WOMEN HIV INFECTION IN PUERTO RICO IN A POPULATION OF PREGNANT INTERMEDIAL TRANSMISSION

BARRERA, J., ZORRILLA, C., HAZ, C., ROSSIGNOL, R. J., DE LA VEGA, A., CHIROQUEZ, J., PUERTO RICO, U.S.A.

Findings. The prevalence rate was 1.47%, the most common risk factor was being a sexual partner to an IV drug user (54%) followed by IV drug use by the patient (17%). The mean gestation was 34 and the mean parity was 2.3. None had sexual relationships by marriage or consensual union 71%, the mean number of lifetime sex partners was 2.6 (excluding patients who were prostitutes). The most common prenatal complication was diabetes mellitus (14%) followed by preterm labor 18%. Smoking was reported by 56% of patients. Mean weight gain during pregnancy was 22 lbs. Cesarean section rate was 15%. Perinatal mortality was 9.5% and post-neonatal mortality 4.2%.

Mean birth weight was 3,209 g, although 41% of the babies weighed 2,500 g. 7% of the patients elected pregnancy termination and 30% underwent post-partum sterilization. 7% of cases progressed to ARC/AIDS. Maternal mortality was also high (2.3%) and ascribed due to AIDS.

Conclusion. Perinatal as well as post-neonatal mortality is increased in the offspring of seropositive pregnant women. Maternal mortality is also increased significantly in this group of young women. Since the two maternal deaths occurred within one year post-partum in women whose neonates had congenital pneumonia, we may identify infection of the fetus as a risk factor for development of over disease in the mother.

M.B.P.29 Reproductive history (RH) of HIV antibody Positive (HIV Ab+) women in a high risk group in a prospective study

REVELLE, A.L., PUEL, J., THIRICRE, J., BENOIST, H., FORTIN, J.-C., ATLANTIC, SEASIDE, USA.

Objective. To describe the reproductive life of a cohort of HIV Ab+ women followed in a prospective study.

Methods. Pregnancy information on 43 HIV Ab+ women whose children are enrolled in a prospective study was obtained by interviewing mothers directly (n=39) or the child's guardian (n=13). Mean follow-up was 13 mo (range 2-20mo).

Results. Seven women had one subsequent pregnancy and 2 were pregnant twice.

Pregnancy	Index of child's age
1	12 mo
2	12 mo
3	18 mo
4	18 mo
5	13 mo
6	4 mo
7	4 mo
8	4 mo
9	5 mo

Conclusion. Despite counseling for risk associated with HIV, a high percent of HIV Ab+ women in this cohort became pregnant an average of 8mo after delivering an HIV Ab+ child. Future studies will need to address knowledge of HIV seropositivity and its impact on rates of pregnancy among women in a high risk area for HIV.

M.B.P.26 EFFECTS OF HIV INFECTION ON PREGNANCY.

REVELLE, A.L., KORDICH, W.E., PUEL, J., THIRICRE, J., BENOIST, H., FORTIN, J.-C.
*Service de Gynécologie-Obstétrique, Hôpital La Grange; **Service de Virologie, Hôpital Purpan; ***Service de Pédiatrie B, Hôpital Purpan, Toulouse; ****Association "Le Patriarche", Saint-Cesair, France.

Objective. We compared the complication-rate during pregnancy and the perinatal period among HIV antibody positive former drug addicts (group A), 68 HIV antibody negative present drug addicts (group B), and 2017 patients without a history of HIV infection or drug addiction (group C). The purpose of this study was to define the influence of HIV infection on pregnancy.

Methods. We assessed the following parameters: fever during pregnancy, hypertension, fetal malformations, fetal growth retardation, premature labor, the APGAR score, and postpartal complications.

Results (in %).

	Fever during pregnancy	hypertension	fetal growth retardation	premature labor	the APGAR score	postpartal complications
A	16.1	5.4	5.4	10.8	16.2	10.8
B	7.4	1.3	5.9	22.0	14.7	6.8
C	2.3	1.4	1.6	8.7	4.2	6.0

Conclusion. HIV infection appears to have no influence on the course of pregnancy, and does not increase fetal mortality. Complications such as fetal malformation, growth retardation, and premature labor seem to be more closely related to drug addiction and concomitant low socio-economic status, than to infection with HIV.

M.B.P.28 COMPARISON OF LIFESTYLES AND HIGH RISK SEXUAL BEHAVIOR BETWEEN HIV-SERO-POSITIVE AND HIV-SERO-NEGATIVE PREGNANT WOMEN

ZERRILLA, C., ROMAGOSA, J., TORRES, J., MORALES, J., ANDERSON, K., UNIVERSITY OF PUERTO RICO SCHOOL OF MEDICINE, SAN JUAN, PUERTO RICO.

Objective. To compare the frequencies of different types of high risk sexual behavior and lifestyles during pregnancy in sero-positive vs sero-negative to HIV.

Methods. Personal interviews obtaining sexual histories and risk factors were performed in 61 HIV positive and 67 sero-negative pregnant women.

Findings. Age, gravidity, marital status, weight gain during pregnancy and number of prenatal visits did not differ among groups.

Anal intercourse was significantly more common by sero-positive patients, while there were no differences in oral intercourse with or without ejaculation (26% vs 26%).

Cigarette smoking was significantly more frequent among the HIV positive women (26% vs 26%), as was the relative frequency of sexually transmitted diseases (26% vs 26%). Significantly more sero-positive pregnant women had risk factors for HIV transmission than sero-negative (76% vs 56%). Of those with risk factors, more sero-positive women were sex partners of IV drug users (62% vs 36%).

M.B.P.30 DRUG ABUSE AND PREGNANCY: CONCOMITANT RISK FACTORS FOR HIV INFECTION

WELLS, SARA M., KATZELBAH, K.A. and FINNegan, L.P., THOMAS JEFFERSON UNIVERSITY, PHILADELPHIA, PENNSYLVANIA, U.S.A.

Women who are intravenous drug users or who are partners of intravenous drug users engage in behaviors that put them at high risk for developing human immunodeficiency virus infection. When the woman is pregnant, there is the additional problem of perinatal transmission to her unborn child. Data which included sociodemographic and psychological profiles as well as sexual and drug use habits was collected on 90 drug dependent pregnant women enrolled in a comprehensive treatment program in a study aimed at reducing HIV infection among IV drug abusing women and accordingly the perinatal transmission of AIDS. All the clients consented to confidential ELISA tests on initial evaluation and every 3 months while pregnant. Psychosocial profiles revealed that 52% had been subjected to physical or sexual abuse; 11% were homeless; and 46% were adult children of alcoholics or children of substance abusers. Drug histories showed that these women were addicted an average of 10 years; 62.5% were polydrug abusers and 35% used cocaine alone; 39% of the women are current IV drug users. Of these 90 women studied, 4.5% came into the project HIV positive, but without symptoms of HIV infection. None of the other 95.5% who tested negative to the extent seroconverted while participating in the project. As a result of this project, it is apparent that counseling women with regard to those specific risk factors must continue to reduce the incidence of perinatal HIV infection.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.37 AZT'S EFFECT ON RESPONSES TO PNEUMOCOCCAL VACCINE (PV).
Glasgow, Richard D.V., Weller, S. and Schiffman, G. C.
NYC Health 18th Hospital, St. Vi., *SUNY-Health Science
Center, Brooklyn, NY, USA.

Objective: To evaluate AZT's effect on PV-induced antibody (Ab) responses in patients (pts) who are treated with AZT. **Methods:** PV was administered to 48 pts who were treated with AZT. Ab titers to 12 P capsular antigens were measured by RIA for all pts pre- and 30 days post-PV and for certain AZT pts prior to AZT institution (10 pts) and/or 8 mos post-PV (13 pts). **Results:** Aggregate Geometric Mean Ab Titer x Dev. (no Ab/ml)

Group	Pre-PV	30-day Post-PV	8 mos Post-PV
No AZT	7007 ± 2.0	751.8 ± 2.1	594.9 ± 4.7
AZT	564.1 ± 1.3	512.9 ± 1.3	594.9 ± 4.7

Pre-AZT Ab levels (477,241.8) were similar to pre-PV levels (531,362.5) for pts treated with AZT for less than 13 wks (pre-92) pre-PV. "Protective" levels (post/pre ratio > 2.14 Ab. titer > 2000 ng Ab/ml) were achieved for AZT (ratio 1.7) but not the non-AZT group 30 days post-PV. For AZT pts, 30-day post-PV type specific levels were "protective" for types 4, 6, 9, 14, 16, 18, 19F, 23F but not 1, 3, or 12F. "Protective" aggregate levels were present at 3 mos for 6/13 pts (ratio 1.15) but not for the 7 pts dead (564,344.9; ratio 1.0) 14 mos post-PV.

Conclusions: AZT has no effect on Ab levels prior to vaccination. Vaccinated AIDS/AZT pts receiving AZT develop "protective" levels at 30 days, whereas those not receiving AZT do not. Patients with waning of aggregate Ab levels at 8 mos have poor short term survival.

M.B.P.38 Growth of the Cat Scratch Disease Bacillus from Skin Lesions and blood in two HIV positive men.
McE. Ford J. and Oliver J. St. Vincent's Hospital & Med Ctr of New York, U.S.A.

We report 2 patients who presented with fever and disseminated papular and nodular skin lesions within 10 weeks of seropositive serology. One patient also had lymphadenopathy. Both biopsied showed pleomorphic organisms in the Marchini-Scharr silver stain and electron microscopy of one biopsy was positive for coccobacillary forms consistent with the Cat Scratch Disease bacillus (CSD).

Morphologically, the lesions presented a pattern which resembled that of a pyogenic granuloma with anastomosing vessels and an acute inflammatory infiltrate. On occasion, a definite vitreous component was also noted. No evidence of Kaposi's sarcoma was noted. Culture of the skin lesions in both patients yielded gram negative pleomorphic organisms in Bacteroides Brest Infusion medium grown at 30°C in 2 weeks. Blood culture from one patient yielded identical organisms in Bacteroides Brest culture at 30°C. The medium incubated at 30°C which showed a negative growth curve of 30. The asexual viable showed a negative reading after 4 months. Bacteriologic therapy led to improvement in one patient and clearing of all lesions in the second patient.

We recommend that the microbiological work-up of HIV positive patients with disseminated skin lesions should include special stains and cultures for the CSD bacillus.

M.B.P.39 EMPIRIC ANTIHISTOXYTIC OF FEBRILE EPISODES IN HIV CARRIERS
Mazzoni, Emanoel J., Basso, S. and Kawanishi, C. C.
Infectious Unit MARSELLA FRANCE.

Objective: to test the efficacy of an empiric Antihistoxycy in HIV infected to cure bacterial infections of febrile episodes before an opportunistic infection is documented.

Methods: in a series of 40 febrile episodes (temperature > 38.5 more of 48 hours) without any clinical sign of opportunistic infection and before bacteriological results is obtained we used 2 case days of therapy in a randomized study: Arm A: PEFLOXACIN 400 mg b.i.d. plus TORBAMYCIN 3.5 mg/kg/12h. Arm B: CEFALOTIN 1g/12h plus TORBAMYCIN 3.5mg/kg/12h. If an opportunistic infection occurs: the study is stopped. All patients were infected with HIV 1, group III and IV of CDC's.

Results: At the onset, 36 episodes were available; in 28 cases fever was sensible to antibiotic and bacterial infection was documented in 9 cases bacterial infection was highly probable in 10 cases; opportunistic fungal systemic infection was associated in 8 cases; AMPHOTERICIN B is added to antibiotics to obtain a pyrexia. Failure was observed in 8 cases; in those cases an opportunistic infection was documented several days after therapy. No difference is observed between arm A or B.

Conclusion: an empiric antibiotic combination therapy seems to be effective to treat febrile episodes in HIV carriers. In most of our documented bacterial infections, such combination as PEFLOXACIN or CEFALOTIN plus TORBAMYCIN is in vitro and in vivo sensible. This empiric strategy can prevent the dissemination of co-infection with bacterial stains frequently isolated in immunocompromised hosts especially in intravenous drug addicts (32/60 in this series).

M.B.P.40 COMPARATIVE STUDY OF CLINICAL AND PATHOLOGICAL

DIAGNOSIS IN 35 PATIENTS WITH AIDS
Del Bianco, R.; Sullemann, J.; Araujo, M.F.; Prado, P.;
Carvalho, D.; Mesella, R.L.; et al.
Hospital Infância Ribalda
Centro de Referência e Tratamento-Aids, Sao Paulo, Brazil.

Objective: Analysis of the clinical and laboratory diagnosis comparing to the pathological findings.

Methods: 35 patients were studied: 25 (71.4%) homosexual men, 4 bisexual, 1 isosexual, 1 heterosexual, 2 drug addicted, 1 recipient of blood transfusion and 1 child of antibody positive mother (8.6%). All the patients had evidences of immunologic deficiencies and serologic tests positive (Eliass and Western Blott).

Results: The average days of permanence of these patients in the hospital were 35.3 days. Many opportunistic infection were recognized clinically: M. Tuberculosis in 12 patients (34.2%), P. Carinii in 9 (25.7%), gondii in 4 (11.4%), herpes simplex in 3 (8.5%) and C. neoformans in 3 (8.5%). In the pathological exam the M. Tuberculosis were found in 10 patients (28.5%), M. avium in 3 (8.5%), T. gondii in 4 (11.4%), C. neoformans in 3 (8.5%) and CMV in 11 (31.4%). **Conclusion:** M. Tuberculosis is often found in these patients determined by clinical laboratory and pathological findings.

M.B.P.41 APPORT DE LA TOMODENSITOMETRIE AU DIAGNOSTIC DES COMPLICATIONS PULMONAIRES DU SIDA DE L'ADULTE.
Trotot, P. N., Barrois -Francia, E., Mariches, M. M., Levillain, R.,
Etiennet, Pasteur; AHPH, Saint-Joseph, Paris, France.

Objective: évaluer l'apport de la Tomodensitométrie (TDM) au diagnostic précoce et au suivi des atteintes pulmonaires au cours du SIDA de l'adulte.

Méthodes: rapport de cas dossier de 300 derniers patients hospitalisés. Parmi ceux qui présentaient des complications pulmonaires, déterminées par la TDM, 127 ont été étudiés. **Résultats:** dans les atteintes au foyer, la TDM met le plus souvent d'aucun apport supplémentaire par rapport au simple cliché pulmonaire.

Par contre dans les atteintes diffuses elle peut être déterminante en reconnaissant l'infiltrat alvéolaire et de la pneumocystose et son évolution éventuelle vers l'effusion centrolobulaire périphérique conglomérée. L'alvéolite oedémateuse alvéolaire, la miliaire tuberculeuse interstitielle, ou les nodules disséminés du sarcose de Kaposi.

Conclusion: le caractère traumatique et la précision anatomique de la TDM méritent que dans les atteintes au SIDA, avant le lavage alvéolaire, ou tout au plus possible, un élément essentiel du diagnostic et du suivi thérapeutique.

M.B.P.42 EVOLUTION OF LUNG HIV-SPECIFIC CTL ACTIVITY AND CLINICAL CORRELATIONS. GUILLET, P., *PASTEUR ST. JOSEPH, PLATA, FERRER ET NYARD C. et al. Lab. Immun., Hôp. Fils-St-Joseph, Paris

OBJECTIVE: We previously described lung HIV-specific class-I-restricted CTL activity in patients at early stages of HIV disease. In this study, we prospectively evaluate the level of anti-HIV CTL activity during the course of the disease. 2) we analyze both consequences on lung function and its clinical relevance.

METHODS: A cohort of 81 HIV-positive patients was evaluated with long-term follow-up studies for 17 of them. The specific cytolytic function of lung lymphocytes was tested on autologous alveolar macrophages and cell lines expressing HIV proteins. The lung function was simultaneously evaluated.

RESULTS: The intensity of alveolar CTL lysis specific for HIV was markedly reduced in AHC and AIDS patients when compared with healthy seropositive carriers and patients with the lymphadenopathy syndrome (p < 0.01), although a weak activity could still be detected in a few AIDS patients. In sequentially studied patients, we observed a progressive decline in CTL activity as the clinical status deteriorated. In another hand, in those patients with significant CTL activity, some respiratory disorders could be defined including worse cough, interstitial pneumonitis and abnormalities of gas exchange. An improvement of lung function was paradoxically observed in some patients several months before the onset of opportunistic lung infection, as a parallel with the disappearance of CTL activity.

CONCLUSIONS: Our data strongly suggest a protective role for HIV-specific CTL. Although they can be deleterious to the function of the lungs.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.43 THE VALUE OF GALLIUM-67 SCAN IN THE DIAGNOSIS OF LYMPHADENOPATHY IN SEROPOSITIVE HIV-INFECTED PATIENTS.
Podanasser-Daniel; Ricart, J.; Bolea-F., Bonin-B., Romagos, V.; Godia-F., Hospital de Bellvitge, University of Barcelona, Barcelona, Spain.

Objective: To study the utility of chest gallium-67 citrate scan (GCS) in the differential diagnosis of enlarged lymph nodes in HIV-infected pts with constitutional symptoms.

Patients and methods: Nineteen HIV-positive pts (15 drug addicts and 4 non-smokers) with fever and/or weight loss and localized or generalized lymphadenopathy were evaluated with chest GCS. A positive GCS was considered when an increased focal uptake in cervical, axillary and/or supraclavicular nodal areas was observed. Subsequently, a lymph node biopsy was done in all pts. Results: In 9 pts GCS displayed an increase uptake in one or more nodal areas. One of them had follicular hyperplasia while in the other 8 biopsies showed angioimmunohyocytocytosis (7 M. tuberculosis and 1 non-specified atypical mycobacterium). Five of them had also mediastinal uptake. Two pts showed negative GCS. Biopsies showed follicular hyperplasia in 9 and Kaposi's sarcoma in 2 of the remainder.

Conclusion: This preliminary study suggests that in HIV-infected pts with constitutional symptoms and lymphadenopathy, a negative GCS probably represents follicular hyperplasia. In this setting, a surgical approach to the enlarged nodes suggests Kaposi's sarcoma is suspected. Conversely, a positive GCS strongly suggests a mycobacterial infection.

M.B.P.44 IMMUNOPHENOTYPY AND SERUM IMMUNOGLOBULIN (SIV) IN HIV INFECTION IN ADOLESCENTS.

Podanasser-Daniel; Ricart, J.; Bolea-F., Bonin-B., Romagos, V.; Godia-F., Hospital de Bellvitge, University of Barcelona, Barcelona, Spain.

Objective: To analyze the lymph node histopathologic changes in patients with HIV infection, and the clinical and epidemiological characteristics. In 20 patients.

Methods: The study group included 21: 3 patients with HIV infection (seropositive and seronegative), 18 patients with HIV infection (seropositive and seronegative). Histopathologic findings were determined in one or more nodal areas. Results: In 10 pts GCS displayed an increase uptake in one or more nodal areas. One of them had follicular hyperplasia while in the other 8 biopsies showed angioimmunohyocytocytosis (7 M. tuberculosis and 1 non-specified atypical mycobacterium). Five of them had also mediastinal uptake. Two pts showed negative GCS. Biopsies showed follicular hyperplasia in 9 and Kaposi's sarcoma in 2 of the remainder.

Results: Lymph node were made. The most frequent lymphadenopathy in HIV infection was made in 10 patients and determined 49 times (26 patients). The histopathologic findings are shown in the following table:

Diagnosis	Number	Sex	Percentage
Mycobacterial infection	11	24.0	** In some cases the diagnosis was confirmed by culture
Follicular hyperplasia	9	19.0	
Kaposi's sarcoma	2	4.0	
Angioimmunohyocytocytosis	1	2.0	
Non-specified atypical	2	4.0	
Unchanged	7	15.0	

J. tuberculosis was identified in 14 (76.3%) of 18 cases of mycobacterial infection. Within the pattern of histopathologic appearance, 10 patients with HIV infection were classified in group A GCS and 10 in group B. The most frequent lymphadenopathy in HIV infection was made in 10 patients. The histopathologic findings are shown in the following table:

Diagnosis	Number	Sex	Percentage
Mycobacterial infection	11	24.0	** In some cases the diagnosis was confirmed by culture
Follicular hyperplasia	9	19.0	
Kaposi's sarcoma	2	4.0	
Angioimmunohyocytocytosis	1	2.0	
Non-specified atypical	2	4.0	
Unchanged	7	15.0	

Conclusion: There is the most frequent lymph node infection in patients with HIV infection. The most frequent lymphadenopathy in HIV infection was made in 10 patients. The histopathologic findings are shown in the following table:

M.B.P.45 SEROPOSITIVE DISSEMINATED COCCIDIOIDOMYCOSIS IN PATIENTS WITH HIV INFECTION.

Amalita, Riana, Barlow, M., Aull, S., Larson, B., Leeson, Jr., Los Angeles County/University of Southern California Medical Center, Los Angeles, California, U.S.A.

Objective: Serologic testing for complement fixing (CF) antibodies to *Coccidioides immitis* is commonly employed to assist in the diagnosis and management of patients infected with this fungus. CF reactions in patients with concurrent HIV infection and disease due to disseminated *C. immitis* are assumed to be false-negative antibody responses.

Methods: After noting a case of disseminated *C. immitis* with negative CF reactions, we reviewed our experience in patients with both HIV and disseminated *C. immitis* infection with this fungus. CF reactions in patients with concurrent HIV infection and disease due to disseminated *C. immitis* were reviewed for false-negative antibody responses.

Results: Disseminated *C. immitis* and HIV infection were found in 11 patients; 8 had CF antibody titers performed. CF antibodies were detected in 6 of 8 serum samples (in a range of 1:16 to 1:256). Six patients also had serological testing of CF antibody response. Six patients (range 1:1 to 1:16). Two patients had persistently negative CF antibody tests.

Conclusions: Serologic testing for *C. immitis* CF antibodies may be negative in 25% of patients with disseminated disease when there is concurrent HIV infection. Histopathology and culture remain the most reliable method for the diagnosis of disseminated coccidioidomycosis.

M.B.P.46 COCCIDIOIDOMYCOSIS AMONG PATIENTS INFECTED WITH HIV. A PROSPECTIVE EPIDEMIOLOGIC STUDY.

Amel, Emil B.; Deitz, C.; Geligian, J.M., Tucson Veterans Administration Medical Center, University of Arizona, Tucson, Arizona, U.S.A.

Objective: To prospectively follow HIV-infected individuals for the development of coccidioidomycosis in an area endemic for *Coccidioides immitis* in order to determine risk factors associated with acquisition of this fungus. Infection.

Methods: Patients infected with HIV and living in Tucson, AZ have been followed since May 1988. Clinical evaluation and laboratory tests, including T4 lymphocyte count, coccidioidal skin-tests and lymphocyte transformation assays were performed on entry and every 4 months thereafter.

Results: A total of 50 individuals have been entered. 57 are men, 47 are white; mean age = 37 yr; mean T4 = 438. Since the study began, 3 patients have developed active coccidioidomycosis. Using clinical, epidemiological and immunologic data, analysis of the 50 individuals without active coccidioidomycosis revealed that 8 have clear evidence of prior coccidioidal infection, 14 have no evidence of prior coccidioidomycosis, and 8 are too immunologically compromised to make that determination. For the remaining 25, data is incomplete; hence, 11 of 28 individuals so far evaluated either have active coccidioidomycosis or evidence of prior infection.

Conclusion: These preliminary data from a prospective study indicate that coccidioidomycosis represents a major infection among HIV-infected individuals living in an area endemic for *C. immitis*. Further study will be required to determine whether active coccidioidomycosis in this cohort is due principally to reactivation or acute acquisition of infection.

M.B.P.47 SUCCESSFUL TREATMENT OF ACYCLOVIR-RESISTANT HERPES SIMPLEX II WITH FOSFANET (A HERPES WITH AIDS)

D. Shaw, J. Buller, E. B. Blair, S. A. Hopkins, M., St. Louis, MO, U.S.A.
* Section of Neurovirology, Division of Infectious Disease, Cook County Hospital, ** Division of Virology, Department of Laboratory Medicine, Hahnemann University, *** Burroughs-Wellcome, Co., Chignov, MA, U.S.A.

Objective: Investigation of fosfarnet as an alternative treatment of acyclovir-resistant herpes in the HIV infected patient.

Methods: A 38 y.o. black man with HIV positivity for 3 months and CD4 T4 cells decreased with AIDS had severe subconjunctival, perioral, and perioral HSV II infection in November, 1989. He had lesions extending from the nose superior to the perioral area. There was no response to intravenous acyclovir 10 mg/kg TID and acyclovir for 14 days. The addition of ribavirin produced no additional benefit. A trial of foscarnet was discontinued after 5 days due to severe neutropenia and thrombocytopenia. AT and acyclovir at 20 mg/kg/day were resumed, with serum levels of 48 µg/ml (peak) and 20 µg/ml (trough), and no response was observed. HSV sensitivity to a drug-acyclovir, AM-4, a fosfarnet - treated by automated colorimetric analysis are shown in table 1:

Drug	IC ₅₀ (µg/ml)
Acyclovir	10 ^{-4.8}
Fosfarnet	10 ^{-4.4}
AM-4	10 ^{-4.4}
Fosfarnet	10 ^{-4.4}

Fosfarnet was begun at 20mg/kg TID, the serum creatinine was 2.0 mg/dl.
Conclusion: Symptomatic herpetic conjunctivitis, and there was complete healing after 3 weeks. No residual or relapse has been observed. The patient is currently stable on AT.
Conclusions: Fosfarnet is an effective alternative therapy for acyclovir-resistant (RI) deficient or R2 mutant acyclovir-resistant herpes simplex virus II in persons with AIDS. Early diagnosis by culture and sensitivity is essential. Further clinical trials of fosfarnet are warranted.

M.B.P.48 FOSFARNET TREATMENT OF ACYCLOVIR (ACV)-RESISTANT HERPES SIMPLEX VIREMIA (HSV) INFECTION IN AN AIDS PATIENT.

Shaw, S.F., Amey, C., Pollock, J. Mills, St. Louis, MO, U.S.A.
* Section of Neurovirology, Division of Infectious Disease, Cook County Hospital, ** Institute for HIV Research, Division Medical Center, Co. and *** Area Clinical Research Associates, Hopkinsville, MA, U.S.A.

Objective: To assess the efficacy of intravenous fosfarnet for treatment of acyclovir-resistant herpes in the HIV infected patient.

Methods: Data was obtained prospectively and retrospectively from the charts of 26 patients in the U.S. receiving fosfarnet for herpes infection for ACV-resistant HSV. Results: Twenty-six patients had 34 episodes of acute/recurrent HSV (25 percent, 7 orofacial, 1 genital, 1 whitish) that progressed despite therapy with intravenous (19 patients) and high-dose oral (7 patients) ACV, vidarabine (15 patients) or ganciclovir (3 patients). All initial lesions were susceptible in vitro to fosfarnet and resistant to ACV. Patients received fosfarnet for 10-63 days (mean 18.2). Twenty-two patients responded dramatically with re-epithelialization of lesions; one patient failed to demonstrate clinical improvement. All thirteen patients who were re-treated during therapy with fosfarnet had cessation of viral shedding, one as early as day 3. In three patients, therapy was discontinued due to adverse effects (2 leukopenia, 1 anorexia), and 1 patient died of unrelated causes after 2 days of therapy. Fourteen patients had recurrences of HSV at an interval ranging from 2 to 8 months after therapy. Eight were re-treated successfully with fosfarnet, 3 with ACV, and 3 have not yet been re-treated. Eight patients have received maintenance therapy with fosfarnet.

Conclusions: Fosfarnet is an effective and relatively non-toxic agent for therapy of acyclovir-resistant HSV in AIDS patients. Based on the limited experience in this series of 26 patients, vidarabine is less effective than fosfarnet in treating ACV-resistant infection. Recurrence of herpetic lesions is common after discontinuation of antiviral therapy.

Aspects Cliniques Clinical Aspects of AIDS

M.B.P.40 SUCCESSFUL THERAPY OF PROGRESSIVE ACYCLOVIR-RESISTANT ORAL-FACIAL HERPES SIMPLEX WITH INTRAVENOUS FOSCAMNET IN AN AIDS PATIENT

Sill, Richard K., Kaufman K., and Levy CS.

Washington Hospital Center and George Washington University Medical Center, Washington, D.C., U.S.A.

Objective: To determine the clinical efficacy of intermittently administered intravenous foscamnet in the treatment of progressive acyclovir-resistant herpes simplex virus infection.

Method: A 31-year-old homosexual white male with a history of AIDS post-pneumocystis pneumonia developed a type 2 herpetic lesion on his left upper lip. The lesion resolved initially with oral acyclovir but recurred several months later and progressed to involve the majority of the patient's face despite multiple courses of oral and intravenous acyclovir. Antiviral susceptibility tests were obtained for this isolate.

Results: Using a VERO tissue culture and plaque reduction assay, the virus was shown to be resistant to acyclovir *in-vitro*, but susceptible to vidarabine and foscamnet. Despite two weeks of intravenous vidarabine the lesion failed to respond. Therapy was changed to intravenous foscamnet (10 mg/kg every eight hours). After a three week course of treatment the lesion had completely re-epithelialized except for a peripheral crust. However, the lesion re-occurred once foscamnet was discontinued and herpes simplex was again cultured.

Conclusion: Intravenous foscamnet has efficacy in the treatment of clinically significant acyclovir-resistant herpes simplex infection, but chronic suppressive therapy may be required.

M.B.P.50 ULCERATIVE HERPES SIMPLEX (UHS) IN AIDS PATIENTS.

Cernantini, Guido, Gerboni, S., Meoni, N., Osuni, M., Muratori, S. and Alessi, I.

1st Clinic of Dermatology, University of Milan, Milan, Italy.

Objective: To define the diagnostic procedures, to evaluate the response to therapy and to assess the course and final outcome of 8 HIV positive patients with UHS of the anogenital area.

Methods: Tzanck's smear, histology, electron microscopy, cultures and immunocytochemical methods for HSV antigen were used to confirm the clinical diagnosis. ACV therapy was done. The patients were followed for herpetic recurrences, other AIDS manifestations and immunological parameters up to 20 months. At enrollment, Tzanck's smears were found positive in 8 patients, HSV type 2 was demonstrated in 7, a profound immunosuppression and concurrent opportunistic infections were present in 7. Acyclovir was healed the lesions in all patients, but one or more recurrences were observed in 6. The new herpetic episodes were ACV sensitive in 5 patients, while in 3 *in vivo* and *in vitro* resistant HSV type 2 strain was isolated in one patient. This patient was successfully treated by Foscamnet. During the follow up, 7 patients developed other major AIDS infections and 3 patients died.

Conclusion: Several methods are necessary to diagnose UHS. ACV therapy is usually effective. The survival time of patients with UHS seems longer than that of patients with other major opportunistic infections.

M.B.P.51 SUCCESSFUL TREATMENT OF SEVERE, ACYCLOVIR-RESISTANT HERPES SIMPLEX VIRUS TYPE 1 PROCTITIS IN TWO PATIENTS WITH AIDS: USE OF GANCICLOVIR

Reed, M.D., England, J.M., and Fletcher, C.M.

East Carolina University, Erie, Pennsylvania, North Carolina, USA; *Mayo Clinic, Rochester, Minnesota, Boston, Mass, USA; **University of Minnesota College of Pharmacy, Minneapolis, Minnesota, Minn.

Objective: To report on the efficacy and safety of continuous intravenous acyclovir (ACV) for the treatment of severe, ulceroactive proctitis caused by ACV-resistant herpes simplex virus (HSV) type 1 in two patients with AIDS.

Methods: Two patients were obtained on octane lipid media, inoculated onto tissue culture, and observed for cytopathic effect optimal for HSV. HSV isolates were typed with restriction endonuclease digestion. ACV plasma levels were measured by RIA. HSV sensitivity to ACV were determined by measuring viral growth by quantitating viral DNA with an HSV specific radiolabeled probe in the presence of varying concentrations of ACV. Results are expressed as an ID₅₀.

Results: Both patients developed severe ulceroactive proctitis from HSV type 1 with prolonged despite prolonged courses of oral ACV followed by 3 weeks of intravenous ACV administered at 10mg/kg every 8 hours. Both patients' isolate developed ACV resistance with ID₅₀ values of 100 units (normal for HSV type 1 is 1 unit). Continuous infusion ACV was administered at 14.4-0 mg/kg/hr via infusion catheters to maintain ACV levels in plasma between 20 and 30 µg/ml. Within a week of this therapy, the patients' stool improvement in their proctitis and by the sixth week had total healing of their lesions. Serum creatinine levels remained normal. The continuous infusion was accomplished in an outpatient setting with weekly visits and ACV and creatinine determinations.

Conclusion: Continuous infusion ACV was effective and safe in treating severe HSV-induced proctitis in two patients with AIDS despite the development of high level resistance to ACV and previous failure with ACV administered in divided doses.

M.B.P.52 ACICLOVIR THERAPY OF ACUTE RETINAL NEURITIS SYNDROME (ARN) IN AIDS PATIENTS

Fraclasca, Patricia

Augenklinik am Krankenhaus Harlaching, Munich, FRG.

Objective: To prove whether Aciclovir long term therapy is necessary to prevent relapses of Acute Retinal Neovitis Syndrome (ARN) caused by Herpes simplex Virus (HSV) or Varicella Zoster Virus (VZV) as opportunistic ocular infection.

Methods: Retrospective report on 4 patients with ARN. 3 had got ACICLOVIR therapy for extracocular herpetic infections over a limited period before, one received ACICLOVIR initially for treatment of ARN and HSV encephalitis (1500 mg/d intravenously), followed by long term therapy (100 mg/d per os) over a 8 months follow up period.

Results: In the 3 cases with extracocular diseases ARN occurred several weeks after suspension of ACICLOVIR therapy causing rapid visual damage. In one case initial ACICLOVIR therapy provided resolving of ARN and cerebral symptoms, maintenance therapy has prevented relapses for 7 months.

Conclusion: ARN should be an indication for long term therapy with Aciclovir to prevent blindness in AIDS patients.

M.B.P.53 HIV, HUMAN PAPILLOMAVIRUS, AND CERVICAL DYSPLASIA IN MAIROSI PROSTITUTES

Epstein, R.I., Kiviat, S., Plummer, R., Nandi, E., Wasyk, P., Holmes, K., University of Washington, Seattle, WA; *University of Montreal, Montreal, QC, Canada; **National Cancer Institute, Bethesda, Maryland, USA.

To determine whether HIV infection in women is associated with an increased frequency of human papilloma virus (HPV) infection or cervical dysplasia, we studied 145 Maïrosi prostitutes. Cervical smears were obtained for cytology and HPV detection by dot filter hybridization (ViraPap).

Results: The mean age of the study population was 36 years. The average number of sex partners per week was 4.6; 63% of women were seropositive for HIV, of whom 76% had generalized lymphadenopathy; none had overt AIDS. Thirty-two (24%) of 138 women had cervical HPV infection. Including 21% of HIV positive and 13% of HIV negative women. Five (14%) HPV types were 16/18, 14 (44%) were 31/33/35, and 13 (41%) were other. No association was noted between HPV infection and age, number of sex partners, use of spermicides or hormonal contraception, or lymphadenopathy. Of 125 cervical cytologic examinations, 2 (2%) showed cervical intraepithelial neoplasia (CIN). 13 (12%) showed atypia, and 108 (88%) were normal. Only 1 (4%) of the women with HPV had CIN.

Conclusion: Prostitutes in Maïrosi have a high prevalence of HPV infection but no association between HIV and HPV was observed. Cervical dysplasia was present in only 2% of HIV seropositive women. This cohort will help to determine whether the natural history of HPV infection and the risk of HPV-associated cervical dysplasia is affected by concurrent HIV infection.

M.B.P.54 PREVALENCE AND RISK FACTORS FOR HIV-1 INFECTION IN PATIENTS WITH ACUTE PELVIC INFLAMMATORY DISEASE (PID)

Sharon Safiro, BJ Daniel, BL Hauser, R Edson, W Crombholme, RL Sweet, et al; University of California, San Francisco, SF General Hospital, USA.

Objective: To examine temporal trends and risk factors for HIV-1 seropositivity in a population of women admitted with the diagnosis of acute PID.

Methods: This is an extension of our continuing retrospective analysis of stored sera from women admitted to an urban county hospital with acute PID. Sera from the years 1985-1988 were anonymously tested for antibody to HIV-1; demographic data and 15 separate risk factors were extracted by blinded chart review. In January 1989, we initiated a prospective study utilizing anonymous seroprevalence testing for HIV-1 and coded risk factor questionnaires; we will report on this data as well.

Number	% HIV seropositive	HIV seropositivity
1983	0/36	0
1986	2/63	3.2
1987	4/95	4.2
1988	8/119	6.7

Of the risk factors, intravenous drug use correlated significantly with HIV-1 seropositivity (OR = 23.2, 95% CI = 5.0 - 106.9). Among other risk factors, type of drug used, number of sexual partners, and previous history of sexually transmitted diseases did not correlate.

Conclusions: Overall seroprevalence of HIV-1 was 4.2% (95% CI = 2.4% - 6.4%) in women admitted for acute PID in 1985-1988, and increased from 0 to 6.7% during this time period. This is contrasted with a seroprevalence of 0.9% in 1148 obstetric patients at San Francisco General Hospital; risk factor analysis will attempt to discern differential risk factors in these populations.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.55 DIAGNOSTIC ET TRAITEMENT DES LÉSIONS CERVICO-VAGINALES ET VULVAIRES À PAPILLOMAVIRUS CHEZ LES FEMMES SÉRO-POSITIVES POUR LE VIRUS VIH.

Caubet, Patrick; Foulques, M.; Blondon, J.; Lefranc, J.P. Hôpital de la Salpêtrière, Paris, France.

Objectif: Décrire, à partir de l'observation de 29 patientes (âge moyen: 37 ans) séro-positives pour le virus VIH (75,5 % à contamination par toxicomanie intra-veineuse), les principaux caractères épidémiologiques, diagnostiques et pronostiques des lésions cervico-vaginales et vulvaires dues à une infection à papillomavirus (HPV).

Méthodes: Les lésions dépistées par l'examen coloscopique ou cytologique et confirmées histologiquement furent ensuite détruites par vaporisation au laser CO₂.

Résultats: 58,6 % des frottis cervico-vaginaux révélèrent une infection à HPV, et chez 6 patientes l'histologie cervicale a retrouvé des anomalies allant de la dysplasie légère (2 cas) ou modérée (3 cas) au carcinome invasif (1 cas). 38 % des patientes présentaient des lésions vulvaires à HPV associées. Après destruction au laser (13 patientes) le taux de récurrences est de 23 % (recu moyen de 11,2 mois).

Conclusion: La fréquence élevée des lésions génitales et papillomavirus chez les patientes infectées par le VIH rend nécessaire leur dépistage coloscopique et cytologique afin d'assurer leur éradication avant ou au début de leur évolution vers la dysplasie.

M.B.P.56

Human immunodeficiency virus and human papilloma virus in the cervical intraepithelial neoplasia (CIN) in development of past intravenous drug abusers (PVIDA) women.

Maria Luisa Muzylas, E. Conti*, L. Nevasi, D. Imperiale, A. Agorosi, M. Conti VII and IV* Department of Obstetrics and Gynecology, University of Milan, Italy

Objective: To investigate a possible association between HIV and HPV infections in the development of CIN.

Methods: 209 PVIDA (101 HIV pos, mean age 25.2 yrs, S.D.±3.9; 108 HIV-, mean age 25.8 yrs, S.D.±4.6) women, residing in a rehabilitation community where investigated by cervical cytology, colposcopy and by compositically directed biopsy. Statistical significance was evaluated by chi square analysis and by Fischer's exact test.

Results: CIN was found in 18 HIV pos (17.8%), and in 7 HIV neg (6.5%). CIN + HPV (Pap smear + histological examination) were found in 13 HIV pos. (12.9%) and in 4 HIV neg (3.7%).

HPV (Pap smear + histological examination) was found in 25 HIV pos (24.7%) and in 7 HIV neg (6.5%).

CIN is more frequently observed in HIV pos than HIV- women (P<.05) and control group (1534 university students, CIN 1.1%, P<.0001). Association between HPV and CIN is significantly greater in HIV pos (P<.05). Cytological and histological evidence of HPV infection are more frequent in HIV pos (P<.01).

M.B.P.57 GENITAL ULCERS (GU) AND HIV INFECTION IN AN URBAN SEXUALLY TRANSMITTED DISEASE (STD) CLINIC

Chirshin, Reilly; Dillon, S.; Delaviz, J.; Landerman, SH;

McConeck, W. SUNY Health Science Center at Brooklyn, New York.

Objective: To investigate the association of genital ulcers (GU) and HIV infection in persons attending an STD clinic in Brooklyn.

Methods: Beginning 10/88, our STD clinic pts were routinely offered HIV testing. HIV risk factors were assessed by interview at the time of testing. Clinic records were available for 213 pts who underwent HIV testing and were retrospectively reviewed to determine STD diagnoses.

Results: 16/73 (22%) of STD clinic pts tested were HIV+. GU were present in 8/16 (50%) HIV+ pts compared with 12/57 (21%) HIV- pts (OR=3.75, p<.03).

This trend increased when those with admitted HIV risk factors (H=5) (IVDU, homosexual, sexual partner with AIDS) were excluded (OR=5.6, p<.02). 7/8 HIV+ pts with GU were women and 5/7 of these women had no admitted HIV risk factors.

The etiologies of GU in HIV+ pts were: 3 herpes simplex, 1 syphilis. In the remaining 4 were not diagnosed definitively. Only one HIV+ pt admitted a history of previous GU. 5/16 (31%) HIV+ pts had >1 concurrent STD's diagnosed at presentation compared with 7/57 (12%) HIV- pts (NS).

Conclusion: We have noted an increasing incidence of GU disease in our STD clinic during the last 2 years. These data suggest that GU may be associated with HIV infection. As these pts were HIV seropositive at presentation, it is likely that acquisition of HIV infection either antedated or was coincident with their GU disease. The former possibility suggests an increased risk of GU disease in persons already HIV+, the latter suggests an increased rate of HIV transmission from sexual partners with GU disease.

M.B.P.58

THE RISK OF PROGRESSION OF CERVICAL DYSPLASIA IN WOMEN WITH HIV

Bradbeer C.S, Heyderman E. St. Thomas' Hospital, London, UK.

Objective: To assess the prevalence and the risk of progression of cervical dysplasia (CIN) in women with HIV.

Methods: Ten unselected women with HIV were prospectively investigated for CIN over a mean of 26 months (range 5-6).

Results: Seven have shown evidence of progression or development of CIN over the study period, no spontaneous regression was noted. Of the five who required ablative therapy, three developed recurrence of CIN after treatment. A high incidence of infection with the genital wart virus was also noted. Results for a larger number of subjects will be presented.

Conclusion: These results have implications for the provision of colposcopic services and treatment facilities as part of the management of HIV in women.

M.B.P.59 CERVICAL INTRAEPITHELIAL NEOPLASIA IN HIV INFECTED WOMEN

Solo, Diana; Frenedra, A.; Rubio, F.; Latorre, A. and Abad S. C.P.S. Centro. Madrid Council, Madrid, Spain

Objective: We have previously described a high incidence of genital infection, cervical intraepithelial neoplasia (CIN) and also carcinoma of the cervix in HIV infected women. The aim of this paper is to compare the incidence of genital infection and CIN in three different groups, to clarify the relationship between HIV infection and CIN.

Methods: Three groups were compared: Group I, HIV infected women (IVDU and women infected by heterosexual transmission); Group II, control group (seronegative women with similar characteristics to group I) and Group III, prostitutes (prostitutes who were not IVDU and were seronegative).

Vaginal smear, colposcopy and microbiological study were done in all the cases. In cases of abnormal smear or colposcopy, cervical biopsy was done.

Results: Five out of ten women in group I, one out of ten women in group II and two of 23 women in group III were found to have a CIN.

	I HIV (N=10)	II CONTROL (N = 10)	III PROSTITUTES (N=23)
CIN	5	1	2
Normal findings	5	9	21

Conclusions: No statistical differences $\chi^2 = 2.14$ (p 0.5) could be demonstrated between the HIV infected group and the control group. Significant differences between group I and group II were found ($\chi^2 = 4.85$ p 0.05). No differences were found in the infection rate of the three groups.

More cases and controls are now being enrolled, to clarify the lack of differences in these groups.

M.B.P.60

HIGH RATES OF CERVICAL DYSPLASIA, CERVICAL INTRA-EPITHELIAL NEOPLASIAS (CIN) AND HUMAN PAPILLOMA VIRUS INFECTION IN HIV INFECTED FEMALE PATIENTS

K. F. Hiller, R. Lutz, S. Baur, M. Stauber, University of Munich, I. Women's Hospital, Munich, Federal Republic of Germany.

Objective: To show the important role HIV infection plays in the development of dysplasias of the cervix uteri, cervical intraepithelial neoplasias (CIN), and the close relation to high rates of human papilloma virus infections observed in HIV-infected female patients.

Methods: 38 female patients were examined in regard to their immunologic status. Lymphocyte stimulation tests were performed, cytology of the cervix uteri, colposcopy, human papilloma virus DNA-hybridization by Southern Blot and Viratype testing (GibCO Ltd.) and "open reading frame" protein detection tests were performed. In some cases histological evaluations of CINs are available.

Results: More than 15% of female patients in an age group of 20-30 yrs. show cytological signs of cervical dysplasia, approx. 8% show cervical intraepithelial neoplasias (CIN). In more than one-third of all patients we found clinical aspects, cytology or laboratory testing positive for human papilloma virus infection of various types.

However, in two-thirds of patients with signs of dysplasia we found evidence for the presence of human papilloma virus infection. Percentages are even higher in patients during pregnancy (approx. 25% of patients with dysplasia). First results of "open reading frame" protein testing will be presented.

Conclusion: The synergism of HIV infection, subsequent immunosuppression and human papilloma virus infection lead to high rates of dysplasia and cervical intraepithelial neoplasias particularly in pregnancy.

M.B.P.61 INFECTION IN HIV-SERONEGATIVE INDIVIDUALS WITH THE EBNA 20 EPSTEIN-BARR VIRUS SHORTEL: CORRELATION WITH 14 LYMPHOCYTE MARKERS

Baldoni M.C., De G. G., Scudato G., Maglietta C., Andriano A.M.,*
Mazzoni Gian-Marco et al.

*Istituto Oncologico Centro Multiuso Universitario, Cremona;

*Laborio HIV Study Group, Istituto Carcano, Pavia, France.

Objective: EBV is associated with 8 cell lymphomas in HIV-infected individuals.

It is now a well established fact that, in the general population, 2 subtypes of EBV exist, referred to as EBNA 20 and EBNA 21. The aim of this study was to determine the prevalence of infection by the rarer subtype, EBNA 20, in HIV-positive subjects, as well as the intensity of the antibody response, according to the number of circulating T4 lymphocytes.

Methods: EBNA 20 was transfected in Rat 1 epithelial cells. Test sera were titrated by antigen-enzyme/immunofluorescence or by polymerase chain-transfected rat 1 cells (R1). In EBNA 1, EBNA 20 and EBNA 21 transfected cells. A total of 209 HIV-seronegative Caucasian individuals were studied, including 107 subjects with more than 200 T4 cells/mm³ and 102 patients with less than 200.

Results: Data of prevalence and Geometric Mean titres are summarized in the following table:

	VCA	EA	EBNA 20	EBNA 1	EBNA 20	EBNA 20	
> 400 IU	63	79	91	82	83	prevalence	
< 300 IU	53	41	67	77	75	GMT	
< 400 IU	100	71	86	70	71	prevalence	
< 300 IU	46	41	52	36	36	GMT	

Conclusion: Our results suggest that 1) prevalence of, and response to, EBNA 20 subtypes of EBV increases as the number of T4 cells falls, as opposed to those with EBNA 1, and 2) dual infections with both EBNA 20 and EBNA 21 subtypes might exist.

M.B.P.63 EFFECTS OF rHC-CSF ON SECONDARY INFECTIONS IN AIDS

Kishida, Satoshi; Mohri, K.; Sogayama, H.; Nakagawa, A.;
Hikita, Y.; Shimada, E.; Nakamura, T.; Nakamura, T.*

*The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.

Objective: The effects of recombinant human granulocyte-colony stimulating factor (rHC-CSF) on secondary infections in AIDS patients were evaluated. **Patients and Methods:** Four consecutive AIDS patients (hemophiliacs) with various infections and leukocytopenia were treated with intravenous rHC-CSF. Patients' profiles are summarized in Table 1. The rHC-CSF was donated by KIRIN Brewery Co., Ltd. (Tokyo, Japan). **Results:** In cases 1, 2, and 4, the number of CD4 increased three to seven folds, and current infections were controlled by the administration of 0.1 µg/kg rHC-CSF. In case 3, however, rHC-CSF (0.1 - 0.2 µg/kg) showed only a little effect. This may be due to simultaneous administration of acyclovir and ara-A. No adverse effect was observed in any of these patients. The number of CD4⁺ cells and the levels of p24 antigen did not change during the course of the treatment.

Table 1. Background of Patients in This Study

Case	Age	Sex	Indicator disease	Current infection	Pathogens
1	31	M	Cryptosporidiosis	recurrence of CM	C. meformans
2	30	M	PC pneumonia	TM, septicemia	St. epider., Klebsiella
3	41	M	Candida esophagitis	SE, Mycobact.infer.	VCM, Mycobact.
4	37	M	PC pneumonia	abscess	St.aureus

Conclusion: In AIDS patients, rHC-CSF was very effective in the treatment of bacterial and fungal infections unless other agents suppressing the bone marrow are not used simultaneously with it.

M.B.P.65 INCREASE OF FACTOR VIII ACTIVITY IN HIV INFECTED PATIENTS.

Garza, Sergio,* Rivas, P.,* Arciles, A.,** Vessari, P.,* and Torres, A.*

*Laboratorio de Diagnóstico y Referencia Epidemiológicos, Secretaría de Salud, México, D.F.; **División Malattie Infettive, *Servizio di Immunopatologia, **Laboratorio Chimico-clinico, Reggio-Emilia, Italy.

Objective: To demonstrate an abnormal coagulation profile associated with HIV.

Methods: We have evaluated hematostatic function in 20 patients with HIV-infection. All the patients included in the study were treated with AZT. We measured APTT, Fibrinogen, FVIII, FVIIII and FXa: Factor VIII, VIIII and X activity were carried out, using plasma from General Diagnostic, a pool plasma from 20 donors used as control.

Results: These results show no significant difference in APTT, Fibrinogen, Factor VII and X activity, however there is an increase in Factor VIII activity.

	Fibrinogen	APTT	FVIIII	FVIII	FXa	FVIIII
HIV infected patients	300	30	80	80	80	80
Control	300	30	80	80	80	80

Conclusion: These preliminary results should be approved with further investigation to determine if the changing in Factor VIII activity is related to a FVIII antigen modification and this situation is an epiphenomenon to an acute serologic response or it is associated with hyper-coagulability.

M.B.P.62 ASSOCIATION OF EPSTEIN-BARR VIRUS IN EPITHELIOID ANGIOSIOMAS OF AIDS PATIENTS

Benjamin Constant,* Unger E.R.*

*Henry University, Atlanta, Georgia.

Objective: Epithelioid hemangioendothelioma-like vascular proliferations, recently described in AIDS patients, have been associated with bacilli similar to those found in sarcomatous diseases. Since other vascular lesions present in AIDS patients, in particular Kaposi's sarcoma, have been associated with CMV, we investigated the possibility of viral associations with epithelioid angiosiomatosis.

Method: In-situ hybridization was performed on formalin fixed, paraffin embedded tissue from 2 cases using cloned histiotyping probes for CMV, herpes simplex (HSV), HIV and EBV.

Results: Immunohistochemistry had evidence of opportunistic infection at the time the biopsy was obtained and the lesions regressed spontaneously. Hybridization with CMV, HSV and HIV were negative, those for EBV were positive in both lesions. Hybridization signal for EBV silver stains in the nuclei of endothelial cells and in occasional histiocytes. Bacilli were demonstrated with only one of the lesions by silver stains.

Conclusions: This is the first report of EBV associated with this entity and the first time that EBV viral genome has been seen in endothelial cells. Our data suggest that EBV may be involved in the pathogenesis of these lesions but further studies are necessary.

M.B.P.64 PREVALENCE AND CLINICAL SIGNIFICANCE OF COON'S

TEST AND OLD AGGLUTININS IN AIDS-PATIENTS

Reuter J., Gathof H., Heinrich B., Matheis A., Hecker F.,
Gombel P.-D., Hildebrandt Wöhrden, FPG, Bad Polzliken.

* Transfusion Service of the Red Cross, München, F.R.G.

OBJECTIVE: To determine the prevalence and pathogenetic/diagnostic relevance of positive direct anti-coagulin tests (DAT) in AIDS patients (PTS).

METHOD: 34 (28%) out of 145 consecutive AIDS PTS (CDC criteria) attending our clinic presented with anemia requiring transfusion. Antibody screening was performed including C3, C3d, C4, anti-IgG/KA, IgG and cold agglutinins (CA). Retrospectively diagnosed hematologic parameters and therapy were studied.

RESULTS: 47% (16/34) showed a positive agglutination in at least one test. C3d, anti I, CA and IgG occurred most frequently (16/34/7/4 out of 16). 75% (12/16) had leukopenia (<4000/µl), 50% (8/16) had thrombocytopenia (<150000/µl) and 38% (6/16) showed both. Hyperfibrinogenemia (1.6 g/l) was present in 81% (13/16). Only 2 out of 16 DAT+ PTS showed hemolysis. 63% (10/16) of the DAT+ had proven mycobacteriosis (8 sputum in contact to only 17% (3/18) of the DAT- PTS (p<0.01). Other diagnoses and therapy of the DAT+ PTS showed no significant difference in prevalence (PCP, CMV, MBL, toxoplasmosis).

CONCLUSION: Autoimmune versus infectious pathogenesis of DAT in AIDS has been discussed in the literature. Our results show a correlation of mycobacteriosis with DAT suggesting rather infectious than autoimmune pathogenesis.

M.B.P.66 THERAPY OF SALMONELLA INFECTIONS IN AIDS PATIENTS.

K. Reinton, S. Rodriguez, and P. Wessell. The University of Texas M.D. Anderson Cancer Center, Houston, Texas, USA.

Objective: To evaluate the efficacy and toxicity of newer agents - ceftriaxone (CTX) and ciprofloxacin (CFP) compared to ampicillin (AMP) and trimethoprim/sulfamethoxazole (TMP/SMX) for Salmonella infections.

Methods: Ten AIDS patients with severe Salmonella gastroenteritis were treated with standard or newer agents. Patients were monitored for response, toxicity and recurrence (clinical follow-up - 6 months). **Results:** - All 5 patients treated with AMP or TMP/SMX responded initially but all relapsed - one with bacteremia. Two responded to a 5 day course of 1.6 CTX (no relapse). One received only 2 doses of CTX before therapy was stopped for a skin rash. He responded but relapsed 1 month later. Two patients responded to oral CFP. CTX & CFP were well tolerated.

Drug	# of Pts.	Outcome	Follow-up
ampicillin	2	response	relapse
trimethoprim/sulfamethoxazole	2	response	relapse (bacteremia) 1 pt.
ceftriaxone	3	response	relapse=1 pt.
ciprofloxacin	2	no response	no relapse

Conclusion: Aggressive therapy of Salmonella gastroenteritis in AIDS patients may prevent bacteremia and dissemination. Agents such as CTX and CFP may be superior to, less toxic, and have fewer side effects than standard drugs. These newer agents have high biliary concentration and may attenuate the chronic carrier state. Oral agents (CFP) may also increase compliance. They need wider clinical evaluation to establish efficacy and optimal length of therapy.

M.B.P.79 DISSEMINATED HISTOPLASMA IN A DENISH AERIPATIENT.

SHIBUKAWA, I. I.
Infectious Diseases, Hygiene Hospital, Department of
Infectious Diseases; *Department of Pathology, Copenhagen,
Denmark.

Objective: To present the first case of disseminated histoplasmosis (DH) in an European AIDS pt. **History and findings:** A 35-year-old homosexual with 7 weeks of fever, chills, a slight cough and a weight loss over the last 3 months. Examination showed a Kaposi's sarcoma of the mouth, oral thrush and a temperature of 38.4°C. No lymph node swelling or organomegaly. White blood cell count was 2.700/mm³ and CD4 cell count was zero. A sputum smear showed diffuse/few intracellular proliferates and from the bronchial lavage gram-stain and smears were cultivated. Therapy was started with penicillin and isotretinoin 200 mg daily. A liver biopsy showed granulomas and a biopsy of the lower extremity was normal. A CT-scan of the abdomen showed a slight hepatomegaly and several lymph nodes in the retroperitoneum. Six weeks after admission he still had the fever and was losing weight. Zidovudine 1200 mg daily was started and an explorative laparotomy was done with the exclusion of a mesenteric lymph node. Histological examination showed typical histoplasma (H) in the retroperitoneal skin test and histoplasma serologic test of the serum and blood with all negative. He was treated with i.v. Amphotericin B 20 mg/day for 2 weeks to a total of 4.5 mg/kg. Then the treatment was changed to oral Fluconazole 200 mg/day. The patient lived in Venezuela from 1983-1986 but otherwise in Europe. A CT-scan 2 months later showed regression of the lymph nodes and no organomegaly. Clinow remains after the diagnosis of DH is the feeling with oral Fluconazole 200 mg/day without any signs of relapse or other opportunistic infections. DH cell count is 250/m³.

Conclusion: DH should be considered in immunodeficient patients also from non-endemic areas. A detailed travel history is essential. This patient got a much lower CD4 count than recommended but it seems to be sufficient when followed by oral Fluconazole.

M.B.P.81 HISTOPLASMA IN AN AIDS PATIENT TREATED WITH TRIMOPRIMIDAZOL

**TOULI, HIGLEY, RIGBY, JENKINSTRY, SHAWSON, PI
Campbell, C. M.; Cassard, R. ***

*St. Stephen's Hospital, London, England, *Mycobacterial Reference
Laboratory, London, England.

Objective: Histoplasma has been described in AIDS cases in endemic areas. We report a case which developed in a severely immunocompromised patient resident in the U.K.

Methods: A 34 year old HIV antibody positive patient with a previous AIDS diagnosis of cerebral toxoplasmosis and Mycobacterium tuberculosis in the lung and neck nodes, presented with a two month history of skin lesions on the face and back and painful, swollen left foot. Biopsy of the fifth metatarsal and oral biopsy of the head granulomatous skin lesions showed the large tuberculate macroconidia of Histoplasma capsulatum. The patient was Argentinian but had not been in that country for ten years.

Results: He was already being treated with trimoprimidazole 200mg twice daily for pneumocystis carinii but has since been switched to the triazole trimoprimidazole 200mg daily in an attempt to eradicate the fungus. His lesions have healed completely and feels much better since commencing therapy. He remains well at six months follow up. Treatment in the past has been with intravenous amphotericin B and flucytosine or oral ketoconazole. It is interesting that this patient was already on ketoconazole when he developed the skin and bone lesions suggesting poor drug absorption or a resistant strain.

Conclusions: We believe this to be the first AIDS patient to develop this infection in the United Kingdom to be successfully treated with trimoprimidazole.

M.B.P.83 HEMORRHAGICA PURPURA SEPTICEMIA IN AN AIDS PATIENT

WITH A SEVERE RICKETTSIA CAPSULATA INFECTION.
CAHANEY, DENNIS M., LEWIS, J.M., and OLSEN, C.
University of Southern California, Los Angeles, California, U.S.A.

Objective: To describe a septicemia in an AIDS patient caused by *Rickettsia* sp. This organism has not been previously described as a cause of fungemia in AIDS patients.

Methods: A 42 year old homosexual man diagnosed with chronic *Cryptosporidium* diarrhea and receiving central hyperalimentation developed a fever. Blood was obtained from the in-dwelling Hickman catheter for culture on 6 occasions over a 48 hour period. Blood was inoculated into BACTEC M9EA bottles and processed in a BACTEC 9600 system and then plated onto Sabouraud agar. Blood for culture was also obtained using the Dupont Instalar Igmis Concentration method and inoculated onto Sabouraud agar. The Hickman catheter was removed.

Follow-up: Blood cultures were obtained.

Results: Blood cultures drawn from the Hickman catheter grew *R. rubrum* using both culture systems. *R. rubrum* has a distinct pink coral color. Following removal of the catheter, peripheral blood cultures yielded no growth and the patient deservosed.

Conclusion: *R. rubrum* has been rarely reported to cause septicemia. *R. rubrum* may cause septicemia in AIDS patients with Hickman catheters. Catheter removal alone may result in cure without specific anti-fungal therapy.

M.B.P.80 CHRONIC SUPPRESSION OF DISSEMINATED HISTOPLASMA IN HIV PATIENTS WITH ORAL KETOCONAZOLE

ROBERT MILHART and J. BREWER. St. Luke's Hospital, Kansas City, Missouri, USA.

Objective: To review the course of ten consecutive patients with disseminated histoplasmosis and HIV disease treated with intravenous amphotericin B (AMB) followed by chronic suppressive oral ketoconazole.

Methods: Clinical and laboratory data was reviewed retrospectively on all patients we have seen with histoplasmosis and HIV (No.1). One case, in which death occurred shortly in AMB treatment, is not included.

Results: Diagnosis was made by smear and culture of bone marrow (No.1), blood (No.2), lung tissue (No.3), colon (No.4), and bronchoalveolar lavage (No.5) Both patients received 1000 to 2400 mg of AMB followed by 400-600 mg ketoconazole orally per day. Patients have been followed from one to 24 months on ketoconazole. Average months of disease free follow-up = 11.5. Two patients relapsed, but remain alive, having been retreated with AMB. One relapse, at 6 months on ketoconazole, was associated with trimidazole treatment. The other relapse, at 21 months, was associated with ribavirin treatment. Two of the 10 patients died. Both died of other HIV related conditions. Both had negative bone marrow smears for histoplasmosis shortly before death.

Conclusions: Chronic suppressive oral ketoconazole may be a reasonable alternative to chronic intravenous AMB in selected patients with histoplasmosis and HIV disease.

M.B.P.82 DEMONSTRATION OF HISTOPLASMA IN HIV INFECTED PATIENTS

SHAW, T.A.V., BULLOCK, LINDSEY M., HANLEY, C., GARDNER, M., SERRA, M. S.; SIM, P.S.; MORIS DE SA, C.
Caffre & Gubie University Hospital - University of St. Andrews, St. Andrews, Scotland

Objective: To analyse all serological investigations using AMB HIV infected patients.

Methods: A review of records of all patients with AIDS (PWA) seen at University of St. Andrews HIV Clinic from November 1981 to August 1984. HIV infection was confirmed by ELISA. Direct immunofluorescence and/or immunofluorescence techniques. All immunofluorescence lesions were confirmed by biopsy and/or culture when needed. Patients were evaluated for age, sex, race, stage of infection and type of lesions. We did not evaluate treatment or response to treatment.

Results: We found immunofluorescent histoplasma in 277 patients (15.8%), 212 male (58.7%), 65 female (23.7%), most of the patients presented were than 40 years of lesion.

SEX or RACE	PATIENTS	%
Male	158	57.2
Female	65	23.7
White	268	97.1
Black	6	2.2
Hispanic	3	1.1
Unknown	1	0.4
Others	64	23.1

Conclusions: Immunofluorescent histoplasma are common among HIV infected patients. It is possible to make a definite diagnosis of HIV infection observing the skin. Serologic diagnosis of HIV infection using the skin. Serologic diagnosis of HIV infection using the skin.

M.B.P.84 SEPSIS FROM INJECTED CATHETERS IN PATIENTS WITH AIDS

ROSENBLATH, JOSEPH B., GASTNER, C., GARDNER, M., SERRA, M. S.
Case Western Reserve University, Cleveland, Ohio, USA.

Objective: To assess the frequency of catheter-related sepsis (CRS) in AIDS patients. A review of records of all patients with AIDS (PWA) seen at University of St. Andrews HIV Clinic from November 1981 to August 1984.

Methods: A review of records of all patients with AIDS (PWA) seen at University of St. Andrews HIV Clinic from November 1981 to August 1984. HIV infection was confirmed by ELISA. Direct immunofluorescence and/or immunofluorescence techniques. All immunofluorescence lesions were confirmed by biopsy and/or culture when needed. Patients were evaluated for age, sex, race, stage of infection and type of lesions. We did not evaluate treatment or response to treatment.

Results: Thirty-four of 130 PWA had catheters (C) placed; 33 were evaluable. Indications for C included treatment with amphotericin B, hyperalimentation (HMA), or dantrolene (D) and need for venous access (R/33). Fifteen episodes of CRS occurred in 12/33 C, with 0.4 CRS/100 C-days. Mean (SD) time to CRS was 14(9) days. Organisms recovered were *S. epidermidis* (8), *S. aureus* (4), *Corynebacterium JE* (1), *P. aeruginosa* (3) and *A. albicans* (1). There were no deaths related to CRS and no instances of endocarditis. Mean C life was 14(9) days in infected catheters (IC) and 34(9) days in uninfected catheters (UC) (p<0.1). Dematitis was present at 36% of IC and 38% of UC (p=0.67). Sixty-seven percent of RedSpot® C and 30% of Roviac® (Hickman®) C became infected (p<0.13). Age, sex, race and HIV risk factors were similar in IC and UC. The 2 groups did not differ in duration of AIDS, number of opportunistic infections, Karnofsky status, response, or MALT use.

Conclusions: We found a high overall frequency (36%) of CRS in our PWA. CRS occurred up to 20 times more often than in comparable non-AIDS patients, as reported in the literature. RedSpot®-C were more frequently associated with CRS than Roviac®/Hickman®-C. Possible explanation: CRU use high infection rate include presence of dematitis, prolonged catheter use at home, and host response factors.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.97 VISERAL LEISHMANIASIS IN HIV-ASSOCIATED INFECTION. REPORT OF 3 CASES.

Alfon J. F. Balboa, María Rosa R. Belmonte, J. H. and Villalongo C. A.
Hospital San Borja (Chillan), and Hospital San Clemente (Chillan),
Chileno, Chile, Soud.

Objective: To report visceral leishmaniasis (VL) cases observed among HIV infected adult patients in two hospitals from Northwestern Chilean town in Antofagasta Regional medical area.

Methods: We retrospectively review all cases of VL diagnosed among adult (18-60 years old) patients seen in our hospitals from 1985 to the end of 1989. We report all cases in which HIV infection was also detected, with special reference to the clinical and immunological status, and treatment outcome.

Results: From 1985 to 1989, 3 cases of adult VL have been diagnosed in our two hospitals. In 2 of the 3 cases HIV infection was also detected. Three patients had history of intravenous drug abuse. 1 patient reported HIV infection through intake of commercial injection factors to reverse sodium effect, and 1 patient acquired his previous risk behavior. Four patients are men. Age ranged from 18 to 70 years. Two patients relapse cases contact with drug. Fever and adenopathy were initially present in all cases. VL was the first severe infection in all patients, and in 2 cases B2-lymphocyte count recovered from blood cultures during the course of VL. CD4 lymphocytes were < 60/mm³ in all cases. Diagnosis of VL was made by bone marrow aspirates. High titers of Leishmania antibodies were found in all cases in which they were tested. Negative ureteric (Kojima) therapy was used in all cases. Two patients showed clinical improvement, without apparent relapse. Three patients didn't show clinical response to treatment, and two of them died from VL. Three patients and AIDS case definition criteria (1 existing syndrome, 1 recurrent B2-lymphocyte, 1 indicators of response).

Conclusion: Visceral leishmaniasis may be the first severe infection in HIV-infected patients. In these cases it may run an unfavorable course despite appropriate therapy. Like others, we propose that adult VL should be considered as opportunistic infection in HIV infection, and include in serological AIDS case definition. All adult patients with VL should be studied to rule out HIV infection, even in endemic areas.

M.B.P.99 HIV SEROLOGY AND VISCERAL LEISHMANIASIS IN CAMEROON

FORONDE, E.*, ZIENGE, L.**, KAMPELE, L.***

C.H.U.S.S. YAOUNDÉ, CAMEROON. **UNIVERSITY HOSPITAL YAOUNDÉ, CAMEROON *** MINISTRY OF PUBLIC HEALTH, YAOUNDÉ, CAMEROON.

Objective: To do a study on the seroprevalence of HIV1 and HIV2 antibodies among patients with visceral leishmaniasis (V.L.) in the region of Kousséri (far North of Cameroon).

Methods: Of 48 patients (22 males, 24 females) with clinical suspicious signs of V.L. (deteriorating general state, profuse fever, anemias, liver and/or spleen enlargements) specific tests were done (fast blood count, leishmaniasis serology, trypanosoma antigen test on bone marrow aspirate), then HIV1 and HIV2 serology.

Results: The diagnosis of V.L. was confirmed on 9 patients. Out of these 9 patients 1 was found HIV1 positive. None was found HIV2 positive.

Conclusion: V.L. should be considered as an opportunistic infection of AIDS.

M.B.P.101 DETECTION OF HIV-1 IN CEREBROSPINAL FLUID (CSF): CORRELATION WITH PRESENCE AND SEVERITY OF THE AIDS DEMENTIA COMPLEX

Zhai, Huijun, Dr. Brev, R.J. Khan, R. Galliano R. Price, M.D.
Memorial Sloan-Kettering Cancer Center, New York, NY, USA.

Objective: To assess the presence of HIV-1 in CSF by antigen capture and virus isolation in relation to severity of the AIDS dementia complex (ADC). **Methods:** PMA was assayed by antigen capture (Abtest) and by virus isolation (using PMA-stimulated PBs as indicators) in CSF and serum/blood samples from HIV-1-infected patients at various stages of ADC at the time of clinically indicated lumbar puncture. Results were correlated with clinical ADC stage.

ADC Stage	Number of Samples	p24 Antigen	HIV-1 Isolation
None	24	0	0
1 (mild)	7	4	2
2 (moderate)	10	8	5
3 (severe)	6	10	10

Correlations: ADC Stage vs CSF p 24 antigen (p < 0.001) vs CSF Virus Culture (p < 0.01).

Conclusion: While p24 in both CSF and blood correlate with ADC Stage, its detection in CSF is insensitive to mild-moderate disease and in blood is relatively nonspecific. Likewise, isolation of HIV-1 from both fluids is nonspecific, and thus, neither method is highly useful for clinical diagnosis. The increase in CSF antigen with falling isolation rate remains unexplained. These results suggest that brain dysfunction may not relate to virus replication within the brain in a simple fashion.

M.B.P.98 Unusual Etiology of Leishmaniasis in Chile

Bello, J. M. and A. S. Urquiza, R. G. Velasco, L. V. Barreda, J. P. H. Martínez, J. G. Rodríguez. J. de Internal Medicine and Nephrology, III Hospital Chile in Santiago, Antennas University of Santiago, Santiago, Chile.

Visceral leishmaniasis is an endemic disease in Spain with a distinctive clinical picture. We report the patients with HIV in whom the diagnosis of leishmaniasis was established from unusual pathological materials.

Case report No. 1: 47-year-old male, Spanish, HIV-positive, with history of recurrent adenitis and cerebral lymphomas. In January 1989, he was admitted with severe pancytopenia, *Pneumocystis carinii* pneumonia and disseminated intravascular coagulation. He was treated successfully with an organophosphorus antidote. In October 1989, he was admitted with fever, weight loss and the signs of acute leukemia. Bone marrow examination in the presence of relapsed Kaposi's sarcoma lesions and the absence of acute leukemia, showed infiltration by leishmaniasis. There was improvement of the patient's general condition after treatment with sodium stibogluconate at a daily dose of 400 mg. In spite of this adequate treatment, a relapse of bone marrow infiltrate still showed the presence of leishmaniasis.

Case report No. 2: 39-year-old patient with hepatitis type A, well-controlled, with chronic liver disease and HIV infection, whose illness began in October 1989. In October '90, he was diagnosed of bacterial meningitis and leishmaniasis. The month later he was admitted with cough, expectoration and fever of three week duration and a relapse of bone marrow infiltrate. Bone marrow examination in the next year, *Pneumocystis carinii* infection, the immunohistochemical (immunoperoxidase) and there on clinical improvement after three months of chemotherapy with the drug miltefosine. The CSF leukocytes revealed the presence of abundant neutrophils.

Conclusion: We would like to draw attention to the presence of atypical clinical picture of visceral leishmaniasis as a poor treatment response. It is likely that some of these infections may also manifest some form of their clinical picture as described. In other certain conditions such as drug, liver, immunosuppression or in the HIV infection. So the findings, then for serological, positive in the specific functions of Kaposi's sarcoma, should encourage the search for this organisms, even in the absence of clinical clues to suspect this infection.

M.B.P.100 Tropical diseases of HIV patients in non-endemic countries: A case of visceral leishmaniasis and a case of tropical Pyomyositis

Elting, J., Eickenbrecht, J.F., Borghard, P.*, Ströhmeier, G. Department of Medicine and Pathology, University of Düsseldorf, 4000 Düsseldorf, Koorenstraße 5, FRG.

Tropical diseases such as visceral leishmaniasis are often reported in HIV patients from tropic, subtropic and mediterranean regions. We report 2 cases. Among 220 HIV patients seen at the Department of Medicine, University of Düsseldorf, in 1989, we found 2 patients (1% with a tropical disease. Case 1: A 31 year old male i. v. drug abuser presented with hepatosplenomegaly, pancytopenia, hypergammaglobulinemia and peripheral lymphomas. Bone marrow aspiration and biopsy showed visceral leishmaniasis. He was successfully treated with sodium stibogluconate. Case 2: A 28 year old female HIV patient, infected by heterosexual contact, was admitted to the hospital for persistent fever and abdominal pain. CT-scan showed pyomyositis and abscesses of left psoas muscle. Operative drainage and microbiological evaluation excluded Mycobacterium tuberculosis but revealed hemophilic streptococcus group A as the etiologic agent. Pyomyositis was hemophilic streptococcus group A as the etiologic agent. Pyomyositis was previously thought to be limited to the tropics, but this patient had never left W.-Germany.

Conclusion: Tropical diseases can be found in HIV patients even outside endemic areas.

M.B.P.102 CEREBRAL ABSCESS CAUSED BY TRYPANOSOMA CRUZEI IN A PATIENT WITH AIDS

Martin Rodriguez*, E. Sprine*, A. Cavalcanti*, A. Carneiro*, L. Severina**, Hospital de Clinicas de Porto Alegre, Universidade Federal do Rio Grande do Sul; **Instituto de Pesquisas Biologicas, Porto Alegre, Brazil.

Objective: To report a cerebral abscess caused by *Trypanosoma cruzi*. **Case Report:** An 18-year-old white woman with acute HIV infection arrived at the hospital with fever, focal neurological signs and a history of convulsions. She came from the southwest region of Rio Grande do Sul state. A cerebral CT showed multiple cerebral abscesses. The upper half lymphomonocytic predominance (D 50) and low glucose level. Bacteriological, fungal and immunological exams were negative. Amphotericin B, anti-tuberculous and anti-neoplastic drugs were empirically started in a sequential form, without improvement. A new lumbar puncture showed *Trypanosoma cruzi* unfortunately, it was the last one, and the patient died before any treatment could be started.

Conclusion: This is the first case we have noticed of a cerebral abscess caused by *Trypanosoma cruzi*. It is important to remember that HIV-associated opportunistic infections depend on pathogen prevalence in a certain region and the knowledge of the place of origin of the patient will aid in the search of a diagnosis (the southwest of RS is an endemic region of Chagas' disease, which is caused by *Trypanosoma cruzi*).

M.B.P.103 ROLE OF PULMONARY FUNCTION TESTS(PFT) AND CD4 LYMPHOCYTE COUNT FOR DIAGNOSING LUNG COMPLICATIONS IN AIDS
G.Parré, M.Clotet, M.Sala, J.Morera. Pneumology and Infectious Diseases Unit, Hospital "de Badalona" Germans Trias i Pujol, Spain.
Objective: To assess the value of PFT and CD4 lymphocyte count for an early diagnosis of pulmonary diseases in HIV seropositive homosexual patients.
Methods: 27 patients with HIV-seropositive homosexual patients. All denied drug abuse. 22 out of 33 were included in stage III and 12 in stage IV-C2.
Results: We determined: Forced Expiratory Volume in one second (FEV1), Forced Vital Capacity (FVC) and Carbon Monoxide transfer Factor (TLCO). Simultaneously CD4 lymphocyte count, was also evaluated. Ten out of 33 had previous HIV-TLCO determination. According to the TLCO obtained we divided patients in 3 groups that were submitted to different procedures. Results: Group A (normal PFT): 27 patients, CD4: 1.678 ± nm3; Group B (normal FEV1 and FVC): 17 patients, CD4: 1.618 ± nm3; Group C (normal FEV1 and FVC): 10 patients, CD4: 1.618 ± nm3. All patients had normal chest X-ray and without opportunistic infections nor Kaposi's Sarcoma; Group D (mild restrictive disease, TLCO below 65%): 8 patients, CD4: 1.191 ± nm3, all had Pneumocystis carinii pneumonia (PCP), a table showing all methods and results would be presented. Conclusions: 1- TLCO between 65-80% is seen in HIV-seropositive patients in whom PCP is ruled out, although histopathological findings have demonstrated inespecific interstitial pneumonitis; 2- TLCO below 65% even in asymptomatic patients with normal chest x-ray must encourage to further explorations since PCP is very probable; 3- CD4 cell count below 250 x nm3 argues for a necessary primary PCP prophylaxis in HIV seropositive patients; PCP occurs only in patients with CD4 count below 250 x nm3 and total lymphocyte count below 900 x nm3. (95.5% of cases in our series)

M.B.P.105 Repanator A., Siede W.H., Brode H.D., Nöbmann-Maignan H., Ullrich D.W.E., Seiffert U.B.

Chemotherapeutisches Forschungsinstitut (Georg-Speyer-Haus), Zentrallaboratorium, Klinikum J.M.Goethe-Universität, Frankfurt FRG, Institut für Laboratoriumsmedizin, Universitätsklinikum, Bonn FRG.

"Elevation of lactate dehydrogenase in asymptomatic AIDS patients"
Plasma of 115 anti-HIV positive patients without clinical symptoms was analyzed for lactate dehydrogenase (LD), its isoenzymes (LDI) and beta-glucuronidase. Total LD was elevated in 73% of these patients, the median value was 233 U/l (normal population: median 154 U/l, 97.5 percentile at 200 U/l). The underlying isoenzyme pattern most frequently showed elevation of LDI II (in 78%) and LDI III (in 82%). As pneumocystis-pneumonia could be excluded as cause, this pattern is characteristic for origin of the elevation in the lymphatic system. Patients were further subgrouped according to T4 cell counts. Despite no correlation was found, it might be speculated that LDI II and III levels reflect the destruction rate of lymphocytes. This is supported by our observation, that total LD and LDI II and III are more frequently elevated in patients with positive HIV-antigen test. Roughly 40% of the patients show elevation of LDI V and IV and beta-glucuronidase as consequence of liver affection as verified by elevated transaminases.

In contrast to other reports it can be stated, that elevation of plasma lactate dehydrogenase with prominent isoenzymes II and III is a frequent phenomenon in anti-HIV positive patients without pneumocystis-pneumonia. This might reflect the disease activity in the lymphatic system.

M.B.P.107 ADENOSINE DEAMINASE (ADA) LEVELS IN SERA OF PATIENTS WITH HIV-1 INFECTION

Valls, V., Edo Javiera, Pignaredo, I., Roca, V., and De Salencia, R.E. Department of Medicine, Hospital Clinico San Carlos, Madrid, Spain.

Objective: To assess the value of serum ADA quantification as a predictor of active M.tuberculosis (Tb.) infection and degree of immunosuppression in HIV-1 seropositive patients.

Methods: We quantified serum ADA levels in 38 HIV-1 seropositive (HIV+) patients: 9 with proven Tb. infection (Gr. I), and 29 without Tb. infection (Gr. II). Control groups consisted of 13 HIV-1 seropositive (HIV+) patients with proven Tb. infection (Gr. III) and 40 healthy HIV- volunteers (Gr. IV).

Results: ANOVA analysis showed that serum ADA levels were significantly elevated ($p < 0.01$) in Gr. I (48.39 ± 22.26 U/l), Gr. II (35.74 ± 16.4 U/l), and Gr. III (24.54 ± 11.82 U/l) when compared to Gr. IV (8.6 ± 4.6 U/l). ADA levels were statistically different ($p < 0.01$) in HIV+ (Gr. I + Gr. II) compared to HIV- (Gr. III + Gr. IV) patients. No statistical differences in ADA levels could be demonstrated between Gr. I and Gr. II. In the HIV+ patients we were unable to demonstrate any correlation between ADA levels and CD4+ cell count, active Tb. infection or opportunistic infections of HIV+ patients. Cross belonging to NRS stage showed the significantly higher levels of ADA. Using a backward logistic regression analysis we found that ADA serum levels were correlated ($p < 0.0001$), IgM levels ($p < 0.0001$), peripheral monocytes counts ($p < 0.0001$), IgM levels ($p < 0.0019$) HIV-1 antigenemia ($p = 0.05$) (NP=0.82, NP=0.79, $p < 0.001$).

Conclusion: Quantification of ADA serum levels in HIV+ were useful for the presumptive diagnosis of Tb. infection, however in HIV+, ADA levels were not useful predictors of degree of immunosuppression or of active Tb. infection.

M.B.P.104 THE EFFICACY OF SCREENING TESTS FOR INFECTIOUS DISEASES IN PERSONS WITH SYMPTOMATIC ARC
Gardin, Fred, Hartigan, W., Oster, C., and the VA Cooperative Study Group on the Treatment of ARC.
VA Medical Center, Washington, D.C., U.S.A.

Objective: To evaluate the efficacy of screening tests for secondary infections in patients entered in a multi-center study of zidovudine for ARC.
Method: Entry criteria for this study required patients to have T4 counts between 200-500, and symptoms of ARC such as fever, sweats, weight loss, fatigue, lymphadenopathy, or thrush. Baseline screening to identify active infections included a chest x-ray (CXR), serologies for syphilis, hepatitis B (HB), cryptococcus, a urine culture for cytomegalovirus (CMV), and blood cultures for CMV, fungus, and mycobacteria.

Results: Of 205 patients enrolled, 99% are male, 69% white, and the mean age is 40. HIV risk factors include 61% homosexual, 18% IV drugs, 9% mixed, and 12% other. Mean baseline T4 cell count was 340. Significant lymphadenopathy is present in 36%. ARC has been present over 6 months in 58%; systemic symptoms at screening in 55%. Tests completed to date: CXR abnormal in 19/191 (10%). Reactive serologies for syphilis 29/187 (16%). HB surface antigen 19/169 (11%), and cryptococcus 0/156. CMV urine positive in 3/86. Blood cultures complete to date for CMV (86), fungus (92), and mycobacteria (87) have all been negative.

Conclusion: In a population of symptomatic ARC patients with depressed T4 cells, routine screening for infectious agents may be of limited value. CXR, and syphilis and HB serologies appear warranted, however more expensive tests should await specific indications.

M.B.P.106 67 GALIUM SCINTIGRAPHY OF CHEST IN AIDS PATIENTS. ANALYSIS OF 150 CASES.
Narciso P.; De F.M.; Pignatelli F.; Rossi M.A.; Sirtes F.; Vico Giuseppe U.S.L. N/10 "L. Spallanzani" Hosp. Dept. Infectious Diseases/A.C. Forlani Hosp. Dept. Nuclear Medicine, Rom, Italy.

Objective: To evaluate the importance of chest 67 Ga scintigraphy in diagnosis of pulmonary disease in AIDS patients, with negative or dubious X findings.
Methods: In the last two years 152 AIDS patients showing symptoms of lung diseases were studied with Ga scan; in 95 subjects diagnosis was performed after sputum culture, BAL, bacteriological and histological examination. An imaging of transvenous scan obtained with plasma source of 57 Co (10 ml, 370 MBq) was used. Scan was classified as negative if low/background ratio was 1.5; as positive if 1.5 2; ++ if 2.5; +++ if 2.5 3; ++++ if 3.

RESULTS:

GROUP N.	SCAN	GROUP	0	+	++	+++	++++
PCP	34	2	7	2	16	7	2
C.M.V.	11	-	5	3	2	1	-
C.M.V. and other...	6	-	3	1	2	-	-
FUNG.	5	-	3	3	-	-	-
MILIARY TB...	6	-	1	1	3	1	-
OTHER	7	-	4	3	-	-	-

CONCLUSION: 1) High diffuse pulmonary concentrations of 67 Ga in AIDS patients seem to be related to an increased production of PCP also in chest X negative or dubious cases; 2) low or negative Ga uptake in localized or extended pulmonary diseases indicates an increased probability of HIV-1b pulmonary TB 67 Ga scintigraphy allows a more accurate diagnosis of illness extent and activity.

M.B.P.108 CLINICAL MANIFESTATIONS OF AIDS IN WOMEN FROM SAO PAULO, BRAZIL

Ferreira, A.C., Grandi, J.L., Fernandes, M.E.¹
1, Paulista School of Medicine, Infectious Diseases Unit;
2, Reference Center for Aids, Sao Paulo, Brazil.

Objective: To detect the most common clinical presentation, mortality rate and "cause mortis" of women with Aids.

Methods: We studied a sample of 55 women that had clinical manifestations of Aids and were treated in those two institution above, during the period of January 85 to January 89.

Results: Those 55 women with Aids correspond 22% of the Aids case in women from Sao Paulo State. The mortality rate was 22%.

Table 1. Most common Clinical Presentation

number	Occurr	25	19	5	3	6
Pneumon(infect.)	44	33	8	5	10	6

Conclusion: The clinical presentation of Aids in women will be discussed in this study.

Session d'affichage Poster Session

Aspects Cliniques Clinical Aspects of AIDS

M.B.P.127 DIAGNOSIS AND GRADING OF CMV COLITIS: COMPARISON OF H&E STAINING, DNA IN SITU HYBRIDIZATION, AND IMMUNOPEROXIDASE STAINS FOR EARLY AND LATE AFFECTIONS.

Richard Bariletti, MD, Yi-Tin Shiu, MD, D. Dieterich, MD NYU Medical Center, New York, NY.

The diagnosis (dx) of CMV colitis and grading of its severity have become important issues since specific treatment has become available. We compared the results of H&E stains, in situ hybridization (ISH), and immunoperoxidase stains for early and late CMV infections (IFP) in order to determine the most accurate method for dx and grading. We examined 38 colon biopsies (dx) of 30 AIDS patients suspected of having CMV colitis. In 10 the dx CMV inclusion bodies (IB) were seen on H&E stains and both ISH and IFP were negative. In 18 the CMV IB were seen on H&E stains and all were positive either by both ISH and IFP (2), only ISH (2), or only IFP (4). The numbers of infected cells to a single biopsy were 1 to 221, IFP yielding the highest counts and H&E the lowest. The severity of infection was graded by relating the total number of infected cells to the number of biopsies. Grade I was defined as 1-4, grade II as 5-5, and grade III as 10 or more infected cells per biopsy. Grades were graded the same by all techniques in 11 and varied in 17. Overall findings on H&E stains and those based on ISH or IFP in 6. Lowering of grades based on IFP or ISH occurred in 11 cases, and was accompanied by a marked increase in tissue IFT for these special reports. We conclude that (1) dx of CMV colitis based on the identification of CMV IB on H&E stained sections is accurate, (2) although IFP identifies the greatest number of infected cells, this gate is sensitivity is outbalanced in endoscopy by the loss of tissue after cutting of levels, and therefore (3) grading is best performed on H&E stains.

M.B.P.129 THERAPY OF CYTOMEGALOVIRUS (CMV) INFECTIONS WITH GANCICLOVIR

Robert S. Rodriguez, F. Cervantes, J. Nelson, G. Brown, A. Eise, G. P. Body, and P. Mansell. University of Texas M. D. Anderson Cancer Center, Houston, Texas, U.S.A.

Objective - To evaluate the efficacy and safety of ganciclovir for the therapy of CMV infection in AIDS patients.
Methods - HIV infected patients with various CMV infections received ganciclovir (10 mg/kg/d for 14d). Response and toxicity were monitored.
Results - Forty-eight patients, 46 men, 2 women (median age 38) were treated. Sites of infection were retinitis - 30; colitis - 14; pneumocystitis - 2 (multiple sites in 2 pts.). Response rates were:

Response	Retinitis	Colitis	Pneumocystitis
Improved	3 (50%)	13 (50%)	2 (100%)
Stabilized	7 (50%)	1 (7%)	0
No change/worse	5 (25%)	0	0

 Patients with retinitis who failed to respond (including 2 with retinal detachment) generally had a greater than 10 day delay in initiation of therapy. The patients with colitis improved despite developing colonic perforation. One patient developed disseminated disease including adrenitis. More than 50% of patients who responded received maintenance therapy with ganciclovir. Therapy was generally well tolerated, however 23% of patients developed neutropenia (WBC <1000/mm³). Nausea and confusion were seen infrequently.
Conclusion - Ganciclovir is safe and effective in initial and maintenance therapy of CMV retinitis and gastroenteritis.

M.B.P.131 IN VITRO SECRETION OF CMV SPECIFIC ANTIBODIES BY PERIPHERAL BLOOD CELLS FROM HIV INFECTED SUBJECTS.

Vendrell, Jean-Jacques; Begonyi, M.; Ducros, J.;...; Reyes, L.;...; Hupert, M.P.;...; Carrozzini, R.;...;...

INTRODUCTION: Antispecific capacity for in vitro secretion of HIV antibodies by the circulating B cells of HIV infected subjects has been evidenced. Since CMV infection is very often associated with AIDS disease an assessment of CMV specific B cells could also be evidenced in the blood stream of HIV seropositive subjects.

METHOD: Supernatants of overnight cultures of the PBMC from 57 HIV seropositive and 4 HIV seronegative subjects were incubated in wells from Behring Diagnostics CMV ELISA kit. In vitro antibody secretion was detected using a low sensitive amplifying enzymatic complex.
RESULTS: at 50 positive, 5 negative and 1 intermediate CMV in vitro antibody production tests (IVAP) were observed with HIV positive PBMC and positive, 20 negative and 1 intermediate with the 24 HIV negative controls. In while all HIV seropositive were also HIV-IVAP positive, all CMV seropositive subjects were not IVPo (CMV-IVAP positive). Co-treatment of PBMC with CMV infected cells specifically inhibits CMV and not HIV-IVAP. CMV-IVAP positivity was shown to be a transient phenomenon in HIV negative and a persistent phenomenon in HIV positive subjects.
CONCLUSION: The detection of CMV antibody secreting cells in the blood stream could provide a marker of active CMV infection and thus constitute a tool for the diagnosis and the early treatment of CMV opportunistic infection in AIDS disease and in other cases of immune deficiency.

M.B.P.128 A RANDOMIZED CONTROLLED CLINICAL TRIAL OF FOXCARNIT FOR THE TREATMENT OF CYTOMEGALOVIRUS RETINITIS IN PATIENTS WITH ACQUIRED IMMUNODEFICIENCY SYNDROME.

Dewey, R.P.; Lane, H.P.; Marmorstein, J.;...; Hennessey, J.P.;...; et al. National Institutes of Health, **Food and Drug Administration, Bethesda, MD, USA.

Objective: To evaluate foxcarnit (trifluoromethyl phosphoramide) for the treatment of cytomegalovirus (CMV) retinitis in persons with AIDS.
Methods: Foxcarnit has been shown anecdotally to be effective for the treatment of CMV retinitis, a sight-threatening infection for which there is no approved therapy in the US. To evaluate its efficacy, a randomized controlled clinical trial was designed to compare foxcarnit, with and without AZT, to AZT alone in the treatment of non-sight threatening CMV retinitis. Patients on the AZT arm are eligible for open label foxcarnit once progression is documented. Foxcarnit is given as a course of 60 mg/kg intravenous qd for a 3 week treatment period followed by 90 mg/kg daily maintenance, both adjusted for renal function, until progression of retinitis is noted. Evaluation of retinitis and progression is performed by a masked reading center using serial photographs. A total of 100 and 48 subjects in placebo and foxcarnit arms respectively were randomized to each of the 3 arms. Initial leukocyte counts ranged from 1.6K to 3.0K/mm³ (median 1.9K), total granulocytes ranged from 0.8 to 2.5K/mm³ (median 1.6K), and T4-coum counts ranged from 6 to 31/mm³ (median 10). Five subjects had PCP and 1 had CMV retinitis as their first AIDS-defining infections.
Conclusions: Many persons screened for this study have been ineligible due to inadequate ophthalmologic and medical evaluation prior to presentation. Baseline and interim data and retinal photos showing progression of retinitis and response to foxcarnit will be presented.

M.B.P.130 TREATMENT WITH GANCICLOVIR (D.R.P.G.) IN H.I.V. CARRIERS WITH CMV IN THE BRONCHIOALVEOLAR LAVAGE

Michael Finaud*, C. Tamalet** and P. Casanova*. Hôpital Cochin, *Infectious Diseases Unit **Virology Unit, Marseille, France.

Objective: Describe the efficacy and long term follow up of treatment with Ganciclovir (GNCV) in HIV carriers when CMV is isolated from bronchoalveolar lavage (BAL).
Methods: In a series of 21 patients with mild symptoms of pneumonitis (cough, fever, dyspnea, interstitial abnormalities) without pulmonary symptoms but fever. We had treated with Ganciclovir 5 mg/kg twice daily for 14 days. CMV was systematically cultured from the bronchoalveolar lavage; this special concern all HIV carriers group I, III and IV of CDC's all positive for CMV but without any other opportunistic infection.
Results: 16 patients received Ganciclovir; 5 received no treatment. 2 patients had a disease free survival period characterized by no relapse and no opportunistic infections for 36 months; 1 for 24 months; 7 for 18 months; 4 for 12 months and 2 for 6 months. Of the five who did not receive treatment; one died at 3 months of HIV pneumonia; 3 developed other opportunistic infections after 8 months and 1 after 12 months. No serious side effects were observed.
Conclusion: Ganciclovir when CMV is isolated from bronchoalveolar lavage is safe and could protect the immune system of cytotoxic effects of CMV in HIV carriers and could delay the apparition of opportunistic infections.

M.B.P.132 EFFICACY AND TOXICITY OF GANCICLOVIR TREATMENT IN AIDS-RELATED CMV RETINITIS.

Huberman Hillel, Choukroun S.;...; Saxon L.;...; Vangeli M.;...; De Seldi R.;...; Thonnes...

INTRODUCTION: Hillel, Huberman Hillel, Choukroun S.;...; Saxon L.;...; Vangeli M.;...; De Seldi R.;...; Thonnes...
Objective: To evaluate the efficacy and toxicity of Ganciclovir (G) maintenance treatment in HIV-infected patients, at the onset of CMV retinitis.
Methods: Patients with CMV-retinitis were randomized in two groups: I) with maintenance treatment 5 mg/kg/d 5 days/week; II) without maintenance treatment; and were followed-up for 9 months. In both groups the CMV-retinitis was first treated with 10 mg/kg 20 days with 100 mg/kg q.d. Therapy was stopped when CMV-retinitis was completely resolved, and toxicologic toxicity was evaluated.
Results: 20 patients were enrolled in the study. Results concern 14 patients (5 M., 1 F.) mean age 40 years (r: 28-63), mean Karnofsky index: 75% (r: 50-100%), randomized in two groups: I: 10 pts. (100%), comparable for clinical status, toxicologic toxicity, as well as initial treatment (mean duration: 20.7 days, r: 10-28). Patients in group I relapsed after a mean 4.6 weeks (1:20 times whereas those in group II relapsed after 3.1 mean 1.6 weeks, 1:5 times (Figure 1). 3 patients died in group I. There was no difference in parameters studied for toxicity (table 1).

Parameter	Group I		Group II	
	n	%	n	%
Survival	10	100	10	100
Relapse	10	100	10	100
Death	3	30	0	0
Toxicity	10	100	10	100
Mean duration of treatment (days)	20.7		20.7	
Mean duration of relapse (weeks)	4.6		1.6	

Conclusion: In this study, patients in maintenance relapsed less frequently and later than the group II patients. These results have practical implications as far as drug association and patients' cost are concerned.

M.B.P.139 HIV SCREENING OF COMMERCIALY AVAILABLE BLOOD PRODUCTS IN INDIA.

Tripathy, S., Chaudhuri, R., Singh V.B., Seth, P., Varghese P. and Mishra, P. S.
 * Clinical Immunology Services, Department of Medicine, AIIMS;
 * Department of Microbiology, AIIMS, New Delhi, INDIA.

Objective: To describe the result of HIV screening of commercially available blood products in India.

Methods: 105 samples of blood products (via-immunoglobulin preparations, Factor VIII cryoprecipitate and a variety of blood products) of 1 American and 5 Indian companies were tested for the presence of HIV antibodies using the Moleczymus competitive ELISA kit. Presence of HIV antibodies was confirmed by Western Blot (Dupont).

Result: Of these 105 samples, 31 were found to contain HIV antibodies by the ELISA method. They were subsequently confirmed by the Western Blot test. Their results and their medical, social and legal implications have generated a lot of controversy in the country.

M.B.P.141

RISK FACTORS FOR HIV AMONG NEW YORK BLOOD DONORS IN 1980.
SEIDOR, BLUMBERG, Kessler, D., Berge, P., Andrews, S., DeVelle, C., New York Blood Center, New York, NY, USA.

Objective: To evaluate current trends in risk factors for HIV Ab+ blood donors in order to reduce their risk of blood supply.

Methods: We compared blood donor risk factor patterns identified from 1974-76, 1980 with April 1980-1986 data as reported by Keelin, et al.

Results:

Units Collected	Jan-Dec 1980	April 1980-May 1986
Anti-HIV positive	415,000 (240-260)	470,000
Donors interviewed	176(443)	470(1143)

Risk Factor	1980	1986
Male-Bisexual	31%	60%
IVDU	1%	4%
Blood Recipient	1.7%	1.8%
Met. High Risk Partner	26%	15%
Met. Multiple Partner	6%	7%
Heterosexual U.K. Risk	17%	7%
Other Risk	16%	3%

Donor interviews indicate that, heterosexuals with high risk partners, 68% have a greater perception of risk and ability to transmit HIV by transfusion than do heterosexuals with 1 or more partners of unknown risk (58%).
Conclusion: There has been a clear shift in risk factors among blood donors from homosexual/bisexual activities toward the IVDU and heterosexual donor population. An education has been effective in decreasing the donating homosexual population, renewed educational efforts should target sexually active heterosexuals.

M.B.P.143 CHANGING PROFILE OF HIV-SEROPOSITIVE BLOOD DONORS.

Wallis, Penny; Burkard, W.; Elliot, M.; Lee, S.; Sinclair, M.
 Canadian Red Cross Blood Transfusion Service, Vancouver, B.C.

Testing for the HIV virus was instituted in October 1981 to B.C. In the 3 years since, 453,000 units have been tested and 23 donors identified as HIV positive (0.05). 8 donors were also identified in the investigation of 14 cases of transfusion associated AIDS (TAA). 25 of the 33 seropositive donors were in self-identified high risk groups: 31 homosexual or bisexual males and 1 former partner of a bisexual male. All 8 donors implicated in TAA had self deferred an average of 26 mo. (range 6-34 mo.) prior to commencement of screening for anti-HIV in B.C. All 8 had been regular blood donors donating q-6 mo up to the time of their self deferral. In contrast, of 25 donors identified during the first 3 years of screening: 3 (bisexual males) were regular donors (63 mo.) and were picked up in the first few months of testing; none fell at risk for HIV infection. 5 were q-6 mo. donors up to an average of 22 mo. prior to screening (range 16-40 mo.) and then self deferred. However, 4 returned as donors within 5 mo. and 1 at 36 mo. post testing. Another 4 donors are sero-converters; of these, 1 had never donated blood prior to testing, 1 donated on 1 prior occasion. Of the remaining 13 donors, 3 had donated once prior to testing (2 within 1 mo. of testing); 10 were new donors. Although donors implicated in TAA had voluntarily self deferred well before testing for HIV and did not return, there remain self-identified high risk people who have enrolled as new donors since the advent of screening, presumably to be tested. Furthermore, some previously self-deferred donors in high risk groups are now returning to donate. This underlines the need for continuing efforts to discourage such behavior and for creative screening methods which will identify such donors on the clinic.

M.B.P.140 DETECTION OF HIV MARKERS PRIOR TO IgG ANTIBODY SEROPOSITIVITY IN PLASMA DONORS.

Suzuki, S.; Kikuchi, M.; Miller, J.S.; Coombs, R.W.; Perry, R.V.;; No, D.D.;**; Stewart, J.L.;**; Saito, S.;**;**;**
 *Abbott Labs. N. Chicago; ** Univ of Washington, Seattle WA; ***Centraal Pathologisch Laboratorium, London; **** UCLA School of Medicine, Los Angeles CA, USA.**

Objective: Determine the sequence of occurrence of HIV markers pre-seroconversion. Assess the utility of HIV antigen (HIV Ag) detection in plasma donors.

Methods: Pre-seroconversion serial samples at 3 to 7 day interval were obtained from 7 healthy plasma donors who seroconverted (U) licensed HIV antibody screen positive; licensed western blot positive; HIV plasma culture, HIV antigen, IgM anti-HIV, anti p24 antibody, and radio immunoprecipitation were performed on 36 samples available.

Results: In 5 donors, HIV antigen was detected prior to or simultaneously with IgG anti HIV. All HIV Ag positive samples were infectious for cultured normal peripheral blood mononuclear cells; most were also IgM anti HIV positive. The disappearance of HIV Ag and, to a lesser extent, of plasma infectivity was concurrent with the development of the IgG immune response. Although the improved sensitivity of recombinant antigen derived screening or anti p24 assays shortened the window period preceding seroconversion, HIV antigenemia and plasma viremia were the only markers of HIV infection for several days in 2 cases.

Conclusion: HIV infectious units from plasma donors can be eliminated from the plasma supply by HIV Ag screening.

M.B.P.142

SELF-EXCLUSION BY HIV ANTIBODY POSITIVE BLOOD DONORS
SEIDOR, BLUMBERG, Kessler, D., Andrews, S., DeVelle, C., New York Blood Center, New York, NY, USA.

Objective: To assess the self-exclusion (SE) behavior of HIV antibody seropositive blood donors resulting in reduced risk of blood supply.

Methods: 133 HIV Ab+ blood donors were interviewed and counseled in 1980. RETURNING and RISK FOR HIV INFECTION notes during the counseling sessions were retrospectively quantified.

Results: Eighteen (13.5%) self-excluded, while, overall only 1% of blood donors were self-excluded. Criteria for donor self-exclusion: 1) were male 50%; 2) were bisexual 40%; 3) were intravenous drug users 10%; 4) were multiple partners 10%; 5) were heterosexual U.K. risk 10%; 6) were other risk 10%; 7) were blood recipients 10%; 8) were HIV recipients 10%; 9) were HIV recipients 10%; 10) were HIV recipients 10%; 11) were HIV recipients 10%; 12) were HIV recipients 10%; 13) were HIV recipients 10%; 14) were HIV recipients 10%; 15) were HIV recipients 10%; 16) were HIV recipients 10%; 17) were HIV recipients 10%; 18) were HIV recipients 10%; 19) were HIV recipients 10%; 20) were HIV recipients 10%; 21) were HIV recipients 10%; 22) were HIV recipients 10%; 23) were HIV recipients 10%; 24) were HIV recipients 10%; 25) were HIV recipients 10%; 26) were HIV recipients 10%; 27) were HIV recipients 10%; 28) were HIV recipients 10%; 29) were HIV recipients 10%; 30) were HIV recipients 10%; 31) were HIV recipients 10%; 32) were HIV recipients 10%; 33) were HIV recipients 10%; 34) were HIV recipients 10%; 35) were HIV recipients 10%; 36) were HIV recipients 10%; 37) were HIV recipients 10%; 38) were HIV recipients 10%; 39) were HIV recipients 10%; 40) were HIV recipients 10%; 41) were HIV recipients 10%; 42) were HIV recipients 10%; 43) were HIV recipients 10%; 44) were HIV recipients 10%; 45) were HIV recipients 10%; 46) were HIV recipients 10%; 47) were HIV recipients 10%; 48) were HIV recipients 10%; 49) were HIV recipients 10%; 50) were HIV recipients 10%; 51) were HIV recipients 10%; 52) were HIV recipients 10%; 53) were HIV recipients 10%; 54) were HIV recipients 10%; 55) were HIV recipients 10%; 56) were HIV recipients 10%; 57) were HIV recipients 10%; 58) were HIV recipients 10%; 59) were HIV recipients 10%; 60) were HIV recipients 10%; 61) were HIV recipients 10%; 62) were HIV recipients 10%; 63) were HIV recipients 10%; 64) were HIV recipients 10%; 65) were HIV recipients 10%; 66) were HIV recipients 10%; 67) were HIV recipients 10%; 68) were HIV recipients 10%; 69) were HIV recipients 10%; M.B.P.145 CLOTTING FACTOR TREATMENT AND CD4 COUNTS IN ANTI-HIV-1(S) SERONEGATIVES.

The Transfusion Safety Study donors represented by Siegel, George F., et al. are receiving instructions in New York City, Miami, Detroit, Seattle, San Francisco, and Los Angeles, USA, except South Blood Center, Seattle, Washington, USA.

Objective: To determine whether reductions in CD4 counts among anti-HIV-1(s) seronegatives are related to type or intensity of treatment.

Methods: Data for anti-HIV-1(s) patients with Factor VIII (FVIII) or IX deficiency were analyzed by type and amount of treatment received from 1981-1985, defined as FVIII units, FIX units or FVIII units from cryoprecipitate (Cryo). Analysis was limited to 344 patients treated with FVIII concentrate, FIX concentrate or cryo only. Statistical inference was based on the rank correlation coefficient between amount of treatment and CD4 count.

Results: Median CD4 counts above or equal to treatment. Units = annual measurement.

Year-FVIII units	n	median CD4	correlation of FIX units			correlation of cryo units		
			r	p	units	r	p	units
1	20,620	534			0.17	0.00	0.20	0.00
2	13,935	497	-0.28	0.00	0.46	0.00	0.47	0.00
3	10,765	392			0.40	0.00	0.44	0.00
4	68,988	338			0.26	0.00	0.30	0.00

Conclusion: Increasing treatment was correlated with lower CD4 counts in those receiving FVIII or cryo, but not FIX. Heterogeneous proteins could be responsible for the observations in FVIII-treated patients. Relative risk of the variability in CD4 (r), however, is related to treatment intensity, which may itself imply an index of increasing duration of HIV infection. (Supported by Contract No. N01-HB-4-7003 of the National Heart, Lung and Blood Institute.)

M.B.P.147 PROTOACTIVATION OF HIV-1 WITH MERCOPYRINE 540

Rayne, James C., Harvey, R.L., Gonsky, L.L., Wayne State University, Detroit, Michigan, 48201, and Veterans Administration Medical Center, Allen Park, Michigan, U.S.A.

Objective: Mercopyrine 540 (MC 540), a thymidine dye, inactivates enveloped viruses following exposure to white light. We conducted an experiment to determine if MC 540 with light inactivates HIV-1, since phototherapy may be useful for inactivating viruses transmitted by blood transfusion.

Methods: Cell-free supernatant from HIV-1/IIa cells was mixed with MC 540 (30 ug/ml), then exposed to white light for 60 minutes. Untreated V8 cells were added to treated viral supernatant and virus adsorbed at 37°C for 2 hours, resuspended and incubated at 37°C in 80% DM for 7 days. Subsequent p24 antigen (Abbott) was measured at 7 and 10 days post-infection.

Results:

Solution	p24 optical density	
	Day 7	Day 10
HIV (no light, no MC 540)	0.737 (+)	0.818 (+)
HIV (no light, with MC 540)	0.450 (+)	0.873 (+)
HIV (with light, no MC 540)	0.139 (+)	0.203 (+)
HIV (with light, with MC 540)	0.044 (-)	0.056 (-)

Conclusion: MC 540 with white light inhibited HIV replication as determined by p24 antigen immunosay. Studies are in progress to determine if MC 540 has similar activity against cell-associated virus.

M.B.P.149 HIV SEROPREVALENCE AMONG HEALTH BLOOD DONORS IN 31 HOSPITALS IN ZAMBIA

Dr. P. W. Ndlovu, Ndlovu, Chikwa L., Nkhosi R., Tadder S., Sibayanga J., MRC/ISS/Health Services, London UK and *University Teaching Hospital, Lusaka, Zambia.

Objective: To screen blood for HIV infections in all the Blood Transfusion in Zambia with a view to limiting transmission. Secondly to provide information on the seroprevalence of HIV among health blood donors in Zambia.

Methods: Using a National Blood Transfusion record book all donors were interviewed in 31 hospitals in Zambia. Sex, Marital Status, address, Age, Social behaviour and Travel were recorded. HIV abs was screened using ELISA.

Results: HIV seroprevalence varied from place to place. The rural areas had 0%. The urban rural had 0-11 while the urban areas had 6-10%. The big cities ranged up to 11%.

Conclusion: HIV is a new disease in Zambia and is currently confined mostly to big cities and any part of Zambia with urban infection.

M.B.P.146 SEROLOGICAL EVIDENCE OF PRIOR SEXUALLY TRANSMITTED DISEASES IN HIV-1 SEROPOSITIVE BLOOD DONORS

Alan E. Williams, K.W. Cranley, T. Grandinetti, M. H. Sullivan, and the American Red Cross Collaborative HIV Study Group, Jerome H. Holland Laboratory, Rockville, MD, USA.

Objective: To serologically characterize HIV-1 seropositive blood donors who may carry AIDS risk behavior.

Methods: AIDS risk behaviors were defined as: all IV drug use or sexual contact with an IV drug user, or b) direct or primary partner contact with a gay or bi-racial male. These data were collected by in-person interview following test result notification from 156 HIV seropositive former blood donors and 155 age, sex, and race-matched controls. All subjects were tested for anti-HIV, anti-CW, anti-chlamydia, and anti-HSV.

Results: Prior behaviors likely to have increased AIDS risk were identified by in-person interview for 131/156 HIV+ former donors (83%). Twenty five donors were classified as having no identifiable risk (19%). The proportion of both RISK and HIV+ donors having additional STD markers was significantly higher than controls for all markers. In contrast, the proportions of RISK and the RISK HIV+ individuals reactive for all STD markers except anti-HSV did not differ significantly.

Conclusions: HIV+ donors as a group are significantly more likely to have serological evidence of prior exposure to other STDs. This exposure is also evident for donors who deny traditional AIDS risk activities. While none of the STD-related assays studied would have sufficient predictive accuracy to be used for blood screening purposes, they may serve as a mechanism for further characterization of these individuals.

M.B.P.148 p24 HIV ANTIGEN SCREENING OF BLOOD DONORS

Erica, Jost, Gathor, M.; Bækker, U.; Georru, P.; Rott, H.; Baumgarten, P.; Bergman, H.V.; Betsch, M.; Gierlich, U.; Dehnbach, P.

*Festschefer Institute, University Munich, Fed. blood Transfusion Service, Fed Cross, Munich, FRG, *Adair, Martin, FRG, *Blood Transfusion Service of Saarland, Federal Republic of Germany.

Objective: Screening blood donations only for HIV-1 antibody (anti-HIV) leaves open the possibility that a donor was in the period (4-12 weeks after infection) of being anti-HIV negative but infected and possibly positive for HIV-antigen (HIV-Ag). So several blood centers have evaluated the advantage of HIV-Ag screening in populations with different HIV prevalences.

Method: HIV antigen capture immunoassay (M. Chicago, IL) were used.

Results:	number of donations	Anti-HIV+ /HIV-Ag+	Anti-HIV+ /HIV-Ag-	Anti-HIV- /HIV-Ag+	Anti-HIV- /HIV-Ag-
Bavaria	359,870	0	16	0	0
Berlin	45,481	0	1	0	0
Bonn	24,117	0	1	0	0
Vienna	215,750	1	9	0	0
Linz	62,577	0	2	0	0
Innsbruck	52,190	0	3	0	0

It is particularly important that 6 donors became Anti-HIV positive 2 to 6 weeks after having been tested HIV-Ag negative.

Conclusion: In these 620,017 blood donors HIV-Ag testing failed to detect

M.B.P.150 RISK OF HIV-1 TRANSMISSION BY BLOOD TRANSFUSIONS IN

San Francisco PRIOR TO ANTI-HIV-1 SCREENING
Burch, Michael, Hanson, S., Young, M., Mark, J., and Perkins, L.
Irwin Memorial Blood Centers, San Francisco, California, and *Centers for Disease Control, Atlanta, Georgia, USA.

Objective: To estimate the proportion of blood transfusions that were infectious for HIV-1 during each of the seven years preceding introduction of routine anti-HIV-1 screening.

Methods: 1,554 previous donations by 149 former blood donors now known to have AIDS or HIV-1 antibody were plotted according to donation date. Using the observed seroprevalence of late 1984 donors (0.24%), and assuming a parallel seroprevalence with that reported for other high-risk persons in San Francisco between 1978 and 1983, the proportion of all donors who were high-risk and HIV+ was extrapolated for each earlier time point. The likelihood of recipient infection per unit exposure was then calculated by multiplying by the known infectivity rate (0.90) of a seropositive transfusion.

Results: The risk of infected transfusions rose exponentially from 1978 (<0.01) through 1982 (1.24). The risk plateaued in 1983 and then declined precipitously in 1984, despite continued spread of the virus in the local community.

Conclusion: The derived risk/time curve is validated by an alternate risk estimate based on reported dates of transfusion of known infected recipients, and has been of value in designing recipient counselling, notification and testing strategies.

M.B.P.167 ANTI-HIV SCREENING OF BLOOD DONORS IN CANADA (NOVEMBER 1985 TO DECEMBER 1986)

Barbara G. Gagnon, ADRIA, A. and WHITTINGTON, N.S.
THE CANADIAN RED CROSS SOCIETY, OTTAWA, CANADA.

BETWEEN NOVEMBER 1985 AND DECEMBER 1986, THE CANADIAN RED CROSS SOCIETY SCREENED OVER 3.7 MILLION UNITS OF BLOOD FOR ANTI-HIV USING ENZYME IMMUNO ASSAYS (EIA). THE UNITS FOUND TO BE REPEATEDLY REACTIVE BY EIA WERE DISCARDED AND THE ANTIBODY STATUS CONFIRMED BY WESTERN BLOT (WB). DURING THIS PERIOD, 14,313 (0.38%) UNITS WERE FOUND TO BE EIA REPEATEDLY REACTIVE AND WERE DISCARDED. ONLY 395 (0.11%) OF THE UNITS TESTED WERE FOUND TO BE WESTERN BLOT POSITIVE AND THE DONORS WERE INFORMED OF THEIR ANTIBODY STATUS.

ALTHOUGH THE REPEATEDLY REACTIVE RATES WERE NOT SIGNIFICANTLY DIFFERENT WITHIN THE CATEGORIES STUDIED, WB POSITIVE RATES DIFFERED SIGNIFICANTLY. THE ANTI-HIV SEROPREVALENCE WAS TWO TO FOUR TIMES HIGHER IN THE URBAN POPULATION THAN IN THE RURAL POPULATION. THE SEROPREVALENCE IN THE PROVINCE OF QUEBEC REMAINED CONSISTENTLY TWO TO FOUR TIMES HIGHER THAN THE REST OF THE COUNTRY. THE WB POSITIVE RATE WAS QUALITATIVELY HIGHER AMONG THE FIRST TIME DONORS THAN IN THE REPEAT DONORS. THE WB POSITIVE RATE WAS FOUR TIMES HIGHER AMONG THE MALE DONORS THAN THE FEMALE DONORS. THE HIGHEST SEROPREVALENCE WAS OBSERVED IN THE MALE DONORS OF 17 TO 29 YEARS OF AGE.

DURING THE STUDY PERIOD, THE WB POSITIVE RATE WAS DECREASED CONSIDERABLY, FROM 0.0343 IN THE FIRST QUARTER OF 1986 TO 0.0058 IN THE LAST QUARTER OF 1986, WHICH MAY BE MAINLY BECAUSE THE DONOR POOL HAS ACTED DYNAMICALLY AND THE WB POSITIVE DONORS ARE PERMANENTLY DEFERRED FROM DONATING.

M.B.P.159 TRANSFUSION AND HIV, FINNISH NATIONAL BLOOD BACK PROGRAM.

Koistinen, Jukka, Finnish Red Cross Blood Transfusion Service, Helsinki, Finland.

HIV situation in Finland by Dec. 31, 1986: 24 positive, of them 26 with a history of blood donation since Jan. 1, 1982, seven diagnosed at blood donation. The 26 donors gave blood 88 times for 99 products, of which 41 were used and 55 discarded, in addition some parts of 17 units were separated for F VIII, cryoprecipitate, interferon or plasma for albumin.

Results of the blood components used

	No. of units to hospitals	No. of patients	HIV pos.	HIV neg.	0	1	2	3	No. infom.
Whole blood	5	0	3	4	2	0	0	0	0
Red cell conc. (RBC)	23	3	5	11	1	1	0	0	3
Platelets	10	2*	0	0	0	0	0	0	2
Leukocytes	2	0	1	0	0	0	0	0	0
FFIII	44	2*	15	20	0	0	0	0	0

RE-HIV results of the patient are not known; Dupont had died of reasons not due to HIV; Home patient received two HIV pos. platelet concentrates. Two patients died of AIDS after receiving RBC in 1983 (died 1985) and 1984 (died 1987). One received HIV pos. platelets in 1984, started having opportunistic infections in 1985. One received RBC in 1985, got LAs in 1987. The one who got 2 units of HIV pos. platelets died a year later of leukemia without symptoms of AIDS. Two hemophiliacs are HIV pos. since 1984 due to cryoprecipitate. Of the donors 11 were first time donors, but their donations occurred equally between years 1982-86 suggesting that blood donation was not used for HIV testing.

M.B.P.161 RISK OF TRANSMISSION OF HTLV-I BY TRANSFUSION

B. F. Poek, et al.
Texas A & M University, College Station, TX. *Johns Hopkins Medical Institutions, Baltimore, MD. ** St. Luke's Episcopal Hospital, Houston, TX. U.S.A.

Objective: A prospective seroepidemiologic study was conducted to determine the incidence (I%) of seropositivity to HTLV-I in a cohort receiving multiple transfusions of blood/plasma components screened for antibody to HIV-1.

Methods: Preoperative and postoperative serum samples were collected from 2,749 adult cardiac surgery patients who received 20,983 transfusions of blood components (17,823 cellular components). Preoperative and postoperative samples were serologically compared for evidence of human T-cell leukemia virus type I (HTLV-I) infection.

Results: Five incident and two prevalent infections were detected in the study population. The observed risk of HTLV-I transmission by transfusion was 0.024% (5/20,983) per unit with 95% upper bounds of 0.052%. The risk per cellular component was 0.028% (5/17,823) with 95% upper bounds of 0.056%. Comparison of the five seroconvertors with sets of controls who received an equivalent number of blood components supported the transfusion of plasma as particularly associated with HTLV-I transmission.

Conclusions: These data suggest that despite similar modes of transmission and some overlap in risk groups, HIV-1 screening is not a satisfactory surrogate for HTLV-I. These results also provide important information about the risk of HTLV-I transmission by transfusion of blood components prior to specific screening of donor units for HTLV-I.

M.B.P.158 HIV-2 SEROPREVALENCE IN DIFFERENT GROUPS TESTED IN UNIVERSITY COLLEGE HOSPITAL, Ibadan, NIGERIA

Eric Enyien & Yannis Galis
Dept. of Haematology, University College Hospital (UCH) Ibadan, Nigeria.

Objective: To determine the relative frequency of HIV-2 among different groups tested in U.C.H. Ibadan

Methods: U.C.H. is the apex hospital in South Western Nigeria and is located in Ibadan, the largest city in Africa South of the Sahara desert with an estimated population of about 6 million. A total of 6,395 blood samples have been screened in this centre since July 1987.

Category	No. screened	ELISA +ve	WB +ve
Blood donors	5760	4	4
Haematology 4 other patients	537	3	3
Volunteers etc.	337	1	1
TOTAL	6395	8 (0.125)	8 (0.095)

Two of those who tested positive among patients probably acquired the infection through blood transfusion.

Conclusion: It is concluded that HIV-2 is present among different categories of persons in Ibadan. Transmission in some cases was probably via infected blood transfusion. A study of its effect(s) on the course of other diseases in this environment is being undertaken.

M.B.P.160 ABSENCE OF HIV SEROPOSITIVITY IN CHILDREN WITH SICKLE CELL ANEMIA AT KENYATTA NATIONAL HOSPITAL, NAIROBI, KENYA.

Nwera Samuel E. Biyora, Maw, J. J., Kinchua, P.M.K. and Kitonyi, G.W.
Departments of Paediatrics, and Haematology University of Nairobi, Nairobi, KENYA

Objective: To find out whether frequent blood transfusions increase the risk of transfusion-related HIV infection in children with sickle cell anaemia.

Methods: One hundred and ninety-eight children with sickle cell anaemia were transfused 1-13 times (mean 2.4) between 1982 and 1987. In Kenya routine screening of blood banks for HIV infection began in 1987. The HIV status of these children was compared with 231 non-transfused children: 106 with sickle cell anaemia and 125 children with haemoglobin AA. In both transfused and non-transfused children age ranges were similar and were 1-12 years. All children were tested with Westcozyme ELISA test in duplicate. All tests were performed at least 6 months after the last transfusion. Fifty five transfused children were rechecked one year later.

Results: All 428 children were HIV negative.

Conclusions: Our findings suggest that HIV seropositivity is low in Kenyan children. Furthermore, even though blood was unscreened in 1982-1987 transfusion did not increase the risk of HIV infection in our study children.

M.B.P.162 PREVALENCE OF HTLV-I ANTIBODIES IN BLOOD DONORS

IN THE NETHERLANDS
Van Der Pijl, Geert*, Lelia, N.**, Beekun, H.**, Ehlers, P.**, Bakker, E.**, Huismen, H.***
* Red Cross Blood Bank, Amsterdam. ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, the Netherlands.

Objective: To establish the prevalence of HTLV-I antibodies in blood donors in the Netherlands.

Methods: Serum samples from regular blood donors (n=20,037) were tested with 2 commercially available ELISA for HTLV-I antibodies. Repeatedly ELISA negative samples were tested for confirmation with commercially available WB strips and ¹²⁵I-RIBA developed in our institute.

	ELISA reactive	Western Blot	¹²⁵ I-RIBA
	n	positively	pos index
donors	20,037	49 (0.244)	26 (0.134)
		1	14
		1	10

Only 1 donor was found confirmed positive for HTLV-I antibodies with p19, p24, p26, p28, sp16 in WB and p24, p26, p28, p19/p24 in ¹²⁵I-RIBA.

Conclusions: the prevalence of HTLV-I antibodies in blood donors in the Netherlands is low and in the order of 0.005 %.

M.B.P.163

COMPARISON OF IMMUNOASSAYS FOR EARLY DETECTION OF HIV-1 SEROCONVERSION WELLS, V.J., Phillips, J.; Schoenbach, J.; Szeles, J.; Centers for Disease Control, Atlanta, GA, USA.

Objective: To evaluate various immunoassays for their ability to detect early seroconversion to human immunodeficiency virus (HIV) type 1 infection. **Methods:** Pre- and post-pulse panels for 13 individuals identified by various immunoassays as having seroconversion (positive Western blots) to HIV-1 were tested by 7 immunoassay employing 5 different technologies. **Tests used were:** Organon Teknica Virusomate enzyme immunoassay (EIA); Sero-Git Particle Agglutination Test (PAT); Gilead Recombinant Immunoassay (RIA); DuPont Western blot (WB); and three immunofluorescence assays (IFA), Electro-Blotronics (EBI), Cellular Products (CP), and Fluoromax (FL). **Western blots** were judged positive, indeterminate or negative by the criteria of the Assoc. of State and Terr. Pub. Health Lab. Directors (ASTHED).

Results: Listed are the number of times each method was first or tied with other methods to give a definite result: PA (11/12), EIA (7/12), RIA (6/12), WB (3/12), CP (3/12), EBI (9/12), FL (6/12).

Conclusions: The PA test was found to be the most sensitive test. The PA test became positive 3-5 days before other methods. Sensitivity of the PA test varied among the three IFA compared, EBI was the second most sensitive test overall, while CP was the least sensitive. Western blot detected antibodies to gag proteins at about the same time as the PA became positive but did not meet the ASTHED positive criteria in one panel until 20 days after the PA became positive. EA, RIA, and FL were similar in their sensitivities.

M.B.P.164

COMPARISON OF NEW HIV-1 SEROCONVERSION ASSAYS ON SIX HIV-1 ANTIBODY ASSAYS
Santoli, L.; Green, J.; Ghee, J.; Dow, E.; Sachs, R.;
Nash, S.; and Heller, J.S.

Univ. of Illinois, Urbana, IL; North American Biologics, Inc., Miami, FL, U.S.A.
Univ. of Utah, Salt Lake City, UT

Objective: An evaluation of six detection systems for HIV-1 antibody was performed on a total of 49 early seroconversion samples from nine donors. **Methods:** Viral and recombinant enzyme immunoassay (Abbott, Labs and Cambridge Biotech), and rapid detection assays (Abbott and Cambridge) were evaluated on a pool of 49 HIV-1 seroconversion samples including from nine donors.

Results: Of the 49 seroconversion samples tested, both recombinant EIA detected 42 (86%) samples at positive, Abbott's fast track (recombinant) also detected 42 samples as positive, which was followed by the Abbott modified viral EIA that detected 41 samples as positive. All positive of seroconversion samples progressed from negative to seroconversion status at the completion of the latex agglutination assay. With negative to positive; however, there was no sample detected as positive for two donors and the majority (36) were positive for only the earliest blends with subsequent blends becoming negative. The samples that were detected as negative in the latex agglutination test for these six donors were positive by all other assays. The results for these six donors on the latex agglutination assay most closely corresponded to their activity IgG reactivities.

Conclusions: Results suggest the latex agglutination assay appears to have reduced sensitivity compared to the other assays in this evaluation on samples having low levels of IgG typically contained within seroconversion series.

M.B.P.165

PROGRESSIVE CHANGES WITH TIME IN EXPRESSION OF CARBOHYDRATE ANTIGENS IN PBL OF HIV INFECTED PATIENTS

Ejima, J.; Horiuchi, M.; Kashiwagi, M.; Uchida, D.;
Oshiro, H.; Fudo, H.; Imai, Y.; Imai, N.; Nishimura, M.;
University of Calgary, Calgary, Canada. Japan Immunosorb Laboratory,
Takanashi, Japan. Prochilika Hospital, Calgary, Canada.

We have found in vitro that HIV infection of TALL lymphocytes causes significant expression on the lymphocytes of a carbohydrate determined by the Hc-1 monoclonal antibody (J Exp Med, 1988; 167: 323). Patients with AIDS have high levels of Hc-1 expression and asymptomatic patients have low levels of expression. Over 200 HIV positive patients have been followed prospectively to determine if Hc-1 expression correlates with clinical stage or prognosis. Hc-1 expression above 15% on lymphocytes was associated with poor clinical state or evolving infection and a low absolute T4 lymphocyte count. Continued high level of Hc-1 expression and low T4 counts persisted to patients receiving zidovudine. Hc-1 expression may have some value as a marker of progressive disease and could also be involved in the pathogenesis of cell destruction. A continued evaluation of this cohort would appear merited.

M.B.P.166

PACKED RED BLOOD CELL (PRBC) TRANSFUSION (TX) THERAPY FOR ANEMIA IN PATIENTS WITH AIDS AND ARC: INCIDENCE, ASSOCIATED FACTORS, AND OUTCOME

Zacharias, M.; Weiser, T.; Volberding, P.; Purzman, D.; Toy, PTCY, Feigal, D.; UCSF and HF General Hospital, San Francisco, CA, USA.

Objective: Determine the incidence, associated biologic factors and clinical outcome of PRBC Tx therapy (Tx) in patients with HIV disease. **Methods:** We reviewed records of the UCSF General Hospital (UGH) Blood Bank and identified 263 likely AIDS and ARC patients (pts) who received 154 units of PRBC between July 1, 1987, and June 30, 1988. A probability sample of 80 of these pts were randomly selected for detailed chart review. Of this sample, 78/80 were confirmed to have AIDS (84%) or ARC (16%).

Results: Based on the primary causes of the 80 AIDS pts, we estimated a Tx incidence of 0.36 (0.89 PRBC units)/pt/year for pts with AIDS and 0.11 (0.27 PRBC units)/pt/year for those with ARC. Of the 77 Tx's studied in detail, antimicrobial drug therapy, zidovudine therapy, and disseminated M. avium complex (MAC) infection were the sole likely etiologic factors in 20%, 14%, and 12% of the Tx's, respectively. To assess the role of MAC, the 263 Tx's pts were compared with the 574 pts who had blood submitted to the SFH Hematology Laboratory during the same time period. The above blood yielded MAC with a relative risk of 5.2 for Tx-requiring anemia. After 80% of Tx's, the pt returned to home.

Conclusion: Most PRBC Tx's administered to AIDS or ARC pts were clinically appropriate Rx. Applying our incidence data to the US PRBC estimates of future AIDS cases, we estimate that in 1990 the expected Tx needs of pts with AIDS and ARC will represent 1-2% of the total PRBC supply in the US.

M.B.P.167

SCREENING OF BLOOD DONATIONS WITH EIA COMBINED TEST (COMBI IgG EIA) BY USING SYNTHETIC PEPTIDES TO DETECT ANTI-HIV 1 / ANTI-HIV 2.

Hamerabek, R.; Kawanishi, T.; Kawahara, M. B.; Hiasaka, H.; Cavagnoli, K.; Guerra C. C. C. and Saterling, L. S.

Centro de Hematologia de São Paulo and Hospital Israelita Albert Einstein, São Paulo, Brazil

Objective: To evaluate the behaviour of the EIA test containing synthetic peptides (Pharmacia Comb i IgG EIA) for screening blood donation.

Methods: 2503 random samples and 25 anti-HIV-1 + Comb i IgG EIA were performed in comparison to EMI EIA test. Western blot was the confirming test.

Results: 9 random samples (0,36%) out of 2503 EMI + and confirmed by WB were strongly + with Comb i IgG EIA; 26 samples (1%) EMI false + were - with Comb i IgG EIA; 19 samples EMI true + were in accordance with Comb i test while 1 out of 6 false + samples was + with the Comb i test.

Conclusion: The Comb i IgG EIA proved to be sensible and agreeing when compared to EMI test.

M.B.P.168

DETECTION OF ANTIBODIES TO HUMAN IMMUNODEFICIENCY VIRUS BY VEIN AND CAPILLARY BLOOD FROM EARLY SEROCONVERSION

Chen, C.; Chen, S.; Kuo, K. M.; and C. H. Riggs
Centers for Disease Control, Rockville, MD, USA. Wesley Community Health Center, Boston, MA, USA.

Objective: The ability of rapid application test to detect antibodies to human immunodeficiency virus (HIV-1) in capillary and venous whole blood samples was evaluated.

Methods: RecombiPep™-HIV-1 IA is a five minutes latex agglutination (LA) test which uses polystyrene beads coated with recombinant gag antigen to detect antibodies to HIV-1. Capillary blood, anticoagulated venous whole blood, and serum samples were collected from 117 high risk patients in a Boston clinic. Pairs of anticoagulated whole blood and serum samples were collected from 57 patients at a hematology clinic and 96 donors at a transfusion center. These samples were tested by latex agglutination and the results were compared to those obtained by a licensed enzyme immunoassay with serum. All positive samples were confirmed by Western blot analysis and, in some cases, by radioimmunoassay.

Results: Using whole blood samples at the recommended 1:10 dilution, all 77 confirmed HIV seropositive samples tested were detected by the RecombiPep HIV-1 IA test. (sensitivity=100%). With 213 seronegative samples specificity was 95.1% with whole blood. In contrast, anticoagulated venous whole blood and capillary blood was 100%.

Conclusion: These data show that the 5 minute LA test can be used to detect HIV antibodies in venous and capillary whole blood.

M.B.P.175 PROBABILITY OF RECURRENCE OF BUCCAL CANDIDIASIS AND ITS RELATIONSHIP TO T4 COUNT AND P24 ANTIGEN.
DOR R. SMITH, MALLAN, J., WILLEY, S.G., GAZDAR.
ST. STEPHENS HOSPITAL, TOTTENHAM, ENGLAND.

OBJECTIVE: To assess time to recurrence of candidiasis after successful treatment and its relationship to T4 count and HIV P24 antigen.
METHOD: 100 HIV positive patients with confirmed buccal or oropharyngeal candidiasis received a 4 week course of either Itaconazole 200mg Q.D. or Metronidazole 200mg B.D. Successful treatment was assessed as clinical and mycological clearance. Patients were assessed for a further 3 months with regular clinical and mycological assessments in conjunction with T4 counts and P24 Antigen levels monitored each visit.

RESULTS:

RESULTS:	WITHIN 1 WKN.		WITHIN 3 WKS.		CLEAR AT 3 WKS.	
	ITRACONAZOLE	25 (74%)	27 (80%)	6 (18%)	ITRACONAZOLE	22 (63%)
MYCOLOGICAL:	22 (63%)	27 (78%)	28 (80%)	7 (20%)	28 (80%)	13 (38%)
TOTAL:	41 (60%)	52 (76%)	56 (80%)	13 (20%)		

T4 (m³): NO. MEAN. P24 Ag(u/ml): NO. MEAN. POS. MEAN.
AT ENTRY: 43 150 AT ENTRY: 58 37 111
RELAPSE: 21 150 RELAPSE: 18 27 124
NON-RELAPSE: 30 124 NON-RELAPSE: 42 21 53
CONCLUSION: 80% of HIV patients with oral candida have a successful relapse within 3 months of a successfully treated episode. T4 levels and P24 Antigen levels are not useful in predicting relapse.

M.B.P.177 MYCOBACTERIAL SKIN INFECTION IN AIDS
Lyovardis, Styllanos and Vaidya, K.P.
Dept. Dermatology, Woodhull Medical and Mental Health Center
Brooklyn, New York 11206, USA.

Cutaneous mycobacterial infection is a rare complication of AIDS. We describe two young intravenous drug addicts with oral candidiasis and mycobacterial ulcers and abscesses.

Case 1. A 23 year old black woman presented with fever, chills, diffuse lymphadenopathy and abscesses in the axilla and adjacent chest wall which required repeated drainage and debridement. PPD and HIV antibody tests were negative. The patient developed marked respiratory distress and chest X-ray suggested septal emphysema. Dermis and subcutaneous tissue showed coagulative necrosis, and numerous acid-fast bacilli consistent with *M. tuberculosis* (Mtb) but no granulomas or multinucleated giant cells. The organism was grown in urine but not in sputum or blood.
Case 2. A 33 year old Hispanic man with history of hemoptysis required drainage of a large abscess of the forearm and debridement of a 4cm ulcer of the anterior chest wall. Necrotizing granulomas in the dermis and in subcutaneous fat of chest wall contained few acid fast bacilli resembling Mtb. Chest X-ray did not suggest tuberculosis but prescopic infiltrates were seen. Mtb was recovered in sputum cultures. The patient developed respiratory distress and coma, and died on the sixth day.

Conclusion: Mycobacterial infection must be considered in the differential diagnosis of skin ulcers and abscesses in intravenous drug addicts, especially in the presence of other manifestations of AIDS, and appropriate bacteriologic studies must be performed.

M.B.P.179 VARICELLE ET INFECTION A HIV.
Peyronnet, Christian; Lescanne M.; Lepout C.; Salmeun, Jean-Pierre F. et Vilard J.-L.
Hôpital Claude-Bernard, 75018 Paris, France.

Objectif: Etude rétrospective de la varicelle chez 15 malades infectés par le HIV (HIV+) entre 1981 et 1988.
Méthode: Parmi 41 malades HIV+ hospitalisés, 15 (35%) ont fait une varicelle. Le diagnostic a été clinique. Une culture de virus varicelleux (VZV) ont été réalisées chez 4 d'entre eux et 4 d'entre eux ont été réalisés chez 3 malades ayant une éruption atypique.
Résultats: 1) Il y avait 12 adultes d'âge moyen 32 ans (18 à 70 ans) et 3 enfants d'âge moyen 3 ans. 2) Dans les groupes 1) ou 2) des CDC, 2 dans le groupe IV-C2, et 8 SIDA. Un malade a eu une lésion varicelleuse 31 mois et un autre 3 mois auparavant. Un contact varicelleux a été retrouvé chez 6 malades. Un malade, HIV+ asymptomatique, a fait une varicelle éliminante et est décédé d'une complication intracérébrale disséminée malgré l'aciclovir. Trois SIDA ont fait une éruption atypique avec une dissémination chronique contenant le VZV. Un malade a été traité par vidarabine et 11 par aciclovir i.v. Un SIDA a fait 3 recrudescences de varicelle avec des lésions atypiques malgré l'aciclovir.
Conclusion: La varicelle des sujets HIV+ peut être récurrente et se complique par des lésions atypiques. Le risque de formes mortelles justifie l'aciclovir i.v.

M.B.P.176 PROBABILITY OF DEVELOPING AIDS IN HIV-INFECTED PATIENTS WITH MOCOUTANEOUS LESIONS.

Colmenero Benito, J.; Nolasco, J.; Paganola, A.; Pallares, J.; Gudiol, F.
Hospital de Bellvitge, University of Barcelona, Barcelona, Spain.

Objective: To study the role of mucocutaneous lesions (MCL) as a predictor of AIDS in HIV-infected pts.
Patients and methods: Two hundred thirty nine HIV-positive pts without AIDS were followed during a mean of 13 months (1-81). The follow up period began when HIV antibodies were detected in non MCL-group or when MCL were observed in MCL-group, and finished with last visit made before December 88 or with the development of AIDS. MCL were diagnosed using clinical, histological and/or microbiological criteria.

Results: Eighty nine pts (27%) had one or more MCL (34/150 [54%] drug addicts 15/70 (51%) herpesvirus, 4/15 (27%) herpesvirus, 6/63 (10%) candida and 12 of 88 with MCL developed AIDS. MCL were oral thrush(4 pts), hairy leukoplakia(4), seborrheic dermatitis(3), herpes simplex(2) and staphy(3), folliculitis(1) and oral ulcers(1).

The Kaplan Meier survival method shows a percentage of free-AIDS pts at 20 months of 45% (95% confidence interval 38 to 54) in those with MCL comparing with 98% (95% confidence interval 92 to 114) in those without MCL (p<0.0001).

Conclusion: Our findings show that the presence of MCL in HIV-positive pts may indicate an increased risk of developing AIDS in the following months, although some of these lesions may have a different role as a predictor of AIDS. These pts may be considered for antiviral therapy.

M.B.P.178 HYPERKERATOTIC DISSEMINATED HERPES ZOSTER IN PROLONGED AIDS
Alan M. Seiner, M.D.; V.S. Rappaport, M.D.; J. Orens, M.D.; R. Heller, P.D. & University Clinic, Medical Center
Cincinnati, Ohio; U.S.A.

Unusual infectious diseases as well as unusual presentations of common infectious diseases have frequently been reported in patients with AIDS.

We report two cases of an unusual presentation of a varicella zoster virus infection in prolonged AIDS.

These hyperkeratotic, crusted skin nodules developed after the generalization of typical herpes zoster and progressed despite oral and intravenous acyclovir. Both patients had secondary *Candida albicans* infections of the crusted lesions and evidence of atypical Mycobacterial infection. One patient had cultures of blood and skin positive for *Mycobacterium intracellulare*. Of interest, both patients ultimately developed a verrucous squamocarcinoma (confirmed by clinical presentation and DNA).

We believe that our patients represent a presentation of disseminated herpes zoster unique to the AIDS patient that will be encountered more frequently in the future. The unrelenting, disfiguring nature of this disease as well as its apparent unresponsiveness to Acyclovir is of particular concern. One of the patients succumbed to his squamocarcinoma while the other developed it during a worsening of his skin lesions. This clinical picture may be a harbinger of a rapidly fatal outcome.

M.B.P.180 "NON-INFECTIOUS" DERMATOSES: CORRELATION WITH CD 4⁺ -LIMPHOCYTES AND STAGE OF HIV-INFECTION

Orbomorf, Falk, Schöfer, R. and Hillbrand, K.
Klinische J.V. der Universität, Dept. of Dermatology, Frankfurt, FRG.

Objective: To investigate whether other dermatoses, regarded as "non-infectious" or not, allow a clinical evaluation of the stage of HIV-infection.
Methods: Over a 2-year period, 267 HIV-infected patients (254 male, 13 female) were examined 12 times on an average. At first manifestation of a skin disorder, stage of HIV-infection and CD counts were recorded.

Results: On entry of the study the mean CD 4-count was 407/ml.

	CD 4						
	10 ⁶ /l						
Seb. dermatit.	17 (1)	21 (8)	30 (23)	40 (34)	29 (78)	340	
Pruritus	6 (1)	13 (7)	34 (80)	32 (78)	17 (72)	372	
Herpesvirus	11 (2)	13 (11)	26 (20)	34 (28)	24 (63)	264	
Rhinitis-Sinusitis			22 (48)	17 (46)	126		

(SEB. dermatit. stage; Seb. dermatit. "Seborrheic dermatitis")

13 patients (4.9%) had lesions typical of psoriasis vulgaris. On progression of the disease in 179 cases CD counts were lower than 200/ml.
Conclusion: "Non-infectious" dermatoses were more frequent and severe in advanced stages of HIV-infection and increased with decreasing CD counts. The results were related to clinical signs of cellular immunodeficiency indicating the risk of the individual for severe opportunistic infections.

M.B.P.181

MANIFESTATIONS CUTANÉES ET VIMÉROLOGIQUES CHEZ LES MALADES INDIQUÉS PAR LE VIH EN CÔTE D'IVOIRE FRANÇAISE

Centre Hospitalier de Cayenne, Cayenne, Guyane Française.
Centre Hospitalier de Saint-Maurice, Saint-Maurice, France.
 130 cas de S.I.D.A. ont été rapportés de 1980 à 1986 dans une population de moins de 100.000 habitants incluant 20.000 immigrants haïtiens et un petit nombre de prostituées de Banto-Doungou.
 Les principaux modes de transmission du VIH sont de type hétérosexuel (87,6%), et maternel/fœtal (10,7%).

Un seul cas a été constaté chez un homosexuel (0,78%) et il était porteur d'un sarcome de Kaposi. Un autre cas a été constaté chez un homme hétérosexuel ; il cas sur le 130 est un taux très bas pour le **SARCOME DE KAPOSI**. L'infection acquise le plus fréquemment rencontrée est le **CHANDRIER** et l'infection causée le **PRURIT**; cette manifestation est le meilleur signe d'orientation vers le test sérologique et se doit pas être confondue avec la gale chez l'enfant.

L'HERPÈS ZOSTER, le **SYPHILIS** et les infections à **PAPILLOME VIRALES** ont une incidence élevée, une évolution sévère, mais l'herpès et la zone peuvent être traités par l'Acyclovir.

La **TRICHOMONOSE** est fréquemment observée et son rôle pour la transmission du VIH de la femme à l'homme n'est pas encore très important, le parasite obtenu en Espagne récemment est le plus préjudiciable du séduis.
 3 cas de **CONDUITES** doivent être mentionnés en raison de l'épidémiologie par contact anales ainsi ; la faible agressivité de l'**Epithéliobacterium** **epithelialis** nécessite un défaut immunologique causé par être réellement pathogène. Une **LEPTE LEPROMATOSE** **incerta** a aussi été observée.

M.B.P.182

DERMATOLOGICAL MANIFESTATIONS AND HIV INFECTION

Hove, E. A. V., Williams, E. J., University of Limpopo, M.C., Germ. M., M. J. Dyer, J. S. Maitland, M. S. C. V.
 Graham's Bantu University Hospital - University of Limpopo (Grahamstown) - Beaufort

Objective: To analyse all dermatological manifestations among HIV infected patients.
Methods: We made a retrospective study of all dermatological lesions among patients attending our "AIDS" Clinic from November 1983 to August 1986. HIV infection was confirmed by ELISA. Informed immunodeficiency and/or immunological lesions. All immunologic lesions were confirmed by biopsy and/or culture when needed. Patients were evaluated for age, sex, time of onset of infection and site of infection; we did not evaluate treatment or response to treatment.

Results: We found dermatological manifestations in 227 patients (10,8%), 212 male (93,9%), 15 female (6,1%). Most of the patients concerned were true type of infection.

TYPE OF LESION	PATIENTS
Kaposi's sarcoma	48
Herpes zoster	47
Other herpes	28
Other fungal	47
Bacterial	31
Syphilis/dermatitis	56
Others	26

Conclusions:
 1) Dermatological manifestations are common among HIV infected patients.
 2) Skin biopsy illustrates a significant diagnosis of HIV infection by the skin.
 3) Immunologic manifestations are common among HIV infected patients.

M.B.P.183

MANIFESTATIONS CUTANÉES-MUQUEUSES DU SIDA AFRICAIN

Centre Hospitalier de Dakar, Dakar, Sénégal.
Dr. Ball M.D., Banga E. J., Faly/Mao A.A.,* Faliel-Damouche K.* et al.***

C.H.U de Dakar, *Centre des Maladies Infectieuses ; **Service de Dermatologie ; ***Institut d'Odontostomatologie de Dakar, Dakar, Sénégal.

Objective: Décrire les manifestations cutanéomuqueuses observées chez le SIDA Africain atteint de SIDA (HIV-1, HIV-2).

Methods: Etude rétrospective des dossiers de maladies hospitalières dans le Service de Pathologie Infectieuse. Leur suivi a été fait en collaboration avec un dermatologue du C.H.U. Une iconographie a été établie.

Results: Sur 73 malades atteints de SIDA, 61 ont présenté des manifestations cutanéomuqueuses (83,56) comprises, 16,45 muqueuses et 70% anales. Les candidoses bucco-pharyngées sont les plus fréquemment observées (70,49%). Le sarcome de Kaposi est rare (4,93%). Les autres manifestations sont retrouvées à des taux variables.

Conclusion: Dans notre étude, nous confirmons la rareté du Kaposi SIDA en Afrique mais retrouvons les manifestations classiquement décrites.

M.B.P.184

PRIMARY HIV-1 INFECTION WITH VIRUS DEMONSTRATED IN HISTIOCYTES OF SKIN RASH

Waller, K. J., Oliver, L. J. and Gorman, S.*****

Hospital and Medical Center, *Foundation for Research on Sexually Transmitted Diseases, New York, NY, USA and **New York City Department of Health, New York, NY, USA.

Objective: To describe a severe case of primary HIV-1 infection.

Methods: The patient is a 22 year old homosexual male who came to New York City from Detroit, Michigan in late June 1988. Upon arriving, he had "monos" and with older homosexual male for several weeks. Approximately 2 weeks later, he had onset of symptoms including headache, neck pain, profound weakness, and aversion to light and sound, with subsequent development of a bright red skin rash on the digits and volar surfaces of the arms, demonstrating Koebner's phenomenon. Sera were collected within 2 days of onset of symptoms, and repeat sera and biopsy of the skin rash taken 7 and 3 weeks later.

Results: The headache persisted 9 days, while the skin rash faded gradually over 7 weeks. The initial sera tested negative for antibodies by both ELISA and Western Blot. The repeat sera taken 16 days later was positive for antibodies by both ELISA and Western Blot. Both the initial and repeat sera were negative by the HIV p24 core antigen ELISA test. The HAE skin biopsy showed a leukocytoclastic vasculitis. Electron microscopy showed HIV-1 virus particles within the cytoplasm of the histiocyte. White blood counts were as low as 3,000, and at the time of the biopsy, T4 cell count was 656, and T8 count was 815.

Conclusion: Primary HIV-1 infection may be severe with symptoms lasting a month. Presence of a skin rash with a mono-like illness should indicate the need for HIV testing in order to make an early diagnosis, creating the opportunity of beginning medical therapy to possibly delay progression of the disease.

M.B.P.185

DERMATOLOGICAL MANIFESTATIONS RELATED TO AIDS IN SENEGAL

Senegal, M. Koyada, L. Ilectchi, B. Di Costanzo, A. J. Georges, J. Testas, M. N. Vohlon
 1 National Hospital Center, BP 943, Bangui, Central African Republic
 2 Pasteur Institute, BP 923, Bangui, Central African Republic.

Objective: To describe and evaluate the frequency of dermatological manifestations in African patients with AIDS.

Methods: One hundred (100) Senegalese patients at the National Hospital Center, Bangui, were chosen according to the WHO/Bangui clinical definition of AIDS and were confirmed to be HIV positive by western blot. Patients were given dermatological examination. Kaposi's sarcomas were confirmed by biopsy, and necrosis by fungal culture.

Results: Pruritic lesions were the most frequent symptom in 27/110 patients, associated in 26/27 cases with specific dermatitis. Generalized pruritic eruption with purpura was seen in 22/27 cases. Kaposi's sarcomas (nodular and papular varieties mainly) in 14/110 patients. The leading viral or generalized herpes infection was HIV with atypical herpes (herpes zoster nodules and infection was **Herpes zoster**). All patients showed mucocutaneous herpes zoster infection. Oral candidiasis was found in 26/110 patients while 26/110 showed.

Conclusions: In this series, dermatological manifestations were detected in the half (52%) of African patients with AIDS. These patients are more likely to present with varicella zoster/mucocutaneous lesions than AIDS patients in Western countries.

M.B.P.186

BASEL CELL CARCINOMA IN HIV DISEASE

Lee, J. J., Barnett, J.*****
 Department of Medicine, University of Wisconsin Medical School (Milwaukee Clinical Campus), Milwaukee, WI, USA, **Department of Surgery, University of Wisconsin Medical School, Madison, WI, USA

Objective: To describe an unusually high incidence and atypical presentation of basal cell carcinoma (BCC) in HIV infected men.

Methods: Cases of BCC in HIV infected patients (total) were collected from local practices and from 2 dermatologic referral practices. **Results:** 6 pts with 14 BCC were seen, all saw white males (1 AIDS, 3 BCC, 1 pre-AIDS), 1 high risk, mean age 48 (range 28-65), 4 pts were from a group of 111 HIV infected males followed for 81-33 years (mean 14), 12/14 BCC in this group. 3 facial/11 truncal BCC (2/7 ratios); 8 extracted for size and latitude=82. One pt developed 8 truncal lesions over 3 years. 8 pts experienced as multiple synchronous BCC (BCC expected) 2 pts had small surface lesions but deep tissue invasion. 3 pts had MPU lesions (oral condylomata, parotid condylomata, facial warts) and 1 had molluscum. All were treated by primary excision. 3 also had Mohs chemotherapy. No metastatic or locally destructive lesions have occurred. 82 annual incidence of BCC among white males in the HIV infected group vs 188 expected for age and latitude; 6% annual incidence of truncal lesions in 188 expected. **Conclusion:** BCC may occur frequently in some HIV infected groups, may present atypically, and should be looked for and treated aggressively. Cutaneous such as MPU may be involved.

M.B.P.187 PROCRISIS IN HIV INFECTION: CLINIC, HISTOLOGY AND HLA TISSUE TYPING

Maximilian, S. Wallman, D.J. Landthaler, M.J. Braun-Falco, D.

Dermatological Department of Ludwig-Maximilians-University, Munich, FRG.

Abstract: To determine differences between procrisis manifesting before HIV infection (group I) and procrisis occurring after HIV infection (group II), 160 patients in a study 4.5 % (16/328) of patients suffering from procrisis vulgaris were divided into two groups and clinic, therapy, histology and human lymphocyte antigens (HLA) tissue typing were evaluated. 86 patients were affected in 3/5 of group I patients and 74 belonging to group II. All patients - except one group II - showed typical clinical procrisis. Nail deformities were seen in 60 % of group I and 37.5 % of group II. In three patients treated with sidonipine quick improvement of cutaneous lesions could be seen. Histology was typical for procrisis vulgaris in 2/3 biopsies of group I and 9/12 of group II. HLA tissue typing showed that HLA-Dw6, a sign of hereditary procrisis with early onset, was found in 3/3 patients group I but only 2/4 group II. **Conclusions:** Procrisis in HIV infection even without family history shows typical clinical and histological features. HLA-typing seems to be different in the two groups. HIV infection may be an endogenous stimulant leading to provocation or exacerbation of procrisis vulgaris.

M.B.P.188 LES MANIFESTATIONS CUTANÉES DE L'INFECTION AU HIV AU SENEGAL.

MARILLIAMA, FIDJALE et NGORBO, G.
Hôpital Universitaire, Niakhar, SENEGAL.

Plusieurs manifestations dermatologiques sont actuellement associées à l'infection au HIV.

Nous rapportons les résultats de la séroprévalence à l'ELISA/HIV parmi les patients adultes consultant le service de Dermatologie-Vénérologie de l'Hôpital Universitaire de Niakhar-Senegal de 1985 à 1986.

Sur 543 patients testés, 752 ont été séropositifs à l'ELISA. Le taux de séroprévalence relativement élevé a été observé parmi les patients souffrant des dermatoses suivantes : Zona (881=200), prurigo (881=107), dermatite séborrhéique (891=37), dermatose papuleuse prurigineuse adénolésite (911=13), "maladies contagieuses" (871=24), sarcome de Kaposi avancé (901=15), herpes circiné (901=1), névrome géant (891=30), condylomes acuminés (711=78), furoncles (711=31), prurit généralisé (901=19), urticaire (911=30).

Toutes ces dermatoses bénignes pour la plupart devaient plus souvent quand elles sont associées à l'infection au HIV. 2 ou 3 de ces dermatoses ont été associées chez 120 (28%) malades.

41,62% des patients séropositifs présentent des manifestations cliniques uniquement dermatologiques et seuls 60 (14%) malades répondent à la définition clinique de l'OMS du cas de SIDA. Ces manifestations cutanées constituent donc des manifestations précoces du SIDA.

Manifestations cliniques Clinical Manifestations

M.B.P.189 NAIL DISORDERS IN ZIDOVUDINE TREATED AIDS PATIENTS

Dea, P.J. Fallon, F.R. Fried, P.J. Brennan, A.J. Deaconson, Frederick P.J. Jones, J.M. O'Connell, M.C. New York Medical College Westchester Hospital Center, New York, New York, U.S.A.

Objective: Define the frequency and parameters of nail dystrophies in AIDS patients on Zidovudine.

Methods: 38 patients with AIDS or ARC on Zidovudine therapy (AZT) for a mean of 8 months (1-22 month range) returned to be evaluated for the development of nail dystrophies. A group of 38 AIDS patients not on AZT and a group of 38 normal patients served as controls.

Results: History of these 38 AIDS developed progressive nail dystrophies starting on average between 4-6 weeks after initiation of AZT therapy, near development (onset) lesions had transverse bands and generalized nail dystrophies were also seen. Color varied from shades of blue to brownish. The "Hamman" sign developed distally in 11/16 (68%) of patients. Pigment initially appeared at the base of the nail and moved distally. Small

dystrophies also occurred and followed after finger nail dystrophies. No other areas of abnormal pigmentation nor hyperkeratization was noted. Dystrophies were not associated with sun, having AIDS or ARC, other medications used, nor risk factors for AIDS. Black patients were twice as likely to develop dystrophies 6/11 (55%) vs 10/19 (53%) (p<0.500). Sixty three percent (40/63) (63%) (38%) or (38%) (38%) - low dark almost control patients had faint longitudinal brown all streaks of long duration consistent with normal pigmentation variation in these individuals. This contrasted greatly with the unusual colors and patterns seen in AZT treated patients.

Conclusion: Progressive streaking patients with AZT need to be aware of this high frequency of nail dystrophies especially in dark skinned individuals and inform their patients of its possible occurrence in order to facilitate compliance.

M.B.P.190 LIPOSOME ENCAPSULATION FACILITATES ENHANCED KILLING EFFECT OF AMBICAN ON MYCOBACTERIUM AVIUM COMPLEX (MAC) IN SERUM

Patilings R.K., Gangadhara K., Kesavulu, L., Goldstein, J., Debs, R.L., and Mangione, J.F. National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado and *Cancer Research Center, University of California, San Francisco, California, U.S.A.

We demonstrated that amikacin is effective in eliminating *Mycobacterium avium* complex (MAC) from beige mice, challenged intravenously with virulent MAC. However, high dose (50 mg/kg) given daily 5 days a week for 8 weeks is needed for this action. When encapsulated in liposomes consisting of phosphatidyl glycerophosphatidyl choline-cholesterol (1:1 molar ratio), one-tenth of the dose, given in 3 or 4 injections, amikacin effected dramatic reduction in mortality and the number of colony forming units (CFU) of MAC from visceral organs. The amount of drug given via liposome formulation is a fraction of that given by the standard conventional treatment for the entire period. Thus the entrapment effect per unit dose of drug seen in each tissue is several times more with liposome encapsulation than with the free form. Liposome encapsulated amikacin caused high antimicrobial activity against MAC inside macrophages and J-774A cell lines, while the free compound showed negligible activity.

M.B.P.191 HUMAN PAPILLOMA VIRUS (HPV) IN ANAL Bowen'S DISEASE OF HOMOSEXUAL MEN

Lawrence G. Cohen, M.D., Department of Pathology, Lenox Hill Hospital, New York, N.Y., U.S.A.

The incidence of anal carcinoma and lymphoma, uncommon tumors in the general population, are increased in homosexual men. A 5-year review of the anal patients, revealed a series of 40 condylomata (II), 38 cases of squamous cell carcinoma in situ (Bowen's disease)(II) and 15 cases of invasive squamous cell carcinoma (III), between 1980 and 1985.

Confirmed homosexuality was 84%, 62% and 57% and the average age of patients was 32, 37.5 and 49.5 years in groups I, II and III, respectively. AIDS was associated in 16%, 42 and 37.5% of cases. Condyloma was consistent with 52% of the carcinoma in situ and with 32.5% of the invasive carcinomas. Karyotypic atypia was present in 72% of carcinoma in situ. HPV antigens were detected by immunoperoxidase staining in 3 of 13 and by in situ hybridization in 4 of 13 cases of anal Bowen's disease in homosexual men.

58% of HPV type 6/11 was detected in 3 cases and HPV type 16 in 4 cases, one lesion harboring both types 6/11 and 16. HIV antibodies and reversed T3/T4 cell ratios were present in most patients tested. Squamous cell carcinoma in situ generally showed the features of Bowen's disease. The occurrence of anal Bowen's disease in young homosexual males, some HIV positive, and the frequent detection of HPV, suggest an etiologic relationship between HPV and HIV.

M.B.P.192 THREE YEARS OF EVALUATION OF THE CLINICAL CASE DEFINITION OF AIDS IN CENTRAL AFRICA.

A.J. Burgess, J. L. Bhat, J.L. Lombard, M.C. Georges-Courbot, M.D. Whitton, P.R.V. Martin.

1) Institut Pasteur BP 956 BANOU - C.A.R. 2) Centre National Hospitalier BP 956 BANOU - C.A.R.

Objective: To evaluate and try to improve the WHO clinical case definition of AIDS proposed at Banou in 1985. **Methods:** We have applied the criteria of both the clinical case definition of Banou and CDC's one and two definitions to 100 patients hospitalized and distributed into two cohorts of people fitting with each definition. **Results:** Using 3 different "scoring" systems for that evaluation there is not a difference between the results. Among a population of 100 blood AIDS defined on the basis of the WHO workshop, the empirical scoring system one of us previously proposed in 1985 has a predictive value of 90% for affirming AIDS.

The usefulness of simple serologic tests such as ELISA is demonstrated among patients fitting with clinical case definition, the presence of anti HIV antibodies (ELISA) increases the positive predictive value (98.5%). We were also able to emphasize that serologic involvement (e.g. Peripheral Blood Cell Counts, coagul serological assays) never taken into account by the Banou definition is very common and often necessary. **Conclusion:** Developing simple serologic tests deeply facilitates the diagnosis in presence of patients recruited on the basis of clinical symptoms only, and in front of atypical clinical symptoms particularly in patients with neurologic disorders.

Session 4/1985 Poster Session

Aspects cliniques Clinical Aspects of AIDS

M.B.P. 199 HIV INFECTION NATURAL HISTORY. "PERSISTENT" AND "ACTIVE" FORMS DO EXIST AND ARE CLINICALLY DISTINGUISHABLE.

Reinhold, Janssens, R. De Witte, J. A. Bax, G. A. Van, G. A. Van, G. A. Van, G. A. Van.
Centre for the Study of AIDS & Acute Infectious Diseases, U.S. Health Res. Inst., Bonn, West Germany.

Objective: To describe natural history of HIV infection and classify HIV seropositive patients with clinical reliability.

Methods: We included in our trial all HIV-seropositive patients who completed at least one year of follow-up. We considered the occurrence, in the first year, of various clinical and laboratory findings (weight loss, fever, herpes zoster, HIV seroconversion, infectious mononucleosis, neurological symptoms; final Candidaemia, Kaposi's, Cervix adenoma, Chlamydiae, enteric S.S. IgG, SPO 2000 spg/ml, IgM spg, Tuberculosis; PCR 2000/dm³). For each finding we gave the patient a "score" of 1. At the end of the first year of follow-up we considered, for each patient, a "Final Score". Following the main of the infection we classified the patients as having "Persistent Clinical Infection" (Score at least "Active" score) or "Inactive Clinical Infection".

Results: 100 patients (103 T84, 23 Hanes, and 10 Hanes-1) were evaluated. 106 patients received 300 mg zalcitabine from 2 to 2 "Persistent" infection; 23 received 300 mg zalcitabine from 4 to 2 "Inactive" infection. Only 17/106 patients were HIV-1 infection cases follow-up period: 21 months (received from 100 to 100 T84) or 12 months (received from 100 to 100 Hanes-1).

Conclusions: Our data show an overall clustering of HIV-infected patients in two groups. Some patients progress very slowly and are "inactive" at all. Others are very quickly through various stages of the illness and reach full-blown AIDS in a short period of time. Clinical manifestations occurring in the first year of the follow-up are helpful to classify the patients in "Persistent" or "Active" form. These findings have great prognostic and therapeutic implications.

M.B.P. 201 CLINICAL AND AUTOPSY FINDINGS IN HIV-1 SEROPosITIVE PATIENTS.

Affens, Behal, J. Green, V. J. Olopoko, L. L. Barnes, J. J. Senterre, G. A. Van, G. A. Van, G. A. Van, G. A. Van.
Howard University Hospital, Washington, DC, U.S.A. *National Cancer Institute, Bethesda, Maryland, U.S.A.

Objective: To determine the usefulness of the autopsy in HIV-1 seropositive patients by comparison of discrepancies between the pre-mortem clinical impressions, the clinical cause of death and the autopsy findings.

Methods: Cases for review were obtained from the files of the pathology department of Howard University Medical School. From 1983 through 1988, fifty cases were identified as being seropositive by ELISA and Western blot assays. Clinical histories including pre-mortem diagnoses were available as abstracts from the medical record in the autopsy protocols.

Results: Of the 50 cases reviewed, 41 met the CDC criteria of AIDS, 25 pneumonia and 16 at autopsy. There were 37 males and 12 females. Mean age was 35.4 years. Risk factors included homosexuality in 22 cases, intravenous drug use (IVDU) in 15, STDs and homosexuality in 4, blood transfusion in 4 and unknown risk factors in 1 case. The lung was involved in diseases in 37/41 (90.2%) AIDS and 7/7 (100%) non-AIDS cases. Diseases diagnosed only at autopsy included PCP (12/22), CMV (9/9), ES (5/7), disseminated HAI (9/13) and bacteremia (7/21). Pathological cause of death correlated with cause of death on the death certificate in 38, 35 and 44.4% of AIDS and non-AIDS cases respectively. **Conclusions:** The lung was found to be the organ most frequently involved in disease at autopsy. The autopsy diagnosed a significant number (61.2%) of unexpected and undiagnosed AIDS diseases. Autopsy findings modified the clinical impression of the cause of death in 44.0% of all cases. These findings suggest that the autopsy plays a significant role in quality assurance of diagnoses in HIV-infected patients, both AIDS and non-AIDS.

M.B.P. 202 RECURRENT MAXILLARY SINUSITIS IN AIDS PATIENTS.

Redding, Hout, J. J. A. M. van, G. A. Van, G. A. Van, G. A. Van.
Academic Medical Center, University of Amsterdam, the Netherlands.

Objective: The treatment of recurrent maxillary sinusitis in AIDS patients.

Methods: From 1983 until now 311 AIDS-patients have been treated in our hospital. Of this population 112 patients had recurrent maxillary sinusitis one or more times. The diagnosis was made by clinical examination, radiography, and bacteriological culture. Remarkable was the high incidence of Staphylococcus aureus as cause of the infection. When a patient had a maxillary sinusitis for the first time he was treated with amoxicillin, sulfamethoxazole and trimethoprim. Despite this conventional therapy the recurrence rate was high in 28 (32%) of the total population. To avoid repeated treatment with antibiotics we decided to operate patients when they had a maxillary sinusitis for the third time. We made a rhinoscopic approach on both sides, using the technique as has been described by Dr. Butler. The operation microscope was used to have a good view of the operation-field. The sinuses were made large by inferior turbinate. Owing to this a good ventilation of the maxillary sinus has been achieved.

Results: Until now we have operated 14 patients. The follow up period was 4 to 20 months. We have not seen a recurrence. The patient has to stay only 3 days in hospital, the postoperative recovery is fast, with only less discomfort for the patient.

Conclusions: Surgery may be a superior to antibiotics in the treatment of recurrent maxillary sinusitis in AIDS-patients.

M.B.P. 200 HIV-2 IN ENGLAND.

Ayanian, J. J., Maguire, J. J., Kanki, P. H., Baker, R. G., Mayer, R. M., Essex, M. T., Harvard Medical School, Boston, MA; Harvard School of Public Health, Boston, MA, USA; *Brown University, Providence, RI, USA.

Objective: To survey selected populations in New England for exposure to HIV-2. **Methods:** Individuals at risk for HIV-1 infection (men who have sex with African descent (n=128), individual sex partners (n=128), Western blot testing for HIV-1 (n=111), and individuals suffering from AIDS syndromes without definite HIV-1 serology (n=11) were surveyed for HIV-2-specific antibodies.

Results: One individual was seropositive for HIV-2-specific antibodies. This one individual was a 20 year old male originally from the West African region with seven years of extensive travel prior to residing in the United States for the past 7 years. He presented in early 1988 with a 4 month history of anorexia, nausea, vomiting, and watery diarrhea. On physical exam, he was afebrile, had no lymphadenopathy, abdominal tenderness nor occult blood in his stool. Microscopic examination of his stool revealed trophozoites (ball ovals). The patient's symptoms resolved on oral trimethoprim-sulfamethoxazole therapy, but returned 6 months later again with increasing weight loss. This was successfully treated with pyriminone. A laboratory examination revealed a persistently low absolute T cell count. Serologic evaluation indicated a negative HIV-1 Western blot and RIPA for HIV-1 and the same assay showing strong reactivity for HIV-2 envelope and transmembrane antigens. His RFLP-PCR culture revealed a transmissible isolate of 4 weeks and subsequent passage of the isolated virus into continuous cell lines has revealed viral proteins consistent with other HIV-2 isolates by Western blot and RIPA.

CONCLUSIONS: 1) Evaluation of blood samples from selected individuals in New England has identified one patient with an apparent immunodeficiency associated with HIV-2 exposure. Presumably the second case of HIV-2 infection in the United States. 2) In one instance the patient was exposed to HIV-2 in West Africa, the case reveals a fairly long latency period prior to his present health problems. 3) Our selected survey, as seen with other broader surveys, has shown that HIV-2 is extremely rare in the United States.

M.B.P. 202 PAIN IN PATIENTS WITH AIDS

Latovics, A., Lefkowitz, M., H. J. Senterre, G. A. Van, G. A. Van, G. A. Van, G. A. Van.
Pain Management Service, Department of Anesthesiology, State University of New York Health Science Center at Brooklyn, Brooklyn, NY, USA.

The alarming increase in the transmission of AIDS, as well as its poor prognosis, leaves a critical need to evaluate the presence of pain and its current management. A chart review study was therefore undertaken to evaluate these issues in a hospitalized AIDS population.

Ninety-six randomly selected charts of AIDS patients were reviewed in a systematic manner for the prescription of analgesic or psychologic medication, as well as the location and type of pain. Eighty-two patients were male (85%); mean age was 33.4 years; 44 patients (46%) were diagnosed with AIDS during the admission that was evaluated. The most common AIDS syndrome was Pneumocystis carinii pneumonia (37%). The second most common presenting symptom for this hospitalization was pain (26%).

Fifty-two of the 96 charts reviewed (54%) had at least one note of non-procedural pain or analgesic prescription. The most prevalent location of pain was musculoskeletal (22%). There was no significant relationship between intravenous drug abuse, specific AIDS syndromes, duration of illness, and the incidence of pain or pain medication prescription. Nearly one-third of patients with pain received codeine (31%), followed by acetaminophen (27%) and acetaminophen with codeine HCl (Percocet). In only seven instances but one, the scheduling was on an as-needed basis, rather than a fixed schedule.

This study suggests that pain is a major issue in AIDS patients that may be largely overlooked and not managed optimally. A methodology for the prospective evaluation of pain in AIDS patients as well as alternate pain management techniques are recommended.

Manifestations pulmonaires

Pulmonary Manifestations

M.B.P. 204 NONCARDIAC ANTIESTHESIOLOGIC INJECTIONS IN PATIENTS WITH THE ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS).

Coste, Lencastre, Pulgosa, P. J. Woodard, D. Berk, A. Fiala, M. Lynch, R.
Sections in Infectious Diseases and Thoracic Surgery, Eisenhower Medical Center, Rancho Mirage, CA, and Section of Medical Oncology, Harbor-UCLA Medical Center, Los Angeles, CA, USA.

Aerobic colonization such as mycobacteria, rhodococcus, and nocardia frequently cause disease in immunosuppressed hosts including patients with AIDS. Although only a half dozen individuals with nocardiasis and AIDS have been detailed in the literature, we have recently treated 4 patients with pulmonary nocardiasis, 3 of whom had brain involvement. In 3 the diagnosis was only established by invasive techniques (bronchoscopy, closed and open lung biopsy). Chest x-rays revealed lobar infiltrates which showed intense uptake with gallium⁶⁷, although antimicrobial brain abscesses in 2 were documented by the same biopsy study. Three of 4 individuals colonized by treated with sulfonamides due to allergy or severe pancytopenia. All received multi-drug therapy with isoniazid, rifampin, trimethoprim and isopropyl to which the organism showed marked in vitro sensitivity.

The patients recovered fully on this regimen and improved. We conclude that invasive studies are needed to establish a diagnosis of nocardiasis in patients with AIDS, and although multi-drug regimens are effective treatment in individuals unable to tolerate sulfonamides.

Session d'affichage Poster Session

Aspects cliniques Clinical Aspects of AIDS

M.B.P.205 PLEUROCENTESIS IN AIDS PATIENTS WITH

SCLEROTHORAX AND SPONTANEOUS PNEUMOTHORAX AND
Schulenburg S., and Quinn J. *Trinity New England Medical Center,
and *Lambert Shattuck Hospital, Boston, MA, USA.

Objective: Review the outcome of spontaneous pneumothorax in AIDS patients.
Methods: Retrospective review of known PTX cases in 2 institutions in 1988.
Results: Spontaneous pneumothorax is a recently recognized occurrence in patients with AIDS, having been noted during episodes of pneumocystis carinii pneumonia (PCP). Pleurocentesis for persistent air leaks has been performed successfully. We report the successful outcome of sclerotherapy (with tetracycline or talc) for persistent air leaks. Brief case outlines:

Case	Tissue	Active	Lesions	PTX	Sclerosis	Complications	Outcome
1	PCP	+	no	30 d.	TCM	wound infec ⁿ	resolut ⁿ
2	bronchitis	PCP	erythro	30 d.	TCM	wound sepsis	death
3	PCP, no PTX	prob.	PCP	25 d.	TCM, talc	none	resolut ⁿ
4	PCP, hemt.	pleural PCP	43 d.	no	multiple chest	alive with	resolut ⁿ
		pneumonia	bact. pneum.	02:138 d.	no	tubes	chest tube

Conclusion: All PTX were significant and required CT placement. PTX, sometimes recurrent, have been seen in AIDS patients with previous underlying lung disease, frequently prior episodes of PCP. Active lung disease was usually present. Aerosolized pentamidine prophylaxis was used in 3 of 4 patients. Healing of the PTX was prolonged. Tetracycline or talc pleural sclerotherapy was frequently successful and avoided pleurocentesis. Complications included chest tube site infections and consequent sepsis. Aggressive therapy of PTX with sclerotherapy is recommended.

M.B.P.207 PNEUMOTHORACES IN PATIENTS WITH AIDS

Schulenburg S., Teitel, S.E., Garvey, M., Dickmeyer, M.,
Bernhard, L., Golic, J.M., et al.
Memorial Sloan-Kettering Cancer Center (MSKCC), New York, New York, USA.

Objective: To describe the natural history and risk factors for a poor outcome in patients with AIDS who develop pneumothoraces.
Methods: Cases of pneumothorax (PTX) in patients with AIDS were reviewed and their medical histories were abstracted onto standardized forms. To maximize case finding, all patients with a discharge diagnosis of "PTX" from 1980 - 1988 at MSKCC were crosschecked with a hospital-based AIDS registry.
Results: Of 1120 patients with AIDS, at least 11 (1%) had a PTX and of these, 7 have had pneumothoraces in both lungs. Ten were male and 9 had concurrent pneumocystis carinii pneumonia (PCP). Eight (73%) patients had good outcomes (left the hospital); however, of these, 3 required sclerostosis and one required a thoracotomy. Three (27%) patients died. Those who died were more likely to have a history of previous non-infectious pulmonary disease (3/3 vs. 1/8; p=0.02), to have 2 pathogen isolated from their lung and appearing to cause infection during their PTX (3/3 vs. 0/8; p=0.06) or to be smokers (3/3 vs. 3/8; p=NS).
Conclusions: PTX in patients with AIDS appears associated with PCP. It has a high mortality and is associated with a high mortality. Risk factors for death include a history of non-infectious pulmonary disease and multiple pathogens isolated from and appearing to cause infection in the involved lung.

M.B.P.209 FATAL ADVERSE REACTION WITH INDUCED SPUTUM IN PATIENTS WITH PLEURAL EFFUSION.

Nelson, M.R., E. Smith-Da, B. Hawkins, D. Ozaibad, B.O.
St. Stephens Hospital, Fulham Road, London, England.

Objective: To report possible life threatening adverse reactions with sputum induction and for bronchoscopy in HIV patients with suspected Pneumocystis Carinii Pneumonia (PCP) and concurrent pleural effusions.
Methods: All patients with PCP and pleural effusion and for bronchoscopy for PCP over a six month period had a chest x-ray prior to and post investigation.

Results: Of 83 investigated patients, 28 had documented Kaposi's Sarcoma (KS) or lymphoma. 4 of these 28 had a pleural effusion. These 4 patients underwent sputum induction, followed by 2 who had bronchoscopy. All 4 patients had marked worsening of their pleural effusion with increasing dyspnea. Two of the patients died within 24 hours (4 and 16). Necropsy showed pulmonary KS with pleural involvement in one and pulmonary lymphoma in the other. The others responded initially to insertion of intercostal drains but died at 28 and 33 days from respiratory complications. No other patient with or without KS or lymphoma developed a pleural effusion following investigation. In none of the 4 patients was pneumocystis documented on sputum induction or BAL, or were KS seen.
Conclusion: Induced sputum may give rise to potentially life threatening pleural effusion in patients with minor effusion resulting from KS or lymphoma.

M.B.P.206 ROLE OF HIV INFECTION IN ALTERATION OF PULMONARY

FUNCTION IN INTRAVENOUS HEROIN ADDICTS (IHA)
Fargelli Balazs, Maria A. Genswein, G. Maria F. Saba, M. Adriano M. Falasone, Fratelli Hospital, Milan, Italy.

Objective: We studied a group of IHA with AIDS frequently develop interstitial lung disease. In IHA HIV infection could represent a cause of further pulmonary damage. We studied and patients (pts) to evaluate the role of HIV infection in alteration of respiratory function (RF).
Methods: RF tests, blood gas analysis and CD4 lymphocyte counts were performed in 37 IHA, with no pulmonary symptoms and normal chest x-rays, 20 male and 10 female, 12 HIV- and 21 HIV+, 4 belonging to group II of CDC classification system, 11 to group III and 4 to group IV. Results: Only CD4 expressed as percent of the predicted (74.6±11.5 vs. 56±4.7, p<0.001) and CD8 lymphocytes counts were performed in 23 IHA, with no pulmonary symptoms and normal chest x-rays, 12 HIV- and 11 HIV+, 4 belonging to group II of CDC classification. **Conclusions:** These data show that HIV had no significant reduction in CD4 in comparison to HIV- IHA. The absence of clinical symptoms and/or radiological abnormalities of pulmonary disease suggests a subclinical pulmonary infection or at least a milder HIV- IHA. Since CD4 abnormalities, that we mostly find in HIV- IHA, are present in the asymptomatic stages of the infection and are not related to CD4 lymphocytes reduction, we suggest that interstitial lung involvement can be due to a direct action of the virus rather than to a subclinical opportunistic infection.

M.B.P.208 SPONTANEOUS PNEUMOTHORAX IN AIDS PATIENTS ON PENTAMIDATE

AEROSOLIZED PREVENTION. G. Saba, S. Rossetti, M. Saba, M. Douglas, J. Vaccaro, M.D., Phillip P. Pierce, M.D. *Georgetown University Hospital and *George Washington University Hospital, Washington, DC, U.S.A.

Objective: Spontaneous pneumothorax (SP) is the most frequent pulmonary complication in AIDS. The development of spontaneous pneumothorax in a combination of PCP. In order to assess the risk of pentamidine prophylaxis, two groups were retrospectively examined. Group I consisted of 127 patients who received pentamidine prophylaxis (pentamidine 100 mg via "Respigard II" nebulizer system every other week). Group II was 35 patients who received parenteral (4 mg/kg monthly) prophylaxis. Both groups had similar demographic characteristics. In Group I there were 8 pneumothoraces while there were no pneumothoraces in Group II (Fisher's p=0.48). The duration of aerosolized prophylaxis ranged between 3 to 13 months. Bilateral pneumothoraces were present in 50%. The majority of the patients with pneumothorax had evidence of active PCP (75%) and cystic lung disease (62%). Chest tube evacuation was required in 75% and 38% of patients died of progressive respiratory failure.

In conclusion, our retrospective review shows no statistically significant increase in number of pneumothorax in AIDS patients receiving aerosolized pentamidine. The occurrence of pneumothorax in these patients represents poorly controlled infection rather than a direct effect of aerosolized pentamidine.

M.B.P.210 CELL DIFFERENTIALS IN BRONCHOALVEOLAR LAVAGE (BAL) AND TRANSBRONCHIAL LUNG BIOPSY (TBLB) FROM PATIENTS WITH

ADVANCED HIV INFECTION AND DIFFUSE PNEUMONIC INFILTRATES.
Musi, Michael L., Schneider, S.L., Grossbard, M., Falk, S.,
Malar, B.B., Miller-Spöck, J.,
Div. of Pulmonary and Infectious Dis., Dept. Internal Med. and **Dept. of Pathology, Hospital of J.V. Goethe-University, Frankfurt/F.R.G.

Objective of the study: To compare cell differentials in BAL with histologic findings we performed TBLB and BAL with 300 x NaCl concentration in 30 HIV patients with P. carinii pneumonia (PCP) and 60 HIV patients with other diffuse pulmonary infiltrates (144 male, 6 female, age: 38±10 years).
Methods: Cell differentials (lymph-BAL [L] and PM-BAL [P]) were performed on cytocentrifuge slides (Cyto Spin stains) of BAL. We counted 1000 cells. Biopsies were taken using fiberoptic guidance. The specimens were graded as showing accumulation of mononuclear cells (MM-C), widened alveolar walls (AW), alveolar exudate (EX), signs of CMV infection (CMV).
Results:

	N	MM-C	AW	EX	lymph-BAL	PM-BAL
PCP	90	36%	4%	84%	17±1%	9±1%
Non-PCP	60	4%	6%	7%	14±1%	9±1%

Neutrophils in BAL were related to alveolar exudate on TBLB and presence of P. carinii (ANOVA, p<0.01). No other relations between BAL and TBLB were found. We conclude that accumulation of mononuclear cells and widening of alveolar walls not related to PCP are frequent findings in patients with advanced HIV infection and diffuse pulmonary infiltrates. We suggest that they may reflect a "non-specific interstitial pneumonitis".

Aspects cliniques Clinical Aspects of AIDS

M.B.P.217 REACTIVATION OF ACUTE HEPATITIS B IN AIDS
Roberto Luzzati, G.D. Ferri, M.Malese, M. Rossi, P. Zucchinello* and D. Bassetti. Institute Infect. Diseases, Verona* Department Pathology, Verona, Italy.

Objective: To investigate the role of HIV on the outcome of HBV infection, we describe a reactivation of acute hepatitis B in a patient with AIDS.
Methods and Results: The patient was a 20 year old male, drug addict, HBe Ag, anti-HBe, HBe Ag and anti-HBe antibodies to the delta Ag were assayed by radioimmunoassay. Serum HBV DNA was detected by spot hybridization. In 1982 this patient had acute hepatitis B and appeared to recover. Fully clearing HBe Ag, HBe Ag and HBV DNA. The activities of his liver enzymes were persistently in normal range. He presented PGL and ARI, respectively in June 1986 and in January 1987. Full-blown AIDS (cerebral toxoplasmosis) developed in July 1987 and then the patient received long-term zidovudine and zalcitabine/prazidavine/trimethoprim therapy. In June 1988 acute hepatitis B reoccurred with AST 12000 U/l, clinical jaundice, progressive hepatic failure and death. Recovery of acute HBV infection including HBe Ag, HBe Ag and HBV DNA, reappeared while delta-Ag was persistently negative. The post-mortem liver biopsy was consistent with confluent hepatic necrosis.
Conclusion: Infection with another HBV subtype is unlikely. This pattern strongly suggests a late reactivation of HBV. Thus, although the virus is present it may not thought to be directly cytotoxic for liver cells, acute hepatitis B may still reappear in the course of AIDS.

M.B.P.219 CORRELATION BETWEEN HIV AND HBV INFECTIONS.
Stefano Alamanni, Maria M. Damore, A. Scafaro, C. Corti, G. University of Turin, Turin, Italy.

Objective: HIV and HBV infections: possible interactions.
Methods: 600 ANSIV (1974-76, 36,000/ml, 13,300/ml recipients, 10,000/ml, 13,300/ml) were tested for HBV-serum, immunological and clinical findings. 200 were followed up for 24 months (2-3), 10 had hepatic biopsy.
Results: 485 were positive for HBV-serum: 66 HBeAg (22.4%); 330 anti-HBe; and 63 only anti-HBe. 23% of the followed up anti-HBe and anti-HBe patients lost the positivity for HBeAg. 14 showed a primary HBsAg: 6 with clinical evidence of acute hepatitis (only 7 became anti-HBe). The hepatic biopsies revealed 6 CH3 and 30 CH4.
Conclusion: High prevalence of HBV-serum in ANSIV patients (in prevalence IMA). Frequently loss of HBeAg (especially in anti-HBe); transient reappearance of HBeAg in the ANSIV-carriers; reduced onset of anti-HBe and prevalence of HBeAg in primary HBV infection; positive markers of viral active replication in chronic hepatitis with low levels of viraemia and reduced histological injury in sequentially biopsied patients. HBV infection does not condition HIV infection in a significant way.
Acknowledgment: This work was supported by the "C. D'Agostini" Foundation.

M.B.P.221 INFLUENCE OF HIV INFECTION IN HEMITITIS BILIA CHRONICA CONDITIO.
Giuseppe Alamanni, Maria M. Damore, A. Scafaro, A. Pavesi, J.C. Castella, Immunology, Medicine, Infect. Diseases, Public Health, Turin, Italy.

HIV infection in very small way influences B cell chronic conditio. In the other hand, drug addiction is one of the most important way of transmission of the hepatitis B virus (HBV). For these reasons, the aim of the present work was to study the influence of anti-HIV positivity in HBV infection, as well as in the biochemical response of HBV and prevalence of HIV (HIV).
Forty three anti-HIV positive patients were included. Half of them were HBsAg (40%) and the rest referred to serological response (HBeAg, anti-HBe, HBsAb, anti-HBc, HBeAg, HBeAb, HBsAb, anti-HBc, HBeAg, HBeAb, HBsAb, anti-HBc).
HBsAg and anti-HBe were detected by radioimmunoassay. Serum HBeAg (HBeAg) was tested by immunoblot and anti-HBe was determined by indirect hybridization using a ³²P-HBeAg obtained from the PH820 vector.
Out of the 43 patients, 15 (35%) were anti-HIV positive (13 HBsAg and 2 anti-HBe). All of them were seropositive and 2 presented serum anti-HBe respect to the HBV markers. There were no differences between these subjects with or without HIV infection, neither in the presence of serum HBsAg (HBeAg vs HBeAb), respectively up to the IgG anti-HBe positivity (HBe vs anti-HBe, respectively). In contrast, anti-HBe was detected in 14/15 (93.3%) anti-HIV positive cases with anti-HBe and only in 14/28 (50.0%) anti-HIV negative cases (p < 0.01). The biochemical response of HBV and HIV (anti-HBe and anti-HBe positivity) was found in a significant higher percentage (p < 0.05) in those HIV-seropositive patients (32/43) than in the negative cases (10/28). The same occurred with the simultaneous presence of anti-HBe and anti-HBe (HBe vs anti-HBe) in the anti-HIV positive subjects as in the anti-HIV negative patients (p < 0.05).

In conclusion, anti-HBe was detected in a higher percentage among HBV carriers with HIV infection. Moreover, in these patients, the simultaneous HBsAg and HBV replication was more frequently observed. During the follow-up, it will be required the clinical evolution of both group of anti-HBe positive patients with and without HIV infection.

M.B.P.218 HIV INFECTION AND DELTA HEPATITIS IN INTRAVENOUS DRUG ADDICTS
Irene Balzar, G. Bhat, K. and Govindarajan, S.* SUNN-Health Science Center, Rockville, New York and *Sancho Los Angeles Medical Center, Downey, California, U.S.A.

The recently suggested close correlation between HIV and delta hepatitis virus (HIV) may merely reflect high double-exposure rates in promiscuous homosexuals.
Objective: To correlate delta markers with stage of HIV disease in intravenous drug addicts, IVDA.

Subjects: 819 (pre-1986) IVDA: 35 with AIDS, 30 HIV positive and 17 HIV negative.
Methods: HIV antibody measured by repeat ELISA testing (Abbott). Total anti-HIV (Abbott); IgG anti-HIV, IgM anti-HIV and delta antigen (RIA); HBeAg, anti-HBe and anti-HBe (Abbott RIA).

Results: 1) Seventeen subjects tested positive for anti-HIV by Abbott ELISA; 8/16 of the 17 were HBeAg positive. Only the six HBeAg positive subjects were IgM anti-HIV positive.
2) IgM anti-HIV was present in 2 of 17 (11.8%) HIV negative; 4 of 30 (13.3%) HIV positive, but none of 35 AIDS subjects (p < 0.005, Fisher's exact test); AIDS vs non-AIDS.

Conclusions: The data suggest a high false positive rate of anti-HIV in non-HIV positive sera with the ELISA technique and that anti-HIV production (IgM and IgG) may be lost in IVDA with AIDS.

M.B.P.220 MODULATION OF VIRAL HEPATITIS IN HIV-1 INFECTION
Rajesh K. Vohra, R. Nagar, Sunil Bhatnagar, K.M. and Hans G. Jürgens, Medizinische Klinik und Poliklinik der Johannes Gutenberg Universität Mainz, Mainz, Germany.

OBJECTIVE: To study the outcome of HBV infection in HIV-1 infected patients.
METHODS: In a group of 208 HIV-1 infected patients 216 (70%) had evidence of prior HBV infection. Monoclonal and in vivo assays comprise greater than 80%. The prevalence of chronic HBV carriers, as determined by HBeAg positivity for longer than 6 months among HIV-1 infected patients yielded in 43%.
RESULTS: Our data demonstrate low activity of SODT and SODT in patients coinfected with HIV-1 virus. Individuals suffering from chronic active hepatitis, asymptomatic HIV-1 infection and 14 months later 400 were significantly increase of HBV-DNA in contrast to asymptomatic HIV-1 and HBV infected individuals. On the other hand HIV infected patients tend to have a mild course of chronic hepatitis.

CONCLUSION: Our data show evidence that suppression of cellular immunological reactions had beneficial effects on the clinical and histological outcomes of HBV infection. However, there are no data showing any spontaneous clearance of HBV in AIDS patients. One might therefore expect that there is a correlation between markers of cellular immunity like T4 and T8 positive cells in HIV-1 infected patients and the clinical course of chronic HBV infection.

M.B.P.222 THE EFFECT OF HIV ON CHRONIC HEPATITIS B: A STUDY OF 130 HIV POSITIVE MEN Balazs Bal, Balazs Bal, University of Sydney, Sydney, New South Wales, Australia.

Objective: To determine the influence of concurrent HIV infection on clinical and biochemical markers of HBV infection.
Methods: Serum markers of HBV replication (HBeAg and HBV-DNA) and disease activity (alanine transaminase, ALT) were analyzed for 150 male homosexual HBV carriers, 82 (54.6%) of whom tested positive for antibodies to HIV.

Results: Subjects positive for HIV antibody were more likely to express HBeAg (62 of 80 cases) and HBV-DNA (52 of 87) in their sera than HIV seronegatives (35 of 67 (p<0.001) and 35 of 70 (p<0.005) respectively). The degree of immune suppression however, did not seem to affect the influence of HIV on HBeAg/HBV-DNA expression. In HBeAg seropositive subjects, concurrent HIV infection was associated with lower serum alanine transaminase (ALT) levels (p<0.005). This effect increased relative to the degree of immune suppression as determined by diminished CD4 lymphocyte counts. Conversely, in patients not expressing HBeAg in serum there was a weak trend (p<0.100) towards higher ALT levels with concurrent HIV.
Conclusion: This study suggests that whilst chronic hepatitis B is less severe when accompanied by HIV infection, greater viral replication may make it more contagious and resistant to antiviral therapy. These data support an immune mediated pathogenesis for hepatitis B and have implications for its control.

M.B.P.223

LIVER DISEASE IN PATIENTS WITH AIDS
BRANDO-MILLO C.*, SILVA, N.A.*; CORREIA LEM, H.B.*; BRABELO, A.C.*; OLIVEIRA, C.T.*; OLIVEIRA, A.C.*; OLIVEIRA, H.B.*; OLIVEIRA, H.B.*
 *Hospital Federal e Univer. - Universidade do Rio de Janeiro, Brazil
 ** Centro de Hematologia Santa Catarina - Rio de Janeiro, Brazil

The evaluation of clinical, biochemical, serological and morphological data of liver involvement in high risk groups patients with was the aim of this work. Our purpose was to determine the spectrum of liver diseases in AIDS and the clinic-morphological correlation in order to ascertain if any clinical or pathologic feature was characteristic of AIDS.

Material: We have evaluated 81 patients with AIDS, being 20 homosexual (24.4%) and 61 seropositive (75.6%) men.

Methods: We studied hepatitis B virus (HBV) serum markers by commercial kits for the detection of HBsAg, anti-HBsAg, anti-HBeAg, HBeAg and anti-HBeAg. Liver function tests including aminotransferase, total bilirubin, alkaline phosphatase were performed. Mostly of the liver biopsies were obtained percutaneously, but some samples were obtained from surgery material.

Results: The great majority of the patients were asymptomatic. More than 80% of the sera were anti-HBs and anti-HBe (+). Serum aminotransferase levels were slightly elevated in those rates the upper limit of the normal range in the majority of the patients. Chronic persistent hepatitis, chronic active hepatitis and cirrhosis were the most frequent findings in hepatitides. Granulomas due to *M.tuberculosis* were also other morphologic features.

M.B.P.224

THE INTERACTION OF HIV AND HEPATITIS B VACCINATION IN A COHORT OF HOMOSEXUAL AND BISEXUAL MEN
Buchbinder, Susan C.*, Nelson, A.R.*; **O'Malley, P.***; Barnhart, L.*; Ruffnerford G.*; Hadler, S.**
 *Dept. of Public Health, San Francisco, CA; **Viral Diseases, CDC, Atlanta, GA, USA.

Objective: To evaluate the effect of HIV infection on efficacy of the hepatitis B vaccine (HBV) and the effect of HBV on AIDS disease progression. **Methods:** 350 homosexual/bisexual men participated in a randomized controlled trial of HBV from 1985-1988. We began follow-up studies of HIV-related diseases in 1983. We compared peak hepatitis B surface antibody (HBsAb) throughout follow-up (16-16). We also compared the prevalence of AIDS and loss of immunity in 2 groups: men who were HIV seropositive (SP) prior to first dose of HBV (N=26) and men who remained HIV seronegative (SN).

Results: SP were less likely than SN to develop immunity (56% vs 80%, p<0.03). Of men achieving immunity, SP had significantly lower peak responses and were more likely to lose immunity than SN (p<0.01). Kaplan-Meier analysis examining loss of immunity from time of first vaccine dose showed 41% of SP (95% CI=17%-63%) lost immunity by 20 months versus 56% of SN (95% CI=45%-67%) at 72 months. There was no difference in the prevalence of AIDS and ACB between SP versus HIV-infected men receiving placebo.

Conclusion: Plasma hepatitis B vaccine is significantly less efficacious in HIV seropositive than seronegative men. A majority of seronegatives also lose antibody over time, indicating the need for studies of the efficacy of booster doses. The hepatitis B vaccine does not cause acceleration of HIV-related disease.

M.B.P.225

TOXOPLASMOSE OCULAR AU COURS DU SIDA
FLORES, S.*, ZANON, L.*; **Barthem, Sophie**, de Truchis, P.*
 Coulaud, J.P.; Salazar, A.C.*

* Hôpital Claude-Bernard, ** Hôpital Pitié-Salpêtrière, Paris, France.

Objectif: Décrire les caractéristiques de la toxoplasmose oculaire (TO) observée chez les patients (Pz) HIV +.
Méthodes: De 1984 à 1988 un examen de Fond d'Oeil (FO) a été fait par les mêmes ophtalmologues chez les Pz HIV ayant des troubles visuels et/ou asymptomatiques (2 FO) chez les asymptomatiques (OC II), 4 FO) (OC III et (OC IV). 1 FO/mois/78 SIDA). Les critères de TO étaient: vitre clair, prédominance de l'atteinte du pôle postérieur, foyer en règle unique/horbe floue, taille variable + plaques de névrite, extension en l'absence de traitement(s).
 Classification sous 71 espèces/foyers.

Résultats: Dix cas de TO (5 observés, 2 adhésions: 1 HIV 1, 1 HIV 2; 1 COV < 120) ont été observés: 1 1984-86; 2 automne TO/49 nouveaux cas de toxoplasmose (TO): 1 1987; 1 3 TO/20 TOX; 1 1988; 7 TO/33 TOX. Sept cas ont été résolus par une baisse de l'acidité visuelle; 3 étaient asymptomatiques. Une autre TO avait précédé 10 TO chez 8 Pz (2,6,7,72 mois). Chez 6 Pz la TO a été la 1ère TO. Neuf Pz étaient sous AZT. Cinq Pz ont une TOX cérébrale associée (4 simultanées, 1 découvre 2 mois après la TO). Cinq n'ont pas de TOX cérébrale détectable (clinique/histologie). La classification a été obtenue 10 fois/10 sous priméthamine (P) + sulfadiazine (S) ou P/sulfadiazine (2 Pz).
Conclusion: 1) Dix cas de TO ont été observés en 1987 et 1988 - 2) La TO peut être la 1ère TO - 3) La TO est associée 5 fois/10 à une TOX cérébrale détectable - 4) Le traitement permet la cicatrisation des lésions - 5) La prophylaxie des rechutes est identique à celle des TOX cérébrales.

M.B.P.226

TOXOPLASMOSE OCULAR AU COURS DU SIDA
Shakirov, Yegor, Meprova, H.C.*; Peltova, B.**;
 Zayon, S.*; Vachetov, S.*; Lashin, S.*

* Hôpital Claude-Bernard, ** Hôpital Saint-Antoine, *** Hôpital Pitié-Salpêtrière, Paris, France.

Objectif: Préciser Les signes cliniques et ophtalmologiques (OP) de la toxoplasmose oculaire (TO), son évolution sous traitement (trt) et ses relations avec la survenue d'une toxoplasmose cérébrale (TC).
Méthodes: Étude rétrospective des cas de TO chez des patients (pts) atteints de SIDA, depuis 1981 dans 2 services de maladies infectieuses.

Résultats: Il s'agissait de 8 hommes, 6 homosexuels, vu en 1983 (n=5), 1984 (n=2) et 1988 (n=7). 7/8 pts avaient une acuité visuelle, 52/10, et 3/8 pts une fièvre. Tous avaient une choriorétinite du pôle postérieur, associée à une hyalite. Chez 7/7 pts, l'angiographie confirmait le foyer choriorétinien et la ponction de la chambre antérieure nous montrait pas de symptômes locaux d'œdème. Le trt a été débuté 12 j (0-20) après les premiers signes de la TO. Les pts ont reçu clindamidine, 1,2-4, 8 g/j (n=7), sulfadiazine, 800 mg, en spiramécine, 3 g/j (n=6), associées à une prophylaxie (50-100 mg/j, pendant 45 j), supplémentées à dose réduite chez 6 survivants. La TO a cicatrisé chez les 8 pts, après 37 j (21-90). Une rechute s'a été manifestée après 5,5 mois (1,5-9). Une TC est survenue chez 7/8 (78) pts. A fois, TC et TO étaient reconnues simultanément et l'évolution de la TC était favorable; mais 3 fois la TC se révélait 9, 36 et 30 j après la début du trt de la TO, et son évolution n'était pas évaluable.
Conclusion: La TO est devenue plus fréquente au cours du SIDA. Son diagnostic repose sur l'examen OP. Une TC associée doit être recherchée.

M.B.P.227

OCULAR INVOLVEMENT IN CHILDREN WITH HIV INFECTION
Bullini, B., Bertoni, G., Chiamp, M., Mosconi, P.,
 Pizzoni, M., Pizzoni, M., Bertoni, A.*
 *II Ophthalm. Clin., **IV-Pediatr. Clin., ***Infect. Dis. Clin. University of Milan, Milan, Italy.

Objective: Evaluation of ocular involvement in children with HIV infection in respect to adult AIDS.

Methods: The 44 report on ophthalmological findings in 57 HIV seropositive children. According to the definition proposed by CDC (April 1987) seropositive infants were 15 in P-0 class, 16 in P-1 class and 18 in P-2 class. 7 patients became negatives and 3 died.

Ocular examination, at the start and every 3 months, included: ocular reflexes and motility, fundus and ERG in pathologic cases only.

Results: Ocular signs observed in 13 children (22.8%) were mainly represented by optic nerve involvement (optic disc pallor and atrophy, papilloedema), CMV retinitis in occurred in 2 cases (1/6 vs > 50% in adults). Retinal microangiopathy was never observed in HIV seropositive children.

Conclusions: Pediatric AIDS is believed as a new idiom disease with very different clinical and biologic characteristics in respect to adult AIDS as well as from the ophthalmological point of view.

M.B.P.228

VITREOUS FLUORESCENTOMETRY IN HIV INFECTION
Buzzi Salinelli, L., Azzidi, P., Confignarini, E., Ricchi, S.,
 F. Chiari, E., Caraceni, S.*
 *Cattedra Clinica Diagnostica II - **Istituto Malattie Infettive Università di Bologna, Bologna, ITALY.

Objective: To evaluate the ability of vitreous fluorescentometry to detect HIV in lesions of vascular endothelial cells.
Methods and Results: We have studied 18 subjects with HIV infection (5 AIDS with 2, 11 and 3 MHC) in all patients all were examination including vitreous fluorescentometry, indirect ophthalmoscopy, and vitreous fluorescentometry. In spite of the fundus normality the vitreous fluorescentometry readings were constantly above normal, showing average fluorescence values of 2.4, 3.2 and 4.87 g/l respectively in the anterior, middle and posterior vitreous.

Conclusion: Etiology and pathogenesis are unclear but the role of circulating immune complexes deposition, increase blood viscosity and HIV direct effect on vascular endothelial tissue, are discussed. The fluorescein angiographic documentation of microaneurysms, telangiectasias, focal areas of non-perfusion and capillary leakage in patients with HIV infection provides a pattern of microvascular retinopathy very similar to the diabetic one. Nevertheless fluorescein angiography is not a qualitative technique and the use low sensitivity in some cases. The fluorescentometry permits on the contrary a qualitative evaluation of the alterations of blood barrier which can be diagnosed by vitreous fluorescentometry before any clinical and fluoresceinographic detectable lesion.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.241 GASTROINTESTINAL (GI) STRUCTURE AND MUCOSAL FUNCTION IN HIV POSITIVE PATIENTS.

Choudhry, R., Richardson, L., Shung, W., Kelly, J., Gill, J., AIDS Research Interest Group, University of Calgary, Calgary, Alberta Canada.

Unexplained weight loss and diarrhoea are relatively frequent in HIV infected patients. We have investigated 15 patients in whom no gastro-intestinal pathogens could be identified to see if functional or structural changes in the small intestine could account for their weight loss and diarrhoea. Nineteen patients (17 males, 2 females) were investigated by endoscopy. Biochemical testing demonstrated normal red blood cell folate and vitamin B12 levels in all patients. However, serum ferritin levels were increased in 12 patients. 5-lysoase absorption tests were abnormally low in 8/13 cases. Duodenal aspirates were negative for giardia lamblia. Light microscopy failed to show any structural abnormality in both upper and lower bowel biopsies. In contrast ultrastructural changes were demonstrated in all patients at the epithelial stromal junction of intestinal crypts with scattered degenerative or necrotic fibroblasts interspersed with reactive hyperplastic fibroblastic cells which appeared to lay down excessive collagen beneath the epithelial cells. These findings suggest that certain biochemical and ultrastructural abnormalities are common in HIV positive patients even in the absence of infectious pathogens. Defects in carbohydrate absorption and ultrastructural changes may be responsible for some aspects of HIV enteropathy.

M.B.P.243 HEMOPHAGOCYTIC HISTIOCYTOSIS IN THE LIVER OF AN HIV-INFECTED FOREIGN BORN ISRAELI

Neufuss, David M.*; Tempesta, R. *; and Strenger, R.J.**
*Mach Israel Medical Center, New York, N.Y. U.S.A.; **Hessau County Medical Center, East Meadow, New York, N.Y. U.S.A.

Objective: To report a case of hemophagocytic histiocytosis in the liver of an HIV-infected former IV drug user.

Methods: Clinical data over 27 months and two liver biopsies, including one studied by electron microscopy, were reviewed.

Results: A 32 year old former IV drug-abusing male had HIV antibody by ELISA and Western blot. Altonic endoneurase (ALT) was initially 83 U/l and increased over six months to 458 U/l, at which time the first liver biopsy was performed. Fatigue and abdominal pain were correlated with increased ALT levels. During the next 6 months, ALT ranged from 37-316 and symptoms improved. On the biopsies liver architecture is preserved, but the portal tracts display mild to moderate fibrosis, focal mononuclear infiltrative and scantest ductular proliferation. The parenchyma in fact, except for rare necrotic cells, along the sinusoids are clusters of immunopositive phagocytosing and prominent Kupfer cells exhibiting erythrophagocytosis, and in Disse's space there is increased collagen. A few scattered lipid granules appear near central veins. Fever, chills is negative.

Conclusion: Lacking evidence for other infections previously associated with hemophagocytic histiocytosis, we suggest that HIV may rarely cause the syndrome, which may be associated with manifestations of liver dysfunction. Definitive exclusion of other causes of erythrophagocytosis is not possible, however.

M.B.P.245 SPONTANEOUS RESOLUTION OF CANDIDA SPIRITRIS(CE) IN A SERO-CONVERTING PATIENT

B. Clotet, G. Sivera, A. Boix, A. Josa, M. Ribera, C. Tural, M. Dominguez, J. Tor, M. For. Respiratory Diseases Unit, Gastroenterology Service, Blood Bank Unit, Hospital de Bellvitge, Barcelona, Catalonia, Spain.

Objective: To report a case of CE in a seroconverting patient and to discuss whether CE in HIV infection should always be considered a criterion for AIDS. Material: A 22 year-old white man admitted because of a mononucleosis-like syndrome. He was drug addict since the last 6 months.

Results: The endoscopy and esophageal biopsy demonstrated CE.
April 20, 1988: EIA screening p24 50 41 HIV Ag WB
May 10, 1988 cut off - - - - - +
May 20, 1988 EIA: (beta1ng): HIV Ag - - - - - +
EIA: (beta1ng): HIV Ag - - - - - +

An esophageal endoscopy performed 15 days later demonstrated spontaneous resolution without having received any antifungal therapy. Discussion: In view of our findings we suggest that CE should be considered a criterion for AIDS at least for informing the patient that is suffering an AIDS when there is associated another opportunistic infection or when this appear subsequently in a short period of time (less than 4 months) when the patient has a persistent low t4 count (2500) over a long period or when there is HIV antipneumia (excluding the seroconverting patients). All other cases should be followed closely to understand better the prognostic significance of CE. In our experience HIV seropositive patients not fulfilling the criteria commented above have been followed for long periods (45 months) without developing other opportunistic infections.

M.B.P.242

HEPATITIS B VIRUS INFECTION AND Non-A, Non-B HEPATITIS.
Galligan, J., Macgregor, N., Martin, M., J., Macgregor, C., Payne, S., & Gerber, S., Hepatitis Unit, Federal Health Dept, Sydney, Australia.

It has been reported that hepatitis B virus chronic carriers with anti-HIV positive have less hepatic injury than those without infection. However, it is still unclear the influence of HIV among patients with chronic Non-A, Non-B HBSV infection. Thus, we have studied the hepatic injury degree in chronic HBV hepatitis with or without HIV infection.

There were included 32 patients with chronic HBV hepatitis. Eight of them are anti-HIV negative (5 with a posthepatitis level and 3 drug abusers), and the other 24 were seronegative HIV carriers (all drug abusers). The presence of anti-HIV was confirmed by Western-Blot.

The levels of albumin were higher among those HBV patients anti-HIV negative (4.2 ± 0.1 g/dl) than in the HIV seropositive ones (3.6 ± 0.2). On the other hand, the transaminase were increased in the anti-HIV positive subjects when comparing with the anti-HIV negative cases (182 ± 10 U/l vs. 94 ± 7.9 U/l), respectively, although there were not statistically significant differences. The results were similar between both groups of patients (anti-HIV + HBV or chronic active hepatitis (CAH), 25% of chronic persistent hepatitis (CPH), anti-HIV - HBV or CHB, 25.0% and 22.0% respectively).

In conclusion, patients with chronic HBV hepatitis and HIV infection present higher levels of transaminase. It is suggested that the hepatitis B virus could have a direct cytotoxic effect and that the immune response is not involved in the hepatic injury. However, as the causal agent of the hepatitis B virus is not yet identified, this should be proven in future research.

M.B.P.244 ULTIMATE PHASIS-INDUCED LYMPHADENOPATHY IN ADVANCED HIV DISEASE.

Kiloh, Wilbert, Walker, M., Francis, M., Logan, S., Lewis, P., Fleming, A. & St. Mary's Hospital, London, United Kingdom, University of Leeds, United Kingdom.

Objective: To characterise the cause of opportunistic ulceration in advanced HIV disease in the absence of infection with CMV or HSV.

Methods: Endoscopy and biopsy was performed on 5 homosexual men presenting with severe dyspepsia. Three HIV seropositive men with dyspepsia were used as controls.

Results: Endoscopy revealed large ulcerated ulcers (0.5 cm in diameter) in the pyloric and/or antral mucosa in the 5 patients with dyspepsia, and was microscopically normal. In the 3 controls. Subsequent histological examination of biopsies from the ulcerated areas showed features of viral lymphadenitis in all cases; multinucleated giant cells (3), perinuclear inclusions (3), individual cell necrosis (3), and epithelial necrosis/hyperplasia (2). There were no histological features of HIV infection in any of the cases, and evidence of cervical infection was seen in only 1 of the 5. CMV was not detected in any of the cases by immunocytochemistry or DNA in situ hybridisation. Material from 4 of the 5 cases and 3 HIV seropositive controls was available for ISH in situ hybridisation for HIV and HSV. HSV DNA was detected in 3 of the 5 cases and none of the controls. HIV DNA was detected in 1 of the 4 cases and 2 of the 3 controls.

Conclusion: A lesion histologically similar to Oral Thrush lymphadenitis can occur in the pyloric and antral mucosa in advanced HIV infection where it may cause significant ulceration. HIV may be closely related to the lymphadenitis seen in these cases.

M.B.P.246 DETECTION OF HEPATITIS B VIRUS DNA IN PERIPHERAL BLOOD MONONUCLEAR CELLS FROM ASYMPTOMATIC ANTI-HSV CARRIERS

P. Baranoni, Imposimato, G. Mosella, M. C. Martines, J. C. Ferrer, V. Carrozz, V. Heparatology Unit, Fondazione Sime, Sesto, Sanpiero, Spain.

It has been suggested that hepatitis B virus DNA can act as a cofactor in the development of AIDS in anti-HSV positive patients. Also, HBV-DNA has been detected in peripheral blood mononuclear cells (PBMC) from anti-HSV carriers. The aim of this study was to determine the presence of HBV-DNA and HIV-DNA in PBMC from HBV-DNA (+) (10⁷ cells) were obtained from 23 asymptomatic anti-HSV carriers (16 of them were positive to the hepatitis B virus surface antigen, HBeAg, and 7 negative to HBeAg, and from 20 anti-HSV negative patients (10 with HBeAg and 10 without this marker). Anti-HSV was detected by EIA and confirmed by Western Blot. The HBeAg test was performed by RIA. HBV-DNA and HIV-DNA were detected by dot-blot hybridization in total extracted cellular DNA from PBMC.

The results are summarized in this table:

	Anti-HSV		Anti-HIV	
	HBeAg	HBeAg	HBeAg	HBeAg
	N=15	N=7	N=20	N=10
PBMC	1/15	0	17/20	0
HBV-DNA	7/15	0	17/20	0

HBV-DNA was found in a similar percentage of PBMC from anti-HSV positive and negative patients. No differences were observed in the TA/T4 ratio in HIV-seropositive patients with or without HBV-DNA in PBMC (1.1 ± 0.37 and 0.9 ± 0.3, respectively). HBV-DNA was detected in 10/21 (47%) of asymptomatic anti-HSV carriers. HBV-DNA and HIV-DNA were present in 2/23 (9%) of these patients. In conclusion, the incidence of HBV-DNA in PBMC of anti-HSV positive or negative patients is similar. There is a small percentage of patients with HBV-DNA and HIV-DNA simultaneously in the PBMC.

EDWARDSHAWKINS IN AIDS PATIENTS: A PROSPECTIVE STUDY IN 24 PATIENTS.
Hage L., Naylor's, Victoria, R., Lindqvist, R.,* Pedersen, C.*
* Dept. of Infectious Diseases, ** Dept. of Cardiology, Mølnare Hospital,
University of Copenhagen, Denmark

Objective: To assess the prevalence and the extent of cardiac arrhythmias in AIDS patients with no cardiac history.

Methods: 24 patients with AIDS for 0-40 days (mean 8) were examined. Twelve had homosexual sex, one man with urethral risk factor and 2 were infected by transfusion. Nine were intravenous drug abusers. All patients were hospitalized: 17 with pneumocystis carinii infection, one with Kaposi's sarcoma and 6 patients with other opportunistic infections incl. CMV and mycobacterial disease. No patients showed signs of clinical cardiac failure. Electrocardiograms were performed on an E.C.G. 2000 ground wire. Conduction included standard leads + 24 ectopic. The ectopes were videotaped and analysed live by a cardiac specialist.

Results: In 20 of the 24 patients we found in 11 patients. Eight patients had slightly to moderate dilatation of the right ventricle chamber 20-30 mm (mean 25.3) and 5 patients had a normal pericardial effusion. No patients had tachycardia more than corresponding to fever. We found no signs of endocarditis, myocarditis or cardiomyopathy.

Conclusions: Minor cardiac arrhythmias seem to be common in AIDS patients with acute infection. In AIDS patients with other infections than intravenous drug abuse they are hardly of clinical importance.

M.B.P.261

RHEUMATIC SYMPTOMATOLOGY IN PATIENTS INFECTED WITH THE HUMAN IMMUNODEFICIENCY VIRUS (HIV): PREVALENCE AND RELATIONSHIP TO CLINICAL AND LABORATORY VARIABLES.
Lindqvist, R.,* Hage L.,* Mølnare, S.,* Mølnare, A.,* Jørgensen, D.,
Cleveland Clinic Foundation, Cleveland, Ohio, USA.

Objective: To define the prevalence of rheumatic symptomatology in a cohort of HIV infected patients as well as its relationships to a variety of clinical and laboratory variables.

Methods: Controlled retrospective and prospective analysis of 75 patients followed for a mean of 39 months. Each subject was serially assessed for the development of rheumatic symptomatology during follow-up for HIV infection.

Results: During the follow-up period, 204 developed articular symptoms including four patients with Reiter's or psoriatic arthritis, and 11 patients with new onset oligoarticular or polyarticular arthritis (group A). Fifty-three patients (71%) had no rheumatic symptoms (group B) and 7 patients (9%) had miscellaneous rheumatic symptoms. Group A patients were more likely to be at an advanced clinical stage of HIV infection (i.e. CDC Class IV) than group B (p<0.001) and had lower hemoglobin, lymphocyte counts, T helper counts and higher ESR values than group B patients (p<0.01). There was no association between articular disease and any specific risk behavior, other sexually transmitted diseases, infections or malignancies.

Conclusion: Articular disease appears to be relatively common in the setting of HIV infection and correlates with both an advanced state of infection and immunosuppression. These data may partially explain the reported sensitivity of such patients to the adverse effects of immunosuppressive drugs.

M.B.P.263

"REDUCED CORTISOL PRODUCTION AND ADRENAL HISTOPATHY IN PATIENTS WITH AIDS".
LEITE, D.S.,* ACEITURI, A.C.; SADER, H.,* DIAS, R.S.,* KATZ, C.R.,* MOTTA, P.R.,*.* Escola Paulista de Medicina - São Paulo - SP - Brasil.

Objective: To verify adrenocortical reserve and adrenal histopathology in patients with AIDS.

Methods: To verify adrenocortical reserve we measured plasma cortisol levels before and 60 min. after ACTH stimulation (Cortrosyn®, 250 µg IV bolus) in 28 patients with AIDS, 5 with ARC, 10 with chronic non AIDS diseases and 32 normal subjects. Adrenal histopathology was studied in 17 of the 20 patients with AIDS who died. The 95% confidence intervals (CI) for the ACTH-stimulated cortisol levels was established at 38.4 µg/dl.

Results: Five (18%) AIDS patients presented values below the CI: 13.4 ± 1.4 µg/dl. All 5 had massive adrenal necrosis at post-mortem examination (2 had AIDS complicated by tuberculosis and 1 Cryptosporidium parvum). Sensitivity and specificity of the ACTH test compared with the presence or absence of significant necrosis was 71.4% and 100%, respectively. No patients with ARC or chronic non-AIDS diseases had decreased cortisol response to ACTH stimulation.

Conclusion: Since 18% of patients with AIDS had proven adrenal necrosis with sufficient beneficial result from glucocorticoid replacement therapy, we suggest that a rapid ACTH test should be performed in every such patient.

M.B.P.260

IMMUNOLOGICAL MONITORING IN HIV INFECTION.

Edwards L., Hage L.,* Naylor's, Victoria, R.,* Lindqvist, R.,* Pedersen, C.,*
* Dept. of Internal Medicine and Neurology, ** Hospital Unit of AIDS, Mølnare Hospital of Victoria, Victoria, Sweden.

The involvement of the peripheral nervous system (PNS) in patients with infection by the human immunodeficiency virus (HIV) is less well known than that of the central nervous system (CNS). Because of the rarity of these conditions, and the interest of their diagnostic and therapeutic aspects, we report 7 patients with HIV infection and abnormalities of the PNS. There were six males and one female, with an age range of 15 to 45 years, with the following conditions: the usual polyneuropathy - the chronic inflammatory demyelinating polyneuropathy and three plexopathies. At the time of the diagnosis of the PNS involvement, three polyneuropathy patients were stage IV-C and one IV-D; whereas the plexopathy patients were stage II and two were stage III. Immunological diagnosis of antibodies against cell and cerebral cytoplasts. All patients with axonal polyneuropathy had severe impairment of their peripheral conduction with advanced axonal degeneration which suggests that the neurologic involvement may be the result of metabolic and nutritional causes (an acetazolamide intoxication), rather than HIV or other organ specific infection. Both demyelinating polyneuropathy patients did not receive treatment on patient referral treatment with the other had a right foot entrapment. In none of the four of these had patients received antiretroviral without treatment. Six of the seven patients with plexopathy did respond to corticosteroid therapy.

All four polyneuropathy cases had features of both types of polyneuropathy (axonal and demyelinating). In two patients we observed at different times with their clinical course, transition from one type of neuropathy to the other. This case suggests that the polyneuropathy constitutes a single entity, with variable clinical and electrophysiological features.

M.B.P.262

JOINT, BONE AND MUSCLE LESIONS AND HIV INFECTION.

Bohm, Jan, F. Forster, St. Youle, NS; Wainman, DA; Lawrence, AC; Seiffert, AC; Wainman, St Stephen's and St Mary's Hospitals, London, UK.

Rheumatologists at our hospitals have been referred 196 HIV-positive patients since 1983, representing about 4% of the known HIV-positive population in our area. Thirty homosexual men and 2 women presented with acute, asymptomatic, peripheral, non-erosive, seronegative arthritis (mean 4 joints affected). Associated features included parotitis (12 patients), rheumatoid factor (12 patients), pleuritic fasciitis (12), urethritis (12), conjunctivitis (4) and uveitis (1). Four of 5 patients tested had HLA-B*27. Two with recent diarrhoea had serological evidence of yersinia infection. No microorganisms were identified in joint material except for HIV in 4 patients. At onset of arthritis only 2 had AIDS and 9 were not known to be HIV-positive. Six patients have progressed to AIDS, 4 have died. In 4, including those progressing to AIDS, joint symptoms have been severe, persistent and poorly responsive to NSAIDs. In 5 arthritis has resolved. Other rheumatic lesions seen include infective lesions (7 patients) including one with disseminated histoplasmosis, molluscum/arthralgia (10), with features suggestive of myositis in 32, spinal pain (19), non-inflammatory peripheral arthropathy (8), and soft tissue lesions (12). Rheumatic syndromes in HIV-positive patients are becoming better defined. It is unclear, however, whether HIV itself is a genuine risk factor for some of these, especially aseptic arthritis. The London experience may help to clarify this issue. Pathogenetic mechanisms, including the role of microorganisms and immunodeficiency, require further study.

M.B.P.264

DIABETES INSIPIDUS AS A COMPLICATION OF CEREBRAL TOXOPLASMOSIS IN AN AIDS PATIENT

Emshoff, Dragan; Singh, R.; Gevart, R.
St. Stephen's Hospital, London, England.

Case presentation: A 52 year old homosexual HIV-positive patient presented with sudden onset headache, dysphasia and blurred vision. He had a low grade pyrexia, right sided upper motor neurone 7th nerve palsy and left sided homonymous hemianopia. Brain CT scan showed multiple localised frontal, parietal and occipital white lesions (left & right) cystic enhancing lesions suggestive of brain toxoplasmosis. He responded very well to treatment with Fansidar (one tablet b.i.d.), his signs and symptoms disappeared and he was discharged on maintenance Fansidar at a dose of one tablet every alternate day. Six weeks following the beginning of his brain infection he developed polydipsia and polyuria. Diabetes insipidus was confirmed with normal blood glucose, urine osmolalities never exceeding 172 mOsm/L and plasma osmolalities of over 300 mOsm/L. In spite of clear evidence of hypothalamic dysfunction his anterior pituitary function was normal with a good cortisol response to hypoglycaemia, normal T₄ (82 mU/L), prolactin (576 uIU) and normal responses to LH, LHRH and FSH in the respective releasing factors. Treatment with DDAVP resulted in rapid resolution of diabetic symptoms.

Conclusions: Neurogenic diabetes insipidus can follow cerebral toxoplasmosis in AIDS patients.

M.B.P.271 HYPERONEMIC HYPOLIPOTEMIA ASSOCIATED WITH HIV INFECTION

Kessens, D.J. Heil, T.J. Bernis, S.J. Dowd, S.J. Clumick, N. Balan
Free University of Brussels, Brussels, Belgium.

Objective: Hyperonemic hypolipidemia associated with HIV-1 infection has been reported (F. Kalin, 1987). In order to evaluate the occurrence of this anomaly we set up a retrospective study.

Methods: We measured plasma cortisol (F), aldosterone (Aldo) and renin activity (RA) by specific radioimmuno assay as well as plasma and urinary ionogram in 21 HIV-1 infected caucasians (CDC stage 2 to 4). Control population was comparable for sex, age, and sodium dietary content. Statistical analysis was performed using Mann-Whitney test and multivariate analysis.

Table	number of subjects	median range	SD (mg/dl)	range	SD (mg/dl)	range
Controls	7	150 (100-200)	0.15 (0.04-0.39)	24 (10.3-4.4)		
HIV-1 +	217	170 (40-300)	0.07 (< 0.001)	1.4 (0.1-10)		

RA was significantly higher in patients than in controls (p < 0.001). Aldo and FRA were significantly lower in HIV-1 infected patients (p < 0.001), neither of the parameters varied according to stage. Three patients presented an hyperonemic hypolipidemia with persistent hyperkalemia.

Conclusion: Hyperonemic hypolipidemia with intact glucocorticoid secretion in HIV-1 infection suggests a dysfunction of the interglomerular apparatus rather than a primary adrenal damage (J. Glasgow, '85). The early presence of these features (stage 2) rules out any causal effect of opportunistic infections (stage 4) (L. Mastroianni '87), but suggests a direct effect of the virus or an auto-immune reaction.

M.B.P.272 ACQUISITION OF THYROID BIOCHEMICAL ABNORMALITIES (TBA) IN COMPARED IMMUNODEFICIENT SYNDROME (AIDS) AND OTHER IL-NEVERES.

Boudoux, Pierre; Bonny, M.; Clumick, N.
Saint Pierre University Hospital, B-1000 Brussels, Belgium.

Transient TBA are currently observed in nonthyroidal illness (NTI) and particularly in severe infections but their incidence in AIDS is not yet known. Therefore, we studied the thyroid function in 102 patients with AIDS (groups 1 to 4) aged 18-78 (group 1) and 102 age-matched controls with various infectious diseases (group 2) and 4 AIDS uninfected patients aged 15-69 (group 3), admitted to our medical service. Thyroid function was assessed by serum T4, T3, FT4, FT3, TSH, TSH-R. When a thyroid disease was suspected, a complete panel of investigations was performed including free T4 and T3, and T3 test.

A low T3 syndrome was observed in 20% of all patients, including AIDS patients. Thyroid diseases were found in 10% in group 1, 11% in group 2, 14% in group 3, 2% in group 4. In the thyroid-diseased patients the other TBA were distributed as follows (% in groups 1/2/3): decreased T4 (7/52), decreased FT4 (7/7/2), increased T4 (1/6/2), T3 (1/4/1), 4, increased TSH (2/2/2). Moreover, 16 patients of group 2 with high TSH, 4 had normal FT4 indicating euthyroidism. When compared to controls, patients with AIDS, although euthyroid, had significantly different mean values T4 (AIDS vs Controls: 7.4 and 8.2 ng/dl, P<0.05), T3 (1/27 and 1/4/2 ng/dl, P<0.05), FT4 (1.29 and 1.56 ng/dl, P<0.05), TSH (2.1 and 1.4 mU/L, P<0.05). Mean serum thyroglobulin levels were not different in groups 1 and 2.

Conclusion: 1) Decreased T4 frequency is higher in AIDS than in other NTI although the proportion of true thyroid diseases is the same; 2) abnormal TRG level accounts for more than half of TBA, particularly in patients with the T4, 3) consequently, FT4 is the most appropriate tool for screening thyroid dysfunction in AIDS and NTI patients.

M.B.P.273 MYOCARDIITIS IN INTRAVENOUS DRUG ABUSERS WITH AND WITHOUT ACQUIRED IMMUNODEFICIENCY SYNDROME: AN AUTOPSY STUDY

Rehrich, Janna S.; Francis, C.; Navarro C.; Brown, J.; El-Hader, W.
Harlem Hospital Center, College of Physicians and Surgeons, Columbia University, New York, New York, USA.

Objective: To compare cardiac involvement in intravenous drug abusers (IVDA) with the acquired immunodeficiency syndrome (AIDS) to IVDA without AIDS.

Methods: Consecutive unselected autopsies in IVDA performed from 1983 to 1988 were reviewed. Of 177 autopsies of IVDA, anatomic, morphologic and histologic data were available in 42 patients (ages: AIDS: 35 male, age 37-60 with AIDS (defined according to the clinical criteria of the Centers of Disease Control) and 25 pts (non-AIDS) 16 male, age 31-58 years) without clinical AIDS. Myocarditis (MCO) (epimycotic or plasma cell infiltration), dilatation of the left (LWLD), right (RWLD), or both ventricles (BWLD), pericarditis (PCRL), pericardial effusion (PEFL) and endocarditis (ENDO) in both groups are shown below: (Same pts appear in more than one group.) *p<0.05

	MCO	LWLD	RWLD	PEFL	ENDO
AIDS	24	3	7	10	7*
(n=42)					
NON-AIDS	17	4	3	3	4
(n=25)					

Myocarditis is comparable in AIDS and non-AIDS and is not related to cardiac chamber dilatation, pericardial disease or prostatic infection. Severe bacterial infection, particularly endocarditis, is common in non-AIDS (87%) but uncommon in AIDS (3%). Opportunistic infection occurs in AIDS and is not related to MCO. In IVDA, with and without AIDS, myocarditis is common but unrelated to other pathologic states.

M.B.P.274 THE PATHOLOGY OF THE MALE GENITAL TRACT IN AIDS.

Shevchik, M.; de Silva, M.; Cinnia, William; Armonian, K.; Franchini, J.; and Zambomano, K.* Lenox Hill Hospital, New York, NY, *Western Administration Hospital, Bronx, N.Y., USA.

Objective: The male genital tract of AIDS patients frequently contains lesions and abnormalities which could be clinically asymptomatic.

Method: To study the pathology of AIDS of the male genital tract, the prostates and testes of 80 consecutive AIDS autopsy cases were examined histologically and all were stained with the p17 anti-HIV monoclonal antibody.

Results: The following opportunistic infections were identified: *Trophozoites* of testes (2 cases), cytomegalovirus (5 cases - 1 testis, 4 prostates), candidiasis of prostatic urethra (1 case). Seven tumors were identified in the series. These were apparently AIDS related: 1 non-Hodgkin's lymphoma involving testes and prostates, and 1 primary immunoblastic lymphoma of testis. In addition marked spermatozoal arrest, germ cell degeneration, peritubal fibrosis and Leydig cell depletion were seen in all cases. The anti HIV p17 monoclonal antibody showed small random foci of positive staining in 8 of 14 testes cases studied, located over one or several degenerating germ cells. None of 14 prostates showed few minute foci of epithelial staining.

Conclusion: The male genital tract of AIDS patients contains opportunistic infections, neoplasm and apparent direct infection by the HIV virus.

M.B.P.275 GENITAL ULCERS IN HIV INFECTION

Schanderl, Falk B.; Schöber, R. and Hilbert, R.
Klinikum J.W.Goethe-Universität, Dept. of Dermatology, Frankfurt, FRG.

Objective: To examine frequency, etiology and significance of genital ulcers in HIV-infected patients.

Methods: 267 HIV-positive patients (84 male homosexuals, 164 other risk group: 19 asymptomatic, 147 symptomatic) were examined for genital ulcers, repeatedly over a 4 year period. Genital ulcers were examined clinically, microbiologically, serologically and partly histologically.

Results: Genital ulcers was the most important cause for anal ulcers: 55/267 (21%) had at least one episode of ulcerating herpes anitis. Incidence increased with increasing stage of HIV-infection: 14/50, 14/89, 31/8 (32/61) and AIDS 33 / 129/87. The ulcers were atypical; extremely painful; "punched-out" lesions, showing no tendency to heal. On first manifestation the mean absolute CD 4+ T-lymphocyte count was 219/3 (lowest normal limit=490/ml). 80 % of cultures showed positive results (HSV 11=90, HSV 1=10%). Oral acyclovir was effective even in a dosage of 5 x 200 mg/d for 1-10d. 2 genital ulcers were caused by *Treponema pallidum*, once in combination with *herpesvirus*. Clinical picture and therapy were unremarkable. Anal ulcers occurred and oral ulcers occurred during the AIDS HIV-1 illness.

Conclusion: Genital ulcers should always remind of a possible HIV-infection. Furthermore, ulcerating herpes anitis is a distinct clinical marker for a severe cellular immunodeficiency.

M.B.P.276 NEED FOR GYNECOLOGIC PROTOCOLS IN AIDS PRIMAIR CARE CLINICS.

Marfa, Gerald; Ribble, D.; Hayes, C.; Wolbert, J.; Rodgers, T. J.; Kelly, J. Bellevue Hospital Center/Community Health Project, NY, NY, USA.

Objective: To develop a protocol assuring effective recognition and management of gynecologic disease in the increasing number of women attending a primary care clinic for HIV/AIDS patients. A protocol was designed on the basis of: (1) a questionnaire on gynecologic symptoms and disease administered to 118 HIV/AIDS women at our clinic; (2) review of literature and other available data on gynecologic disease in At Risk and HIV/AIDS women with respect to prevalence, nature of disease; (3) available AIDS management guidelines; (4) available AIDS management guidelines.

Results: Genital herpes and candidiasis, PID, and papilloma virus disease (condylomata cervical dysplasia and carcinoma) were identified as diseases of particular concern in the management of HIV/AIDS women. These diseases were found to be more prevalent, more aggressive, chronic and recurrent, and to require more extensive or different treatment than in HIV/AIDS women. They are not included in most current guidelines for medical management of HIV/AIDS patients, and most gynecologic protocols in primary care have not been modified for HIV/AIDS women. **Conclusion:** Providers should be informed on the unusual manifestations of gynecologic diseases in HIV/AIDS women. Conversely, severe or recurrent STDs should suggest the need for HIV counseling and testing. Special gynecologic protocols and services are necessary but not yet designed for effective management of At Risk and HIV/AIDS women. Data is available for improved management of these patients in the primary care setting, and a trial protocol is now being tested in our clinic.

M.B.P.277 **COURSE OF PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) ON CHRONIC DIALYSIS (D).**

R. Perez Garcia, J. Lillo, J.L. Lopez Gomez, A. Bravo, F. Valdesolano, M.D. Gutierrez-Gutierrez, NEFROLOGIA, HOSPITAL GENERAL DE GRANADA

In July 1987, we evaluated 108 adult patients undergoing Hemodialysis (HD) and CAPD/CRP patients with a functioning kidney allograft (TK) and 126 staff caring for them, the HIV infection. All patients and staff were evaluated serologically by ELISA (Abbott) to identify antibodies to specific HIV antigens. Each positive ELISA was confirmed by Western Blot, in two samples. There were two false positive ELISA reactions. Prevalence of HIV infection (HIV+) was 2.9% in TK; 18% in CR and 10% in staff. Only one out of HIV+ patients was intravenous drug user (IDU), the remaining three not any other risk factors than blood transfusion and 3 of them a previous TK. Also 2 patients with IDU-associated nephropathy requiring chronic maintenance D were included in this study.

The 6 HIV patients on HD and 4 on CAPD were followed during more than 18 months or until they died. The HIV patients were on CAPD 5 continuous, 10 on an isolated unit, and the last one on D 2 sessions were performed using CR guidelines for HIV preventing contagion. There were 10 HIV patients who were observed in the periodically ELISA tests performed every 6 months in patients on D or TK. All patients but one had CD4 count and CD4/CRP ratio reduced. Three out of 6 HIV patients developed Acquired Immunodeficiency Syndrome (AIDS) (2007) and had died between 15-20 months after HIV+ was first detected. Two out of 3 patients who developed AIDS were TK and the remaining only had blood transfusions as known risk factor. Blood transfusion on TK, before 1980 was a likely way of contamination for HIV in our area. HIV patients on D had a high risk to develop AIDS. All patients on D had a poor prognosis.

M.B.P.278 **HENOCH-SCHÖLLER PURPURA & IGA GLOMERULONEPHRITIS ASSOCIATED WITH H.I.V. INFECTION.**
Thompson Igg, Cooper G., Swedell E., Gold J., Melville R., St. Vincent's Hospital, Sydney, Australia.

Objective: A case of Henoch-Schölller purpura & Iga glomerulonephritis in association with H.I.V. infection in a 35 year old male. **Case Report:** A 35 year old male (N.I.V. was since '85) developed purpuric rash on trunk, legs & buttocks (typical H.S. distribution) with arthralgia in Nov-'87. A required 2 months steroid therapy until symptoms cleared. At presentation CD4 413 (500-1400) P24 antigen reactive I-positve & blood on urinalysis. IgM/IgG 1:4 (0.25-48 g/l). FBC, ESR, WBC & immunology screen negative. AZT commenced May '88. Subsequent arthralgia required transfusion and dose reduction. Bacterial pneumonia Nov '88 treated with ampicillin followed by acute renal failure. Creatinine 0.1mg/dl/22/10/88, 0.3mg/dl/3/11/88. Creatinine cleared once 10/11/88 (0.1, 1.5-2.2mg/dl), 24 hour urinary protein 1.67 grams (vol.104 - 0.3 mg/dl). Serology: IgA 1.2g/l (0.1-0.4g/l), IgG 1.2g/l (0.7-1.5g/l). Renal necropsy revealing glomerulonephritis with IgA deposition consistent with H.S. syndrome supported by I.F. AZT ceased. He with pulse stenosis & cyclic prothrombinic time developed haemorrhagic cystitis. Creatinine 0.25 16/12/88 with CD4 599, antigen w/e.

Conclusion: A case of classical H.S. purpura is described, initially responding to steroids, progressing to acute renal failure following an episode of pneumonia treated with ampicillin. The patient was known to be H.I.V. & P24 antigen positive at onset of illness. The association has rarely been described & is not the typical picture of H.I.V. associated glomerulonephritis, i.e. focal segmental glomerulosclerosis with a nephrotic picture.

M.B.P.279 **COURSE OF KIDNEY TRANSPLANTED PATIENTS WITH HIV INFECTION.** *Justine C.A.P., Debbie C., Valérie A.A., Aurélie C.A., Philippe D.* Division of Nephrology, Infectious Diseases and Laboratory, Hôpital Pasteur de Marseille - France.

The status of renal transplantation for HIV-infected renal transplants has been controversial since the first description of such patients infected with HIV. We have followed an endemic transplanted patients who had positive ELISA (ELISA) confirmed by Western Blot (WB) of those had seroconverted after transplantation. Results had been collected before transplantation, then with seroconversion and tested for anti-HIV.

Patients (n)	Before Transp.	After Transp.	Follow up (months)	Transp. (n)	Transp. (n)	Transp. (n)
11 (1)	1 (1)	1 (1)	10	1 (1)	1 (1)	1 (1)
12 (1)	1 (1)	1 (1)	15	1 (1)	1 (1)	1 (1)
13 (1)	1 (1)	1 (1)	17	1 (1)	1 (1)	1 (1)
14 (1)	1 (1)	1 (1)	19	1 (1)	1 (1)	1 (1)
15 (1)	1 (1)	1 (1)	20	1 (1)	1 (1)	1 (1)
16 (1)	1 (1)	1 (1)	21	1 (1)	1 (1)	1 (1)

The average follow-up after transplantation was 38.5 months, and 18 months for HIV diagnosis. The patients presented opportunistic infections (PCP, toxoplasmosis) and were seroconverted. The good results in this short time and the absence of a control group (HIV positive patients on dialysis treatment) do not allow us to establish with certainty of treatment after the best outcome, therefore we can not make a picture of desiring seroconversion attempts to HDG patients infected with HIV.

M.B.P.280 **LACK OF CLINICAL EVIDENCE FOR A GLOMERULOPATHY (GP) IN 203 PATIENTS WITH HIV-INFECTION.**
Brunhards, Ulrike, Brunhards, R., Tschopp, S., Eisenbach, G., Schmel, I. and Decker, H. Herxener Hospital, Herxener, A.G., Germany.

Objective: Several authors described a nephrotic syndrome, frequently progressing to renal failure in more than 20% of patients with HIV-infection of different stages. Though renal histological changes were rather unspecific these authors postulated the existence of a HIV-associated GP. We therefore investigated proteinuria (PU) and serum creatinine (5-crea) in 203 HIV-patients.

Methods: 122 patients (gp+) had early stages of the disease without opportunistic infections (O.I.), 81 patients suffered from acute O.I. (gp-). In case of positive qualitative test (Creatinin), quantitative measurement of PU (Buret) was carried out; when PU was 0.5 g/l 506-gel-electrophoresis (EMG) was performed.

Results: None of 81 patients had a PU 0.5 g/l or an elevated 5-crea. 10/81 patients had a PU between 0.3 and 3 g/l. One further of 81 patients developed a transient PU of 4.7 g/l. Only 3 of the proteinuric patients had a glomerular pattern in EMG. All 3 had CMV- or EBV-infections. 14/81 patients showed a transient elevation of serum IgG (of the asc. 5-crea: 10/81 uol/l) during maintenance therapy for opportunistic carinal infection. 1 PT treated with high dose azidothiadin had to be temporarily dialyzed.

Conclusion: In our 203 HIV-patients no nephrotic syndrome and no sustained elevation of 5-crea was observed. All cases of PU and transient elevations of 5-crea were associated with severe O.I. High doses of potentiated antiprotic antibiotics.

M.B.P.281 **NEPHROPATHY AS THE INITIAL SIGN OF AIDS: LUIZ, PAULO MANTOVANI, GUILHERME S. LOPES ALBANI, V. OLIVEIRA, FRANCISCO FILARDO, RUIBERTO FACELLI, CLAUDIA, CLIMELIA, MELISSA II. ESCOLA DE MEDICINA E CIRURGIA, UNI-RIO, BRASIL.**

AIDS-associated nephropathy is characterized by the presence of focal and segmental glomerulonephritis (FSGS) with rapidly progression to terminal renal failure. We study 308 HIV-infected patients, 280 men and 28 women. Risk factors were: 221 homosexual, 34 heterosexual, 14 unknown, 13 heterosexual contacts, 13 blood transfusion, 6 IV drug addicts. We found nephrotic syndrome (NS) in 3 (0.9%) associated with azotemia in 2 (moderate in 1 and severe in 1). Renal biopsy showed FSGS in 2 an diffuse glomerulosclerosis in 1. All progressed to terminal renal failure, 2 died 2 mo 14 months after the onset of NS. One has been submitted to maintenance hemodialysis for ten months.

In 2 patients IV drug addicts and unknown risk factor; the diagnosis of HIV infection was only possible when they presented opportunistic infections, 3 and 4 months after the onset of NS.

We conclude that NS may be the initial manifestation of HIV disease and we suggest that anti-HIV tests should be done in all adult nephrotic patients.

M.B.P.282 **THE PROGNOSIS OF INFECTIOUS COURSES OF AIDS-ASSOCIATED HEART DISEASE.** *E.A. Riney, A.J. L. Rowan, R.A.J. Reed Institute, Miami, FL, USA, and Hospital Saint-Jacques, Paris, France.*

Although we have found that many infectious causes of AIDS-associated heart disease are treatable, it was unclear if the odds of successful treatment were altered because of the presence of cardiac involvement. We therefore analyzed the results of treatment in our patients and in patients reported in the literature. Successful treatment of infection was defined as eradication of the cardiac pathogen after completion of the intended course of therapy. We found that the odds of successful treatment for tuberculous pericarditis were substantially lower than if the 20 we use extracardiac (24 vs. 50%). The only factor that separated those who succeeded from those who failed therapy was an elevated gamma globulin in those who succeeded. Symptomatic cardiac disease due to toxovium resulted in extremely short survival, regardless of treatment. For asymptomatic cryptococcal meningitis, the odds of successful treatment were no different in AIDS patients with extracardiac disseminated cryptococcosis. But it was only in cryptococcal meningitis that improvement in cardiac function was demonstrated after specific therapy. S. typhimurium endocarditis (SE) was eradicated using conventional medication only and did not relapse, even though no maintenance therapy was given. This suggests that SE may be less than S. typhimurium bacteria without a known focus of infection. T. gondii heart disease appears to require at least 2 months of treatment. These observations suggest that although some infections are less likely to respond to treatment if there is cardiac involvement, the response to treatment is similar to the outcome with only extracardiac disease.

ECG-CARDIOGRAPHIC ABNORMALITIES IN AIDS

Feichtert S, Vissers C, Buijse J and Dunning A. Departments of Cardiology and Medicine (AIDS-unit), Academic Medical Center, Amsterdam, The Netherlands.

Objective: To determine cardiac involvement in AIDS.

Methods: Two-dimensional echocardiography was performed in 32 consecutive patients (mean age: 39 years; range 20-60), with AIDS, CDC-classification IV-C, who did not have cardiac complaints.

Results: Pericardial effusion was present in 13/32 patients (39%). Valvular abnormalities were present in 9/32 patients (28%), of whom 2 had vegetations and 3 a prolapsing aortic valve leaflet. Wall motion abnormalities were seen in 21/32 patients (65%) and varied from moderately depressed regional myocardial function to severe, asymmetric global left ventricular dysfunction (5 patients). Cardiac abnormalities were absent in only 2 patients (6%).

Conclusions: Cardiac abnormalities are common in patients with AIDS and usually led to subclinical - affection of myocardial function.

M.B.P.284

CHARACTERISTICS OF PATIENTS WITH AIDS-ASSOCIATED HEART DISEASE BUT NO IMMUNOLOGICAL OR CHEMICAL INTERVENTION. Dilla J., Krieger, M.D., Oser-Jacques Rommes, M.D., M. Toussaint, M.D., The Heart Institute, Miami, FL, USA, and Hospital Saint-José and Cochin, Paris, France.

We retrospectively studied 41 adult patients (18 known to us, 23 from the literature) with AIDS and seronegative heart disease in whom the cause of the heart disease was assessed by culture and/or biopsy. Fifteen (36%) had no demonstrable cardiac pathogen. (Intrathal, 13 had infectious pericarditis, 8 had infectious myocarditis and 5 had a cardiac tumor. The Nethal group had a higher proportion of fibrinous fibrin showers and a lower rate of the infection of toxoplasmosis (0.07, mean=0.04, x²). The interval from the onset of AIDS or ARC to cardiac symptoms averaged 15.4 months in the Nethal group, versus 5.5 months in the group with a cardiac pathogen (with 3 strong outgroup, p=0.024, Fisher's). The Nethal group tended towards a higher frequency of prior P. carinii infection (p=0.07, Fisher's), and all groups had those with cardiac tumor had a lower rate of prior cutaneous Kaposi's sarcoma (p=0.04, x²). Other findings were equally distributed between groups. HIV was isolated from the heart in only 2 patients (pericardial fluid in 1 patient with infectious pericarditis) in the myocardium of 1 patient in the Nethal group. These data suggest that findings not demonstrable pathogen in an AIDS patient with seronegative heart disease is common, may be due to a prior, healed infection, perhaps related to P. carinii, and probably is not due to a direct cardiac effect of the HIV virus.

M.B.P.285

LEFT VENTRICULAR DYSFUNCTION IN AIDS PATIENTS WITH SEVERE PNEUMOCYSTIS CARINII INFECTION.

Wood Robert D. M.B.B. Tachemont J., Sweeney R.J., Bowden C.T.

LACUSO Medical Center, 3000 Street, Los Angeles, CA, U.S.A.

Objective: Respiratory failure associated to Pneumocystis carinii infection (PCP) continues to have an extremely high mortality. Cardiomyopathy has been described in patients with AIDS (Ruffard SP, 1986). In this study we examined the hemodynamic parameters of patients with PCP and severe respiratory failure.

Methods: We evaluated twelve patients (age = 34-74 yrs) with AIDS, documented PCP and severe respiratory failure (P_{ao2} < 65-1/0.16) requiring PEEP. We chose subjects who had no evidence of any concomitant bacterial, fungal, mycobacterial or viral infection as defined by lack of clinical signs, negative cultures, including blood. Hemodynamic data were obtained with a balloon-tipped pulmonary artery catheter. Cardiac outputs were obtained by thermodilution. Data were examined on admission to the ICU and at 12 and 24 hours.

Results: Our data showed:

Time	MAP	MPAP	PAOP	PCWP	CO	LVDF	SVR
12h	105 ± 10	16 ± 10	16 ± 10	14 ± 10	4.3 ± 1.1	12	80 ± 20
18h	102 ± 11	14 ± 10	15 ± 10	13 ± 10	4.2 ± 1.2	17	88 ± 10
24h	102 ± 12	14 ± 10	15 ± 10	13 ± 10	4.4 ± 1.4	18	78 ± 10

Conclusions: Our patients with PCP demonstrated a hypodynamic state not unlike that associated with sepsis. We found them to have profound myocardial dysfunction, with left ventricular function curves shifted downward and to the right. This may have therapeutic implications in the management of AIDS patients with respiratory failure due to PCP.

M.B.P.286

ELECTROCARDIOGRAPHIC CHANGES IN PATIENTS RECEIVING PENTAMIDINE FOR THE TREATMENT OF PNEUMOCYSTIS.

ALLBaker, Gordon A, Sheward A, Siger P, Gibson C, Haddock SR, Department of Internal Medicine, University of Southern California, Los Angeles, California, U.S.A.

Objective: In 1987, two patients developed bradycardia (POT) on pentamidine for the treatment of Pneumocystis carinii pneumonia (PCP) in the absence of electrolyte abnormalities. The purpose of the study was to evaluate the electrocardiographic effects of pentamidine (PTM).

Methods: We prospectively obtained a series of 12-lead ECG studies in 10 consecutive patients with AIDS and PCP who were receiving PTM. The ECG was obtained before administration of PTM, and 2.5 ± 0.8 days (cumulative dose of PTM 652 ± 214 mg) and 7.2 ± 1.1 days (cumulative dose 1082 ± 588 mg) after therapy. We patient had no other heart disease, thyroid abnormality or electrolyte disturbances.

Results: The heart rate at baseline was 90 ± 16, and did not change on day 2.2 (97 ± 21) or day 7.2 (87 ± 20). Similarly, the PR interval of 146 ± 10 ms remained stable at day 2.5 (142 ± 52) and 7.2 (147 ± 21). Also QTc of 422 ± 22 remained unchanged (419 ± 10 on day 2.5 and 408 ± 28 on day 7.2). Although one patient had mild QTc prolongation from 430 to 510 ms there was no other ECG abnormality.

Conclusion: Pentamidine produced no significant dose related ECG effects. E.TOP appears to be an idiosyncratic complication of PTM. Abnormal QTc prolongation during therapy with PTM is a relatively rare and when present, should be treated as a warning sign of impending TDP.

Néoplasme Neoplasm

STAPHYLOCOCCUS Aureus ENDOCARDITIS IN HIV(+) AND HIV(-) INTRAVENOUS DRUG ABUSERS

Doblets, Eric; Sore, C and Flahault, H. University of Miami School of Medicine, Miami, Florida, USA.

Objective: To evaluate the clinical presentation and outcome among HIV(+) and HIV(-) intravenous drug abusers (IVDA) with S. aureus endocarditis.

Methods: Retrospective chart review of 50 patients hospitalized for S. aureus endocarditis between March 1983 and November 1983 was done. 23 were HIV(+) and 18 HIV(-), 3 patients seroconverted. Age, sex, race, medical history, physical exam, laboratory parameters and outcome were assessed.

Results: Mean age was similar in both groups. More women (63% than men (37%) were noted in the HIV(+) group. No difference in sex distribution was seen in the HIV(-) group. In HIV(+) group, 78% were black americans, 19% white, and 3% hispanic. No racial differences were noted in the HIV(-) group. Fever-TX and cough-SXR were less frequent presenting symptoms in HIV(+) compared with 80% and 72%, respectively, in HIV(-). No differences in physical and chest X-ray findings were noted. Mean haemoglobin (11.7) and white count (11.2) were higher in HIV(+) patients than HIV(-), respectively (10.8 and 10.5). More vegetations were identified in the HIV(-) group than HIV(+) (56% vs 26%).

Recurrence of S. aureus endocarditis was the same in both groups. 4 patients had prior or concurrent opportunistic infections (OI). 4 developed OI within 10 days of endocarditis (11.7%) and white count (11.2) were higher in HIV(+) patients than HIV(-), respectively (10.8 and 10.5). More vegetations were identified in the HIV(-) group than HIV(+) (56% vs 26%).

Recurrence of S. aureus endocarditis was the same in both groups. 4 patients had prior or concurrent opportunistic infections (OI). 4 developed OI within 10 days of endocarditis, 1 of PCP, and 1 of unclassified cause.

Conclusion: HIV(+) patients with S. aureus endocarditis were more likely to be black american women. Poor outcome and high fatality rate favored the HIV(+) group.

M.B.P.288

POLYCLONAL AND MONOCLONAL B-CELL LYMPHOMA IN AIDS

Kanda, Lawrence D., Meeker T.M., Falgat B., Herndon B., Klayman B., Bashi P., Orinetti C.M., McGrath M.P., Department of Medicine and Pathology, San Francisco General Hospital, University of California, San Francisco, CA, U.S.A.

Objective: The identification of clinical characteristics associated with two molecular subgroups of AIDS-associated B-cell lymphomas.

Methods: Immunoglobulin heavy chain (IgH) DNA Ase-I restriction enzyme (E) for Epstein-Barr virus (EBV) were performed on 23 lymphoma tissue specimens obtained at diagnosis from patients with AIDS-associated non-Hodgkin's lymphomas (NHL) and correlated with clinical features.

Results: Fourteen tumors were identified as monoclonal and nine as polyclonal. The polyclonal lymphomas included immunoblastic (6), diffuse large cell (2), and small noncleaved (1) histologies. Monoclonal lymphomas included immunoblastic (3), small noncleaved (5), and large cell (1). Six primary CNS lymphomas were all monoclonal, immunoblastic. EBV DNA sequences were identified in 4 of 7 monoclonal samples and 1 of 4 polyclonal samples. Non-CNS lymphomas patients with polyclonal diagnosis lived longer (median 13 vs 3.3 mo; p=0.003), had higher total T4 cell counts (369 vs 120/mm³, p=0.1), and were more likely to have Stage I disease (4/7 vs 0/6; p=0.07).

Conclusions: The frequency of a prior AIDS diagnosis, performance score, and the frequency of extranodal disease (known prognostic features) were similar in each group.

Conclusions: Molecular analysis suggests two disease processes in patients with AIDS-associated NHL, each associated with distinct clinical features and prognosis.

M.B.P.289 KAPOSI'S SARCOMA IN PATIENTS WITH HIV INFECTION

Latif, Ahmed, Houston S, Mall P, Bassett M, Thornton C, Sitima J, et al University of Nebraska Medical School and Nebraska Blood Transfusion Service, NEB, NE, USA

Objective: To study the clinical features and response to treatment of KS in patients with HIV INFECTION.

Methods: All patients with HIV infection and histologically proven KS were studied. For staging purposes fiberoptic endoscopy was carried out. Patients were treated with combination chemotherapy using acyclovir, 5, zalcitabine and zidovudine.

Results: 100 (80%) patients were male and 22 (18%) were female. The mean age of males was 38 years and that for females was 31 years. Generalized lymphadenopathy was found in 107 (87%) patients. Skin lesions in the form of nodules, plaques or diffuse infiltration were found in 115 (93%) patients. 6 patients had mucosal lesions of KS. Lymphadenopathy but no skin lesions were found in 10 lymphadenopathic KS. Mucosal lesions were found in the buccal cavity (26%), in the nasopharynx (4%), on the conjunctivae (7%), in the bronchi (17%). Two patients had concomitant infection with *Pneumocystis carinii*. 99 patients were treated and of the 76 evaluated treatment failure occurred in 18 (23%) while partial or complete remission occurred in 58 (77%). The cumulative death rate for a 24 month treatment failure occurred in 18 (23%) while partial or complete remission occurred in 58 (77%). The cumulative death rate for a 24 month period was 25.8%. **Conclusions:** Patients with AIDS-related KS respond well to chemotherapy with initial dramatic improvement. However relapses frequently occur. Patients with pulmonary KS have a poorer prognosis.

M.B.P.291 KAPOSI'S SARCOMA - CLINICAL DISTRIBUTION, OPPORTUNISTIC INFECTIONS AND SURVIVAL

James, Carlo, Pheasant, R.G., Diaz, M.K., Eyer-Silve, M.A., Nigam, L.A.; Norris 54, CA.

Centre & Centre University of California, University of Los Angeles (UCLA) - Beverly.

Objective: To evaluate the clinical distribution, opportunistic infection (OI) and survival of AIDS patients with Kaposi's (KS).

Methods: Of 235 patients treated the CDC case definition for AIDS, 39 (16.5%) were diagnosed with KS. These were evaluated for clinical distribution and analyzed for occurrence of opportunistic infections. Cumulative survival rates are assessed in 22 patients (Gutler, Center 1980) with KS with and without OI.

Results: Kaposi's sarcoma occurred in 39 male patients, 39 homosexual (59.2%) and 26 bisexual (66.2%). The sites were treated as in patients (91.8%), lymphoma (16 (77.1%)), post-lymphatic tract (6 (77.1%)), lung (2 (50%)), peritoneal tract (2 (50%)) and brain (1 (11.7%)). We observed infections in 48 (81.2%). Candidiasis was the most frequent OI occurring in 39 patients (66.2%), *Pneumocystis carinii* in 19 (28.0%), Cryptosporidiosis in 10 (16.8%) and cerebral toxoplasmosis in 9 (15.2%). The proportion surviving one-year among 22 patients with KS with and without OI was 88% versus 60% (NS) and three-year and five-year survival was 44% among 18 patients with both KS and OI, one-year survival was 70% but a steep drop occurs thereafter by the years only 7% survive and none survive three years.

Conclusions: The prevalence of OI in our AIDS patients is high (81%). All patients were homosexual men. The majority of KS involved skin, lymphomas and GI tract. Opportunistic infections seem to be responsible for decreased survival in KS.

M.B.P.293 MALIGNANT NEOPLASMS IN SURVIVAL SPECIMENS OF DIFFERENT AIDS RISK GROUPS

W. Nappes MD, Richard Rottenberg MD, G. Sidhu MD; NYU Medical Center, New York, NY, U.S.A.

We examined 1107 surgical specimens from 321 AIDS patients to determine the frequency and site of malignant neoplasms (MN) and differences, if any, among the two major risk groups of homosexual (HS) and IV drug abusers (IVDA). There were 231 patients with HS and 276 patients with IVDA's (21% of HS and 8% of IVDA) and 27 (4%) with malignant lymphoma (ML). Four HS had both KS and ML. Five patients had squamous cell carcinoma (SCC) and one prostatic carcinoma. KS was found in 63 of 319 skin biopsies (20%) and constituted the most common opportunistic disease (OD) at this site. KS was also found in 15 of 81 lymph nodes (18%), 10 of 194 digestive tract bi (5%), 8 of 329 lung bi (2.4%), 4 of 21 esophageal bi (19%), and 1 of 73 liver bi (1.4%). KS was the first presenting OD in 69 of 89 (78%) patients. KS was 7 times more common in HS vs IVDA and was diagnosed in 70 of 187 HS (37%) vs 5 of 120 IVDA (4%). Malignant lymphoma (ML) was found in 14 of 81 lymph nodes bi (17%), 5 of 194 digestive tract bi (2.6%), 5 of 187 bone marrow bi (3%), 3 of 176 skin bi (1.7%), 2 of 8 brain bi (25%), and once each in soft tissues, liver, oral mucosa, and lung. ML was the first presenting OD in 17 of 27 (63%) patients. HS were diagnosed with approximately equal frequency in HS and IVDA [20 of 187 HS (10%), 8 of 120 IVDA (6%)]. ML was, however, more frequently seen in HS (16 of 34 (46%)) than in IVDA (3 of 8 (37%)). SCC occurred in lymph (2), anus (1), penis (1), and skin (1) and exclusively in HS. We conclude that KS is the most frequent MN in HS, and ML in IVDA. ML is more commonly extended in HS than in IVDA.

M.B.P.290 LYMPHOMAS IN PATIENTS WITH HIV INFECTION

Carlo, M. Edg., Guarnier JG, Carr D, Mendrix L'E., Gentry Complex and the Crawford W. Long Hospital of Emory University, Atlanta, GA, U.S.A.

OBJECTIVE: We identified 18 patients with AIDS, AIDS-related lymphoma and with serological evidence of HIV infection, seen at a single hospital since 1982, and analyzed the clinical presentation, type of lymphoma, treatment and outcome to better understand their disease.

METHODS: Retrospective review of medical records and prospective follow up of patients seen since July of 1988.

RESULTS: 16 patients had non-Hodgkin's lymphoma (NHL); 1 Hodgkin's disease, and 1 had the simultaneous presence of both Hodgkin's disease and NHL. All patients were white; homosexual men with a mean age of 36.2 years. In 47% this was the initial presentation of HIV infection. We classified 65% of the cases as high grade (7 small cell lymphoma, 2 large cell, 1 immunoblastic, 1 high grade otherwise unclassifiable), 20% as intermediate grade (5 diffuse large cell, 1 mixed), and 1 patient had a low grade lymphocytic lymphoma. Extracranial involvement was present in 47% with the gastrointestinal tract and the liver being the common sites. Of 12 patients treated with chemotherapy, 7 treated with M2COP-B, achieved complete remission. However, one patient relapsed after 86 weeks. Both patients with Hodgkin's disease achieved a complete remission with MOPP-B.

CONCLUSIONS: High grade malignant lymphomas, frequently with atypical presentations, occur in patients infected with HIV and should be treated with intensive chemotherapy regardless of stage. The response to treatment with M2COP-B is favorable; however, late relapses can occur.

M.B.P.292 LAMAR GRANULAR TUMOR NEPLASIA. ITS INCIDENCE IN HIV INFECTED MEN

AND THE ROLE OF HUMAN PAPILLOMA VIRUS (HPV) AND OTHER RISK FACTORS

J. P. SIEHL, H. BEHRE, H. KROEMER, P. NEMAZI, D. TAYLOR-KENDRICK, S. H. PORTER. The Department of Genito-Urinary Medicine, the Prud Street Clinic, St Mary's Hospital, London, United Kingdom.

A high incidence of cervical dysplasia has been noted in HIV positive women. Therefore, 20 women infected with HIV were studied cytologically and by colposcopy. Results are as follows:

Site of Dysplasia

Site of Dysplasia	HPV	HPV
Uterine Cervix <td>100%</td> <td>100%</td>	100%	100%
Vagina <td>100%</td> <td>100%</td>	100%	100%
Rectum <td>100%</td> <td>100%</td>	100%	100%

Of our study group had evidence of HIV infection and 15% had other well recognized risk factors for each disease, age, sex of 17 men, education, nature of sexual partners, smoking etc. We will present the results of a study, including HIV serology, carefully controlled for these factors and designed to investigate the role of HIV and the immunosuppression caused as a result of HIV infection in the increased incidence of lower genital tract neoplasia in this group.

* CIN = cervical intra-epithelial neoplasia. VCN = vaginal intra-epithelial neoplasia. IN = Intraoral, intra or mucosa. VAIN = vaginal intra-epithelial neoplasia.

M.B.P.294 P-IALL IN HIV-POSITIVE IV DA MAN

Moscar, J.A.C. de Calabro J, Galante L, Landone G, Nara M, Orsato F, Department of Hematology and Pathology, Niguarda Ca Granda Hospital, Milan, Italy.

OBJECTIVE: To present the clinical course of P-IALL in HIV-positive heroin abuser, the response to therapy and the survival. **Methods:** 10 patients (100% of HIV and 100% of P-IALL) were studied. HIV was positive (100% of 10 patients) and HIV RNA was positive (100% of 10 patients). All patients were treated with combination of doxorubicin, cyclophosphamide, etoposide, procarbazine, and procarbazine. Cytogenetic: 100% of 10 patients were negative for CD 22, Bcl-2, and Bcl-6. All patients had a complete remission. All patients were negative for HIV RNA. Two courses of induction therapy (doxorubicin, cyclophosphamide, etoposide, and procarbazine) and one course of consolidation therapy (doxorubicin, cyclophosphamide, etoposide, and procarbazine) were given.

Results: For and short partial remission was obtained. During relapse bilateral pneumonia of low-A few days later the patient developed dramatic bilateral respiratory with fever, myalgia, diarrhea and acute renal cortical CT tumor of the lung. The patient died after "doxorubicin" course. **Autopsy findings:** (indications: disseminated; primary carcinoma by angiosarcoma; metastatic carcinoma; tumor by unknown cause).

Conclusions: P-IALL is rarely associated to HIV-positive men but increasing reports in literature. Some authors are the opinion that the current CDC criteria for AIDS should be widened to include P-IALL in HIV-seropositive subjects. The course was dramatic and therapy ineffective as reported by others authors.

IMMUNAL PRESENTATION AND CLINICO-PATHOLOGICAL CORRELATIONS IN NON HODGKIN'S LYMPHOMA (NHL) ASSOCIATED WITH HIV INFECTION

E. OUBREINER, J.P. PARCET, C. CISELBERGHEIT, J.P. CLAVEL, A. TRUSS, N. KARLAIN, F. JETTEL, N.Y. NICÉ - FRANCE.

We have evaluated the potential correlations between histopathology, clinical expression and immunodeficiency status in 57 patients with NHL associated with HIV infection.

Histopathology (n)	Stage	CD4 count	CD4 cells/mm ³
	I-II	III-IV	IV
Immunoblastic (13)	10	3	10 > 3
Diffuse large cell(29)	13	16	10 > 19
Burkitt (15)	2	13	4 > 11

Patients with immunoblastic NHL had low CD4 cell counts, belonged to CDC group IV and presented usually with localized extranodal (Lympho) testis (2), par (2), lung (2) and colon (1). Patients with Burkitt lymphoma had a disseminated disease with bone marrow involvement in 5/15 and central nervous system involvement in 4/15, but often asymptomatic HIV infection. Patients with diffuse large cell NHL had an intermediate status.

M.B.P.297

KAPOSI'S SARCOMA (KS) IN WOMEN WITH ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS)

Chengy, Tony M. and Slegel F. Queens Hospital Center(CUNY)and Long Island Jewish Medical Center (L.J. Queens and New Hyde Park, N. Y. 11432 and SUNY at Stony Brook, N. Y. 11794, U. S. A.

Most patients(pts) with AIDS related KS are male homosexuals. KS in female patients with AIDS is rare. Objective. To survey cases of AIDS related KS in women and exentire their clinical course.

Methods. Records from tumor registries and patient charts from private oncologists from QHC and LJJ were reviewed. A literature computer search was also used to look for cases of female AIDS related KS. Results. Seven patients range in age from 23 to 34 years; 5 are black, 1 Hispanic and 1 Haitian. Six patients, except the Haitian, are intravenous drug users. All pts developed opportunistic infections: oral candidiasis (7), *Pneumocystis carinii* pneumonia (3), genital herpes (4),herpes labialis(1), CMV infection(7). All pts except one were diagnosed to have KS clinically and confirmed by biopsy; 6 have dermal involvement with visible skin lesions of the trunk and lower extremities. Chest x-ray of those 6 patients showed interstitial infiltrates. Bronchoscopy confirmed KS. The seventh patient presented with angioimmunoblastic lymphadenopathy; later right eye proptosis developed which, on biopsy, revealed non-Hodgkin's lymphoma. She expired 4 months later and on autopsy there was KS in the lung and stomach. Survival of all 7 pts was only 1 to 6 months (median 3-6 months). Conclusion. Women with AIDS related KS have a very aggressive course. All cases presented have pulmonary involvement. We suggest that the putative etiological agent(s) can be transmitted by the intravenous route.

M.B.P.299

PREDICTORS OF SHORTENED SURVIVAL IN PATIENTS WITH KAPOSI'S SARCOMA AND HIV-1 INFECTION

Technica, Barbara; Brunstert, U.; Schwel, I. and Hannover Medical School, Hannover, F.R. Germany.

Objective. To determine clinical, viral and immunological characteristics at the time of diagnosis of Kaposi's sarcoma in patients with HIV-1-infection in correlation to survival.

Methods. HIV-infected patients with biopsy proven Kaposi's sarcoma were enrolled in this study.

Results. During observation period of this study (17 months) 21 patients with HIV-1-infection and Kaposi's sarcoma were identified. 19/21 patients had contracted other bacterial, viral and/or opportunistic infections. In our study the prognosis of Kaposi's sarcoma depends on the appearance of other concomitant infectious agents such as *Pneumocystis carinii*, CMV etc. Furthermore the decrease of CD4/CD8-ratio, prevalence of specific p24-antigen i.e., and loss of specific antibodies to p24-core-protein corresponds with a poor prognosis.

Conclusion. Predictors of shortened survival in patients with HIV-1-infection and biopsy proven Kaposi's sarcoma included loss of specific antibody to p24, p24-antigenemia, decreased CD4/CD8-ratio and/or appearance of opportunistic infections such as PCP.

M.B.P.296

ACCURACY OF KLA DRS AND KAPOSI'S SARCOMA IN TRINIDAD AND TOBAGO

Corneille Bartholomew*, V. Wilson**, F. Cleghorne***. *The University of the West Indies; **Department of Immunology, General Hospital, Port of Spain; ***The Caribbean Epidemiology Centre, Port of Spain, Trinidad.

Although the association of Kaposi's Sarcoma (KS) and KLA DRS has not been found in all reports the majority of studies have shown an increased frequency of DRG both in endemic KS and HIV associated KS. Trinidad and Tobago has a population of 1.2 million people comprising people of African origin (41%), Indian origin from North India (41%), Mixed race (16%), Caucasian 1% and Chinese 1%. The people of African origin came to Trinidad via the slave trade from 1680 and the Indians from North India as indentured labourers from 1845. Up to December 31, 1988 there were 289 cases of AIDS in Trinidad, 288 of whom were Afro-Trinidadians and 25 Indo-Trinidadians. However, there were only 3 cases of KS all of whom were in people of predominantly Caucasian ancestry. There is no IV drug abuse in Trinidad. Statistics of DRG antigen frequencies show a frequency of 31.6 in African blacks, 26.0 in North American blacks, 29.0 in North Indians, 25.2 in Afro Trinidadians and 21.5 in Indo-Trinidadians. On the other hand, while the DRG antigen frequencies were 26.8 in African blacks, 25.2 in N. American blacks and 22.6 in N. Indians, it was only 8.5 in Indo-Trinidadians and absent in Afro-Trinidadians. The frequency of DRG in this population may account for the extremely low incidence of KS in Trinidad and Tobago and supports the epidemiological claims for an association between KS and DRG.

M.B.P.298

LYMPHOMATOUS LEUKEMIA IN HIV-INFECTED PATIENTS

Minoli Lorenz, Maserati, R.; Pan, A.; Malfitano, A.; Sacchi, R. Pagnocco, G. T. Infectious Disease and Hematology Dept., IRCCS San Matteo, Università di Pavia, Italy.

IRCCS San Matteo, Università di Pavia, Italy. Among the 289 cases of AIDS in Trinidad and Tobago there were 288 of whom were Afro-Trinidadians and 25 Indo-Trinidadians. However, there were only 3 cases of KS all of whom were in people of predominantly Caucasian ancestry. There is no IV drug abuse in Trinidad. The frequency of DRG in this population may account for the extremely low incidence of KS in Trinidad and Tobago and supports the epidemiological claims for an association between KS and DRG.

M.B.P.300

TREATMENT OF DISSEMINATED MYCOBACTERIAL INFECTION (MI) WITH CIPROFLOXACIN (CP), ETHAMBUTOL (EB), RIFAMPIN (RIF) AND ISONIAZID (IS)

Chiu, Joseph; Nambawa, J.; Bonesta, S.; Young, L.; Hestonite, P.; and Robinson, J.A., California Collaborative Treatment Group, USA.

Objective. To assess the clinical and microbiological response to a multiple drug regimen for disseminated MI.

Methods. 17 AIDS pts. with sustained MI bacteremia were treated with AMK (7.5mg/kg/day for first 4 wks), CP (1500 mg BID), EB (1500mg/day), and RIF (15mg/kg/day) for at least 3 months. Median time since AIDS diagnosis was 21 wks (range 2-50) and since onset of possible MI symptoms (see table) was 4 wks. (range 0-20)

Results. Log₁₀ median colony forming units (CFU) fell by 1.2 (2.4-1.2) in 4 wks in conflict with decreasing prevalence of symptoms. Improvements were sustained thru 12 wks. In those who tolerated therapy, treatment was terminated prematurely (12 wks) for reasons (n) and hepatitis (n).

NUMBER OF PATIENTS
MEDIAN CFU/ml (range)
FEVER > 38°C
MYCOBACTERIA
RIFAMPIN
ISONIAZID

Conclusion. This regimen relieves symptoms and reduces bacteremia in a majority of patients, but has significant toxicity, requires parenteral administration, and does not frequently terminate bacteremia.

M.B.P.301 PATIENT COMPLIANCE AND TERMINATION IN COMMUNITY-BASED CLINICAL TRIALS OF AIDS TREATMENT. Holzman, Stephen P., and Rosen, J.D. Community Research Initiative, New York, NY, U.S.A.

Objective. To present the analysis of data concerning participant compliance and termination in clinical trials.

Methods. We analyzed drop-out rates for participants enrolled in clinical trials carried out in the past year by the Community Research Initiative. We also estimated the effect of certain interventions designed to diminish drop-out rates.

Results. Of 280 participants in two trials over a one-year period, 60% remain in the trial. Reasons for termination include death, incarceration, illness, voluntary withdrawal, and noncompliance. We estimate that in the latter two categories, a 25% greater drop-out rate would have occurred were it not for our initiation of at-home and on-site visits to provide treatment, and initiation of telephone counselling and on-site supportive intervention to participants and to their lay co-ordinators.

Conclusion. A high drop-out rate should be anticipated in clinical trials involving persons with AIDS/ARC. It can be compensated for by increasing the number of participants, and by supporting personnel to provide aggressive case-management, as illustrated.

M.B.P.302 CLINICAL IMPACT OF CASE MANAGEMENT BY AN IMPAIRED AIDS CLINICAL NURSE SPECIALIST ON COSTS AND QUALITY OF PATIENT CARE. Dale, E. Small, Parkland Memorial Hospital, Dallas, Texas, USA.

Objective. To study the effects of an Impaired AIDS Clinical Nurse Specialist and case management practice on costs, clinical outcomes and quality of patient care.

Methods. The patient populations used in this study were those Impaired admissions in 1988, 1989. The data were categorized as HIV, ARC, or AIDS. The data was analyzed for the 12 time periods related to the appointment of an Impaired-based Clinical Nurse Specialist (CNS) in 1988. Case management included the identification and classification of each patient and upon admission, daily patient contact and anticipatory and comprehensive planning during each phase of the patient's illness. The case management protocol extended beyond hospitalization to include discharge and follow-up into the outpatient AIDS Clinic. Average length of stay (LOS) and readmissions were the indexes used to evaluate cost-effectiveness and quality of care respectively.

Results:

Group I:	1988	Group II:	1987	Group III:	Oct.-Dec. 1988
LOS	11.96	n = 331	LOS	9.03	n = 130
LOS 11.46	11.11	LOS	9.03	LOS	9.03
readmission	31%	readmission	11%	p < 0.05	p < 0.05

The average LOS was 11.46 days in 1988 and 11.8 days in 1987. With the involvement of an Impaired-based AIDS Clinical Nurse Specialist, the average LOS was decreased to 9.03 days. The percentage of readmissions to the institution was 31% in 1988 and 33% in 1987, and only fell to 11% in 1988.

Conclusion: The results of this study indicate that LOS and readmission rates are significantly reduced by the role of an Impaired-based CNS and case management.

M.B.P.303 THE ROLE OF NURSING IN MANAGING COMMUNITY-BASED RESEARCH. Holzman, Stephen P., Rosen, J.D., Bennett, J.J., Elledge, George, P., Community Research Initiative (CRI) New York, NY, U.S.A.

Objective. To describe problems encountered and resolutions developed in management of community-based research from a nursing perspective.

Methods. Identification of problems and resolutions in the following categories: protocol development and implementation, data collection, quality assurance, budgeting for research, case-management in recruitment and retention of research subjects, and personnel management.

Results. The New York CRI is the first free-standing, community-based research organization in the USA. The CRI-model has created methods of managing clinical research trials from a community perspective. The CRI-model has been developed with clinical nurses assuming a major role in management of clinical trials.

Conclusion. Using clinical research nurses to manage clinical trials provides one approach to successful operation of community-based research. Our experience should be of value to those planning or implementing a community-based research model.

M.B.P.304 NURSING IN THE COMMUNITY FOR PEOPLE WITH HIV: DESCRIPTION OF A TRAINING/IMPLEMENTATION PROGRAMME. Ellis, G. Moore, *Oxford Regional Health Authority, Oxford, UK.

Objective. To develop and implement a training programme to ensure the most effective utilisation of community nursing services by people with HIV infection and disease.

Methods. Experience in Oxfordshire of working with HIV disease was confined mostly to acute sector staff, thus blocking the full utilisation of community care by people with HIV. Integration of HIV care into community nursing services was achieved by developing a facility whereby one community nurse from each population-based geographical sector was facilitated for training and work on the in-patient wards.

Results. Nurses were able to facilitate the care at home of patients through liaison between hospital and local primary health care (PHC) teams, and by sharing knowledge and experience with colleagues. The programme was implemented by identifying staff, devising a training curriculum and providing the policy and resource back up which was necessary. These processes will be fully described in the presentation.

Conclusion. Care in the community must be actively developed. The specialisation of services in the acute sector reduces the care options for the patient. Such development is most effective when implemented through the PHC team setting in the community.

M.B.P.305 PROJECTIVE REPORT ABOUT SELF, FAMILY, ENVIRONMENT AND DISORDER ASSOCIATED WITH ORBITIC NERVE IMMUNODEFICIENCY VIRUS INFECTION IN CHILDREN. Scholtz, P., Carter, Susan, Aborn, J., and Hanson, J., Baylor College of Medicine Children's Hospital, Houston, Texas.

Objective. To demonstrate that the child with AIDS and symptomatic HIV infection can describe the progression of physical discomfort through the use of colors, body outline drawings, and visual analog.

Methods. Projective drawings and visual analogs are solicited monthly over a 2 year period while children are outpatients at a hospital clinic. Drawings are analyzed using standard analysis paradigms for children's art. Visual analogs (facial scales) are analyzed on the interval level comparing parent and medical report of the child's health to the scores on the scale.

Results. Preliminary results on 8 children over an 11 month period indicate that children can pinpoint in drawings sites of physical discomfort, as well as sources of psychological distress. The 3 children with stable family lives indicate varying degrees of physical discomfort through their drawings, but depict happy self, family, and environment, thus showing a relatively low visual analog score (the lower the score, the "happier" the child) while children with less stable home environments and/or behavioral disorders have higher visual analog scores.

Conclusion. Preliminary results indicate that communication through art work can be constructive and predictive in children who may not be able to communicate their feelings verbally. These drawings are also helpful in determining sites of discomfort, therefore enhancing healthcare.

M.B.P.306 INFECTION CONTROL NURSE ROLE: POWERFUL CHANGE AGENT IN THE PSYCHIATRIC SYSTEMS IN THE USA. Shalla, Debbie, Pappas, J., Gordon, **, Connecticut Mental Health Center, Yale-New Haven Medical Center, New Haven, **University of New Haven, West Haven, CT, U.S.A.

Objective. Psychiatric units tend to stress psychosocial rather than medical aspects of care. Practitioners in these settings are generally less comfortable with Infection Control (IC) procedures and are concerned about how these adversely affect the established therapeutic milieu. The successful integration of AIDS patients on these units will depend on the Infection Control Nurses (ICN) ability to innovatively conceptualize the role as a key organizational change agent. Using a frame of reference common to psychiatric-mental health nursing (PMHN) and sociology, attention is focused on the pivotal role of ICN in shaping organizational response to the first cohorts of HIV affected persons in psychiatric systems.

Methods. Relevant concepts are presented, drawn from data gathered from participant/non-participant observations, survey responses and informal interview of staff, patients and families. Confidentiality is maintained by presenting illustrative case material synthesized from published and unpublished sources.

Results. Given the anxiety engendered among psychiatric administrators and staff, the ICN in thrust into promulgation and must shape policies and procedures that govern patient treatment and staff behaviors. In an atmosphere rife with uncertainty and fear, the confiding tasks will entail on the part of the ICN: rapidly develop a plan that maximizes administrative goals, facilitates treatment and protects patients, families and staff. Realization of these needs requires the successful integration of AIDS patients on psychiatric units requires the ICN who attends to the interrelationships of biopsychosocial theories, research and practice. The ICN, who has a strong background in both IC and AIDS, can be a powerful positive force and leadership and acceptability to the IC policies and procedures in a psychiatric system.

M.B.P.307

RIV SELF ASSESSMENT AND CARE PROGRAM

Tom Barnagale, R.N., AIDS Nurse Clinician, AIDS Clinic, Parkland Memorial Hospital, Dallas, TX.

OBJECTIVE: To develop a comprehensive program of preventive care services for eligible clients utilizing a Registered Nurse (R.N.) as a consistent primary caregiver.

METHOD: The client must first thoroughly understand what Human Immunodeficiency Virus (HIV) is and what it means to them. Secondly they must understand normal vs. abnormal in reference to their health status. Finally they must be taught how to assess themselves for any changes in their health status. The components of the program are HIV counseling according to C.D.C. standards, complete physical, exam for HIV infection staging, and patient education to teach the client to perform self-exams to assess for changes during their health care visits.

Eligibility criteria are ascertained by the R.N. Clinician, and are: HIV seropositivity, desire and mental ability to learn self-assessment. Projected outcomes include increases in client and staff satisfaction, reduction of avoidable events, hospitalizations and need for emergency services, maintenance of health, independence and financial stability.

CONCLUSION: This program allows for the earliest entry of the client into the healthcare network while allowing them to remain productive members of society through their health and physical status assessment.

M.B.P.308

OUTBREAK OF NORWEGIAN SCABIES AMONG HEALTH-CARE WORKERS

Kelly, Ann; Fry, C. St. Stephen's Hospital, London, England.

Objective: To control an atypical outbreak of Norwegian Scabies amongst patients who were immunosuppressed on an AIDS ward. Scabies was diagnosed and treated 40 health-care workers and their partners and close contacts. Preventing the spread to non-infected persons from one severely infested patient.

Method

- 1) Diagnosis and surveillance of an outbreak of atypical Norwegian Scabies and identifying infested health-care workers and patients.
- 2) Co-ordinating the treatment by ensuring all ward personnel were contacted and treated simultaneously. One other patient was treated at the same time.
- 3) Continued surveillance until all personnel were asymptomatic.
- 4) Standards of the ward had to be maintained and ensure infested staff were not giving direct patient care.

Results

- 1) Effectively contained the outbreak.
- 2) Prevented spread to uninfected persons.
- 3) Maintained the high standards of nursing care on the ward.

Conclusions

- 1) When patients are seen with skin problems Norwegian Scabies may be considered, an outbreak can be prevented.
- 2) Treatment of staff is essential if it proved to be effective.
- 3) Health-care workers and patients followed up as re-infestation could occur.

M.B.P.309

DEVELOPING COMMUNITY NURSES SKILLS IN HIV/AIDS PROGRAMS

Eric Thomas, and Robinson BS*, Pratt MS*, Willis CS
KypreosIII MS*, Newbury MS*, *Department of Health, London England, UK and **British Heart Foundation for Nursing, Ministry of Health Visiting, London, England, UK. **Beverly Health Authority, London, England, UK.**

Objective: A Government initiative aimed at improving levels of understanding among community nurses of HIV infection and AIDS, to provide opportunities for them to examine personal attitudes which may be obstacles to effective care and preventative treatment; to encourage their participation in HIV programmes.

Method: Workshops of two day duration were held in 14 Health Regions in England to demonstrate dissemination of information by a cascade effect: between 20 and 40 minor nurse managers took part in each. Sessions were facilitated by a team experienced in the care of HIV infected patients. On completion each participant was asked to list specific initiatives to be implemented locally. Six months later participants were followed-up to determine achievements, barriers encountered and possible solutions to them. An evaluation was made of the effectiveness of the Workshop with a view to services making recommendations on local and national policy.

Results: Various initiatives set up demonstrated that Districts with low HIV prevalence encountered difficulties in sustaining the initiative. More enthusiastic follow-up was demonstrated in districts with perceived growing AIDS caseloads. In all participants, levels of confidence improved.

Conclusions: A method of initiating cascade communication is a beneficial method of using key people who, after analysing their own attitudes to the subject, had sufficient influence to effect change.

M.B.P.310

FINAL HOME HEALTH CARE FOR PATIENTS WITH HIV DISEASE

Camp, Susan E., RN, BSN, EMDORTA, Anthony J. Windsor Home Care, Inc., New York, N.Y., U.S.A.

Objective: To develop and implement a program for the transfer of the comprehensive health care of the AIDS patient to the home setting, providing a more desirable alternative to the costly hospital setting particularly in light of the shortage of beds in hospitals where AIDS is endemic.

Methods: Describe and implement a program which encompasses total health care services for the AIDS patient in the home setting.

Results: Program components developed and implemented are: 1) Physicians (w/eligible a compassionate) in the care of the AIDS patient with a sound belief level in home care as a viable alternative; 2) Nursing service case management & coordination focused on the AIDS patient in complete collaboration with the physicians; the following services are necessary: a. Direct caregivers specially trained in the care of the AIDS patient with IV therapy and teaching progress for patients & family. b. "Wellness" program is inherent for sound health practices & counseling. b. Vendors to provide IV therapy pharmaceuticals & supplies, durable medical equipment, medical transport & lab services who are sensitive to the special needs of the AIDS patient. c. Therapeutic professionals such as SW, Pn, On, & ST to provide rehabilitative services & crisis intervention. d. Community support services for meal delivery, job care & support group for patient & family. 3) Health care cost payers with cost-effectiveness & compassion for the AIDS patient/prevention for home health care. 4) Out-patient facilities to provide for necessary transfusions, invasive procedures & testing. In 1988, 350 patients have been provided with this type of care in the HDU metropolitan area.

Conclusion: AIDS patients can receive cost-effective, comprehensive, safe and compassionate home health care.

M.B.P.311

INTERDISCIPLINARY HIV CARE MANAGEMENT TEAM

Tom Barnagale, R.N., K. Joy, RN, MS, L. Kukurty, MSN, Parkland Memorial Hospital, Dallas, TX.

OBJECTIVE: To develop a system to coordinate appropriate home care services for persons with AIDS (PWA's) within a model utilizing components from existing nursing process and social work case management models.

METHOD: Establishing a hospital-based case manager to assess patient needs and coordinate implementation of necessary medical and social services through regularly scheduled weekly networking case conferences. Collaboration of existing community-based AIDS service organizations involved with Parkland patients to provide needed hospital, clinic and community-based services.

RESULTS: By discussing emotional, psychosocial and health care needs of 25-40 patients at each meeting and identifying actual and potential problems, group members discuss means of addressing them without duplicating efforts and providing for smooth transition for the client from hospital to home or clinic to home. With few exceptions the team can assure discharge to home for our patients.

CONCLUSION: Networking has made it possible to start discharge planning on admission and as a result, decrease length of stay. The team now has the ability to quickly respond when healthcare outcomes do not meet expectations.

M.B.P.312

A DESCRIPTION OF NYC'S GAY POPULATION AS A LEGITIMATE COMMUNITY: AND IT'S RESPONSE TO HIV DISEASE.

Smith, Donald G., Aylken, K., May, K.*
Mount Sinai Medical Center, New York, New York, USA, ***New York University School of Education, New York, New York, USA, ****University of Arizona, Tucson, Arizona USA.**

Objective: (1) To describe and evaluate the NYC gay population as a legitimate community by standard definitions. (2) To perform a nursing assessment on the affect of HIV disease on the community and recommend nursing interventions.

Method: A needs assessment was performed by interview with groups representing the community. NYC's Office of Gay and Lesbian Health Co-sponsors, interviews of NYC gay males and a literature review of published studies on AIDS within the community.

Results: The NYC gay population identifies themselves as a community and meets current definitions of community. The assessment showed direct affect on the community. It identified goals for the community's health: (1) Return of the community to a state of health. (2) To prevent an increase of the number of AIDS cases within the community. (3) To reduce the number of other STD's. **Conclusion:** We identified a community, who's health is in crisis. It has identified it's own goals on returning to health, and developed a response through community involvement. We identified and described the services that can assist the community in it's return to health, by developing nursing programs to support the Parkland Hospital's ongoing community educational program on prevention. (3) Planning additional nursing for the community.

M.B.P.313 LOS ANGELES PEDIATRIC AIDS NETWORK (LAPAN): A COUNTY-WIDE MODEL TO MAXIMIZE SERVICE DELIVERY FOR CHILDREN DIAGNOSED WITH HIV AND AIDS RISK FACTORS.
Gorell, D.C., Huxley, Mary E., California Children Services, Los Angeles, California, USA.

Objective: To promote interagency collaboration and facilitate effective service provision to children with HIV and their families. This project addresses current and future resource needs, clinical case management of all HIV patients, and social service concerns. **Methods:** Hospitals and community-based organizations (CBO's) were brought together to form the LAPAN Coordinating Council. An automated case management system is being developed to facilitate communication, create a common data base and use of CBO's. Terminals will be placed and social workers assigned at 7 participating hospitals. A formal needs assessment has been completed. Joint collaboration has also been established with staff from an HIV-funded treatment grant and a CDC Pediatric Surveillance Grant. LAPAN has also established a Consortium (APAC) to increase communication and exchange ideas among front-line professionals providing direct services. **Results:** The demonstration project has developed an automated case management system, methods to prevent duplication of service delivery, and has enhanced utilization. **Conclusions:** The creation of an infrastructure to manage pediatric HIV cases in a complex is critical. Multiple use of resources and joint planning was essential to meet the needs of this multi-problem population.

Supported by MCH grant #HRN PO 901-01-0.

M.B.P.315 COMPREHENSIVE CARE PROGRAM FOR CHILDREN WITH HIV-RELATED PROBLEMS AND THEIR CARE GIVERS
Bisag, Stanley, King, S.M., Amerson, C., Palmer, S., Goldie, R., Szewczyk, L., Lafave, A., et al. Hospital for Sick Children, Toronto, Canada.

Objective: To provide comprehensive medical, social and psychological care and support for children with HIV-related problems and their care givers.

Methods: HIV positive children and their care givers are followed by a team of medical specialists, along with team members from nursing, psychology, psychiatry, social work, clinical nutrition, pharmacy, pastoral care and Children Aid. These comprehensive care programs are coordinated to provide optimal care. These include the Hemophilia Comprehensive Care Program, the Adolescent Medicine Program and the HIV Comprehensive Care Program. Psychiatric involvement emphasizes development of coping mechanisms for dealing with stress. Serial psychometric testing is done.

Results: To date, about 50 HIV-positive children are followed by the combined programs. Of these, 35 are children with hemophilia, 5 are neonatal transmissions, 4 are blood transfusion recipients and 5 are adolescent street prostitutes.

Conclusion: An integrated program combining medical, psychological and social services provides optimal care for children with HIV infection and their care givers.

M.B.P.317 THE EFFECTIVENESS AND FEASIBILITY OF HOSPITAL-BASED SUPPORT GROUP INTERVENTIONS FOR PARENTS OF HIV-INFECTED CHILDREN

Fagan, Nancy E., Church, J.A., Mitschke, K.T., Childrens Hospital of Los Angeles (CHLA), Los Angeles, California, USA.

Objective: To evaluate the effectiveness of a support group for parents of HIV-infected children. **Methods:** 21 group members were recruited from the Clinical Immunology Center at CHLA and other referral agencies in Los Angeles. HIV status, CD4 count, were tested from asymptomatic to full-blown AIDS. Mode of transmission included blood transfusion (15) and perinatal (6). Group met bi-weekly from 1/87 through 8/88. **Results:** During the first six months, attendance ranged from 7-11 participants; all had children with treatment-associated HIV. 24 parents elected not to attend the group, citing feelings of increased stigma and isolation. Others discontinued participation citing depression and anxiety induced by clinical problems described in other participants' children. As the proportion of perinatal cases increased, participation in group declined. **Conclusions:** Ongoing group support intervention for parents with HIV-infected children resulted in unmet needs. Difficulties, dysfunctional families are additionally burdened by the ramifications of HIV in multiple family members. Support group attendance may be a priority. Alternative support services must be developed to meet the needs of this multi-problem population.

Supported by the State of California, administered by the Department of Health Services, Los Angeles County AIDS Program Office.

M.B.P.314 THE DEVELOPMENT OF A PRENATAL-PEDIATRIC AIDS LIAISON SERVICE AT A MUNICIPAL HOSPITAL.

Lauzier, Ester, Ureyes, L., Tropes, J., Grier, P., Abisago, B., Wata, L., Woodhull Medical & Mental Health Center, Brooklyn, NY, USA.

Objective: To describe the development of a unique Prenatal-Pediatric AIDS Liaison Service at a municipal hospital.

Methods and Results: Woodhull Medical & Mental Health Center, a division of NYC Health and Hospitals Corporation, is a large municipal hospital serving an impoverished black and latino community with a high incidence of IVUD and a high seroprevalence rate for HIV. In-crowded outreach, counseling and testing, specifically targeted to women and children at risk for HIV infection, has resulted in the need for a comprehensive, interdisciplinary approach to perinatal HIV infection. The Prenatal-Pediatric AIDS Liaison Service (P-PALS), funded through the NYC Department of Mental Health, was developed to provide the necessary linkages between the Departments of Obstetric, Pediatrics, Psychiatry, Medicine and Ambulatory Care to provide a family-oriented approach which optimizes continuity of care. The focus of the program is to assist the HIV positive pregnant woman and her family in coping with the possibility that her infant may be born HIV positive and to provide ongoing social, psychiatric and medical care for families who have children with HIV associated illness. The professional staff is comprised of a team which includes a child psychiatrist, social worker, nurse clinician and child life worker. Issues of foster care placement will also be highlighted.

Conclusions: Unified early intervention will improve the care of the woman and her child, diminish the need for long term placement, and provide a model of care based on the family rather than focusing individually on the mother and child.

M.B.P.316 LES SOINS INFIRMIERS FACE A L'EPIDEMIE DE SIDA
Schneeberger, Claudie, Val de Marne, France.

Devant la complexité de cette épidémie, dépasser les différents rôles de l'infirmière en matière de soins infirmiers. Dans l'accueil et la prise en charge des malades atteints du SIDA, l'accompagnement tout au long de la maladie et dans les derniers instants de la vie en organisant les mesures préventives permettant une plus grande sécurité dans les gestes techniques des soignants.

En développant une attitude professionnelle appropriée respectant l'homme dans ses différences lui assurant la confidentialité, tés et préservant sa dignité.

Dans le cadre des actions de prévention la responsabilité de l'infirmière dans la participation aux programmes d'information de la population pour apprendre à éviter le SIDA.

Son rôle dans l'éducation pour modifier les habitudes les plus intimes et conduire chaque personne vers une gestion globale de sa santé en développant des attitudes responsables.

M.B.P.318 HIV AND MATERNAL CHILD HEALTH: EXPANDING THE EXPERTISE AMONG PROVIDERS

Pis, C., Quacknabush, Maria, M., E****, Hanes, A.,****, Schejter, M.,****, Mays, A.,****

** Education Program Associates, Campbell CA; ***University of California AIDS Health Project, San Francisco; ****California Department of Health Services, Maternal Child Health Branch, ****California Department of Health Services, Office #209, California, U.S.A.

Objective: To describe a training program which seeks to expand HIV expertise among non-physician health personnel in maternal child health (MCH).

Methods: In California, 150 contract agencies throughout the state provide maternal child health care with the support of the State Department of Health Services. These programs include prenatal health care, follow up for high risk and selected infants, care for disabled or at-risk children, health care and parenting education for new parents, etc. However, many MCH providers in the state feel the HIV expertise rests primarily with a few specialists in major urban areas (San Francisco and Los Angeles). This presentation will describe techniques for expanding HIV expertise to maternal child health providers throughout the state and discuss a specific training protocol designed to help accomplish this.

Results: Five two-day trainings will be held throughout the state by May 30, 1989. We will offer preliminary evaluation of the program's success. The complete training manual will be available for review.

Conclusions: A training program for maternal child health providers can expand HIV expertise to individuals and areas that are not currently confident of their ability to provide such care.

Supported in part by a grant from the California State Office of AIDS, contract # 88-9450.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.325 COMBINATION (VINNIN B₂) SUPPLEMENTATION DOES NOT IMPROVE THE HEMATOLOGIC TOXICITY OF AZIDOTHYIMIDINE (AZT) THERAPY

W. Ballard, G. J. Frenkel, H. H. Berman, H. J. Fischl, J. M. Hirsch, D. J. and the California Collaborative Treatment Group, University of California, San Diego, CA.

Objective: AZT and B₂ deficiency both produce neutropenic anemia. Low serum B₂ levels (<400 pmol) are associated with increased risk of granulocytopenia in AIDS and AZT patients taking AZT. Accordingly, we conducted a controlled trial to see if monthly B₂ injections could prevent hematologic toxicity from AZT.

Method: 170 AIDS and AZT patients with serum B₂ levels >200 pmol who were requiring (120) or taking (44) AZT at standard doses (1-1.5 grams/day) were randomly assigned to receive either four monthly IM injections of 1 mg of B₂ or no injections. Serum B₂, ANC, absolute neutrophil counts (ANC), hemoglobin (HGB) mean corpuscular volume (MCV), platelets (PLT) and AZT dose were followed monthly for at least six months.

Results: Mean B₂ levels were increased four weeks after the first injection and remained elevated compared to controls throughout the study. Although by chance 50% of patients had higher AZT levels than controls at entry (287 vs 247, p<.03), all subsequent mean AZT, ANC, MCV, HGB, NEU, and platelets were similar for all comparisons. No differences in AZT tolerance or transfusion requirements were found.

Conclusion: Four monthly IM injections of B₂ sufficient to increase serum B₂ levels did not reduce the hematologic toxicity of AZT given for currently licensed indications.

M.B.P.326 ZIDOVUDINE MONOTHERAPY-A PROSPECTIVE STUDY

Patena, Barry Wilson, Cliff Finching, A. J. Medical, Institute of Medical Pathology, St. Mary's Hospital Medical School, London, England.

Objective: To study the relationship between Zidovudine (AZT) administration, myopathy and creatine kinase (CK).

Methods: 102 AIDS patients were seen monthly and clinical features of myopathy were recorded, including weight, muscle fatigue, reduced power and muscle wasting. Monthly CK levels were ascertained. 78 of the patients were on regular AZT (usual dose 1000-1200mg/day) and 23 of these had been treated for 300 days or more. 24 patients not on AZT were studied as a control group to delineate other causes of CK rise.

Patient	Onset of Myopathy Days on AZT (s)	Onset of Rise in CK Days on AZT (s)	x-y (Days)
1	217	260	43
2	426	275	31
3	430	300	30
4	512	270	24
5	378	326	52
MEAN	366	312	52

Results: Myopathy was severe and disabling, mainly affecting the legs and was associated with a rise in CK. CK continued to rise to very high levels (10000/1) during treatment. Dose reduction was ineffective, but survival clinical recovery occurred within 9 months of stopping AZT. CK levels fell to normal within 4 weeks.

Conclusion: 1. Sustained rises in CK provide the first indication of Zidovudine myopathy, hence it should be routinely performed.
2. Myopathy is a progressive disabling complication of Zidovudine therapy, occurring in 18% of patients on long-term therapy (>300 days).

M.B.P.327 NON CONCLUSIVE RESULTS IN HIV WESTERN BLOT ANALYSIS OF HOMOBIOPSY TISSUE

C. Pallas, G. S. Basso, J. Barrio, F. de la Cruz, L. Barquez, Immunology Laboratory, Instituto Nacional de Salud, Lima, Peru.

Objective: To describe the pattern of reaction of Monoclonal sera with non conclusive results in Western Blot. Material: 100 Western Blot (WB) results from 100 patients with HIV-1 infection. Results: 100 WB results were analyzed by ELISA for HIV-1 and HIV-2 antibodies and with non conclusive results in Western Blot were classified in relation with their protein band reaction. Some of them were tested by different commercially available WB kits. The frequency of the different observed patterns of reactivity was estimated.

Results: The most frequent observed reactivity patterns were reaction with p 24 band for HIV 1 WB (18%) and p28 for HIV 2 WB (10.4%). However in HIV 2 WB, 10.4% of sera reacted showed reaction with p24, p28, p36, p55 and p18 without any reaction with glycoprotein bands. Non conclusive results were more frequently found in HIV 1 than in HIV 2 WB. Some non conclusive sera by LAV BLOT II when tested by HIV 2 Dupont de Nemours and RT-VL-91 WB Western Blot showed non conclusive pattern of reactivity. Same happened when non conclusive sera by HIV 1 Bio-Rad WB were tested by HIV 1 Dupont de Nemours WB. Non conclusive results appeared in sera from all the studied population groups. Immunohistochemical appearance of non conclusive results in WB analysis of ELISA positive Monoclonal sera seem to be independent of the reagent used and due to sera or individuals characteristics.

M.B.P.328 A STUDY OF THE SAFETY AND EFFICACY OF RECOMBINANT HUMAN INTERFERON (r-HU-IFN) IN AIDS PATIENTS WITH ANEMIA INDUCED BY THIS DISEASE AND ZIDOVUDINE (RETROVIR, AZT) THERAPY

Galipz, J. F. Thompson, J. Amalfi, A. Abela, R. M., Turpen, T. J. *North Medical Group, Sherman Oaks, CA, *Ortho Pharmaceutical Corp., Raritan, New Jersey, USA.

Objective: To determine if anemic AIDS patients who are all on concomitant zidovudine therapy and are transfusion-dependent have any measurable change in their hematocrit, hemoglobin and reticulocyte count after treatment with r-HU-IFN.
Methods: Nine anemic subjects with a pretreatment HbA_{1c} of 30% or less were treated with ascending doses of r-HU-IFN up to 900,000 units weekly for 24 weeks. Patients were on daily doses of zidovudine of 400 to 820 mg. The hematocrit, hemoglobin and reticulocyte count were obtained on a weekly basis.
Results: All but one subject attained a hematocrit of 38-40% during the 24 week trial, becoming transfusion-independent.
Conclusions: r-HU-IFN appears to be a possible adjunctive therapy for AIDS patients who are anemic due to their disease and zidovudine therapy. This drug merits further side-by-side clinical trials.

M.B.P.329 MYOATRY ASSOCIATED WITH LONG-TERM ZIDOVUDINE THERAPY

Finch, Richard; Gagnon, S; Utaschewski, H; Petrovec-Zelen, J; Desautels, J; Torres, S; Bender, A. University of Miami School of Medicine, Miami, Florida, USA.

Objective: To evaluate the frequency and clinical presentation of myopathy associated with long-term zidovudine therapy.

Methods: Patients receiving zidovudine for 140 were assessed, using medical history, physical exam and blood tests. Patients identified with possible myopathy were evaluated with EMG and muscle biopsy.
Results: 50 patients (33 AZT, 17 AKI) had received zidovudine for a mean of 13 wks (range 40-140 wks). 15 (30%) had myopathy as manifested by myalgias-10%, muscle wasting-8%, and rhabdomyolysis-7%. Muscle groups involved included proximal muscles in the lower extremities-100 and upper extremities-7%, and intercostal muscles-10%. Associated symptoms included arthralgias-17%, weight loss >10%-8%, and parosmia-8%. Blood tests included persistently elevated LDH (11-25 normal) and CK (1.5-8.5 normal). EMG was consistent with myopathy. Muscle biopsy showed degenerated myofibers, non microvascular changes, and mild inflammation. Myopathy occurred in 58% of AKI patients and 18% of AIDS patients. Onset was between 52-107 wks of therapy and in patients having received a mean cumulative dose of 600-800mg. 8 patients required drug. Symptoms improved within 1-6 wks. LDH decreased in all patients by 8 wks and CK in 87% of patients by 4 wks. 4/8 patients developed recurrent symptoms within 1 month of restarting zidovudine.
Conclusions: Myopathy is common in patients receiving long-term zidovudine. Proximal muscle wasting in the lower extremities was the most common finding. Increased LDH was an early indication of myopathy.

M.B.P.330 HIV ASSOCIATED MYOATRY: FEATURES IN 21 PATIENTS AND ROLE OF AZT

Galipz, J. F. Thompson, David Wolfe, D., Farraye, J., Bender, A. Mount Sinai Medical Center, New York, NY.

Objective: To describe the features of 21 patients with HIV-associated myopathy as well as the role of AZT in this disorder.

Methods: All patients were evaluated at Mount Sinai Hospital. Electrophysiologic testing included nerve conduction studies and needle electromyography (EMG). Muscle biopsies were processed by light and electron microscopy, and viral localization performed with immunohistochemistry and ³²P in situ hybridization.

Results: 16 patients had AIDS, 4 had ARC, and 1 was asymptomatic HIV-seropositive. 5 had been diagnosed as AIDS during syndrome. All presented with proximal muscle weakness. Creatine kinase (CK) levels were elevated over a wide range (mean 128 DU/24). EMG revealed myopathic motor units in 17 patients, with abnormal spontaneous activity in 17. Muscle biopsy findings in 30 patients included inflammatory or noninflammatory myofiber degeneration, membrane ripples, cytoplasmic bodies and vacuolization. 8 of 9 patients treated with corticosteroids improved. 10 patients had never been treated with AZT. Of 21 patients on AZT, the myopathy worsened after AZT withdrawal in 4, and 2 improved with its reinstatement.

Conclusion: Myopathy is associated with HIV infection, and may be misdiagnosed as AIDS during syndrome. Corticosteroid therapy is effective. In our series, AZT does not appear causally linked to this disorder.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.331 SERUM LEVEL AND SERUM KINETIC OF ZIDOVUDINE:

INVESTIGATION WITH A RADIOIMMUNOASSAY (RIA)
Kösem, Stefan; Ruf, B.; Pannhorst, J. and Pöhl, H.-D.
*I. Department of Nuclear Medicine, *II. Department of Nuclear Medicine,
Rudolf Virchow University Hospital, Frank University, Berlin, FRG.

To evaluate serum levels and serum kinetics of Zidovudine (Azidothymidine, AZT) with different dosages and dosage intervals, serum samples of patients who had Zidovudine treatment have been investigated retro- and prospectively. Analysis was performed with a radioimmunoassay (ZDV-¹²⁵I-RIA).

Retrospectively 262 serum samples of 47 patients were examined. Blood samples have been obtained two hours after oral application. The mean Zidovudine concentration was 735 nmol/l, 1772 nmol/l, and 1367 nmol/l when dosages of 5 x 100 mg/d, 6 x 200 mg/d and 6 x 300 mg/d were given, respectively.

Prospectively, serum kinetics of Zidovudine has been investigated at start of therapy. Five hours after application of 150 or 300 mg Zidovudine, serum concentration has fallen below 150 nmol/l, being reported to be the minimal effective serum concentration. After application of 250, 300 and 500 mg, serum concentration have been below 150 ng after 6 hours.

The RIA was highly specific, no cross-reactivity and non-specific reactivity has been found. Zidovudine is an intracellular active compound. Therefore, serum levels are of limited value. After retrospective correlation with the outcome of patients, recommendations of dosage regimens suitable to serum levels are reasonable. In long dosage intervals, effective intracellular concentration may not be achievable.

M.B.P.333 ASSESSMENT BY PCR OF HIV-1 ACTIVITY IN AIDS-KS

PATIENTS TREATED WITH RECOMBINANT INTERFERON ALPHA (rIFN- α)
Espinosa, Jay S., Hewitt, L.K., Metzalin, J., Hawthorne, C., Lane, H.C.*
*Division of Blood and Blood Products, FDA and **Clinical Center, NIH, Bethesda, MD

Objective: To evaluate the effect of rIFN- α on HIV-1 replication in AIDS.
Methods: Eight patients with AIDS-KS receiving daily injections of rIFN- α (Schering) for therapy of KS tumors were studied multiple times over 1 to 2 years for serum levels of HIV-1 antigen (Ag), reverse transcriptase activity (RTA), and gene detection by PCR. PCR was performed on extracted DNA using simultaneous amplification of GAG and ENV sequences followed by selective hybridization with the respective probes.

Results: Five of 8 cases were tumor responders, 4 complete, 1 partial. Prior to therapy, PCR and RTA were positive in all eight cases, and Ag was found in 7 cases (3 tumor nonresponders was persistently negative). Antigen or RTA levels decreased in 5/3 tumor responders (2 Ag, 2 RTA, 1 both). In 1 nonresponder, viral DNA became undetectable despite persisting antigen.

Conclusion: rIFN- α produced decreases in activity of HIV-1 in 6/8 AIDS-KS patients including all 5 cases with tumor responses, but in no case was the decrease shown by all virologic parameters. PCR detection of viral DNA revealed persisting virus activity despite clearance of antigen and RTA. Future drug trials should include monitoring of HIV-1 activity by serum PCR.

M.B.P.335 EFFECT OF ZIDOVUDINE WITH PHASE I AND II METABOLISM IN THE LIVER

N. H. Hopwood¹, L. Mertins, M. Goss, University of Essex,
Essex, Federal Republic of Germany

The nucleoside analogue zidovudine is being employed in the therapy of HIV-infected subjects. The effect of zidovudine on the liver metabolism is of utmost interest. We chose 7 subjects not receiving any supplementary medication and measured the parameters of the liver zidovudine activity (antipyrine elimination index, metabolite excretion and 4-beta-OH-cortisol in urine) before intake of zidovudine 800mg/day as well as after a treatment period of 18 days. Antipyrine and its metabolites were determined by HPLC. Following a two-week intake of zidovudine an induction of the microsomal enzyme system was observed, the excretion of 4-beta-OH-cortisol increased significantly from 342 to 697 g/24 hours. The half-life of antipyrine decreased from 12.2 to 10.1 hours. Centrally, the phase-2-metabolism of the antipyrine metabolites nor- and 4-OH-antipyrine were significantly lower. These altered from 8.32 to 6.29 min/ml, and from 11.8 to 9.4 min/ml, respectively. This effect by zidovudine seems almost exclusively due to the inhibition of the glucuronidation in the liver. The clearance of metabolite of the glucuronidated nor-antipyrine and of 4-OH-antipyrine decreased by 18 and 29%, respectively.

On grounds of these results, clear interaction will occur during the simultaneous application of zidovudine with other drugs metabolised by phase I and II liver metabolism.

M.B.P.332 PHARMACOKINETICS (PK) OF ZIDOVUDINE (ZDV) IN ADULT

PATIENTS WITH HIV INFECTION AND HEPATIC DISEASE (HD)

Itzaki, Masaru; Ochiai, K.; van der Horst,
C. M.; Raash, R. V.; Dassen, S. van; Huis, H. van; et al. *University of Washington, Seattle, WA, USA, **University of North Carolina, Chapel Hill, NC, USA, ***University of Massachusetts, Amherst, MA, USA

Objective: To determine ZDV's PK in patients with HIV infection and HD. **Methods:** In an ongoing study, patients were stratified into 3 categories of stable HD according to serum ALT (CS to 200K normal), TBIL and PT. On sequential study days, each patient received a single dose each of ZDV 120 mg IV followed by ZDV 200 mg PO. Multiple blood samples were obtained. ZDV and GDV conc. were determined by HPLC and analyzed using noncompartmental methods.

Results: Five patients (3 males, 2 females) with HD and ALT values ranging from 1.5 to 10 X normal and normal TBIL and PT values completed the study. ZDV/GDV PK are presented below:

PK	HD	GDV	HD	GDV
C _{max} (ng/ml)	1.5 ± 0.5	1.5 ± 0.2	1.9 ± 0.3	3.4 ± 1.4
AUC (ng/ml x hr)	1.6 ± 0.5	2.8 ± 0.4	1.7 ± 0.1	7.9 ± 0.9
T (h)	0.7 ± 0.1	...
T _{1/2} (hr)	1.6 ± 0.3	1.9 ± 0.7	1.7 ± 0.5	1.4 ± 0.2
Cl _{CR} (L/hr)	2.1 ± 1.0	...
TRC (L/hr/kg)	1.1 ± 0.4	...	1.3 ± 0.3	...

Conclusion: Preliminary ZDV and GDV PK data in patients with mild HD is similar to previously reported data in patients with normal renal and hepatic function. Patients with moderate and advanced HD are under study.

M.B.P.334 BAYESIAN ESTIMATION OF THE PHARMACOKINETIC PARAMETERS

OF CHRONIC ZIDOVUDINE (ZDV) THERAPY IN HIV INFECTED PATIENTS.
Janina Y. Tsai, R. Joseph Guglielmo, Harry Hollander, and R. Mohammed. School of Pharmacy, Medicine, Univ. of Calif., San Francisco, CA, USA.

Objective: To determine whether the individual pharmacokinetic parameters of ZDV can be estimated by Bayesian approach from data collected during multiple routine clinic visits in HIV infected patients.

Methods: Eighty patients with AIDS or ARC receiving oral ZDV therapy at the AIDS Clinic of the UCSF Medical Center were recruited. On the morning prior to each routine clinic visit, the subjects recorded the dose and exact time of taking the last two doses of ZDV during the clinic visit; an additional plasma sample was drawn at the time of routine blood sampling. This procedure was repeated for four clinic visits. Plasma ZDV levels were assayed by HPLC. The plasma concentration-time data was analyzed by Bayesian analysis using TM500 and Drugpac.

Results: Preliminary results indicate a mean terminal half-life of 1.33±0.39 hours, an average bioavailability of 90.4±10.8%, a body clearance of 1.04±0.11L/hr, and a volume of distribution of 1.94±0.44L/kg.

Conclusions: Results are in agreement with literature data. Our results using population pharmacokinetics suggest that the pharmacokinetic disposition of ZDV is unchanged within HIV infected patients on chronic ZDV therapy.

M.B.P.336 ZIDOVUDINE LEVELS IN SERUM AND METABOLIC AND HEMATOLOGIC EFFECTS

IN PATIENTS WITH HIV INFECTION AND HEPATIC DISEASE
Ishari-Foppa C., Lazzarin A., Ronchi P., Cloque F., Beale R. I.
Clinic of Infectious Diseases, University of Milan, Italy.

Objective: To evaluate virologic and hematologic effects of different concentrations of zidovudine (ZDV) in p24 antigen and reverse transcriptase (RT) and active ARC and AIDS patients.

Methods: Six AIDS and two ARC subjects received ZDV 10 mg/kg qd for 4 weeks, followed by 5 mg/kg qd for 5 months). RT from lymphocytes and p24 antigen (RIA) before were detected monthly. ZDV levels were evaluated (RIA, ZDV/ACT, log scale) on day 30 and 60 at 0, 30, 60 minutes after oral administration.

Results:	p24 POS	RT POS	Mean ZDV levels (ng/ml)
-month 0	6/8 (100%)	6/8 (100%)	0 min 30 min 60 min
-month 2	0/6 (0%)	2/6 (33%)	-day 10 0.3 4.8 6.7
-month 6	3/6 (50%)	5/6 (83%)	-day 80 0.3 4.8 3.3

Subjects with mild hepatitis (ALT < 3 times upper normal) values had a high peak concentration (10 mg/kg) longer than other patients.

Conclusion: A dose of 5 mg/kg is sufficient to obtain a mean concentration of the drug 2 to 3 times above the "in vitro" minimum inhibitory doses for HIV-1. In hepatocentric patients with normal ZDV levels, a prolongation peak concentration is sufficient to induce anemia. Only the evaluated doses, ZDV can reduce virus replication (shown by negative antigenemia), but doesn't inhibit it completely.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.337 A PRELIMINARY STUDY OF SERUM AZT LEVELS IN HIV-INFECTED INDIVIDUALS

W. A. Riddle, R. K. King, M. A. King, J. A. Spera, K. A. Tonjes, T. J. Wainwright, M. S. et al.
University of California, Davis, California, U.S.A.

Objective: To determine whether serum AZT levels correlate with clinical efficacy and/or toxicity, and whether acamtoprofen (A) effects serum AZT levels.

Methods: We measured serum AZT levels in 10 patients receiving varying oral doses, of whom 3 had rises in CD_4 from a mean of 327 to 535; 3 had no change in CD_4 and 4 had a decline in CD_4 . One patient had clinical improvement, 3 had definite toxicity from AZT. Through levels were drawn just prior to the AZT dose, and peaks were drawn at 1 and 2 hours post dose. Three patients were given (450 mg q 6 hrs x 48 hrs) and levels were rechecked. Levels were measured by both RIA and HPLC methods.

Results: Mean AZT levels (537 ng/ml) in patients taking 1200 mg of AZT per day correlated with dose. A did not affect peak or trough levels of AZT at the dosage of A used. Toxicity does not appear to be related to serum AZT levels in this small study population. In one patient with underlying bone marrow injury, 100 mg of AZT q 12 hr produced profound red cell toxicity (peak 1000 ng/ml).

Conclusions: A longer study which correlates serum and intracellular AZT and peak and trough levels with measures of efficacy (CD_4 , p24 antigen, β_2 microglobulin and clinical improvement) and toxicity (anemia, granulocytopenia, myelocytosis, neuropathy) may give important information about AZT in treatment of HIV infection.

M.B.P.338 INTERACTIVE PHARMACOKINETICS OF ZIDOVUDINE AND ACETAMINOPHEN

Paulo, George J., Piacasinski, R., Shuman, M. and Ho M.
Pittsburgh AIDS Clinical Trials Unit, University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

Objective: Since both Zidovudine (ZDV, Retrovir) and acetaminophen (Tylenol) are metabolized by hepatic conjugation, competition for conjugating enzymes may result in reduced elimination of either or both agents with a potential for increased toxicity. This study was done to evaluate the potential interaction between ZDV and acetaminophen.

Methods: Pharmacokinetics of ZDV after IV administration (2.5 mg/kg) was studied in 7 HIV-infected patients with normal renal and hepatic function after 3 days of maintenance oral ZDV (100-200 mg q8h) and with acetaminophen after 3 days of both ZDV and acetaminophen (650 mg q6h). Multiple blood and urine samples were collected over 48 hrs following the IV dose of ZDV. Serum samples were heated (56°C) for 35 min then extracted with a C18 solid phase column. ZDV was quantitated by HPLC. Serum concentration versus time data were analyzed using compartmental and non-compartmental methods.

Results: ZDV alone ZDV/Tylenol t p value
 Mean $t_{1/2}$ (hr) 19.4 ± 2.9 20.4 ± 4.0 > 0.05
 ZDV clearance (ml/min/kg) 0.73 0.63 > 0.05
 Mean $t_{1/2}$ (hr) 1.27 ± 0.35 1.26 ± 0.27 > 0.05
 vol. of distribution (L/kg) 2.27 ± 0.27 2.02 ± 0.27 > 0.05
Conclusions: Our study indicates that acetaminophen does not affect the distribution or elimination of ZDV.

M.B.P.339 A SENSITIVE AND SPECIFIC HPLC METHOD FOR THE DETERMINATION OF ZIDOVUDINE AND ZIDOVUDINE GLUCURONIDE IN PLASMA AND URINE

Madaya, Mohamed A. and Sawchuk, R. A.
University of Minnesota, Minneapolis, Minnesota, U.S.A.

Objective: To develop a sensitive and specific HPLC method for the determination of zidovudine (AZT) and zidovudine glucuronide (GAZT) in plasma and urine.

Methods: The method involves the use of double internal standards, allowing reference of AZT peaks to the appropriate internal standard, the choice depending on the range of concentrations encountered. Free (unconjugated) AZT is quantified by extraction with 5% isopropyl alcohol in chloroform. Total (conjugated and unconjugated) AZT is quantified by incubating the samples with bacterial β -glucuronidase and phosphate buffer at pH 6.8 for 4 hours at 37°C. The samples are then extracted as described for free AZT. GAZT concentrations are calculated by difference, corrected for GAZT MW. The mobile phase consists of 9% acetonitrile in monobasic ammonium phosphate. We used a C18 column, and UV detection at 266 nm.

Results: The coefficient of variation of the between-run and within-run assay precision is < 10% and the coefficient of variation of the assay accuracy determined from the analysis of quality control samples is also < 10%. We saw no interference from various over-the-counter and prescription drugs often used in treating the infectious complications of AIDS.
Conclusion: Using this method we are able to quantify AZT and GAZT in human plasma and urine samples obtained over a 12-hour period after a single oral dose of 200 mg of AZT.

M.B.P.340 PHARMACOKINETICS OF AZT AMONG HIV INFECTED PATIENTS TREATED BY TIRAZOLONE

Merle, Jean P., Patron, Y. and Pillot, C.
CHU-Saint Etienne, State University of Liois, Reims.

Objective: Symptomatic HIV infected patients are frequently submitted to Antiretroviral (ART) therapy in association with immunomodulatory drugs. We were interested to investigate the pharmacokinetic properties of AZT during the administration of Tirazalone, a new antipneumocystis compound.

Methods: Seven patients (5 patients CDC AC2 and 2 patients CDC AC1), regularly treated by AZT for at least 4 weeks at the dose of 3 ± 0.1 mg/kg/day were submitted to two pharmacokinetic studies. The first was carried out during treatment by AZT only (test A) and the second after Tirazalone (12 x 100 mg q8h) was added to AZT for at least 2 weeks (test B). Pharmacokinetic profiles were estimated by blood sampling at 0, 30, 60, 120, 240, 360 minutes after the oral intake of 200 mg AZT. AZT serum concentrations were determined by a radioimmunoassay method using a iodine-125 tracer.

Results: AZT was not detectable in the sera prior to the tests. AZT peak serum levels were observed 30 minutes after the oral intake respectively in 5/7 and 7/7 patients during tests A and B. Mean maximal values (2446 ± 437 vs 2107 ± 257 ng/ml; NS) were comparable in the two profiles and were in the range of those previously reported. However, two patients presented better profiles of AZT concentrations during Tirazalone treatment.

Conclusions: These results confirm that AZT is rapidly absorbed from the gastrointestinal tract. Tirazalone seems to have no deleterious effect on the pharmacokinetics of AZT. The higher concentration observed in two patients during Tirazalone treatment could be the consequence of the improvement of the digestive conditions and consequently a better absorption of the drug.

M.B.P.341 MOLECULAR INTERACTION OF RECOMBINANT B INTERFERON AND ZIDOVUDINE IN THE TREATMENT OF AZT PHARMACOKINETICS IN HIV-1 INFECTED PATIENTS

Wang, Huiqing*, Lok, J.P.**, Douvier, S.M.***, Snodgrass, W.R.***, Ahmed, U.M.*** and Toller, R.***
 *Department of Internal Medicine, **Pathology and ***Pediatrics, The University of Texas Medical Branch, Galveston, Texas, U.S.A.

Zidovudine, the drug of choice for patients with AIDS, is known to be metabolized by mammalian systems into a variety of metabolites including 5'-phospho-3'-deoxy-5-O-glucuronide (GAZT). Interferon are known to alter the microsomal enzyme system responsible for metabolism of some drugs. The aim of this study was to investigate the effect of combination therapy of recombinant Interferon- β (rIFN- β) and AZT on the pharmacokinetics and rates of metabolism of AZT in HIV-infected patients. AZT was given orally (200 mg every 4 hours) for 8 weeks prior to initiation of rIFN- β therapy (90x10⁶ IU/day, subcutaneous). Serum samples were obtained prior to and at days 3 and 5 following initiation of rIFN- β therapy. Serum was analyzed by high performance liquid chromatography (HPLC) for both AZT and GAZT. The serum data were analyzed by computer assisted pharmacokinetic program which calculates rates of AZT metabolism. The half life for AZT was increased 2 to 3 folds by day 15. The half life of AZT was distinguished from 1.18 hr prior to rIFN- β therapy, to 0.4 hr and 0.08 hr at days 3 and 15 respectively. Volume of distribution (Vd) was 7.7 L/kg at day 0 and increased significantly to 7 and 5.8 L/kg on days 3 and 15 respectively. Other kinetic parameters were also determined. In conclusion, this study indicates that rIFN- β inhibits the rate of AZT metabolism in AIDS patients.

M.B.P.342 INTRAVENOUS AND ORAL PHARMACOKINETICS OF ZIDOVUDINE IN HEMODIALYZED PATIENTS WITH NORMAL HEPATOCYTOGENICITY AND URINE INJECTION

Hughes, Doug; Olson J., Portanova A., Taylor C., Plank C. and Beilman R.
 University of Rochester Medical Center, Rochester, NY, U.S.A.

Objective: To compare intravenous (iv) and oral (po) zidovudine (ZDV) kinetics in HIV-infected hemodialysis patients during chronic dialysis.

Methods: Five patients received ZDV 100 mg po q8h (total 240 mg) for 12 weeks; iv and po kinetic studies were performed every 6 weeks. ZDV and ZDV-glucuronide (GDV) were measured in plasma by HPLC.

Results:

	12					
ZDV-iv-2h(nmol/ml)	1.2 ± 0.4	1.2 ± 0.3	0.7 ± 0.3			
ZDV-iv-4h	0.2 ± 0.1	0.2 ± 0.1	0.3 ± 0.1			
ZDV-oral-2h	0.5 ± 0.4	0.4 ± 0.3	0.4 ± 0.1			
ZDV-oral-4h	0.1 ± 0.05	0.1 ± 0.04	0.1 ± 0.08			
GDV/ZDV-2h iv	2.6 ± 0.8	2.6 ± 0.8	2.5 ± 1.3			
GDV/ZDV-2h po	0.2 ± 0.8	0.2 ± 1.9	2.7 ± 1.6			
GDV/ZDV-2h oral	4.6 ± 2.4	4.9 ± 2.2	4.4 ± 2.7			
GDV/ZDV-4h oral	3.0 ± 2.1	3.4 ± 2.0	2.7 ± 1.2			

The iv half-life at 1, 6, and 12 weeks was 3.1 ± 3 h, 2.4 ± 3 h and 2.1 ± 1 h, while after oral ZDV it was 3.1 ± 3 h, 4.2 ± 2 h, and 3.4 ± 2 h. **Conclusions:** Although the mean ZDV levels were similar, a high degree of interpatient variation was noted. The lower concentrations after oral ZDV were most likely due to first-pass metabolism, as indicated by the GDV to ZDV ratio. These data indicate that chronic therapy with a standardized ZDV dosage regimen may result in a variable plasma level profile.

Aspects cliniques Clinical Aspects of AIDS

M.B.P.354 **AZT TREATMENT INDUCES A DECREASE OF SOLUBLE INTERLEUKIN 2 RECEPTOR (sIL-2R) BUT NOT OF SOLUBLE CD8 ANTIGEN (sCD8) SERUM LEVELS IN HIV INFECTED PATIENTS.**
Calli, Massimo; Balotta, C.; Ridofo, A.L.; Cocchi, P.; Uberti-Foppa, C. and Moroni, M. Clinic of Infectious Diseases, University of Milan, Italy.

Objective. To investigate whether sIL-2R and sCD8 levels differ in patients with CD4 counts higher or lower than 400 cells/mm³ and whether AZT influences the serum levels of sIL-2R and sCD8 Ag.

Methods. sIL-2R and sCD8 have been measured in 52 HIV infected patients (12 AIDS) and 12 healthy controls (HC) using an ELISA method (T Cell Science). In 10 AZT treated patients the tests were repeated on the 30th and 90th day of therapy and p24 Ag (T Cell Science) was determined on a parallel.

Results. All patients had markedly elevated sIL-2R and sCD8 levels respectively 17 (SD=10) U/ml in patients vs 35±2.26 in HC, p<0.0001; 990±270 U/ml vs 346 U/ml in HC, p<0.0001. No significant differences were found either between subjects with CD4 cell counts higher or lower than 400 cells/mm³ or between patients with or without AIDS. A significant reduction of sIL-2R serum concentration was observed during treatment in all patients (mean: 1011 U/ml, 1700±1215 U/ml, 1790±1183 U/ml, p<0.005) but 1 presenting persistent antigenemia.

Conclusions. AZT seems to reduce the release of sIL-2R, possibly as a consequence of a reduced destruction of T-helper; no influence can be demonstrated on sCD8 level. Our results suggest that sIL-2R serum level determination could be a useful tool in monitoring AZT therapy effects.

M.B.P.356 **PREDICTIVE VALUE OF CD8 CELL COUNT IN MORBIDITY AND MORTALITY AMONG AIDS PATIENTS TREATED WITH ZIDOVUDINE (AZT)**
Gerard, M.; Somerville, G.; De Milt, Stéphane; Clowse, N. Division of Infectious Diseases, St Pierre University Hospital, Brussels, Belgium.

We prospectively studied a population of 45 AIDS P and 81 ARC P under AZT treatment (1) for a mean period of 34 weeks to assess their immunological and clinical evolution. CD8, CD4, blood cell count and physical examination were obtained monthly. Baseline CD8 cell count lower than 100/mm³ was associated with a higher incidence of opportunistic infections (OI) (37% vs 76-80-0/00) and a higher case fatality rate (25-3% vs 2-4%-p=0.0002). The same correlation was found for low CD8 cell count. There were 10 ARC P and 17 AIDS P with baseline CD8 cell count below 400/mm³ and 71 ARC P and 28 AIDS P with baseline CD8 cell count over 400/mm³. OI occurred during AZT in among 40% of ARC P with CD8 value below 400/mm³ and 8% of ARC P with CD8 value over 400/mm³ (p=0.02). There was no influence of CD8 value on occurrence of OI in AIDS P. Low CD8 cell value in both AIDS and ARC P was also correlated with higher mortality. 60.7% of P died if baseline CD8 cell count was lower than 400/mm³, 3% of P if baseline CD8 cell count was higher than 400/mm³ (p=0.001). Positive predictive value of occurrence of OI and death among P with CD8 value lower than 100/mm³ were respectively 45.8% (57% for ARC P, 41.2% for AIDS P) and 45.8% (42% for ARC P, 47% for AIDS P) if baseline CD8 cell count was lower than 400/mm³ and respectively 18.2% (23% for ARC P, 15.4% for AIDS P) and 4-5% (5% for ARC P, 7.7% for AIDS P) if baseline CD8 cell value was over 400/mm³. In HIV P treated with AZT, low baseline CD8 cell count was a predictive value for developing AIDS in ARC P and CD8 cell count increases the predictive value of CD8 cell count for OI development and occurrence of death.

M.B.P.358 **IMMUNOFLUORESCENCE DEMONSTRATE (ADA) EXPRESSION IN AZT TREATED PATIENTS**
Calli, Massimo; Magnani, G.; Bernini, S.; Ridofo, A.L.; Cocchi, M.***; Fiacco, R.**, Starobin, A.
*Istituto Patologia Bacteriologica e Malattie Infettive, Università di Pavia
**Istituto Di Genetica Biologica ed Evoluzionistica del CNR, Pavia, Italy.

Objective. To assess the expression of ADA expression in AZT treated patients.

Methods. Measurement of ADA activity and serologic determinations of sgp and sgp in erythrocyte extracts of AZT-treated patients (5 ARC, 4 AIDS) with basally untreated HIV-1 infection. The test of ADA activity in 2 µl of treated serum in 1 µl sgp and sgp concentrations were expressed in µmol/30' cell.

Results. sgp and sgp activity were significantly higher (p<0.01) in ARC and AIDS patients (38.17 ± 2.2) compared to controls (28.02 ± 0.8) sgp and sgp concentrations were in the normal range (< 2.5) while sgp values were low (mean 302 ± 146 of the controls).

During AZT therapy. A progressive increase of ADA (100 ± 120) was detected during the first 3 months of the treatment. Subsequently high activities were mostly observed after 3 and 6 months of AZT concentrations (mean 567.7) were by approximately 50% reduction. sgp concentration was low.

Conclusions. We have observed increased ADA activity and decreased sgp concentration in the erythrocyte of HIV/AIDS patients. Such phenomena were caused by AZT therapy. Since ADA and sgp are known to play a common substrate, the greatly increased activity of the former may interfere with nucleotide salvage by the latter. Piv which nucleotide assists may cause.

M.B.P.355 **AZT THERAPY IS ASSOCIATED WITH AN INCREASED CAPACITY OF PHA-STIMULATED CELLS TO EXPRESS IL-2 RECEPTORS (IL-2R). IN MILWAUKEE, ALLEN, KOFFMAN, D., BASK, E.P., ARMSTRONG J.A., PAIS, G.L., SO, N. and Pittsburgh, University of Pittsburgh Medical Center, Pittsburgh, Pa., U.S.A.**

Objective. To determine whether AZT therapy in HIV-infected patients can improve in vitro T lymphocyte function.

Methods. 34 AIDS patients enrolled in the 000 AZT protocol for AZT treatment were essentially evaluated at intervals up to one year. PHA-stimulated mononuclear cells were incubated for 24 hours; the cells were cytofluorographically analyzed for expression of IL-2R by reactivity with CD25 monoclonal antibody.

Results. At time of entry, IL-2R expression were markedly depressed in HIV-subjects. The mean value 5.4 ± 0.9% compared to 6.5 ± 2.6% in heterosexual controls. During AZT treatment, there was a progressive increase in the capacity of cells to express IL-2R. Data was collected by two methods. The average IL-2R, using the last observation, had increased to 13.4 ± 2.6% (p<0.01 compared to baseline). When all values during the treatment period were considered, the mean was 17.0 ± 2.4%. Further analysis suggested that, in the AZT-treated patients, the responsive cells were primarily of the CD8 phenotype whereas, in controls, they were mainly CD4+. During the year of treatment, there was no increase in either PHA of T cell colony responses.

Conclusions: These studies suggest that AZT therapy is associated with a sustained improvement in immunofunctional parameters of T cell reactivity; their capacity to be activated by PHA, as indicated by expression of IL-2R.

M.B.P.357 **QUANTITATIVE DOSAGE OF CORE ANTIBODIES IS A BETTER PROGNOSTIC MARKER THAN HIV ANTIGEN AGENT**
Lemard, Olivier; Proctorakaki, S.; Farber, C.-M. Noptal Braams, UNIVERSITEIT LUIXVE de Bruxelles, Brussels, Belgium.

Methods. During a follow-up period of 0.5 (3.9-5.9 months) sera of 30 European and 16 African HIV infected patients (pts) at all stages of the disease (i.e., asymptomatic, RC, ARC, AIDS) were retrospectively investigated for the presence of HIV antigen (Ag), core antibodies (Ab) and envelope (env) Ab (Abbott Diagnostic-Health Chicago-IL).

Results: In all pts, env Ab were detected in high titers without significant variations during the follow-up. HIV Ag was detected in the serum samples of 16 pts; 1 African with AIDS and 13 European. At the beginning of the follow-up, 10% of the European pts were antigenemic and 20% at the end.

Core Ab were detected during the follow-up period in all the African except in the pt with HIV Ag. The geometric mean titer of core Ab titers was 1/735 in the asymptomatic pts and 1/113 in the AIDS pts. All European pts without HIV Ag were detected during the follow-up period in all the African except in the pt with HIV Ag. The geometric mean titer of core Ab titers was 1/726 in the asymptomatic pts and 1/75-5 in the AIDS pts.

Conclusion: HIV Ag is rarely expressed in African pts; moreover, even in the late stage of the disease, HIV Ag is not detected in 37% of European pts and detection is intermittent. In contrast, the decline or the disappearance of core is clearly related with evolution of the disease, in African like in European pts. Follow-up of quantitative dosage of core Ab seems to be of more value as a prognostic marker than the detection of HIV Ag.

M.B.P.359 **EFFECT OF AZT ON THE LEVELS OF ANTIBODIES SPECIFICITY TO ANTIBODY RESPONSE CELL CROSSLINKING ANTIGENS**
Petrovic, M.; Zira, F.; Turkovic, G.; and Halibauer, M.A.***
***Jewish General Hospital and Trauma Center Hospital, McGill University, Montreal, Canada.

Objective. To assess the effect of AZT cessation on levels of AOC-relevant antibodies in patient sera.

Methods. A standard 6 hour ³⁵S release cytotoxicity assay was used to assess AOC activity longitudinally over a 20 month period in 2 asymptomatic HIV-1 seropositive patients that had transiently elevated AOC activity. In addition, sera from a healthy control seropositive donor was used. Target cells were prepared by incubating peripheral blood mononuclear cells dispersed into 96 well microtiter plates (5000 cells/well). Serial 10-fold-dilutions of sera from each time point for each patient and the control were added to the targets to achieve final serum dilutions of 1:100 to 1:100,000. Effector lymphocytes obtained from a seropositive healthy donor were added to the wells at a effector:target ratio of 3:1.

Results. At dilutions of 1:100 and 1:1000 of patient sera, we noted AOC activity and crosslinking. This activity was less marked at a 10⁴ dilution and disappeared at 30⁴ or lower dilutions. In the control sera, AOC activity diminished progressively in the patients until AZT was stopped. Sera obtained immediately following AZT cessation each over period showed a marked rise of AOC activity to baseline levels.

Conclusions. These data on 2 patients suggest that AOC antibody activity declines in while patients are on AZT therapy. Following activity recovers following cessation of drug. These findings are being expanded to provide further insights into the role of AOC in pathogenesis and/or prognosis in HIV-associated disease.

M.B.P.378 DISSEMINATED GRANULOMATOUS PNEUMONITIS IN A PATIENT RECEIVING AZIDOULOSIN THERAPY FOR PHYLAXIS

Yves Douzals, George Washington University School of Medicine, Washington, D.C.

A 35 year old gay male had Pneumocystis pneumonia in 5/87. He was maintained after on AZ plus oral cotrimoxazole prophylaxis. In 9/88 he again developed weight loss, chronic fevers and dyspnea, and was admitted to the hospital presuming as Pneumocystis was diagnosed, and he was treated with pentamidine, which was switched to trimethoprim-sulfamethoxazole because of renal failure. His status progressively deteriorated, complicated by renal failure, arthritis, dermal eruptions, and a loss of respiratory insufficiency after two weeks. On autopsy he was found to have disseminated granulomatous Pneumocystis involving the lung, heart, lymph nodes, liver, spleen, GI tract, adrenal and thyroid glands and choroid, as well as disseminated cytomegaloviral inclusions.

There have been 17 cases of extrapulmonary pneumocystis reported in the literature, six of these in patients with AIDS. Only four of these, however, have been truly disseminated with multiple organ involvement (one with AIDS). This patient may have progressed to disseminated infection because of his use of azidothymidine, which suppresses infection in the lungs, but has no extrapulmonary effect. As this form of prophylaxis becomes more widespread, extrapulmonary pneumocystis may become more common.

M.B.P.379 PNEUMOCYSTIS CARINI CHOROIDITIS

Carole D.M. Rao, N.A. and Zimmerman, P.L.
University of Southern California and the Basile Doherty Eye Institute, Los Angeles, California, USA

Objective: To describe highly characteristic clinical features and light and electron microscopic findings of P. Carini chorooiditis in three patients with AIDS.

Methods: Three patients were followed asymptotically for AIDS-related conditions; two had Osmegmoscopia minima treated with ganciclovir. New chorooid lesions developed and retinal photographs were obtained. At autopsy, the globes of the eyes were examined grossly, by light microscopy and by electron microscopy.

Results: The characteristic fundus changes in P. Carini chorooiditis consist of multiple slightly elevated, pleomorphic, yellow-white lesions in the chorooid. Some of these chorooid lesions are round or oval, while others are geographic or multilobulated in shape. The lesions vary in size and are usually covered by relatively normal retinal pigment epithelium. However, some of the larger lesions may show areas of mild retinal pigment epithelium denudation consisting of the mottling or granular change. The fundus changes are not associated with choroidal inflammation. The etiology of the fundus pathology was determined by electron microscopy demonstrating P. Carini organisms.

Conclusions: P. Carini can produce characteristic fundoscopic changes in the chorooid and such findings can indicate disseminated P. Carini infection.

M.B.P.380 INCIDENCE OF PNEUMOCYSTIS CARINI PNEUMONIA (PCP) IN HIV INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS-1 (HIV-1)

Erica Jaffe, Madan, A., Daniels, R., Miranda, C. and Sash, A.

Multicenter AIDS Cohort Study, Chicago, IL

Objective: To determine the risk of developing PCP in homosexual men infected with HIV-1.

Methods: 1764 seropositive homosexual men were enrolled into a prospective study of HIV-1 infection in 1984-85. A history, physical examination and T-cell phenotyping was obtained every 6 mo. Outcomes through 7/31/88 are included in the analysis.

Results: Of 1660 men with available baseline CD4 counts, 185 developed PCP. This table stratifies outcomes over 3 years by CD4 number at entry.

CD4 count	n	PCP	6 mo. (%)	12 mo. (%)	36 mo. (%)
0-200	79	22	8.3	17.9	38.2
200-350	231	23	0.4	3.7	24.1
350-500	393	43	0.0	1.3	9.5
500-700	479	46	0.0	0.4	9.0
>700	487	21	0.0	0.0	4.1

Among participants whose CD4 count fell decreased to 200/mm³ at some time during the study, weight loss and thrush significantly (p<0.05) increased risk at 6, 12 and 36 months; fatigue and fever were predictive (p<0.01) for short term (less < 12 mo) development of PCP. Diarrhea, herpes zoster or hairy leukoplakia were not predictive.

Conclusion: Risk of developing PCP significantly (p<0.001) increased with decreasing CD4 cell count. Specific signs and symptoms occurring in immunosuppressed participants significantly add to the risk of PCP.

M.B.P.381 PSYCHIATRIC MORBIDITY IN HIV INFECTED INDIVIDUALS IN INDIA

JACOB K.S., MOSES, S., JOHN, J.K. and JOHN, E.T.

Christian Medical College, Vellore, India.

Objective: To document the psychiatric morbidity among HIV carriers and AIDS victims.

Method: 24 subjects were assessed to document psychiatric morbidity. The diagnosis of HIV infection/AIDS was communicated in the context of the psychotherapeutic support provided. They were followed up for a period of 2 to 6 weeks and additional psychopathology documented. DSM-III criteria were used for diagnosis. Acute, psychiatric morbidity at initial screening included Delirium (1), Major Depressive Disorder (1), Adjustment Disorder with depressed mood (7) and Marital discord (1). After the diagnosis of HIV infection was communicated the additional morbidity included Adjustment Disorder (3), Major Depression (1), Alcohol Dependence Syndrome (2) and Suicide (1). The individual who reacted with Major Depression also developed alcohol dependence and he committed suicide.

Discussion: The possibility that preexisting psychopathology predisposed these individuals to sexual promiscuity needs to be explored. The majority of individuals reacted with depression and could be supported through the crisis.

M.B.P.382 PREVALENCE AND COURSE OF PSYCHIATRIC DISTURBANCES ASSOCIATED WITH HIV INFECTION (CDC CATEGORY II-B IV)

Boon, Frans van den, Broer, Herman*, Broekman, Jitske**

* Netherlands Institute of Mental Health, Utrecht, The Netherlands.

**University of Amsterdam, Dept. of Psychiatry, Amsterdam, The Netherlands.

Objective: Gain insight in the prevalence and course of psychiatric disturbances/disorders in HIV infected persons.

Method: Every newly registered patient in a period of one year at the Academic Medical Centre (AMC) in Amsterdam will be followed during 12 months. A psychiatrist will give a DSM III R diagnosis at entrance, and after 6 and 12 months; a neurological examination will be executed at entrance; a psychiatric interview using the Diagnostic Interview Schedule will be held at entrance and 12 months later; with a bi-monthly frequency several self report questionnaires (General Health Questionnaire, Beck's Depression Scale) will be filled out; a neuropsychological test battery will be administered, and a 10 minute interview will be held.

For those who need psychiatric treatment, interventions and complications (e.g. with medication) will be monitored and registered. Special attention will be payed to organic complications.

Results: Preliminary results will be presented.

M.B.P.383 DIAGNOSIS OF DEPRESSION IN HIV INFECTED INDIVIDUALS

Ross, S.H., Rice, J., Brookshire, D. and Guadet, P.

AIDS Clinical Trials Unit, Washington University School of Medicine, Saint Louis, Missouri, USA.

OBJECTIVE: To examine the presence and course of depression in HIV infected individuals.

METHOD: A random sample of 26 seropositive individuals, 10 ARC and 10 AIDS patients who were enrolled in an AIDS Clinical Trial Unit were evaluated for depression by means of a structured psychiatric research interview. The SADS-L (Schedule for Affective Disorders and Schizophrenia-Lifetime) was used. Responses were made by ARC (Research Diagnostic Criteria) criteria. Subjects were interviewed on the average of 15 months post HIV testing.

RESULTS: Fifty percent (n=22) met criteria for a depressive diagnosis during the interval from HIV testing to the time of the present assessment. Forty percent (n=16) experienced a major depression which lasted a week or longer. Ten percent experienced a minor depression.

Twenty-one percent (n=10) had suicide ideation or death wish. Two subjects attempted suicide. Depression appeared to be less frequent one year or greater after HIV testing, as only two subjects reported current depression with major depression.

CONCLUSION: It is noteworthy that half of the sample had a clinically significant depression. Further, depression appears to be less common as individuals have time to cope with their HIV status.

Traitement de la PCP : Pentamidine et autres médicaments (diagnostic clinique) PCP Treatment: Pentamidine and Other Drugs (Clinical Diagnosis)

T.B.P.1 ÉVALUATION QUANTITATIVE DE PARASITÈMES AU COURS DE LA PNEUMOCYSTE CARINII CHEZ LES PATIENTS ATTEINTS DE SIDA OU D'AUTRES IMMUNODÉPRESSIONS.

NOUË Patricia, PAROÏT A., BÉGIN C., MAYARD C., PAROÏN F., LANGCASTER F.
HÔPITAL TENDR - 4, rue de la chine - 75020 - PARIS

Objectif : Rechercher et, comme pour l'expression clinique, si existe une différence dans l'intensité de parasitemie au cours des pneumocystoses survenant chez les sujets atteints de SIDA ou d'autres immunodépressions.
Méthode : Cette étude concerne 80 patients : 47 SIDA (G1) et 33 autres immunodéprimés (G2); tous ont une pneumocystose diagnostiquée par lavage broncho-alvéolaire (LBA), 29 ont une insuffisance respiratoire aiguë (IRA) avec $PaO_2 < 50$ mmHg. L'intensité de parasitemie a été évaluée sur le nombre d'œufs présents dans 10 μ l du col de centrifugation du LBA selon une méthode semi-quantitative : parasitemie faible < 5, ++, intense > 4+.

Résultats :

Parasitemie	faible G1	intense G1	faible G2	intense G2
$PaO_2 < 50$ mmHg	n = 26	0	19	0
$PaO_2 \geq 50$ mmHg	n = 54	16	32	5

Conclusions : Il existe des différences d'intensité de parasitemie dans les deux populations étudiées en particulier au cours des PRC. 5 sévères avec IRA : parasitemie intense dans G1, faible dans G2.

T.B.P.2 FINAL DIAGNOSIS IN PATIENTS WITH NEGATIVE BRONCHOALVEOLAR LAVAGE FOR PNEUMOCYSTIS. Sills, Zihad*, Veree, G., Forrester, C., Shafiq, A., Johnson, R.S.

St. Michael's Hospital, Medical Center, Newark, New Jersey, U.S.A.

Objective: To attempt and determine a final diagnosis in patients with a negative broncho-alveolar lavage (BAL) for PCP. **Methods:** Review of all hospital charts of HIV positive patients with bronchopathy for suspected PCP. Further analysis of those charts with negative PCP on BAL included clinical symptoms, laboratory examinations, chest x-rays and sputum smears. **Results:** 88 HIV positive patients underwent 93 bronchoalveolar lavages. 17 were negative for PCP. 13 of those were found to be PCP. 23 were included five with positive results on transbronchial biopsy and eight with a compatible laboratory and clinical course. 23 were found to have positive mycobacterial cultures, seven of which were M. tuberculosis. Eight sided endocarditis with embolic pneumonia accounted for six cases. 5 had positive fungal cultures and another five showed CMV. Seventeen remained without a etiologic diagnosis.

Conclusions: Most patients with suspected PCP with negative sputum smears on BAL had an etiologic agent identified. These agents were usually treatable.

T.B.P.3 A PATHOLOGIC BASIS FOR BRONCHOALVEOLAR LAVAGE (BAL) PNEUMOCYSTIS CARINII PNEUMONIA (PCP). BARDI, ROBERTA*, FOWLY L., and SIKKON P. Harbor-UCLA Medical Center, Torrance CA, 90509, USA

Objective: In 60 patients with PCP, > 50 BAL neutrophils predicted mortality more sensitively and specifically than the degree of hypoxemia, hypoalbuminemia or increased LDH (Am Rev Resp Dis, in press). We sought to determine a pathologic basis of excess bronchoalveolar lavage (BAL) neutrophil percentages in Pneumocystis carinii pneumonia.

Methods: Transbronchial biopsies of 20 patients with documented PCP and specimens adequate to assess the histology of the lung parenchyma were reviewed. Biopsies were scored from 0 (absent) to 3 (abundant) in each field for the degree of diffuse alveolar damage (DAD) and for the presence of polymorphonuclear leukocytes (PMN) as well as the presence of capillaritis, edema, chronic inflammation, fibrosis and intra-alveolar or interstitial PMN.

Results: The presence of DAD and interstitial or intra-alveolar PMNs were the most common abnormalities in the lung parenchyma and each was found in 27 of 29 patients. The presence of fibrosis was the least common finding, present in only 6 of 27 patients.

Conclusions: DAD and neutrophilic infiltration were commonly found in the transbronchial lung biopsies in patients with AIDS. Neutrophilic infiltrates are not a well-recognized sequelae of PCP, however, PMNs in the lung may account for more severe clinical manifestations of this disease and provide the basis for staging of PCP with BAL neutrophilia.

T.B.P.4 INTERET ET LIMITES DES EXPECTORATIONS INDUITS DANS LE DIAGNOSTIC DE LA PNEUMOCYSTE DU SIDA.

Delaour, Thery*, Bouc P., Camu, P., Fay, M., Denis, M et Grand, PM**
Hopital Pasteur, Paris, France ; *Hopital Claude Bernard, Paris, France ; **INSERM U14, Paris, France

Objectif: Evaluation diagnostique de l'expectoration induite (EI) comparée au lavage bronchoalvéolaire (LBA).

Patients et méthodes: Un recueil (EI) de LBA a été fait simultanément chez 132 patients HIV positif suspects de pneumocystose dont 23 hospitalisés en soins intensifs. Des azaarés tétraols ont été faits chez 17 patients. EI : recueil après induction par un aerosol salé hypertonique (3 % de sulfate d'hydrogène) LBA : selon la technique habituelle. Traitement des prélèvements : fixation des EI (éthylglycidylthiozobutane) sans centrifugation - coloration par Gram. Imprégnation aseptique vitro Blau de Toluidine O etrou Grand Weigert à la source des lames coudées à 48 h/48 par deux examinateurs.

Résultats:

Maladies Services	LBA (%)	EI (%)	Sensibilité E/LBA (%)
Maladies Infectieuses	50 / 120 (42)	32 / 120 (27)	32 / 50 (64)
Soins Intensifs	16 / 31 (52)	4 / 31 (13)	4 / 16 (25)

Conclusions: 1) Spécificité des EI : 100 % 2) Sensibilité des EI plus faible que les patients de soins intensifs (25 % versus 64 %) probablement dus au traitement et Pneumocystis administré pendant plus de 48 h/48 dans cette série. 3) Induction des expectorations s'est révélée impossible chez 20 % des patients. 4) Au total, chez des patients ne recevant pas de traitement et Pneumocystis, le recueil du LBA pourrait être évité dans 24 % des cas.

T.B.P.5 ANTIBODIES TO PNEUMOCYSTIS CARINII. MIXED LEVELS IN HIV INFECTED PATIENTS DURING PNEUMOCYSTIS INFECTION AND EVALUATION OF PASSIVE IMMUNITIES.

Burns, Sheila B.*, Reed, J.A.*†, Wu, P.A.**†, Stebbins, G.R.**††

* Regional Virus Laboratory, City Health Dept., Edinburgh, Scotland.
† Scottish National Blood Transfusion Service, Edinburgh, Scotland.
†† Infectious Diseases Unit, City Hospital, Edinburgh, Scotland.

Objective: To follow the relationship between *Pneumocystis carinii* antibody levels and acute infection in homosexual males from HIV antibody positive patients with seropositive spouses and to investigate the possibility of using serology.

Methods: Using an RPA based on fusion products of infected rat lung *P. carinii* antibody activities were measured on 8 HIV positive patients and 7 HIV negative immunocompetent patients with respiratory systems. Multiple samples from 25 seropositive positive patients were analyzed and the *P. carinii* antibody levels correlated with available serological data or induced sputum results.

Results: Five patients with proven P.C.P. had an acute fall in antibody levels and a further 3 showed transient antibody following diagnosis and treatment. The same pattern was observed in three patients with suspected but not proven P.C.P. Antibodies to other viruses and serum immunoglobulin did not show a similar pattern. The *P. carinii* antibody levels in 40 blood donors and 10 heterosexual diabetics (HD) samples selected at random was estimated.

Conclusions: The use of IgG in acute infection with *P. carinii* and as seropositive against infection either alone or in conjunction with other therapeutic agents, is worth further evaluation.

T.B.P.6 PURIFICATION AND CHARACTERIZATION OF A MAJOR HUMAN PNEUMOCYSTIS CARINII SURFACE ANTIGEN

Wang, Yeh-Hsin*, Lin, Yeh-Hsin*, Kuo, Kowen, J.A.
National Institutes of Health, Bethesda, Maryland, USA.

Objective: Purified *Pneumocystis carinii* (PC) antigens are needed for investigations into host-parasite interactions and host immune responses. P-25, a 25 kDa protein, is a human and rat PC are antigenically different, antigens of human PC should be used as antigens.

The goal of the current study was to purify a major antigen of human PC. **Methods:** PC were obtained from autopsy lungs of patients that died of PC pneumonitis. Organisms were treated with proteolytic P-25-lysine, and the antigen was purified by HPLC using a size column followed by ion-exchange chromatography. To evaluate the size of the native molecule, a cross-linking study using bis[3-(dimethylamino)carbonyl]suberate (DSB) was done.

Results: Synthesis of purified PC solubilized the predominant antigen, which has a size of 86,000 MW when evaluated by SDS-polyacrylamide gel electrophoresis under reducing conditions. This antigen reacts with a monoclonal antibody (8B3) previously shown to be specific for human PC immunofluorescence studies have shown that it binds to the surface of PC. Reactivity with the monoclonal antibody was used to follow purification. The size of the native molecule, based on sizing column chromatography, was greater than 500,000 MW. Following immunoprecipitation chromatography, a single band of 86,000 MW was seen on SDS-PAGE, and this band reacted with the monoclonal antibody. **Conclusions:** The antigen purified prior to SDS-PAGE suggests that the antigen is a trimer, based on the presence of a new 270,000 MW band in the immunoprecipitate.

Conclusions: A major surface antigen of human PC, purified with a molecular weight of 86,000 MW, was purified from human lungs. This antigen is a trimer. The purified antigen can be used to develop assays to investigate the cellular and humoral response of humans to PC infection.

T.B.P.7

THE DIAGNOSIS OF PNEUMOCYSTIS CARINI PNEUMONIA IN HIGH RISK PATIENTS BY INDUCED SPUTUM USING A DIRECT IMMUNOFLUORESCENT ANTIBODY TEST

Heath-Chicago, Michel; Moore, M.; Rose-Douglas, J.; Connors, J.; Hulme, P.; Harth, B. Beth Israel Hospital, Harvard Medical School, Boston, MA

Objective: Evaluation of the Genetic Systems direct immunofluorescent monoclonal antibody test (DFA) to detect *Pneumocystis carini* in induced sputum.

Methods: Induced sputum (IS) was collected from 27 patients who were HIV seropositive or in a high risk group and had histiophilic infiltrates on chest x-ray, room air PO₂ < 80, and/or a positive Gallium scan. Bronchoalveolar lavage (BAL) was performed on most patients whose IS was nondiagnostic. IS and BAL were processed using published techniques and stained by Toluine Blue O (TBO) and DFA. TBO smears with heavy yeast were considered uninterpretable (TBOU). Slides with 2-3 yeasts were considered positive.

Results: There were 16 DFA positive IS smears of which 10 were also TBO +, 4 were TBOU and 4 were TBO -. Six of these 6 patients who were DFA + but TBO or TBO - were confirmed to have pneumocystis pneumonia (PCP) by BAL, whereas 2 patients had BAL + but a direct culture consistent with PCP. The other 6 were not to follow-up. Eleven IS smears were DFA negative, 10 were TBO - and 1 was TBOU. Six of these were confirmed negative by BAL. Of the 6 remaining patients who did not go on to BAL, 3 responded to specific PCP therapy, 1 had been rechecked to rule out a PCP treatment failure, and a final direct DFA could not be made in 1 patient due to concentrated PCP and extensive debris.

Conclusion: In patients at high risk for AIDS-related PCP, DFA is more sensitive than TBO and makes the diagnosis of PCP by induced sputum a simple, rapid, and highly sensitive test.

T.B.P.8

BRONCHOALVEOLAR LAVAGE (BAL) CMV CULTURE POSITIVITY (CMV+) IS ASSOCIATED WITH BETTER OUTCOME OF IMMUNOCOMPROMISED PNEUMONIA (PCP) IN HIV WITH AIDS.

Arora, JM; Rosenzweig, SM; J. Berlok, A; McWhorter, JA; Richman, DR; Swartz, R. UC San Diego and the California Cancer and Active Treatment Group, San Diego, CA, U.S.A.

Objective: To determine the significance of CMV in confirmed PCP. **Methods:** Retrospective cohort study of all patients undergoing bronchoscopy at UCSD for possible PCP between 1/1/85 and 12/31/87. CMV+ and CMV- patients were compared for prognostic factors at presentation and for outcome. Unfavorable outcomes were death within 30 days and intubation. **Results:** Of 248 episodes, 136 were confirmed PCP. All had BAL fluid viral culture; 122 were unconfirmed or evaluable. 112 cases in women (1 CMV+) were excluded. Analysis of the remaining 122 cases showed: **Prognostic Factors:** Age, sex, PCP, prior AIDS, CMV. **DFI:** BAL-CMV+ (n) 52 (46) >=34 42 (81) >=68 52 (100) >=12 >=14 BAL-CMV- (n) 60 (54) >=34 43 (75) >=68 60 (100) >=12 >=14

Outcome	Death	Intubation	Death or Intubation
BAL-CMV+ (n)	6 (12)	16 (63)	22 (33)
BAL-CMV- (n)	13 (22)	13 (22)	26 (33)
Relative Risk (C.I.)	1.22 (1-1.37)	1.4 (1.04-1.9)	1.49 (1.04-2.04)

p = n.s., p < 0.05, p < 0.02. **Conclusion:** Nearly 1/2 of men with PCP had BAL-CMV+. CMV+ men had similar survival times but apparently better outcome than CMV- men. CMV-mediated immunosuppression may reduce lung injury in PCP. BAL-CMV+ men may have underlying lung dysfunction and present with earlier PCP.

T.B.P.9

A MEASURE OF IMMUNOCYSTIS CARINI PULMONARY LESION. **Richard Robert P. France**, Department of Medicine, University of Cincinnati, Cincinnati, OH, U.S.A.

Objective: To develop a method for estimating the burden of *Pneumocystis carini* (PC) in bronchoalveolar lavage (BAL) fluid of AIDS patients (pts). **Methods:** BAL fluid from AIDS pts with PC pneumonia were prepared with a cytochrome and a modified Wright-Giemsa stain. The number of PC in clusters was compared to the number of nucleated cells counted. Intra- and inter-subject variability was determined by analysis of variance and the P-ratio (P) and P value calculated. **Results:** PC clusters from BAL specimens of 20 pts were counted three times. The cluster number that was associated with 200, 500, and 1000 cells was noted. There was significant intersubject variability for the 200, 500, and 1000 cells (200 cells: P=0.01, 500 cells: P=0.3; 1000 cells: P=6.4, all p<0.001). The correlation coefficient for 500 cells between counts (R=0.81, p<0.001) was higher than 200 cell counts, but similar to 1000 cell counts; the number of clusters with 500 cells was used thereafter. Because the BAL fluid volume may alter the cell differential, we studied BAL specimens aspirated after each of four introduced aliquots of 60 ml saline in 15 pts. There was no significant intrasubject variability (P=10, p<0.5), but there was significant intersubject variability (P=0.3, p<0.001). Sequential lavage specimens from 24 pts before (PRE) and after (POST) therapy for PC pneumonia were studied. Sixteen pts responded to therapy; all had a decrease in PC clusters (PRE=5.4, 1.1 (Mean±S.E.); POST=4.2, 0.0, 0.01). Eight pts had persistent disease; the BAL contained the same or more PC (PRE=5.2, 1.6; POST=5.5, 1.6). **Conclusion:** PC can be quantitated in BAL fluid; this may be useful in assessing therapy.

T.B.P.10

DEFECTIVE PERIPHERAL OXYGEN UTILIZATION IN AIDS PATIENTS WITH RESPIRATORY FAILURE DUE TO PNEUMOCYSTIS CARINI.

Robert C. Allen, Tishchenko, L., Sweeney, R.A., Sojka, S.C., LAC/USC Medical Center, OH 11400, 1200 North State Street, Los Angeles, CA 90033, U.S.A.

Objective: A peripheral defect in oxygen utilization has been described in acute shock and the Adult Respiratory Distress Syndrome (ARDS). Some have suggested that inadequate levels of oxygen transport to peripheral tissues may contribute to the mortality seen in these states. In this study we examined peripheral oxygen utilization in AIDS patients with severe respiratory failure secondary to *Pneumocystis carini* infection (PCP).

Methods: We evaluated twelve patients (age = 34 ± 8 yrs) with AIDS, documented PCP and severe respiratory failure (PO₂ < 215 ± 10) requiring PEEP. We chose subjects who had no evidence of any concomitant bacterial, fungal, mycobacterial or viral infection as affirmed by lack of clinical site and negative cultures, including blood. Cardiac outputs were obtained by thermodilution and oxygen consumption calculated by the Fick equation.

Results: Our data showed:

	CI	Hgb	DO ₂	VO ₂	LACTATE
HR	43 ± 11	10 ± 1.7	539 ± 164	152 ± 82	2.4 ± 1.1
1994	43 ± 17	10 ± 1.5	544 ± 249	145 ± 48	2.5 ± 0.7
1995	44 ± 18	10 ± 1.8	596 ± 262	139 ± 55	4.4 ± 1.8

Conclusion: The patients with PCP and respiratory failure had a systemic dependent oxygen consumption at higher levels of oxygen delivery than have been found in normal humans, suggesting a peripheral defect in oxygen utilization similar to that seen in bacterial sepsis and ARDS. This may be significant with respect to management.

T.B.P.11

Rapid Diagnosis of *Paramecystis carini* pneumonia in Patients with AIDS using a Direct Fluorescent Monoclonal Antibody (DFA) Assay.

Vignani, Albert*, Ng VL**, Chaisson RE**, Hadley WK**, Sparsho, Yajko D** and Hirschel CM, U.S.A. * Johns Hopkins Hospital, Baltimore, Maryland, ** San Francisco General Hospital, San Francisco, California.

Objective: To compare a new DFA (Genetic Systems) with the Giemsa (Diff-Quick) for the diagnosis of PCP from sputum and bronchoalveolar lavage (BAL).

Methods: Induced sputum from patients with suspected PCP was digested, centrifuged and smeared on slides. Heat fixed Giemsa and routine fixed DFA stained slides were examined for trophs and cysts. BAL was done on patients negative by sputum, when possible.

Methods: Of 111 patients evaluated, a total of 60 were diagnosed with PCP. 52/60 with Giemsa on sputum (97% sensitivity) and 51/60 on sputum with DFA (85% sensitivity). 3 patients had PCP diagnosed by both methods as a subsequent sputum after treatment of a bacterial superinfection. 8/23 patients negative on sputum induction were positive by both DFA and Giemsa as were 3 additional patients who had BAL done. Of the 36 patients that did not go to bronchoscopy, other diagnoses apparent in 13 are related to indeterminate. There was one false positive and one false negative DFA specimen was.

Conclusion: This DFA is a rapid, inexpensive method of identifying *P. carini* in sputum and bronchoalveolar specimens and is comparable to the standard high yield Giemsa stain.

T.B.P.12

PREVIOUS INABILITY TO CONFIRM THE DIAGNOSIS OF PRESUMED IMMUNOCOMPROMISED PNEUMONIA (PCP).

Rosenzweig, Samuel A; Sletten, P; Chiu, J; Gluckstein, D; Oeffner, J; Mueller, C; UC San Diego, UC Southern Cal, UC Irvine, Kaiser/Stanford Hospital and the California Collaborative Treatment Group, San Diego, CA, U.S.A.

Objective: To assess the reliability of the diagnosis of PCP and the utility of clinical assessment in distinguishing confirmable cases.

Methods: The presentation, treatment course of persons with PCP was examined. All patients were enrolled into a randomized trial of corticosteroids which required subsequent confirmation of diagnosis. Only patients who had a positive induced sputum or unobscured bronchoscopy were included.

Results: PCP was confirmed in 158 of 202 patients (78 pct and 23% resp.) of PCP. **Findings (sensitivity) (False Pos/Neg) Value Value**

Findings (sensitivity) (False Pos/Neg)	Value	Value
Cough	91	84
fever	72	81
Short Dyspnea	83	80
Wet Dyspnea	44	83
Chest Tightness	56	87
WBC <= 16,000 (cell)	55	41

The present and present probabilities of disease were not significantly different for all findings and combinations of findings (not shown).

Conclusion: The diagnosis of PCP frequently cannot be confirmed. Confirmable and unconfirmable PCP present similarly. No finding alters the probability of confirmable disease to a clinically relevant extent. Actions based on a diagnosis of PCP must be undertaken without caution.

T.B.P.13

A NEW METHOD FOR THE DIAGNOSIS OF PNEUMOCYSTIS CARINII IN BRONCHOALVEOLAR LAVAGE
 M. Desautels*, P. Delattre**, P. Delattre**, C. Kati-
 sa*, N. Denis*, M. Gentilin*.
 *Dept of Public Health, Parasitology and Tropical Medicine, Hôpital de la
 Salpêtrière, Paris, France, et Unité INSERM 213, Paris
 **Diagnostic Pasteur, Marne-la-Coquette, France.

Objective: An indirect fluorescent-antibody technique is compared to a tra-
 ditional silver staining method for the diagnosis of *Pneumocystis carinii*
 (P-C) cysts in bronchoalveolar lavage (BAL) specimens.
Method: 200 BAL-specimens from 140 patients are treated simultaneously with
 the indirect fluorescent-antibody technique (Detect IF L. cariniiTM) and
 Muto's rapid silver staining method.
Results: Of the 200 BAL specimens, 100 are positive for P-C, both method included.
 50.6% of the positive sample are diagnosed by the indirect immunofluorescence
 (IF) method and 49.4% by Muto's technique.
Conclusion: The IF method permits again in the diagnosis of P-C in BAL,
 especially when samples contain a small number of cysts. The technique is
 simple in performance and has the advantage of an easy and a rapid lecture.

T.B.P.15

**PREDICTIVE DATA FOR POSITIVE BRONCHOALVEOLAR
 LAVAGE RESULTS IN PNEUMOCYSTIS PNEUMONIA.** Sims,
Linard, Delgado, Peres, Gr. Forrester, C.
Johnson, E.S., Saint Michael's Medical Center, Newark, New
 Jersey, U.S.A.

Objective: To determine if any factors may be predictive of
 bronchoalveolar lavage (BAL) recovery of PCP in suspected cases
 of pneumonia.
Method: A retrospective review of 127 bronchoscopies performed
 for suspected PCP was undertaken with analysis of hospital
 charts. Symptoms, chemistry profile, arterial blood gases, chest
 x-rays and sputum smears were compared in 61 patients with
 positive and 65 with negative results for PCP.
Results: Those with positive results had an average shorter
 duration of anti-PCP treatment prior to (BAL), had a lower
 incidence of negative chest x-rays, had 100% incidence of
 positive sputum smears and higher lactate dehydrogenase levels.
 Symptomatically those with positive (BAL) had longer duration of
 symptoms and lower incidence of productive cough. Arterial
 blood gas measurements, complete cell counts and V-cell studies
 showed no differences between groups.
Conclusion: There are some laboratory data (arterial dehydrogenase,
 chest x-ray and sputum smears) and/or symptoms (duration and
 productive cough) which can be predictive of positive (BAL)
 results.

T.B.P.17

**How predictive are LHM-elevations for the severity of pneumo-
 cystis carinii pneumonia in AIDS patients?**

Elger, C. Irckenbrecht, J.F. Worth, N. Stromeyer, R.
 University of Medicine, University of Düsseldorf, 4000 Düsseldorf Muenster-5
 FRG.

The elevation of plasma lactate dehydrogenase (LHM) is a common phenomenon
 during pneumocystis carinii pneumonia in AIDS. Prospectively we evaluated
 the reliability of LHM elevation to predict severe respiratory distress:
 arterial oxygen pressure (PO₂) less than 60 mmHg; during pneumocystis
 carinii pneumonia (PCP). A significant negative correlation between both
 values was found (r=-0.46; p<0.001). For LHM values less than 300 U/l,
 only 3 of 32 PCP values were less than 60 mmHg (specificity 86.2%). For LHM
 values higher than 300 U/l only 38.5% of the PCP values were less than
 60 mmHg (sensitivity 38.5%). When LHM values were between 300 and 600 U/l
 the range of PCP values was between 32 and 94 mmHg. Positive and negative
 prediction values of LHM 300 U/l for the diagnosis of severe respiratory
 distress were 50% (16/34) and 61% (12/19), respectively.
Conclusion: LHM and PO₂ are significantly correlate in pneumocystis carinii
 pneumonia. However, due to low sensitive and low predictive value, LHM
 determination is of limited value in prediction of severe respiratory
 distress in pneumocystis carinii pneumonia in AIDS patients.

T.B.P.14

**PNEUMOCYSTIS CARINII: DIAGNOSIS IN NON-INDUCED
 SPUTUM BY IMMUNOFLOURESCENCE**
 M. Hübner*, T. Trachsel*, B. Brubaker*, G. Gerdle*, R. K. S.
 Schedel*, I. Deicher*, H. Schmed. Hannover, Fed. Rep. of Germany.
 *Publ. Health Labs., **Sch. Med., Hannover, Fed. Rep. of Germany.

Objective: To develop a reliable routine procedure for diagnosing
 Pneumocystis (PC) in spontaneously expectorated sputum
 of patients with AIDS or suspected AIDS.
Method: Non-commercial indirect immunofluorescence test (IFT)
 based on polyclonal rabbit-antiserum to PC.
Results: Non-induced sputa of 128 HIV-patients with suspected
 pneumocystosis (PCP) were examined. The IFT was diagnostic in
 50 (39 %) patients. In 30 out of the 78 patients with a negative
 sputum diagnosis, a bronchoalveolar lavage (BAL) was per-
 formed subsequently, because of PCP still was suspected.
 In 3 of these cases PC was detected in the BAL material. An-
 other sputum diagnosis was taken for false-positive due to the
 further clinical course. Thus, on the basis of clinical para-
 meters and comparative sputum/BAL-examination, 94 % sensitivity
 and 99 % specificity of the test was attained in this
 cluster of patients.
Conclusion: Our results suggest that PC is commonly present in
 spontaneously expectorated sputum of HIV-patients with PCP.
 A properly designed immunofluorescence technique makes this
 material a most useful diagnostic specimen.

T.B.P.16

**GENERAL HISTOLOGIC MANIFESTATIONS OF PNEUMOCYSTIS CARINII
 PNEUMONIA (PCP) IN AIDS.** William R. Taylor, G. Pittenger,
W. Lynch, W. G. O'Connell, W. Armstrong, R. Levy, et al.
 National Institutes of Health, Bethesda, MD, USA

Objective: To investigate the pathologic features of PCP in AIDS patients.
Method: 162 lung biopsies (156 transbronchial, 6 open biopsies) from 71 AIDS
 patients with PCP were reviewed. Serial biopsies in 50 patients (2-9
 each) and autopsy study of the evolution of the evolution of
 pathology of PCP.

Results: Several unusual pathologic manifestations of PCP were observed:

Histologic Feature	No. Biopsies (%)
Interstitial Fibrosis	74 (46)
Interlobular	42 (26)
Absence of alveolar septulae	21 (18)
Marked alveolar macrophages	8 (7)
Chronic inflammation	4 (3)
Marked chronic inflammation	4 (3)
Squamous metaplasia	2 (2)
Marked squamous metaplasia	2 (2)
Minimal histologic reaction	1 (1)
Marked interstitial and vasculitis	1 (1)

Conclusion: PCP has a wide spectrum of pathologic manifestations in AIDS
 patients. It is important to recognise unusual pathologic features of PCP
 since it is the most common life-threatening pulmonary complication of AIDS.

T.B.P.18

**COMPARISON OF FIRST EPISODE OF PCP IN COMMUNITY PATIENTS
 AND IMMATES**
Stark, Victoria, Andrew, A. Mayman, R. Weiss, R.
 Albany Medical Center, Albany, New York, U.S.A.

Objective: Compare survival of community patients (CP) and inmates (I)
 diagnosed with their first episode of PCP.
Methods: Retrospective review of all patients with primary PCP admitted to
 the ANC AIDS Treatment Center between 1/1/87 and 10/31/88. Only those
 patients with documented PCP confirmed by bronchoscopy, were included
 in the study. Ethnic origin, risk group, lab parameters on admission, use
 of AZT and survival were evaluated.
Results: 40 community patients and 26 inmates were included in the study.
 In the community patients, there were 80% Caucasian, 10% black, 10%
 Hispanic. Among inmates there were 12% Caucasian, 72% black, 8%
 Hispanic. Risk group data showed community patients 63% H/O homosexual, 20%
 IVDA, 15% other. Inmates had 77% IVDA, 8% H/O homosexual, 15%
 IVDA/ homosexual. 20% of community patients were on AZT prior to admission;
 5% of inmates patients were on AZT prior to admission. Average LHM on
 admission: CP=64; I=60; Average Hct on admission: CP=35; I=33.4.
 Mortality was CP=34; I=24. Mortality in those individuals not on AZT:
 CP=44; I=34.
Conclusion: Inmates with primary PCP arrived at ANC sicker than community
 patients, as evidenced by higher LHM and lower Hct in the inmate
 population. Furthermore, despite presumably similar workup and treatment
 by the medical staff at ANC, inmates did worse than community patients as
 evidenced by their significantly higher mortality.

T.B.P.25 REDUCED DOSE OF AEROSOLIZED PENTAMIDINE TREATMENT FOR PNEUMOCYSTIS CARINII PNEUMONIA (PCP): A 6 MONTH FOLLOW UP
John R. Gomez, Jr., D. Charvoff, H. Hollander, D. Feigel,
J. Golden, Department of Medicine, University of California, San Francisco, San Francisco, California.

Objective: To investigate the toxicity, efficacy, and pharmacokinetics of reduced dose of aerosolized pentamidine for the treatment of mild PCP.
Methods: 45 patients were entered into a randomized trial of reduced dose (3 mg/kg/day) intravenous pentamidine or aerosolized pentamidine (600 mg daily; Respigard-2 nebulator) for mild PCP (Psz 2 to 60 mm Hg). Pentamidine concentrations in plasma and bronchoalveolar lavage (BAL) were measured by HPLC.
Results: Of 23 IV patients, 1 was excluded because PCP was not confirmed, 4 failed to respond to therapy, 12 developed major toxicity and 17/21 (81%) responded satisfactorily. Of 23 aerosolized patients, PCP was not confirmed in 1, 1 received no drug, 4 failed to respond, none developed major toxicity, and 17/19 (89.4%) responded satisfactorily. There were 2 deaths in the aerosolized group. The early relapse rate (3 months) were 0/17 and 10/15 (66.6%) for IV or aerosolized therapy.

Bronchoalveolar lavage concentrations of pentamidine were 89.8 ± 48.4 ng/ml and 110 ± 90.1 ng/ml (p=0.02, NS) in patients with or without relapse. **Conclusion:** Mild PCP responds adequately to reduced dose IV or aerosolized pentamidine. The early relapse rate following aerosolized treatment is high and not prevented by aerosolized pentamidine prophylaxis. BAL concentrations of pentamidine were not correlated with relapse. Pentamidine accumulates in plasma with daily intravenous therapy even in patients with normal renal function.

T.B.P.27 TRAITEMENT DE LA PNEUMOCYTOSE DU SIDA PAR LE DFMO
Clard, Pierre-Marie* ; Darou, A.* ; Puzosman, W.* ; Perrone, C.* ; Wolff, M.* ; Colliard, J.*
*Hôpital Hochel - Claude Bernart, *INSERM U13, 75019 Paris, France.

Objective: Evaluation de l'efficacité et de la tolérance du Dihydrofolylméthotrexate (DFMO) dans la pneumocystose au cours du SIDA.
Patients and Methods: Le DFMO a été administré à la dose de 400 mg/kg/j pendant 15 jours puis 300 mg/kg/j, P.O. pendant 30 jours. L'efficacité a été évaluée chez 22 patients : Groupe I (n=6) PaO2 < 40 mmHg (27-68) ; traitement de première intention. Groupe II (n=17) PaO2 < 63 mmHg (36-52) ; traitement de soins après (non-1) ou échec d'un autre traitement (non-2). La tolérance a été évaluée chez 27 patients.

Results: La durée moyenne du traitement a été de 20 jours (4-27). Groupe I : 3/5 guérison ou amélioration. Groupe II : 15/17 (88%) guérison ou amélioration, 91% de réponses favorables ont été observées chez les 11 patients dont la PaO2 était supérieure à 50 mmHg versus 72% chez les 11 patients avec PaO2 inférieure à 50 mmHg. Les effets secondaires les plus fréquents étaient : hépatites (52%), anémie (41%), neutropénie (37%), diarrhée (30%), et une néphrite partielle du DFMO dans 9/27 cas (33%).

Conclusion: 1) En traitement de première intention, l'efficacité du DFMO semble inférieure à celle des traitements conventionnels. 2) En relais, le taux global de réponse favorable (88%) est élevé mais pourrait être lié à l'effet du traitement antérieur. 3) La toxicité hématologique est fréquente.

T.B.P.29 Eflornithine in the treatment of Pneumocystis Carinii Pneumonia (PCP).
Neil, J.P., Doherty, P., Smith, R., Jones, A., Doherty, R., Sacks, H.S., Hirschman, S.Z., Mc Siney
Hospital, New York.

Eflornithine (E) has been demonstrated to have activity against PCP. From 1985 to 1988 42 patients that had failed or had had significant adverse reactions to pentamidine and TMP-SMX were treated with E. There were 23 definite responses, 17 probable responses, one patient died of another opportunistic infection and 15 patient failed therapy [F]. No differences were observed between responders and failures in the duration of AIDS, number of previous episodes of PCP, presence of other opportunistic infections or KS. Only 1 responder required mechanical ventilation at the start of therapy as opposed to 12/16 failures (p<.001). The initial WBC was 5.09 ± 1.88 in R as compared to 9.18 ± 4.26 in F (p<.01). There was a trend to higher A-a gradient in F (mean 80° F 153 vs R 172 ± 15) but this was not statistically different (p>.2). Adverse effects included thrombocytopenia, in 7/8 of patients; the WBC decline to 653 and hemocrit to 165. No patient had significant bleeding or a secondary infection. Four patients had diarrhea requiring antidiarrheal agents. E is effective therapy in patients with mild to moderate disease. As with standard therapy outcome is poor in patients with severe disease requiring mechanical ventilation. Further dose-response investigation to maximize efficacy and minimize toxicity is indicated.

T.B.P.26 PENETRATION OF TRIMETHOPRIM (TMP) COMPARED WITH THAT OF SULFAMETHOXAZOLE (SMX) IN BRONCHOALVEOLAR LAVAGE FLUID (BALF) DURING PNEUMOCYSTIS CARINII PNEUMONIA (PCP).
Domen, Jean-François*, Durand, S.*, Kizza, M.D.*, Hatcher, J.P.*, Hirsch, A.*,
Hospital Saint-Luc*, Saint-Jacques* and St-Charles*, Paris, France.

Aim: To improve knowledge on local kinetics of high dose TMP/SMX by comparing penetration of TMP and SMX into the extracellular fraction of alveolar macrophages where PCP is present.

Methods: 10 HIV+ patients with suspected (and later confirmed) PCP received a constant infusion of TMP (20mg/kg/6h-SMX (100mg/kg/6h), initiated 2h before BAL. BAL was performed in the right middle lung. Blood and BALF samples obtained during BAL were centrifuged and stored at -80°. TMP and SMX were assayed by HPLC and HPLC, respectively.

Results:

	Serum (µg/ml)	BALF (µg/ml)	PM (f)	(TMP) BALF/(TMP) serum	(SMX) BALF/(SMX) serum
TMP	3.1 ± 1.3	1.9 ± 0.7	76 ± 36		57 ± 40
SMX	162 ± 12	3.0 ± 1.4	1.8 ± 1.2		

Discussion: Although BAL, SMX may diffuse, it is clearly equal for both drugs in one individual patient. Thus, compared to BALF, serum TMP may be used to compare effectiveness of cotrimox given simultaneously to penetrate into the extracellular fraction of alveolar cells.
Conclusion: In patients with PCP, TMP achieves a markedly superior gradient to penetrate into the extracellular fraction of alveolar fluid as compared to SMX. Consequently, a 1:1 ratio present at the site of infection. This study suggests that TMP-SMX drug ratios different from that currently available may deserve studies in experimental models of PCP.

T.B.P.28 AIDS: THERAPY WITH PENTAMIDINE INDETHANATE IN MILD MODERATE CASES OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP).
Amann, Johannes*, Schneider, J.G., Mair, A., Schaefer, J.J., Weiss, M., L'ang, M.,
Kugler, Viktor-Hans-Hospital, FHO, Kaiserstrasse 275, D 800, Berlin 1.

Objective: To examine the effectiveness, side effects and pharmacokinetic data of aerosol therapy with Pentamidine.

Methods: Because of toxic side effects, Pentamidine isothionate by nebulization application can only be considered as a second choice in the therapy of PCP. In an open prospective multicenter study in 1988, ten patients with light to moderate cases of PCP were treated with aerosol therapy. The most important criteria for inclusion in this study were PaO2 over 40 mmHg and expiratory volume over 1.2 liters or 50% of the normal range. The histological diagnosis was supported by bronchoscopy. The patients received 300 mg of Pentamidine daily by inhalation (Respiogard 15) over a period of 21 days. Additionally, the Pentamidine dose in the blood and in 24-hour-urine samples were measured by a modified HPLC method. Controlled factors were blood count, blood sugar, lactate acid, and the laboratory results of the liver and kidney function.

Conclusion: For light to moderate cases of PCP, aerosol therapy with Pentamidine administered by the proper inhalation system presents an alternative to the formerly known methods. However, a 300 mg dosage appears too low. Further research is needed to determine the optimal dosage. **Results:** Eight out of ten patients were successfully treated, although complications were created by accompanying infections and intrapulmonary hemorrhages. The maximal Pentamidine level in the blood stayed in a range from 0.10-0.16 µg/ml. The secretion in the urine was found to be 0.11 - 0.53 µmol of the inhaled dosage. A cumulative effect did not occur. Contrary to the above mentioned method of nebulization application, no toxic side effects were found. Of the remaining two patients, one had an early relapse. The other had to be transferred to another form of therapy due to a secondary sepsis.

T.B.P.30 CLINDAMYCIN PLUS PRIMAQUINE AS PRIMARY THERAPY FOR PNEUMOCYSTIS CARINII (PCP) PNEUMONIA IN AIDS PATIENTS.
John, John L., Feinberg, J.E., Pan, R.P., Plouffe, J.F., Murphy, R.,
University of Maryland, Baltimore, IN "WILKIE AIDS Treatment Branch,
Lanning, G.S., Johns Hopkins University, Columbia Off., Northwestern University, Chicago, Ill.,
San Francisco General Hospital, San Francisco, CA, USA.

Objective: An open-blinded, pilot study to determine safety and efficacy of clindamycin and primaquine for treatment of mild to moderate PCP pneumonia in AIDS patients.
Methods: Histologically proven PCP pneumonia was required for entry. Patients were excluded if they had received prior antimicrobial therapy, if they had received a 4 week course of therapy if they had significant diarrhea, absolute granulocyte count (AGC) < 1000/mm³, platelet count < 100,000/mm³, Hg-A1c > 10, or if they had received clindamycin. Clindamycin 900 mg every 4 hours plus primaquine 30 mg orally per day was administered for the first 10 days. Clindamycin dosage was then decreased to 450 mg orally every 6 hours if patients met defined criteria for clinical response. Total duration of treatment was 21 days. Outcome was determined by a pneumonia scoring system incorporating fever, respiratory rate, oxygen, cough, chest x-ray, supplemental oxygen requirement and chest X-ray, and by change in A-a gradient. Blinically aerosolized pentamidine prophylaxis was begun 2 weeks after completing therapy. **Results:** All 8 patients entered to date showed marked improvement by the 7th day of therapy. Six patients completed treatment with clindamycin and primaquine and were cured. Two patients had received either trimethoprim-sulfamethoxazole or cotrimoxazole during the second week, one developed fever and rash, the other treatment, severe neutropenia (AGC of 300). Both were cured 1-2 weeks later. Additional minor side effects included mild neutropenia and mild methemoglobinemia. No relapse have yet occurred (none follow-up after treatment 1 week; none 1-2 weeks). All patients were cured. **Conclusion:** All improved clinically but failed to complete 21 days of treatment due to rash (2) or mild neutropenia development (1). **Conclusions:** Although further study is warranted, clindamycin and primaquine may represent an alternative therapy for PCP pneumonia in AIDS.

Session d'affichage Poster Session

Aspects cliniques Clinical Aspects of AIDS

T.B.P.31 CORRELATION BETWEEN ICU SURVIVAL AND REQUIRED CPAP/PEEP IN AIDS PATIENTS WITH PNEUMOCYSTIS CARINII PNEUMONIA
Bromberg, A.; Peruzzi, M.; Curtis, S.; Morphy, R.; Cass, J. & Shapiro, S.
Northwestern University, Chicago, IL, USA.

Objective: The survival of patients (pts) with Pneumocystis carinii pneumonia (PCP) and AIDS who require ICU admission and mechanical ventilation has been shown to be poor. This study was undertaken to determine the survival rates of pts with PCP treated with positive airway pressure (CPAP) by mask, CPAP by endotracheal tube, PEEP with mechanical ventilatory support.
Methods: The charts of all pts with PCP admitted to the ICU between 1985 and 1988 were reviewed retrospectively to determine patterns of survival and correlation between survival and treatment with CPAP/PEEP. The pts were treated by the same physician group using established protocols for airway pressure therapy to maintain adequate oxygenation.
Results: Preliminary data from 24 pts requiring CPAP/PEEP revealed that 6/24 (25%) were discharged from the ICU alive, and were ultimately discharged from the hospital. The highest CPAP/PEEP level needed to maintain adequate oxygenation was a mean of 15 ± 3.5 on B20 in survivors and 15 ± 4.5 on B20 in non-survivors. These differences are highly significant at $p < 0.001$ by chi square analysis.
Conclusions: The routinely used CPAP/PEEP to improve oxygenation in pts with PCP. The need for CPAP/PEEP of 15 or greater to create or to maintain acceptable oxygenation is associated with a significantly higher mortality in these pts. This is most likely related to a greater degree of lung involvement with pneumocystis in those requiring higher CPAP/PEEP levels.

T.B.P.33 PROSPECTIVE RANDOMIZED STUDY OF 100% O₂ VERSUS FRACTIONAL INSPIRED O₂ IN PNEUMOCYSTIS CARINII PNEUMONIA (PCP)
Mulliken, J.; Stewart, J.; Hooper, J.A.; Barwood, L.; Madhoo, T.; Lefkowitz, T.
*Marilyn Hospital, Rice, France.

In an open randomized study, 38 AIDS patients requiring low PEEP when arterial PO₂ were higher than 80 mm were treated for 21 days with 100% O₂ at 20/80 (n=21), or aerosolized antipseudomonas Penicillins (40 mg/kg) administered daily during 28 minutes with an ultrasonic nebulizer system (n=17). Patients were comparable in age (38.6 ± 36.5), first PCP episode, arterial PO₂ (51.4 ± 71.2), and clinical and biological severity.
Results:

	n/T	P	# Failures
Number of patients	15	15	
Treatment success	1	2	
Failures	14	13	n = 0.08
	(mean)	(range - 7)	
Therapy effectiveness (adverse reaction)	5	0	n = 0.02
Treatment success without addition of bet	5	0	
(steroid adverse reaction)			
Not re-evaluated after 48 h	0	1	

85 = not significant
Conclusions: In our study a higher number of failures in the P group occurred ($n = 0.08$), but as adverse patient reactions ($n = 0.02$). Number of cured patients without treatment effectiveness are statistically different for the 2 groups. Patients in 100% group experienced more adverse reactions ($n = 0.02$).

T.B.P.35 THE USE OF SURVIVORS IN THE THERAPY OF RESPIRATORY FAILURE COMPLICATING PNEUMOCYSTIS (PCP)
Schiff, R.J.; Hudes, R.; Smith, J.M.; Berg, J.
Hospital & Cornell University Medical College, Manhattan, N.Y., U.S.A.

Objective: We studied the effect of adjunct high dose corticosteroids in the treatment of 16 patients with AIDS and PCP resulting in respiratory failure.
Methods: Retrospective chart review of 16 patients with a PGO-60 on PEEP 5-6.0 and/or PGO-80 on RA.

Results: Steroids were given in a dose of 20-40 mg Methylprednisolone intravenously q8h for 7-10 days. 13 men and 3 women, ages 28-65 were studied. Risk factors included bronchitis (6), TV drug abuse (6) and 4 unknown. 4/16 were previously treated with Zidovudine at the time of admission. In 15/16 respiratory failure complicated the first episode of PCP. In 13/16 mechanical ventilation was required. 4/16 patients died without a response to steroids following respiratory failure. 5 responded and were alive and discharged at 3 weeks. Follow-up. 4 appeared to respond initially but died within 1 month, and 1 initially responded but remains unresponsive in the hospital. Of the 10 patients who appeared to respond, 6 halgases were defined as weaning chart 7 days and PCP either an initial or relapse was required. 4/16 patients died. **Conclusions:** Adjunct steroid initially helped reverse respiratory failure due to PCP in 80%. However, the 1/16 who were high and only 3/16 remained alive at 3 months survive. Last.

T.B.P.32 TREATMENT AND OUTCOME OF PNEUMOCYSTIS CARINII PNEUMONIA IN AIDS PATIENTS
Lindgren, W.S.D.; Pedersen, C.; Nielsen, T.
Department of Infectious Diseases, Hvidovre Hospital, Copenhagen, Denmark.

Objective: To evaluate the efficacy and safety of treating *Pneumocystis carinii* pneumonia (PCP) in AIDS patients.
Methods: Analysis of a standardized protocol from 75 consecutive HIV positive patients diagnosed of having PCP admitted to our department. Eighty nine episodes of PCP were recorded. 87% by histologic verification and 17% by clinical criteria. Chest x-ray of 13 (16%) patients taken since the episode were normal. Patients were treated with sulfadiazine-trimethoprim (ST) 800 mg b.i.d. plus oral dose of ST* 4800/960 mg, median duration 20 days and/or pentamidine (P) 300 mg b.i.d. plus oral dose of ST* 4800/960 mg, median duration 11 days. Two episodes of PCP were not treated. The ST and P regimens resulted both in about 50% objective side effect, but only 10% treated with ST and 20% treated with P had their treatment discontinued because of side effect. Of patients with primary PCP 7 (10%) patients died of PCP, 10% of patients with relapse of PCP. All secondary prophylaxis and 100% patients with recurrent episodes of PCP died during hospitalization. No patient who owed had a normal chest x-ray. Median of ST* 4800/960 mg, average followup time 261 days (range 1-512), compared to 11 (100%) patients who did not receive prophylaxis (average followup time 101 days) (p<0.0001). The survival time after 1 year study patients with primary PCP with the diagnosis made in 1985 (22 patients) and 1987 (39 patients) was 0.82 and 0.74, respectively. As opposed to 1.03 when diagnosed prior to 1985 (15 patients) (p<0.01). Seven (84%) of 11 patients requiring mechanical ventilation were discharged from the hospital. **Conclusions:** In most of our PCP patients, treatment with ST and P and secondary prophylaxis with ST is safe and effective. Controlled studies are needed to verify that ST is superior to treatment with ST and P. Furthermore, early diagnosis of PCP may improve the prognosis. Lastly, mechanical ventilation is a reasonable option when needed in patients with PCP.

T.B.P.34 THE BIOAVAILABILITY OF CO-TRIMOXAZOLE IN PATIENTS WITH AIDS RECEIVING THERAPY FOR PNEUMOCYSTIS CARINII PNEUMONIA
Wells, G.A.G.; Kapewee, M.; White, L.M.; Cairns, O.F. and Mwangi-Njenga, R.
*St. George's Hospital, London, U.K.
*Northcote Hospital, Bristol, U.K.

Objective: To investigate the bioavailability of co-trimoxazole in AIDS patients with normal and abnormal fat absorption.
Methods: Five HIV antibody positive males mean age 36 years (20-60 years), mean weight 60kg (40-70kg) receiving a mean dose of 1200mg/240mg co-trimoxazole for the treatment of P. carinii pneumonia were studied. Plasma concentration time profiles for trimethoprim (TMP) and sulphamethoxazole (SMX) were obtained during a 6 hour dosage interval after the same dose of co-trimoxazole given intravenously and orally.

Serum levels of TMP and SMX were measured using high performance liquid chromatography. Fat absorption was determined by the measurement of 100L in breath following ingestion of a test meal containing ¹⁴C triolein with 60g fat. Bioavailability was calculated using standard pharmacokinetic methods.
Results: The mean bioavailabilities of TMP and SMX in patients with fat malabsorption were 100 (±20%) and 71 (±10%) respectively. By comparison the mean bioavailabilities of TMP and SMX in patients with normal fat absorption were 90 (±40%) and 101 (±70%) respectively.

Conclusions: Pharmacy data suggest that in patients with AIDS oral and intravenous co-trimoxazole achieve similar serum TMP and SMX levels even in the presence of abnormalities of fat absorption.

T.B.P.36 DIAGNOSIS AND TREATMENT OF PNEUMOCYSTIS PNEUMONIA: A SURVEY OF OREGON AND VANCOUVER, WASHINGTON PHYSICIANS
SAMPSON, JAMES H. * SPENCE, CAROL JARE *
*GOOD SAMARITAN HOSPITAL AND MEDICAL CENTER, PORTLAND, OREGON, USA.

OBJECTIVE: To describe how physicians in the state of Oregon and Vancouver Island responded to questions regarding the diagnosis and treatment of pneumocystis pneumonia.

METHODS: Physicians were surveyed in the Portland area (including Vancouver) and the state of Oregon who were primary providers of care to those with AIDS. Physicians were offered \$20.00 payment for their time in filling out the survey. Forty five surveys were sent out with a three week return. **RESULTS:** Thirty four surveys were returned with a 76% response rate. The following were the results found. The top lab tests utilized at the initial evaluation were CBC and ABG. Induced sputum and bronchoalveolar were the primary methods used in the diagnostic workup. The contrastive test marker used in diagnosis was the abnormal chest X-ray. When requested about the initial therapy prior to diagnosis, 29% used TMP/SMX (17) with varying dosages, 25% used oral STS and 23% used Pentamidine (17). In the second survey of choice after failure or toxicity, 19% used TMP/SMX with 53% and Inhaled Pentamidine 15% of the respondents. Physicians used Inhaled Pentamidine as 45% for maintenance therapy, with 20% using TMP/SMX. Only 20% of the respondents did prophylactic treatment. Universal criteria for prophylactic treatment was CD 4 < 200. Overall the physicians had seen approximately 644 patients with the majority seeing 10-20pc. **CONCLUSIONS:** We will use the data to educate involved physicians in treatment.

Session d'affichage Poster Session

T.B.P.43 HIGH RATES OF RESISTANT PNEUMOCOCCUS PNEUMONIAE AND SUSCEPTIBILITY TO AIDS PATIENTS TAKING PENTAMIDINE-ISOXANTHINE PROPHYLAXIS. Miller, Leoni, Oles, D. Denver: Denver General Hospital (DGH), Denver, CO, USA.

Objective: To evaluate occurrence rates of Pneumococcus pneumoniae (PCP) and susceptibility to AIDS patients (pts) receiving pentamidine-isoxanthine (P-I) for secondary prophylaxis of Kaposi's Sarcoma (KS). A retrospective analysis was done of all pts at DGH AIDS Clinic who received P-I from March 1987 through December 1988. All patients had AIDS and at least one episode of PCP prior to initiation of P-I, and were on variable doses of zalcitabine (ZC).
Results: There were 38 pts who received both ZC and P-I (1 tablet weekly) from 0.5 to 22 mg (mean 7.6 mg). They were followed for 3 to 16 mos (mean 10.5 mos) from time of first episode of PCP. Four pts were lost to follow-up, 2 were uncompliant, and 2 had non-PCP related deaths while taking P-I. Of the remaining 30, 16(53%) had recurrent PCP, 14 (47%) discontinued P-I due to adverse reactions, 3 discontinued P-I to receive another form of prophylaxis, and 4 remained on P-I. Adverse reactions included maculopapular rash (4), Stevens-Johnson syndrome (2), hemolytic anemia (2), clostridial linear fasciitis (2), and cellulitis (1). The 3 pts who developed PCP took P-I for 4-12 mos (mean 7.4 mos), and recurrence occurred 0-11 mo (mean 5.8 mo) after their first episode of PCP. Eight pts had three or more disease states, and 1 had pneumoniae PCP, 7 received hospitalizations, 0 of the 16 who discontinued P-I for adverse reactions or uncompliance, 5 developed recurrent PCP 1-7 months after discontinuation, none of these received another form of PCP prophylaxis.
Conclusion: Recurrence rates of PCP in pts taking P-I (53%) were higher than those reported previously and P-I was poorly tolerated, requiring discontinuation in an additional 28% of evaluable pts. High treatment toxicity developed in 16% (Stevens-Johnson Syndrome). Overall, prophylaxis trials are necessary to establish the most effective and least toxic regimen(s) for prophylaxis of PCP in AIDS.

T.B.P.45 SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINII PNEUMONIA WITH SYSTEMIC PENTAMIDINE. Winslow, Dean*, Binca, A.; Lincoln, P.; Smolka, H. and To Young.

*Medical Center of Delaware, Wilmington, DE, USA.

Objective: To determine the efficacy of intermittent systemic pentamidine for secondary prophylaxis of PCP in AIDS.
Methods: Since January 1987, all patients with histologically-confirmed PCP who gave consent and had adequate peripheral venous access were acutely treated with a 21 day course of either TMP/SMX or pentamidine, then given pentamidine 4 mg/kg IV weekly x 4, then 4 mg/kg IV every 4 weeks. Most patients also received zidovudine concomitantly with maintenance pentamidine. Results: Eighteen patients were followed for a mean of 8.5 months to date (range 2-23 months). Three episodes of PCP occurred, but all were mild cases, none of which required ventilatory support. No deaths from secondary cases of PCP have occurred to date. Glucose intolerance developed in one patient after a 21 day course of daily pentamidine followed by 2 months of 4 mg/kg weekly treatment.
Conclusion: Secondary prophylaxis of PCP with systemic pentamidine is effective in preventing mortality from recurrent pneumocystis pneumonia. Larger prospective studies should be done to optimize pentamidine dose and compare this modality to other PCP prophylactic regimens.

T.B.P.47 UTILISATION DE FANERDINE POUR LA PREVENANCE DE LA PNEUMOCOCCOSE ET DE LA TOXOPLASMOSE.

LIVREROZ Jean-Michel, MORILLAS R. A., GARDIN J.P.**, GARDIN J. A., CHATELAIN J.L., et TOUSSAINT J.L.***
*HOPITAL H. BERRIOT, PAV. S, PLACE D'ARNOVA, 69437 LYON Cedex 03
**CENTRE HOSPITALIER, 69008 LYON, FRANCE

Objectif: Evaluer l'efficacité de l'association sulfadoxime-pyriméthamine (Faneridine) en prophylaxie primaire de la pneumococcose et de la toxoplasmose chez des patients atteints par le SIDA.
Méthodes: 42 sujets (39 hommes et trois femmes) ont reçu 3 comprimés de Faneridine sous les quinze jours et une supplémentation en acide folique (Méthylotétrahydrofolate) 5 mg par jour ou Landeroline 50 mg 1 capsule par ou une fois par semaine). Ces patients avaient un taux de lymphocytes T4 inférieur à 200/mm³ et n'étaient pas en traitement par la ZDV.
Résultats: 42 sujets (39 hommes et trois femmes) ont reçu 3 comprimés de Faneridine sous les quinze jours et une supplémentation en acide folique (Méthylotétrahydrofolate) 5 mg par jour ou Landeroline 50 mg 1 capsule par ou une fois par semaine). Ces patients avaient un taux de lymphocytes T4 inférieur à 200/mm³ et n'étaient pas en traitement par la ZDV.
Conclusion: La tolérance et l'efficacité de la prophylaxie primaire de la pneumococcose et de la toxoplasmose par la Faneridine associée à la ZDV a été comparée sous les 15 jours, meilleurs que celle rapportée dans les études antérieures réalisées à des posologies différentes.

T.B.P.44 PRIMARY VERSUS SECONDARY PCP PROPHYLAXIS. Davkin, M.; Roy, J.; Mich, Arroy, Lucas, C.R., Fairfax: Infectious Diseases Hospital, Melbourne, Victoria, Australia.

Objective: To compare the efficacy of primary and secondary PCP prophylaxis. From November 1986, all patients whose CD4 cell count fell below 200/mm³ or who developed an AIDS defining illness (ADI) other than PCP, were offered primary (1^o) prophylaxis with either Depoone 100mg twice weekly, sulfadoxime-pyrimethamine one tablet weekly, or retailed pentamidine 400mg once weekly. Secondary prophylaxis was given to all patients following treatment for their first episode of PCP. One of the above agents or TMP-SMX one bid was used. All but 8 patients received AZT during the study period. Side-effects of the study were PCP, or death. Follow-up continued to December 1989.
Results: 107 pts received 1^o prophylaxis and 93 pts received 2^o prophylaxis.

Depoone	25/81 (31%)	19/48 (40%)
Sulfadoxime/pyrimethamine	2/18 (11%)	6/14 (43%)
Pentamidine	1/8 (13%)	1/20 (5%)
TMP-SMX	0	2/12 (17%)
Death	29/107 (27%)	26/93 (28%)
Mean time to PCP	8,9±6,7 mths	9,4±6,7 mths
Mean PCP-free interval	10,9±1,2 mths	7,4±1,7 mths
Deaths	10	9
Toxicity	13	9

Conclusion: There was no difference in efficacy of primary versus secondary prophylaxis for PCP.

T.B.P.46 CLINICAL AND PHARMACOKINETIC INTERACTIONS OF COMBINED ZIDOVUDINE (ZDV) THERAPY AND SULFADOXIME-PYRIMETHAMINE (FANERDIN) PROPHYLAXIS IN PCP-PCP PATIENTS (MCMC).

Harsh, W.D., Heston, R., Hanson, R., Fan, H., Rosenberg, J., Link, of Calif., Los Angeles, Los Angeles, CA, USA, New York Univ, NY, USA, Children's Hospital, Los Angeles, CA, USA, Univ. of Texas Health Science Center, Dallas, TX, USA, MAAD AIDS Treatment Program, Bethesda, MD, USA.

Objective: Combination anti-retroviral and PCP prophylactic therapy are commonly used in HIV-infected patients. Potential clinical and pharmacokinetic interactions of combined ZDV and secondary PCP prophylactic therapies are investigated in this study. Data from the ZDV/Faneridin cohort are reported.
Methods: 30 AIDS patients received from an initial episode of PCP an randomized schedule to receive ZDV (200 mg q 6h) plus either TMP-SMX (100 mg q 6h) or Faneridin (1 tablet) or zalcitabine (150 mg q 2w). Intensive clinical, biochemical, hematologic, and pharmacokinetic parameters are followed for one year. Among 8 patients receiving ZDV/Faneridin, no significant clinical (especially rash), hematologic, biochemical abnormalities have developed nor PCP recurrence over a mean 16 week (range 8-24 weeks) follow-up period. ZDV pharmacokinetic analyses have shown a prolongation in time to peak ZDV concentration from 0.8 hr, to 2.8 hr, and an increase in $t_{1/2}$ from 1.0 hr to 2.0 hr following the addition of Faneridin in 3 of 5 patients. Steady state ZDV plasma has increased from 0.6-0.8 uM to 4.8 uM after 6 weeks of combined therapy in 5 patients as well.
Conclusion: These data indicate that ZDV and Faneridin are clinically well-tolerated and effective but dosage adjustment may be necessary due to possible pharmacokinetic interaction of the 2 drugs over time.

T.B.P.48 PYRIMETHAMINE-SULFADOXIME IN THE PROPHYLAXIS OF PNEUMOCOCCUS CARINII PNEUMONIA IN AIDS PATIENTS WITH CEREBRAL TOXOPLASMOSES

Pierone, Gerald; Duric, G., Masel, J., and Nicholas, P. N. Sinai School of Medicine, Elmhurst Hospital Center, Elmhurst, N.Y., U.S.A.

Objective: To determine if maintenance therapy with sulfadoxime-pyrimethamine (SP) in patients with central nervous system toxoplasmosis (TSM) and the acquired immunodeficiency syndrome (AIDS) is effective in the prophylaxis of Pneumocystis carinii pneumonia (PCP) and if such patients require additional preventive therapy.
Methods: We reviewed the records of patients maintained on SP following an initial episode of TSM. The diagnosis of TSM was established by the presence of typical ring-enhancing lesions on brain CT scan and clinical and radiographic responses to therapy with SP in patients at high-risk for HIV infection.
Results: 20 patients who had received at least 3 months of SP, including 3 who had had previous or coincident PCP, were identified. The dosage of sulfadoxime ranged from 2-6 grams per day, pyrimethamine 25-50 mg per day. Zidovudine was also administered to 6 patients (31 patient-months). During 162 patient-months of follow-up, none of the patients developed PCP (mean 8.1 months, range 3-20 months).
Conclusion: Maintenance therapy with SP provides effective prophylaxis of PCP in patients with AIDS.

Prophylaxie par la pentamidine Prophylaxis with Pentamidine

T.B.P.49 PREVENTION DES RECHUTES DE PNEUMOCYSTE PNEUMONIAE PAR LES AEROSOLS DE PENTAMIDINE - ETUDE PROSPECTIVE RANDOMISEE CHEZ LES PATIENTS SIDA TRAITES PAR AZT

Dirigeants: J. Lavielle, R. Gaudouet, C. Lapeyre, A. Michon, C. Semail, AG*
*Niphal Roche, *Cadea Biomed, *ROCHEM UN, *Teva Paris, France

Objectif: Evaluer l'efficacité et la tolérance des aérosols de Pentamidine (APM) dans la prévention des rechutes de pneumocystose (PCP).

Patients et méthodes: 51 patients ayant présenté une PCP récente (moins de 5 mois) et ne recevant pas de prophylaxie anti-Pneumocystis ont été randomisés: Groupe 1: AZT plus APM; Groupe 2: AZT seul. Les APM ont été délivrés tous les 15 jours le 1er mois puis tous les mois à la dose de 4 mg/kg par un appareil ultrasonique. Les doses initiales d'AZT (1200 mg) étaient adaptées selon les données hématologiques.

Résultats: Les deux groupes étaient bien comparés sur les critères démographiques de la gravité du déficit immunitaire et du suivi de l'AZT. Parmi 48 patients évaluables, le nombre de rechutes après un seul mois de traitement fut de 222 (5) dans le Groupe 1 et de 1628 (81) dans le Groupe 2. L'aucune réaction indésirable spécifique n'est survenue. Les principaux effets secondaires étaient la toux (41%) et une gêne respiratoire au décours de l'inhalation (2%), conduisant à un arrêt de traitement.

Conclusions: 1) Les rechutes de PCP sont fréquentes chez des patients traités par AZT. 2) Les aérosols de Pentamidine diminuent le risque de PCP. 3) L'irritation bronchique est le principal effet secondaire observé.

Aspects cliniques Clinical Aspects of AIDS

T.B.P.50 COMPLIANCE AND LABORATORY DATA PREDICT RELAPSE RATE OF PNEUMOCYSTIS CARINI PNEUMONIAE DURING PROPHYLAXIS WITH AEROSOL PENTAMIDINE

Dirigeants: W. K. Laidlaw, R. J. Spinks, R. J. Galloway, W. and L. Lohy, R. Department of Medicine, University Hospital, Zurich, Switzerland.

Objectif: To assess the effect of patients' compliance during pentamidine prophylaxis (PX) and of laboratory data during the initial PCP episode on PCP relapse rate (PCPR).
Méthodes: The laboratory courses of all 48 AIDS patients treated with aerosol pentamidine (60 mg every 2 weeks) for PX of PCPR and the laboratory data during the initial PCP episode were retrospectively analyzed. Laboratory courses for lymphocyte subpopulations and serum lactate dehydrogenase (LDH) were available for 30 patients. All PCPR were recorded. Patients who missed ≥ 3 inhalations and at least 15% of all scheduled doses were stratified into the non-compliant Group A, all others into the compliant Group B. Results: Mean duration of pentamidine prophylaxis was 32 weeks (range 2-77 weeks). During the period 50 PCPR occurred (24 per 100 patient-months). Two of these were fatal. Only 15 patients had 100% compliance. Two patients missed a second PCP, both after repeated PCP non-compliance.

Group Patients Initial PCPR: Mean LDH: PCPR: PCPR probability/1st year (95% CI):
A 14 5 284 units 65% (22%-95%) *p < 0.05 (66-86ab).
B 30 5 312 units 18% (5%-49%) *p < 0.05 (10-30ab, 10c).

Person-yr Aerosolized change: Initial PCPR relative risk for PCPR (non-compliant vs compliant):
% missed PX 10% up 1.5* (p < 0.05, multivariate Cox regression, 44 patients)
LDH units 20% down 2.1* **p < 0.05, multivariate Cox regression, 30 patients
LDH/10³ up 28% up

Conclusions: Poor compliance with prophylactic pentamidine inhalations leads to a significantly higher rate of PCPR. The laboratory values significantly associated with higher rates of PCPR were elevated levels of LDH and decreased levels of CD4 lymphocytes during the initial PCP episode.

T.B.P.51 SUCCESSFUL CHEMOPROPHYLAXIS OF PCP BY POSTURAL INHALATION AND LOW DOSE AEROSOLIZED PENTAMIDINE

Dirigeants: S. J. Rodgers, P. Serret, C. Mahony, J. Kelly, J. Kohn, J. D. Nalleva, National Jewish Medical Center, Denver, CO, USA.

OBJECTIVE: To evaluate the efficacy of low dose aerosolized pentamidine administered by postural inhalation. **METHODS:** 97 patients (25 AIDS/ 72 HIV PCP) 45 AIDS intolerant of sulfis drug PCP prophylaxis were followed for a median of 11 months (range 5-19). Pentamidine (leontin) was administered by nebulized nebulizer (1.5-3.5 micrometers) at a dose of 80 mg every 3 weeks via postural inhalation, i.e., in the supine and left and right lateral decubitus positions each for 10 minutes. These experiencing bronchospasm were subsequently prophylaxed with albuterol inhalant prior to each pentamidine administration. **RESULTS:** Of 97 patients followed at risk dose for a median of 11 months there were 3 episodes of PCP (AIDS, 2 AIDS). All 3 episodes were diffuse in nature and were successfully treated with TP pentamidine. All 3 episodes occurred in noncompliant patients who had missed 2 or more consecutive doses (accounting for a 3 week or greater interval between doses). There was no severe adverse reactions to the drug. Minor adverse effects included: cough (44/73), bronchospasm (14/145) and metallic taste (58/102). No episodes of PCP occurred in patients compliant with the protocol.

CONCLUSION: Postural inhalation may allow for improved efficacy and/or reduced dose of prophylactic aerosolized pentamidine. Controlled trials with larger numbers, more efficient nebulizers and of longer duration are indicated.

T.B.P.52 HIGH ADOLESCENT PENTAMIDINE PROPHYLAXIS IN AN INNER CITY POPULATION

Dirigeants: J. G. Johnson*, Hilson, R., Hendrix, J., Small, C.B., North Central Bronx Hospital/Portico Medical Center/Albert Einstein College of Medicine, Bronx, New York, U.S.A.

OBJECTIVE: To determine efficacy, tolerance and compliance (comp) with home aerosolized pentamidine (AP) prophylaxis in AIDS and AIDS patients (gp) of poor, minority and intravenous drug use background in a NYC clinic.
METHODS: Randomized instruction in the use of the Plicontin nebulizer (PN) and in the preparation of Pentamidine for aerosolization. Standardized dose was 60 mg, weekly for the first 4 weeks (wks) and biweekly thereafter. Evaluable pts were followed for 4 wks.

RESULTS: 12/16 were evaluable, 43 males, 13 females; 38 Hispanic, 17 black, 5 white. Mean age 36 (range 22-59). 30/50 (60%) T3, 13/58 (22%) intravenous partners, 15/28 (21%) homosexual, 1 (28) transfusion recipient, 2 (38) non-AIDS. Mean risk: 52/58 (90%) had AIDS; 46/58 (80%) status-post PCP; 6/58 (10%) had AIDS with low CD4 (mean 77). 6/58 (10%) had asthma. Pts were followed for a mean of 23 wks (range 4-44 wks). total 1307 pt wks. 57/58 (98%) were also on AZT. 9/58 (16%) developed PCP. All were noncomp with AP for at least 4 wks prior to PCP. Reasons for noncomp in the 9 pts included: drug use (3), AP-induced respiratory symptoms (1), fear of treatment (3), poor understanding of AP importance (2), 5/9 with PCP (56%) were also noncomp with AZT. Of 48 pts receiving AZT who did not develop PCP, 10 (21%) were comp with AZT. Of 48 AP pts: 4 (8%) were comp with >50% but <100% of AP Rx; 34 (71%) were comp with 100% of AP Rx. 4/48 (8%) were also noncomp with AZT.
CONCLUSION: Home AP by PN is a safe, effective method of PCP prophylaxis in an inner city population of primarily T3. AP comp was less than AZT comp.

T.B.P.53 LOW TONE SAFETY AND EFFECTIVENESS OF AEROSOL PENTAMIDINE FOR PREVENTION OF PNEUMOCYSTIS CARINI PNEUMONIA

Dirigeants: Edward J. Dickover, M.D.; Schmitz, R. and D. J. Armstrong. National Jewish Medical Center, New York, New York, U.S.A.

Objective: To determine the safety of aerosol pentamidine and its effectiveness in preventing PCP compared to historical controls.

Méthodes: Aerosol pentamidine administered weekly for four weeks and then biweekly at a dose of 60 mg via oral ultrasonic nebulizer (Fleisch). Toxicity was judged based on examinations, pulmonary function, hematologic, and biochemical tests. Efficacy was judged based on comparison of rates of PCP versus HAAD protocol, 0/2.

Results: A total of 266 patients were treated for 1-10 months (5.6 \pm 5.2 mos). Most were homosexual men; 902 had AIDS; 711 had a previous episode of PCP. At entry the mean time since diagnosis of AIDS was 11.7 \pm 10.1 mos. There were no serious adverse reactions and no systemic toxicity was seen; 14/21 of patients required a bronchodilator; 91% of patients had a stable or improving pulmonary function. There were 49 side-effects and 71 deaths. A total of 23 cases of PCP occurred; the occurrence rate was 3.81 among patients (<90%) with no previous episodes; it was 4.9% among those (132) with one episode; it was 25.4% among those (63) with two or more previous episodes. There were 6 pneumothoraces and 3 cases of extrapulmonary pneumocystosis. There was no historical control; there was a 16-fold reduction in the recurrence rate of PCP among patients who had one previous episode.

Conclusion: Aerosol pentamidine was safe and it prevented PCP. Higher or more frequent doses may be needed as immune deficiency progresses.

T.B.P.54 AEROSOLIZED PENTAMIDINE FOR THE SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINI PNEUMONIA IN THE ACQUIRED IMMUNODEFICIENCY SYNDROME: A REPORT FROM THE

CANADIAN COOPERATIVE TRIALS

Dirigeants: J. L. Fisher, J. P. Fisher, R. Sankh, A. Gorak, A. Ronald, P. McPadden, D. Pong, W. Taylor, G. Mack, A. Fisher, W. Laid, T. Chen, C. G. Henderson, K. G. Isaacs

OBJECTIVE: To evaluate the safety and effectiveness of aerosolized pentamidine for the secondary prophylaxis of *Pneumocystis carini pneumoniae* (PCP) in the acquired immunodeficiency syndrome (AIDS).

METHODS: Trial Design: randomized, double blind, placebo-controlled. Inclusion Criteria: (1) Recovered from first episode of AIDS-related PCP within 10-24 weeks; (2) No other AIDS defining opportunistic infection or active pulmonary pathology; (3) No antiretroviral or immunomodulating agents (except AZT) during the study; (4) CD4 counts within 300-500 cells/mm³; (5) No PCP in previous 12 months; (6) 40% of total FEV and corrected DLCO >10%. Exclusions: Patients were randomly allocated to receive pentamidine three times per week as placebo. The study drug was delivered as a least bid ultrasonic nebulizer (MAD-25.5-6, Aerogen) (depending on the clinic location) in a nebulized fashion over 15 to 20 minutes. Patients returned 5 days during the trial 14 days follow-up by one day every 2 weeks for a total of 26 weeks. Follow-up: Complete history, physical and laboratory evaluation including AZT were performed at regular intervals. All PCP medications were prescribed using PCP was documented.

RESULTS: 101 patients from 16 centers were randomized at the time the study was terminated. A total of 20 cases of PCP were diagnosed. 23 of these occurred in 20 (79%) placebo-treated patients while 6 occurred among the 84 patients receiving aerosolized pentamidine ($p < 0.0001$ Chi square). Median follow-up was not significantly different in both groups.

CONCLUSIONS: Aerosolized pentamidine is highly effective in the secondary prophylaxis of AIDS-related PCP.

Reported at a poster June 6, 1988.

T.B.P.55 PROPHYLACTIC INHALATION PENTAMIDINE IN PATIENTS WITH HIV DISEASE

Edouard A. A.; DiPaola, L.; St. L.E.M.; Rubinstein, D.*
*Stross Lebanon Hospital, Bronx, NY, USA.

Objective: To evaluate inhalation pentamidine in the prophylaxis of PCP in immunosuppressed HIV positive patients.
Method: We prospectively studied 46 HIV positive immunodeficient patients. 200 mg of pentamidine in 4 cc sterile water were delivered by inhalation every other week using an Aeroneo II apparatus. Three groups of patients were studied. 1. 10 HIV positive patients with a CD4 count less than 250 U/L and no history of PCP. 2. 17 HIV positive patients with a history of PCP but no tissue confirmation. 3. 27 HIV positive patients with histoplasmosis. PCP. **Results:** 46 patients were treated an average of 20.8 weeks. There were 5 episodes of presumed PCP. 19 patients were lost to follow-up. The overall recurrence rate was 13.2%. The results in each group are as follows:

Group	Average Treatment Time (Weeks)	Recurrences	Rate
1	2-30	0	0
2	4-3	1	16.7%
3	2-30	4	14.8%

All 5 of the patients who developed pneumonia were treated with anti-PCP therapy. 3 of these 5 patients died.
Conclusion: We note an overall recurrence rate of 13.2% in patients on aerosolized pentamidine which is below that reported for patients without prophylaxis. Although our numbers are small the study is ongoing. The fact that the majority of our patients were IVDA's and still followed the treatment protocol is encouraging.

T.B.P.57 ABSOLUTE PULMONARY DEPOSITION OF NEBULISED PENTAMIDINE ISETHIONATE

Richard Higgins; O'Donerty, M.; Page, C.; Berlow, D.; Croft, D. and Bateman, N.
St. Thomas' Hospital, London

Objective: To measure the absolute pulmonary deposition of two doses of pentamidine administered using two different nebuliser systems.
Methods: Following salbutamol pre-treatment, 8 patients with AIDS inhaled 50 and 150 mg pentamidine until with 37 MBq (10.5 mCi) ^{99m}Tc human serum albumin (HSA) volume 3 ml via two nebuliser systems. Series 22 Miser (S22M, Medigard UK) and Respigard (R11 Marquest) using gas flow of 6 l/min. Pulmonary and non-pulmonary (oropharyngeal and gastric) deposition was measured using a gamma camera and absolute deposition calculated using a correction derived from lung phantom studies. Spirometry was measured before and after salbutamol and after pentamidine inhalation and adverse effects were recorded.
Results: Absolute pulmonary pentamidine deposition (sqSDM) results are shown in the table:

Nebuliser Dose	S22M		R11	
	Both Lungs	R Lung	Both Lungs	R Lung
50 mg	2,740.42	1,469.22	1,530.31	0,829.15
150 mg	7,449.16	3,749.63	4,470.15	2,429.32

S22M delivered more drug to the lungs and in a shorter time, with over 90% deposited within 15 min. R11 produced less pulmonary, but non-pulmonary deposition and fewer adverse effects. Inhalation of 150 mg pentamidine produced small reductions in FEV1 with both S22M (16.2%, p<0.1) and R11 (7.3%, p<0.1).
Conclusion: Pulmonary pentamidine deposition was greatest using S22M but R11 was associated with fewer adverse effects.

T.B.P.59 PROPHYLACTIC TREATMENT WITH AEROSOL PENTAMIDINE TO PREVENT RELAPSE OF PCP

Bergin Bybo Jensen*, T. Nielsen*, B. Lerche*, V. Sacker*, L. Mathiesen*, P. Skjold*
*State University Hospital, Copenhagen;
**University Hospital, Hvidovre, Copenhagen, Denmark.

Objective: To evaluate the efficacy of aerosol pentamidine in the prophylaxis of PCP relapses.
Patients: 45 AIDS patients who had been prophylactically treated with aerosol pentamidine 60mg every 2 weeks, with an Acorn System 22. The patients had been on pentamidine prophylaxis for 1-2 months (1-4) before start of treatment. Time from AIDS diagnosis to start of prophylaxis was 1-22 months (mean 7.4).
Results: The patients were treated for 1-23 months (mean 8.4). No significant adverse reactions were seen. Falling patient compliance in 2 patients; were followed by relapses of PCP. Of the remaining 43 patients, 2 mild cases of PCP occurred after 8 respectively 9 months of treatment. One was clinically suspected, one histologically verified. The relapse rate of PCP per 100 patient months were 0.544 among patients treated.
Conclusion: Pentamidine aerosol seems to be effective as prophylaxis against relapse of PCP in this regimen. Only mild side effects were observed. A controlled study comparing aerosol pentamidine with co-trimoxazole is in progress.

T.B.P.56 A CLINICAL EXPERIENCE WITH AEROSOLIZED PENTAMIDINE (AP).

Ed Hjaltnings, H. Ferguson, RN Postle, JD
Jacobson & K. Robertson, Parkland Memorial Hospital,
Dallas, TX, USA.

Since 4/22/88 we have treated 308 HIV positive patients with AP 300 mg q month for 112 4/80 days. Four withdraw after 1 treatment because of cough treatments were otherwise uncomplicated. Serial pulmonary function tests in 26 patients before and after 6 months of treatment were:

Pre	94	86	113	20.2
FEV1 (l/min)	1.1	1.1	1.1	21.3
FVC (l)	2.1	2.1	2.1	21.3
P. 95	0.1	0.1	0.1	0.002

14 patients developed PCP while on AP. 1/99 with ARC or ODA <4000, 2/56 with AIDS but no prior PCP, and 11/155 with AIDS and prior of PCP. These 11 had had their last PCP an average of 422 (range 153-908) days before starting AP. 5/11 (45%) of the recurrent PCP episodes were fatal, and 2 were complicated by pneumothorax. For comparison, from 7/1-12/31/88 we saw 93 PCP cases in patients not on AP of which 12 (24%) were fatal and 2 were complicated by pneumothorax. Finally, 3/153 developed bacteremia that responded to antibiotic therapy.
Conclusion: This uncontrolled experience suggests that AP may reduce the frequency, but not the severity, of PCP in HIV positive patients. While AP was well tolerated and blood stable, a decrease in small airway flow (P923-75) appears to be a subclinical but statistically significant complication of therapy.

T.B.P.58 AEROSOL PENTAMIDINE FOR TREATMENT AND SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINII (PCP)

Fleming, LE; Haddad, S.; Weirin, E. and Prallier, T.
University of Lund, Dept. of Infectious Diseases, General Hospital, MALMG, Sweden.

Ten patients with PCP were treated with aerosol pentamidine 400 mg daily for 10 days followed by secondary prophylaxis of 400 mg once weekly. We used the nebulizer Visco MZ that produces particles <2 μ and has a residual volume of 0.2 ml. Monitoring for assessing effectiveness and side-effects included hemoglobin oxygen saturation during exercise, biochemical parameters, FEV1 and VC. Follow-up bronchoscopy was performed at least once after 3-6 days of secondary prophylaxis.
Results: 8/10 patients responded to therapy. 2 patients did not and were given Trimethoprim-sulfamethoxazole (TS) concomitantly. After improvement TS was discontinued and secondary prophylaxis continued. All patients were negative for pneumocystis at follow-up bronchoscopy. Neither clinical signs nor monitored parameters indicated any relapses. Three patients died after 6 weeks, 6 months and 17 months. At autopsy none of them had pneumocystis.
Conclusion: In our study aerosol pentamidine was effective for PCP in 8 of 10 patients. Controlled studies are needed to establish its role in the treatment of PCP. There is also a need to compare different nebulizers. In 10 patients given secondary prophylaxis we observed no relapses. We find this very encouraging. Despite the high dose given no adverse effects were observed besides light cough and complaints of unpleasant taste.

T.B.P.60 EFFICACY OF MONTHLY INTRAMUSCULAR PENTAMIDINE IN THE PROPHYLAXIS OF RECURRENT PNEUMOCYSTIS CARINII PRESENTING (PCP) IN PEOPLE WITH AIDS

Miller, Steven and Sifras, Dennis. HIV Clinic, Johannesburg Hospital, Johannesburg, South Africa.

Objective: To evaluate the efficacy of monthly intramuscular pentamidine in the prophylaxis of recurrent pneumocystis carinii pneumonia (PCP) in people with AIDS.
Method: Fifteen patients who have previously experienced at least one episode of PCP were enrolled in the study. Their ages ranged from 23 to 42 years. All had peripheral blood CD4 counts below 400/uL. These patients were receiving zidovudine 100mg daily, prophylaxis with cotrimoxazole was precluded in 10 patients because of hypersensitivity and 5 because of severe leucopenia. Pentamidine methanesulphonate (Methobid) 300 mg was administered as a monthly intramuscular injection. Patients were prospectively assessed for adverse effects and recurrences of PCP.
Results: Duration of pentamidine prophylaxis has ranged from 6 to 24 months and there has been no recurrence of PCP. Nine patients have died from other AIDS-related conditions since enrollment. Pain at the injection site for 24 to 48 hours was reported by all subjects. One patient developed a sterile abscess following the injection. Hypotension and hypoglycaemia were not documented.
Conclusions: 1) Monthly intramuscular pentamidine methanesulphonate provides effective prophylaxis for recurrent PCP. Side effects are generally minor. 2) Monthly intramuscular pentamidine is more cost effective than weekly aerosolized pentamidine. 3) Intramuscular pentamidine is easy to administer and should be considered where there are no facilities for nebulization.

T.B.P.61 PHARMACOKINETICS OF AEROSOLIZED PENTAMIDINE IN AIDS PATIENTS WITH HISTORIC OR ACUTE PNEUMONIA: THE CARIBBEAN EXPERIENCE

Yana J. Paulson, MD, Roy, M. Rosen, CT, Boylston, P. Gillman, Schools of Pharmacy and Medicine, University of Southern California, Los Angeles, California, U.S.A.

OBJECTIVE: To study the pharmacokinetics of aerosolized pentamidine in AIDS patients who are receiving treatment for mild episodes of Pneumocystis carinii pneumonia.

METHODS: Seven patients received investigational treatment with pentamidine (400 mc/day over 30 min) via the Respigard II nebulizer. Serial blood specimens were obtained from each patient on 3 occasions (days 14, 21, and 28). Serum pentamidine concentrations were measured by high-pressure liquid chromatography.

RESULTS: Maximum concentrations were 14.4 ± 5.3 ng/ml in samples obtained 1 to 2 minutes after completion of the dose. The rate of disappearance from serum was rapid and serum concentrations were undetectable 48-60 minutes after each inhalation treatment. There was no difference in the magnitude of the peak concentrations between day 1, day 14, and day 21 of therapy.

CONCLUSION: No serum accumulation of the drug was noted over the 21 day period of therapy. Urine concentrations are needed to better characterize the pharmacokinetic parameters of inhaled pentamidine.

T.B.P.63 INHALED PENTAMIDINE AS PRIMARY PROPHYLAXIS IN A HIGH RISK GROUP: CONTROLLING EXPERIENCE

William J. Paulson, VJ, Rogopolsky, R. Rothman, P.J. Scarsella, Hill, E. Popoff, C.I., Hill, S.I. Boylston, CT, Los Angeles, CA, 90033, U.S.A.

We have given inhaled pentamidine prophylaxis to 250 patients who are in a high risk group for PCP with T₄ counts below 400. These patients have received 150mg of inhaled pentamidine bi-weekly from 6 months to 21 months. None of the patients have developed pneumocystis pneumonia in this time interval. None of the patients have developed hypoglycemia, impaired renal function, or pancreatitis from their prophylaxis. Serum pentamidine studies have been obtained at periodic intervals and no deterioration has been seen in spirometric values. No pneumothoraces have developed in this group. We conclude that primary prophylaxis with inhaled pentamidine in this high risk group appears to offer significant promise without apparent risk. We believe that further controlled studies of primary prophylaxis urgently need to be done in these seriously immunocompromised patients.

T.B.P.65 EFFECT OF AEROSOL CHARACTERISTICS ON PULMONARY DEPOSITION OF PENTAMIDINE

Hymed, Anita; Newman, S.; Johnson, M.; Talbot, M.; Lee, C.; Clarke, S. Royal Free Hospital, London, UK.

OBJECTIVE: An evaluation of pulmonary delivery of aerosol pentamidine relating alveolar deposition and side effects to droplet size profile of nebuliser.

Methods: In a single blind crossover study, 9 patients with AIDS and stable respiratory status received 150 mg redispensed pentamidine (Acorn System A) Respigard II nebuliser (Marquest) B) Respigard II nebuliser with inspiratory baffin removed and C) Acorn System Z nebuliser (Medic Aid). In 6 patients an Acorn nebuliser modified by addition of an inspiratory baffin (one-way valve inserted, Inter-Surgical) was studied (D). Alveolar deposition (24 hour whole lung retention of radioactivity), incidence of cough and breathlessness and pulmonary function were assessed. Droplet size profiles from the nebuliser systems A-D were characterised and expressed as 1) droplet size $\leq 2 \mu$ (P2), mass median diameter (MMD) and mass median droplet size (d₅₀). **Results:** Droplet size profiles (P2, MMD, d₅₀) were A) 78.9, 1.0 μ m, 4.9 μ m, B) 30.5, 1.7 μ m, 19.1 μ m, C) 39.4, 3.4 μ m, 23.3 μ m (SD) D) 22.1, 1.0 μ m, 8.0 μ m. Alveolar deposition was directly related to P2 and incidence of cough and breathlessness proportional to d₅₀. Insertion of an inspiratory baffin into the Acorn System (D) markedly improved alveolar deposition of pentamidine and reduced adverse airway effects.

Conclusion: Optimisation of droplet size profile from nebulisers can enhance alveolar targeting of pentamidine.

T.B.P.62 COMBINED STUDY OF THE EFFICACY OF INHALED PENTAMIDINE ON THE PREVENTION OF PNEUMOCYSTIS CARINII PNEUMONIA - CONTINUING EXPERIENCE

William J. Paulson, VJ, Rogopolsky, R. Rothman, P.J. Scarsella, Hill, E. Popoff, C.I., Hill, S.I. Boylston, CT, Los Angeles, CA, 90033, U.S.A.

Of the 150 patients receiving inhaled pentamidine prophylaxis to prevent Pneumocystis carinii pneumonia (PCP) reported last year, 58 are now deceased. None of these patients died of PCP. Four patients have had recurrent PCP. Those who have developed recurrent PCP have tended to have multiple mild episodes. All patients have developed pneumothoraces while on this regimen, all after having at least one episode of PCP. Two of these patients required surgical intervention. None of the patients have developed clinically significant side effects from the inhaled pentamidine such as hypoglycemia, pancreatitis, or impairment of renal function. Serial spirometric determinations have shown no deterioration during the course of prophylaxis, although some of the patients did show self-limited deterioration in pulmonary function during acute infectious exacerbations. We conclude that inhaled pentamidine is effective prophylaxis in preventing recurrent PCP.

T.B.P.64 COMPARISON OF NEBULISER EFFICIENCY FOR AEROSOLISING PENTAMIDINE

Smith, Ron; Watkins, D.; Steele, J.; Hills, D.; Cassard, B.C. St. Stephen's Hospital, London, England.

OBJECTIVE: To determine which is the most efficient nebuliser system when used to aerosolise 300mg of Pentamidine Isethionate (Key & Bate Ltd.) in terms of droplet size, aerosol output and nebulisation time.

Methods: The following brands of nebuliser were assessed: Acorn System-21 (Medic-Aid Ltd.) with and without Miser attachment, Respigard II (Marquest Medical Products) and Finneab (Finsons Corp.). Four models of each brand of jet nebuliser were tested at flow rates of 8L/min. The Finneab was tested at maximum setting. Droplet size was assessed using a Malvern Instruments 2400SD laser particle and droplet analyser - aerosol output was assessed by spectrophotometry of solution remaining within the nebuliser. The nebulisation time was also recorded.

Results:

Brand	Flow rate	mg/min	% $\leq 5\mu$	Amount $\leq 5\mu$	Wet time(min)
ACORN	8L/min	2.5	74.6%	143.6mg	15.5
ACORN-MISER	8L/min	3.9	63.1%	ND	ND
RESPIGARD II	8L/min	1.2	96.3%	127.3mg	18.2
FINNEAB	-	4.7	56.3%	82.7mg	4.0

Conclusions: The Respigard II nebulisers produced the greatest amount of small droplets but aerosolised the least amount of drug. The Acorn aerosolised the largest amount of drug of sufficient droplet size to achieve alveolar deposition.

T.B.P.66 LOW PCP RELAPSE RATE USING HIGH DOSE (300MG) NEBULIZED PENTAMIDINE PROPHYLAXIS BUT A HIGH RATE OF OTHER COMPLICATIONS

Don, S. Smith, D. Hird, P. Marquest, B.C. GAZARD, ST STEPHEN'S HOSPITAL, FULHAM ROAD, LONDON, ENGLAND.

OBJECTIVE: To assess the effectiveness of high dose Nebulized Pentamidine on Pneumocystis Carinii Pneumonia (PCP) incidence and whether preventing PCP affects the long term survival in AIDS patients.

Methods: 29 patients received 300mg pentamidine fortnightly on a primary or secondary prophylactic basis over an 18 month period. The number of episodes of PCP and number of deaths from HIV were recorded over this period.

RESULTS: Of all patients on primary prophylaxis, no episodes of PCP and 1 death were seen (average follow up 4.0 months). Of 27 patients on secondary prophylaxis, only one episode of PCP occurred (average follow up 6.1 months). However, of 28 patients who received greater than six months prophylaxis post PCP over a maximum follow up period of 18 months, 11 (39%) died of other AIDS complications. Average time to death was 6.6 months (range 2-16) after their pneumonia. None of the deaths were caused by PCP.

CONCLUSION: Although Nebulized Pentamidine at a dose of 300mg/fortnightly is highly effective at preventing PCP, mortality rate post PCP still remains very high.

Aspects cliniques Clinical Aspects of AIDS

T.B.P.73 Nebulized Pentamidine in the primary and secondary Prophylaxis of PCP
 S. Zuckerman, S. Oswald, J. Gottstein, A. Rehm, S. Miller R. Shalita, K.H. Nalin E.S. Unterwaldt, Frankfurt, Zentrum der Infektions-Medizin, Infektions-Ambulanz, FGO. Although AZT significantly prolongs the survival time after the first PCP episode in the study, maintenance dose of opportunistic infections (OI) principally, of AIDS patients treated with AZT in Frankfurt, 32 (17%) developed PCP. In 12 cases, PCP first occurred under AZT. PCP is the most common OI also under AZT, as a consequence, PCP prophylaxis, aimed at preventing or reducing the occurrence of PCP, is required. We therefore perform an open study to assess efficacy and tolerance of nebulized pentamidine as primary or secondary PCP prophylaxis. One group of patients additionally gets Fansidar 2 tablets/wk as CMV-toxoplasmosis prophylaxis. Pentamidine loading dose is 200mg on 4 or 5 dosing days, maintenance dose is 200mg every 2 weeks, nebulized with Respigard II. Up to now, 63 patients have enrolled in the study, 30 of them had PCP prior to pentamidine prophylaxis. Indication for inhalation prophylaxis was a T4 cell count <150/ μ l and AZT treatment. Results: After a median observation time of 230 days, no patient under pentamidine developed PCP. 20 patients developing PCP during this period received also pentamidine. In the mentioned dosage, the agent was well tolerated, systemic side effects were not observed, however heavy cough. 2 patients additionally needed a broncho-dilator.

T.B.P.75 PROPHYLAXIS FOR PNEUMOCYSTIS CARINII (PCPN) WITH AEROSOL PENTAMIDINE (AP) OR ORAL BISMUTH (OB) IN PATIENTS WITH AIDS OR SEVERE AEC.
 Sings R. Irtong, Nulsara N. Serey, S. Garcia, S. Naranjo, R. Chanté E. et al. St. Vincent Hospital, Los Angeles, CA, U.S.A.

Objective: To evaluate and compare the efficacy and toxicity of AP and OB in the prophylaxis for PCPN in patients with AIDS or severe AEC.
Methods: Between March 1987, 143 patients were enrolled and randomized for the treatment group: AP (150mg every 2 weeks, well-tolerated oral preparation with a minimum inhibitory concentration, 100-150 μ g/ml) or OB (320mg bid, severe AEC). Randomization was stratified into groups with prior PCP (n=70), no previous PCP (n=73), severe AEC. Baseline data of historical controls is approximately 10% at 6 weeks.

Results: Mean length of follow-up was 36 weeks in AP and 26 weeks in OB. Of 118 patients randomized, 62 were on AP and 56 on OB. 28 patients became colonized, were lost to follow-up or expired prior to the first 6-month analysis. Ninety percent of patients in each group were on AZT. Baseline values were not significantly different for either drug in any group. Fisher's exact test: p=0.20.

Baseline Data	AP		OB		p	
	n	%	n	%	<0.05	>0.05
AP	62	53	56	50	0.01	0.15
OB	56	47	62	55		

Conclusion: Prophylaxis were similar in both groups and improvement in diffusion capacity occurred in 82% (AP) and 88% (OB) after 6 months. Development occurred in 12% patients on AP, and much higher dissemination of it, occurred in 7.5% of patients on OB.

Significance: Oral Bismuth and nebulized pentamidine are both effective prophylactic agents for PCPN with similar rates of response and low rates of complications.

T.B.P.77 AZT-AEROSOL PENTAMIDINE vs AZT ALONE IN LONG TERM AIDS SURVIVORS: A RETROSPECTIVE CASE-CONTROL SURVIVAL ANALYSIS. D.D. Hightsmith, DM. Founders, BU Pergamun, 23 J. Infect. Dis. Hospital, Baltimore, VA, USA.

43 of our 609 AIDS patients (4 had PCP, 3) survived >365 days after PCP, 3) received AZT, and 4) were started on aerosol pentamidine (AP), 300 mg q month, >365 days after PCP. Each was matched to a matched control group of 41 patients who fit 1) b), and c), but never received AP. Potential controls were all controls who had survived at least 365 days at the case had survived before the case began AP; the control chosen was the one whose last PCP date was closest to that of the case. Case survival was calculated from the day AP was begun. Control survival was calculated from the day after PCP its matched case was begun on AP. We began AP in June 1988 and offered it to all AIDS patients thereafter. No other factor appeared to influence which of our patients became cases and which controls. 15 cases survived > controls, 4 controls survived > cases, and 10 cases censored values made survival indeterminate (chi-square 14.4, p<0.01). Actuarial survival on AP of the cases was 87% at 60 and 82% at 180 days vs 82% at 90 and 10% at 180 days for the controls (chi-square 10.6, p<0.01).

Within the limits of the retrospective case-control method, the data suggest that AP can significantly prolong life in AIDS patients on AZT who have survived an episode of PCP by > 1 year.

T.B.P.74 EFFICACIA E SICURETÀ DELLA FROFILASSIA CON PENTAMIDINE PAR AEROSOL, IN CASI DI TOCCAZIONE E.V. ITALIANE ATTEINTE DI SIDA, IN TERAPIA CON ZIDOVUDINE.

Orsi R., Quilici R., Veneri F., Sama A., Ghirelli G.L., Doria, Nucleare Infettivo, Antivirale e Sierologia, Ospedale S. Maria, Italy. **Obiettivo:** Profilassi delle primarie e ricorrenti di PCP con le tossicazioni sintomatiche.

Metodo: In marzo 1989 l'auspicio 10 pazienti tossicazioni sintomatiche di SIDA sottoposti al profilassi per aerosol di pentamidine in trattamento stabilizzato, 6 pazienti con comorbo dopo più di 12 mesi, 1 paziente sott'attacco per una primarie crisi di PCP su 47 anni di profilassi, 8 pazienti con trattamento l'auspicio 10 dopo 2-6 mesi, 1 paziente a seguito la profilassi prima di un attacco (da dove viene il risultato che tra i pazienti sott'attacco non si osservò il danno di 100/200 mg/die. L'insediarsi con pentamidine e la profilassi una epistola di PCP. La pentamidine era somministrata a dosaggio di 2 mg/kg/epistola, nei aerosol sotto l'auspicio al corso di 6 giorni, solo, in tutto annuale.

Conclusioni: La PCP arriva dopo il corso di 60% dei pazienti sott'attacco di SIDA. Dopo le pazienti sono profilassi on cruiti e' nelle storie da 10-40% dei pazienti dove le profilassi di 2 mesi dopo la primarie crisi di PCP, l'efficacia e' la sicurezza di la pentamidine per aerosol, a dosi proscritte. Le controindicazioni più gravi sono le puzze che da noi si ha ed le reazioni. Delle norme di distribuzione epistola l'aggiustazione dei aerosol individuali. Sono in ricerca risultati da un altro studio che si può dire essere conclusivo, si costruisce o si descrive il caso. Durante un'esperienza più estesa di PCP, sotto dei primarie epistola, sott'attacco ricorrente da le tossicazioni sintomatiche di SIDA.

T.B.P.76 PNEUMOTHORAX IN PATIENTS RECEIVING AEROSOL PENTAMIDINE FOR PNEUMOCYSTIS CARINII PNEUMONIA PROPHYLAXIS.

Lanning, Clifford S., Wandler, L., Montgomery, A.R.,*; Abensur, D.J., Fogel, D.M.,* and the SCLC Community Consortium.

*Department of Medicine, San Francisco General Hospital, Univ. of California, SF; ** SUNY at Stony Brook, NY, U.S.A.

Objective: To determine the incidence of pneumothorax in patients on aerosol pentamidine for prophylaxis against *Pneumocystis carinii* pneumonia (PCP) in high risk HIV infected patients. **Methods:** 409 patients were randomized to treatment with either 30mg qwk, 150mg qwk or 300mg qwk of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.6 μ m). Pneumothorax was prospectively documented as a complication of aerosol pentamidine (AP) stratified into groups: prior PCP (PCP, n=264), Kaposi's Sarcoma (KS, n=102) or ARC and other AIDS diagnoses (O, n=116). T.B.P.85 MONITORING THE ACCURACY OF THE TOTAL LYMPHOCYTE COUNT TO IMPROVE THE ABSOLUTE CD4 COUNT

Anderson, Robert E., Hirschhorn, D., and Edmondson, S.,**
Wife, Inc.,
Fresno, CA, USA; *Mérieux-Turner Corporation, Mountain
View, CA, USA.

Objective: To improve the accuracy of the total lymphocyte count, a key part of the absolute CD4 lymphocyte count.
Methods: The white cell differential was determined using the Becton Dickinson FACScan with Simulast Software and Simulast Reagents (SD), microscopically on Wright-Giemsa stained smears (smear), and by electronic impedance on the Coulter-Turner Cell Dyn 2000 (SQ) on a citrate-based HIV positive population.

Results: 80 lymphocyte percentages were lowered when additional wash steps, vortex mixing, or aggressive aspiration (Asp) was used in cell preparation.
Mean \pm SD:

Mean \pm SD	WASH	NO-WASH	NO-ASP		
Wash/Total/Asp	34.1	26.2	35.2	1.1 (3.1)	9.6 (25.8)
Wortc/Asp	36.2	33.8	39.2	3.0 (7.8)	5.4 (11.7)
Settler	37.9	37.4	39.4	1.7 (4.3)	2.0 (5.1)

Twenty-one room-temperature ASD whole blood samples held for 0, 24 and 48 hours gave a mean \pm SD of 36.8, 34.9 and 37.3 respectively compared with 34.8 for EDTA.

Conclusion: With best technique, lymphocyte percentages from the FACScan, impedance, and smear methods are comparable. Monitoring all three methods assures good recovery from lymphocyte preparation methods. If processing delays occur, ASD is a superior anticoagulant for lymphocyte phenotyping.

T.B.P.87 FLOW CYTOMETRIC METHODS FOR HIV SEROLOGY AND ANTIGEN QUANTITATION USING RECOMBINANT HIV ENVELOPE (ENV-9) PROTEIN

Campbell, D., Gantsh, J., Gendron, T., Janney, K.,** Rife, S., Douglas, L.D.,
*University of Pennsylvania, Philadelphia, PA, USA. **E. Du Pont de Nemours & Co., Wilmington, DE, USA.

Objective: Flow cytometric (FC) methods were developed as potentially improved alternatives to enzyme-linked immunosorbent assays (ELISA) for the detection of HIV specific antibodies, and for the quantitation of HIV protein.

Methods: Recombinant HIV envelope (ENV-9) protein was covalently coupled to protein absorbent polystyrene microbeads by carbodiimide mediated reactions and served as the solid phase antigen for both the FC serologic assay and for the FC antigen competition assay. The primary antibody probe for both assays was affinity-purified, biotin-conjugated anti-human IgG, while the fluorescence probe was FITC-avidin.

Results: The evaluation of forty four human sera by FC and ELISA revealed a high level of correlation (coefficient of correlation = 0.876) between FC mean channel fluorescence and ELISA endpoint titer. The FC antigen competition assay detected less than 50 picograms of recombinant HIV envelope protein.

Conclusions: The results of the FC HIV antibody detection assay and the FC HIV antigen competition assay demonstrates the potential usefulness of flow cytometry as an alternative method for the quantitation of HIV antibodies and detection of HIV antigen in infected cells.

T.B.P.89 STATISTICAL ANALYSIS OF FLOW CYTOMETRIC DATA: A NON-PARAMETRIC APPROACH

Lacouture, Tracy Gordon, T. Donohue, C. Flow Cytometry
Laboratory, Montreal General Hospital, Montreal, Quebec, Canada.

Objective: To evaluate non-parametric approaches to the statistical analysis of T cell subsets. The enumeration of CD4 positive lymphocytes is currently considered essential in monitoring the course of HIV infection. Lymphocyte subsets are furthermore dependent variables used to enroll patients in clinical trials and as endpoints of treatment. Despite the theoretical importance placed on quantitating T cell subsets little attention has so far been placed on the statistical methods used for analysis.

Methods: Flow cytometric data was obtained on 100 HIV seronegative volunteers and 200 HIV seropositive patients with varying clinical stages of HIV disease. Dual staining of cells with monoclonal reagents conjugated to either fluorescein or phycoerythrin were used to identify T helper, suppressor, inducer, cytotoxic, B6 and activated cells.

Results: The observed distribution of flow cytometric data did not follow a Gaussian probability function and traditional parametric methods were deemed inappropriate for analysis. Percentile ranges and absolute median detection were used instead of standard deviation as dispersion indices; median and mode instead of mean as localization indices. These statistical descriptors provided a clearer view of the skewed distribution of the data (presented using exemplar distributions). A non-parametric test, the Mann-Whitney U-test, was used to be useful for hypothesis testing.

Conclusion: Although statistically less powerful the non-parametric hypothesis testing leads to improved reliability in flow cytometric data analysis.

T.B.P.86 WHERE LIES THE TRUTH? METHODOLOGICAL INFLUENCE ON THE DETERMINATION OF CD4 AND CD8 LYMPHOCYTE SUBPOPULATIONS.

EMMEL, Virginia, Lafferty, R. and G.M.P., University Hoveville, Zaire, Belgium.

Objective: The number of CD4-positive lymphocytes in the peripheral blood of HIV infected patients is an important prognostic parameter. However, the results of CD4 counts from different laboratories are not comparable. One of the reasons might be methodological differences.

Methods: We compared four different methods used to measure lymphocyte subpopulations:
- M1: Enumeration of mononuclear cells on a density gradient (Ficoll-Hypaque), and staining with FITC-labeled monoclonal antibodies against CD4 and CD8 (fluorescence).

- M2: Whole blood was double-stained with FITC-labeled anti-CD4 and PE-labeled anti-CD8 monoclonal antibodies (fluorescence), and red cells were lysed with a one step lysis reagent (B-D).

- M3: Whole blood was double-stained with FITC-labeled anti-CD4 and PE-labeled anti-CD8 monoclonal antibodies (fluorescence), and red cells were lysed with a three step lysis procedure on a Coulter Vantage™.

In all three methods the labeled cells were measured with a flow cytometer (FACS PROFILE, Coulter). Results were compared using a three regression model.

Results: M1 and M2 were compared with blood from 27 HIV-infected patients and from 23 healthy blood donors.

CD4 values obtained with M2 were 40% of the values obtained with M1. Correlation coefficient (r) was 0.3. A comparison of the results of 600 consecutive CD4 determinations by M1 with 600 consecutive measurements by M2 in HIV-infected patients revealed a 2 to 4 order difference. CD8 values correlated less well (r=0.79) but, in contrast to CD4, were about 10% higher if determined with M2 than with M1.

M1 and M3 were compared with blood from 10 HIV-infected patients and from 10 healthy blood donors. CD4 values measured with M3 were 20% higher than M2-determined values (p<0.05), which makes them comparable with M1-determined values. CD8 values, however, were again about 10% higher than M2 than with M3, moving from further apart to more comparable values.

Conclusions: Methodological effects on CD4 (and CD8) values are substantial and have to be considered when comparing different studies. A simple explanation for the observed differences could not be found.

T.B.P.88 IDENTIFICATION AND QUANTITATION OF HIV INFECTED CELLS IN PERIPHERAL BLOOD FROM AIDS PATIENTS BY FLOW CYTOMETRY

McCarthy, James*, Hirsch, S., Stevens, R., and Lehman, J., *Albany Medical Center, Albany NY and **New York State Department of Health, Albany NY.

Objective: To develop a rapid method for quantitating the amount of HIV antigen in HIV seropositive patients. **Methods:** After obtaining informed consent, peripheral blood was taken from patients attending the AIDS Clinic at the Albany Medical Center.

The mononuclear cells were isolated by centrifugation onto ficoll-hypaque, fixed in 90% methanol, incubated with monoclonal antibody to p24 antigen as the primary antibody and then with FITC-conjugated goat anti mouse IgG (Fab) as the secondary antibody. The cells were then treated with RNase A to remove RNA, and then with propidium iodide to determine the cell DNA profile. The stained cells were then analyzed by flow cytometry. Controls consisted of peripheral blood mononuclear cells obtained from HIV-seronegative patients with normal blood counts.

Results: Flow cytometric analysis of treated mononuclear cells revealed that HIV-seropositive patients have essentially no p24 antigen positive cells whereas HIV-seronegative patients had significant numbers of p24 antigen positive cells. The % positive cells correlated with the CDC criteria for clinical staging of the disease in that patients in stage II had fewer p24 positive cells than those in stage III and stage IV. Furthermore, in all cases tested and at each stage of the disease, the p24 antigen-positive cell was of the mononuclear/macrophage lineage on the basis of size as determined by light scatter and adherence to fetal bovine serum coated petri dishes.

Conclusions: These results suggest that flow cytometry can be used as a rapid, quantitative system to determine the antigen status of HIV-seropositive patients which may be useful as an indicator of disease progression.

Diagnostic : Détection des antigènes

Diagnostic: Antigen Detection

T.B.P.90

ANTIGENIQUE VEH AU COURS DE LA PRÉINFECTION
Behavien, D., Puel Zaccagnini, A., Averous S.,** Basse J.,**
*Laboratoire de Virologie, CHU Purpura, Toulouse, FRANCE
**Service de Dermatologie, CHU Dreux, Toulnay, FRANCE.

Objective: Etudier la présence de l'antigène p24 de la primo-infection II et III de l'ordre qu'elle pouvait précéder la séroconversion de 34 malades (A. Lancet 87 (ii:1233) et de quelques notes (Goussard J Lancet 87 (ii:1237 - Allan 19 Lancet 86 (ii:1233) sans ces résultats sont controversés (Dourouac AM Lancet 87 (ii:1205)).

Méthodes: Détection, tirage de 1'antigène p24 (technique Abbott) et confirmation par neutralisation réalisée sur des sérum RNAsse 2 à 6 mois (moyenne 1 mois) avant la séroconversion observée chez 18 patients homosexuels.

Résultats: L'antigène p24 a jamais été détecté avant la séroconversion, toutefois nous n'avons pas disposé de sérum dans le mois précédant la séroconversion.

- Au moment de la séroconversion une antigène a été observée chez 18 sujets Elle a disparue en 1 mois dans 11 cas, en 3 mois dans 7 cas.

- Une antigène a été observée chez un patient un mois seulement avant la séroconversion, elle a disparu en 3 mois.

- L'antigène p24 n'a jamais été observé par un marqueur sérologique précoce et fiable de l'infection VIH; accompagnant la séroconversion, elle est fugace, inconstante, parfois réversible.

T.B.P.91 PRODUCTION AND CHARACTERIZATION OF HUMAN IMMUNODEFICIENCY VIRUS ANTIGENIC DETERMINANTS AND THEIR USE IN DIAGNOSIS OF AIDS

S. Arsenian, O. Voloshin, A. Shevelier, M. Michailov, T. Nikolova, V. Novikova, and E. Swardlow, Institut Pasteur, 200 rue de la Salette, 69631 Lyon Cedex 07, France.
M. M. Shemakina Inst. Biorg. Chem., Acad. Sci. USSR, VERA Biotechnology Minnabodiprogn, **Inst. Immunol. Minskrazd Moscow, USSR.

With a view to have immunodiagnostic kits for detection of AIDS in humans we obtained bacterial strains expressing recombinant proteins which include amino acid sequences of the main antigenic determinants of human immunodeficiency viruses (HIV). The spectrum of expressed antigenic determinants overlaps their variability among different HIV isolates. The content of the expressed recombinant protein in cell lysates amounts to 30-50% that enables one to use the synthesized antigens for immunological reactions without further purification. Using a large panel of sera taken from AIDS patients interaction of the recombinant antigens with anti-HIV antibodies was statistically analysed.

T.B.P.93 USE OF TRITON-X IN THE HIV ANTIGEN ASSAY TO ASSESS THE PRESENCE OF INFECTIVE HIV

James L. Stewart, Ketchum, S. J.; Coombs, R.W., and Allan, J.P., *Abbott Laboratories, N Chicago IL and **University of Washington, Seattle WA, USA.**

Objective: Compare the performance and significance of the current HIV antigen (HIV Ag) capture assay to a modification using Triton X-100 to disrupt potential whole viral particles in the samples.
Methods: Serum plasma samples were tested neat or in the presence of 0.5% Triton X-100 according to previously described methods (Lancet 1986, 2, 123). In some cases, results were compared to the capacity of plasma to infect stimulated normal peripheral blood lymphocytes.

Results: In 36 samples from 7 patients collected at six clinic intervals pre and post seroconversion, 11 samples were HIV Ag + in the presence and 7 in the absence of Triton. All HIV Ag + samples tested were infectious in culture while 3 of 10 HIV Ag- were infectious. In 140 seropositive samples (49 asymptomatic, 41 ARC and 50 AIDS) 52 and 40 were HIV Ag + in the presence or absence of Triton, respectively. This additional sensitivity seemed to correspond to the disruption of whole viruses since in 18 samples where HIV plasma culture was performed, all 15 positive culture samples were positive with the Triton treated HIV Ag assay.

Conclusion: The treatment of samples for HIV Ag testing with Triton X-100 facilitated infective HIV and improved the assay sensitivity by increasing the amount of antigen available to capture. The good correlation between culture infective plasma and positive result of Triton treated HIV Ag assay suggested that the presence of HIV Ag reflected active viral replication.

T.B.P.95 LACK OF CORRELATION OF p24 ANTIGENEMIA WITH CLINICAL STATUS IN HIV INFECTED WOMEN TO INTERCURRENT PREGNANT IN WOMEN WITH HIV INFECTION. **SHARON S.L. SHERMAN, Joyce M. Kucenas S. Bradford S. Brown University Medical Center, Providence, RI USA.**

Objective: To determine the relation between p24 antigenemia, p24 and clinical status in women with HIV infection. **Results:** 24 HIV-seropositive women were serologically evaluated for 24 months, with monitoring of clinical status and p24, and monthly determinations of serum p24 antigen (cpd/ml) in individuals with antigenemia. **Results:** 14 individuals (58%) were (mean age 37), mean p24 count was 787 ± 137 (SD). In 8 women (mean age 34) with AIDS-related complex (ARC), mean p24 was 170 ± 40 (SD). In 8 women (mean age 38) with AIDS, mean p24 was 62 ± 24 (SD). 3 individuals (12.5%) had persistent p24 antigenemia. In the 20 individuals, mean p24 was 63 pp/ml; mean p24 was 62. In the women with ARC, mean p24 was 130 pp/ml; mean p24 was 170. In the women with AIDS, mean p24 was 170 pp/ml; mean p24 was 170. Each antigenemic woman had been clinically stable during the past 12 months. The individual with AIDS had one breast biopsy/immunohistochemistry for paraneoplasia; the other two antigenemic women had no limitation of activities of daily living. **Conclusions:** These data confirm a highly significant correlation between p24 antigenemia and clinical status, but fail to show correlation between persistent p24 antigenemia and either clinical status or p24 counts in 24 HIV-positive women.

T.B.P.92 SENSITIVITY OF FIVE COMMERCIAL HIV-ANTIGEN DETECTION METHODS.

Camilo C., Varela J.M., Vallbona E., Garcia Sals A., Najera R. Instituto de Salud Carlos III, Madrid, Spain.

OBJECTIVES: To present data about the performance of commercial kits for HIV - antigen detection by testing with a panel of sera and infected cell-culture supernatants.

METHODS: To build our evaluation panel we have selected antibody positive sera which didn't show any reactivity for anti-COSE antibodies by the CIA -RA (ENVOACOR HIV-1, Abbott) method.

The chance of a serum to be antigen reactive is higher than 20% was considered positive.

The antigen detection methods used in this work have been: Abbott Enzygnost EIA, the Poot 204 COSE antigen ELISA, ELISA E4 (Eliabiotica Pasteur), Coulter HIV Ag assay and Viroscreen HIV Antigen (Organon). The sensitivity study was completed by testing up the end-point dilution in cell-culture supernatants for each method.

RESULTS: We have found relevant differences of sensitivity by testing the sera panel, and the dilutions.

CONCLUSIONS: We think that our study may give information about the antigen detection ability of five commercial kits. This could be an additional approach in order to decide which HIV antigen detection kit might be selected.

T.B.P.94 EVALUATION OF THE HIV ANTIGEN DETECTION ASSAYS IN EUROPEAN AND AFRICAN SERA

Steenblock, Gabe, van der Groen, G.J., P. van
Institute of Tropical Medicine, Antwerp, Belgium.

Objective: To compare the performance of two HIV antigen capturing systems (EIA) (Abbott and Immoprecip) for the detection of free HIV antigen in human serum.

Method: 100 human serum samples positive (15 African, 219 European), and 60 anti-HIV negative sera were screened with the HIV 1/1 antigen EIA (Abbott) and the Immoprecip HIV antigen (Immoprecip distributed by Dupont and Biotec and Cellcon). Negative samples were tested for confirmation with a neutralization assay of the respective manufacturer.

Results: Initial screening revealed 69 sera reactive in the Abbott and 66 sera reactive in the Immoprecip. Further analysis was performed in both assays. Epitope specific (EIA) of the Abbott reacted in both assays were confirmed with the Abbott test and 96 percent (60/63) were confirmed with the Immoprecip. Six out of the 8 serologically positive samples and 10 out of the 20 serologically immunoreactive sera, were confirmed, antibodies in both Abbott HIV and Immoprecip, were absent or of very low level. In the Immoprecip antigen reactive sera, all of these patients, except one, which was stage 1, were classified as having ARC or AIDS. We therefore presume that negative the assay of the Abbott are true HIV antigen positive sera. The HIV antigen, sensitivity in the African and European sera was respectively 1.9 (1/51) and 2.2 (2/91) (P < 0.0005). When the African sera 3/7 had such levels higher than ratio 10:100 (10:100) were detected while this ratio was 0.6 in 1/8 of the European sera (n = 107).

Conclusion: We obtained more HIV antigen positive samples with the Immoprecip EIA. This observation can perhaps be explained by a higher sensitivity of this test or by its capability to capture a wider range of HIV antigens. Our results confirm that HIV antibody positive sera from African patients contain less often free HIV antigen, possibly because of a higher production of anti HIV antibodies.

T.B.P.96 CORRELATION OF HIV CORE ANTIGEN, ANTIBODY AND IMMUNE COMPLEX LEVELS IN SERA OF HIV INFECTED INDIVIDUALS

Ushayli, E., Longo, J., Goudami, J., Salvez, V., Ust, G., Hollar, S.M., et al.
Natl. Inst. Hematol. Blood Transfusion, Budapest, Hungary; and **Dept. Virol., Acad. Med. Center, Univ. Amsterdam, Amsterdam, The Netherlands.

Objective: To measure the relationship between the presence of HIV core-antigen (core Ag) and anti-HIV (env IC) immune complexes on the one hand, and the amounts of free core antigen, free core and env antibodies on the other. **Methods:** Levels of core Ag and env IC were measured by the method of Ushayli et al. (AIDS, 1, 141, 1987). HIV antibody was detected by a sensitive ELISA assay, free core and env antibodies were measured by the ENVOACOR test. Sera of HIV-infected individuals containing core Ag and/or env IC (10/60) were selected for the study. **Results:** Free core antigen was found in 8/18 samples. Free env antibodies were present in all sera tested, free core antibodies were found in 12 samples. Core IC and env IC were detected in 11 and 14 samples, resp., in 9 sera both types of complexes could be detected. The presence of core IC were associated with increased titre of free core antibodies (13.3±25.5 vs 110.0±32.3, p=0.01) and increased incidence (7/11 vs 1/7, p=0.057) of free core antigen. **Conclusion:** Formation of core-anti-core immune complexes in HIV-infected individuals is related to the increase of the antigen load and binding of antigen to the specific antibody.

Aspects cliniques Clinical Aspects of AIDS

T.B.P.115 REFLEXIONS SUR L'ISOLEMENT DU VIRUS DANS UNE UNITE DE VIROLOGIE HOSPITALIERE

Flary, M., J.-L., Belord, B.,* et Mesquolier, B.*
* Laboratoire de Virologie, CHU St Bordeaux et Université de Bordeaux II, Bordeaux, France.

Objectif: Dépasser les enseignements (comparaison avec d'autres paramètres, TIBRETE) de plus de 400 sites en culture de VIH.
Méthodes: Cas de 400 sites en culture de cultures monoclonaux du sang (TIBRETE) ont été effectués chez plus de 200 sujets (patients suivis dans le cadre d'un protocole thérapeutique, enfants nés de mères infectées, cas de contamination domestique avec autres paramètres adaptés...). Le virus a été détecté dans le surnageant des cultures cellulaires par mise en évidence de la protéine p24 du VIH 1 et d'une activité RT. D'autres paramètres biologiques ont été appréciés (antigène VIH 1, nombre de lymphocytes T4, ...). Au moment de la culture, 100% de lymphocytes.

Résultats: Plus de 200 souches de VIH 1 ont été isolées (efficacité=50 %) ; 80 PCR. Parmi les enseignements suivants :
- Une antigène VIH 1 positive est pratiquement toujours associée à un isolement viral.

- On peut isoler le virus chez des sujets dont le nombre de lymphocytes T4 est effondré au moment de la mise en culture.

- Le virus peut être retrouvé chez des patients recevant de l'AZT depuis plusieurs mois.

- L'isolement viral nécessite une technique de choix pour l'établissement d'un pronostic chez les enfants nés de mères infectées.

- Dans un cas, nous avons isolé le VIH 1 chez un sujet dont les autres paramètres sont demeurés stables.

T.B.P.116 DUAL SEROLOGIC REACTIVITY FOR HIV-1 AND HIV-2 IN ARIZONA

Porter, A.,**; Lee, J.,**; De Cock, K.,**; Colabandera, R.,**;
Besset, G.,**; Keffauz, J.,**; Keffauz, J.,**; Keffauz, J.,**;
*Projet REACTO-CR; **AIDS Program, Centers for Disease Control, Atlanta, GA, USA; **Institut Pasteur, Arizone, Gona d'Ivry.

Objectif: To assess the spectrum of serologic reactivity of HIV infected patients in Arizona; assess the predictive value of ELISA for HIV-1 and HIV-2 infection; and examine dual serologic reactivity by peptide ELISA and polymerase chain reaction (PCR).

Méthodes: 927 hospitalized patients repeatedly reactive by ELISA for HIV-1 and HIV-2 will be confirmed by virus-specific Western blot (WB). A subset of these were tested by type-specific synthetic peptide ELISA (PepSI-1/1-2) and had lymphocytes collected for PCR and virus culture.

Résultats: Of 927 patients repeatedly reactive by ELISA (543 thus far tested by WB), 194 are HIV-1 only; 65 HIV-2 only; and 742 both HIV-1 and HIV-2. Of specimens daily reactive on ELISA, 61% were dually reactive on WB, 16% HIV-1 only, and 0.35% HIV-2 only. While A&E HIV-1 only and 97% HIV-2 only reactive specimens were confirmed by the appropriate WB, 97% of dually reactive specimens were reactive on HIV-1 and HIV-2 WB. Thirty-four specimens daily reactive on ELISA will be tested by PCR. On peptide ELISA, 19/34 (56%) were reactive only to HIV-1, 1/34 (3%) HIV-2 only, and 6/34 (18%) remained dually reactive. Of 98 alone, 28/34 (28%) of these specimens were confirmed daily reactive. Serologic results will be compared with those of PCR and virus culture.

Conclusion: In hospitalized patients in Arizona, dual reactivity on whole virus ELISA is 97% predictive of WB confirmed HIV infection.

T.B.P.117 STANDARDIZATION OF HIV COCULTURE ISOLATION TECHNIQUES IN MULTICENTER CLINICAL TRIALS

Hollander, V., and Rao, S.A.
Virology Reference Laboratory (VRL)/NAID/AIDS Program, Baylor College of Medicine, Houston, Texas, USA

Objectif: To evaluate and effect improvements in the isolation of HIV from PBMCs by laboratories participating in multicenter clinical trials as part of the AIDS Clinical Trials Group (ACTG)/NAID/AIDS program.

Méthodes: Monthly coded whole blood samples are sent by the VRL to ACTG labs for culturing. After an initial evaluation period (7 months), the labs were ranked by their ability to isolate virus. A consensus HIV isolation protocol was developed after comparing the methods and materials used by labs that consistently isolated HIV to the methods employed by labs having difficulty isolating the virus.

Résultats: Critical factors in the isolation procedure include volume of patient blood processed, centrifugation parameters used to recover PBMCs, use of fresh (vs frozen) normal donor PBMCs, concentration of PMA-P in donor stimulation medium, use of natural (vs recombinant) IL-2, time interval before addition of PMA-stimulated donor cells to patient PBMCs, ratio of donor to patient PBMCs, concentration of cells in coculture, and weekly addition of fresh PMA-stimulated donor cells to coculture. The inclusion of polybrene and anti-alpha interferon in the stimulation or coculture medium did not improve isolation efficiency. Since the introduction of the consensus protocol, labs with poor performance status have shown a significant improvement in their ability to isolate HIV.
Conclusion: Achieving equivalent efficacy in isolating HIV from PBMC by the ACTG labs will permit the introduction of more sophisticated virologic end point cell culture techniques for evaluating various anti-HIV treatment protocols.

T.B.P.118 TISSUE CULTURE AND P24 METHODS OF HIV DETECTION COMPARED AND CORRELATED WITH DEMOGRAPHIC DATA IN SPONTANEOUS AIC PATIENTS

Banfield, J., John, G., Brown, J., Weisbach, A.,**; Harkeroff, M., J., Harkeroff, F., and the VA Cooperative Study Group on the Treatment of AIC, Veterans Administration Medical Center, VA, USA.

Objectif: To compare two methods of HIV detection in symptomatic AIC patients and to correlate the results with demographic data.

Méthodes: A overnight blood sample was collected from each of 152 symptomatic AIC patients entering a multicenter, phase III trial of AZT. It was transported overnight and processed by two methods: (a) by standard conventional techniques and employing the culture weekly for 4 weeks by antigen capture; (b) by directly measuring p24 levels in the plasma by standard enzyme immunoassay. Results were compared with demographic data.

Résultats: Method A detected HIV in significantly more patients than Method B did (41 vs. 7%). Method A was positive more often for (a) patients younger than 50 years, those older (53 vs. 40%), (b) patients with 74 counts between 200-299 vs. 300-500 (53 vs. 37%), (c) patients who were energetic vs. those responsive to skin tests (50 vs. 37%). There were no significant differences for sex, race, risk group, or hospital. For the comparisons done, there were also no significant differences for culture time to positive or for absolute p24 levels. Methods A and B correlated to size of the patients but not in 30%, statistically, this is no better than could be achieved by chance.
Conclusion: Issues relating to a more sensitive measure of HIV than is plasma p24 in this patient group, especially in those who are younger, energetic, and have the lower T4 counts. The tests may be measuring different stages of virus replication.

T.B.P.119 SENSITIVITY OF U.S. PMA LICENSED HIV-1 REVERSE TRANSCRIPTASES FOR ANTIBODIES

Bywater, M.,**; Gishizaki, E.; Soudry, K.,** et al. *Centers for Disease Control, Atlanta, GA, USA; **Institut Pasteur, Arizone, Gona d'Ivry; ***National Laboratories, Dugandongon, Burkina Faso.

Objectif: To determine the efficacy of testing for antibodies to human immunodeficiency virus (HIV) type 1 by screening with PMA licensed HIV-1 enzyme immunoassays.

Méthodes: West African sera were tested for antibodies to HIV-1 and HIV-2 with ELISA employing both viral lysate and recombinant peptide antigens and with HIV-1 and HIV-2 Western blots. Based on these results, 55 HIV-2 sera, 19 HIV-1 sera, and 46 sera equally reactive with HIV-1 and HIV-2 immunoassays were selected for testing with U.S. PMA licensed HIV-1 antibody ELISA (see table).

Résultats: The percentage of sera that were positive by each ELISA test are presented in the following table:

SERA	Ortha	EBI	Tatnika	Lab.	DuPont	Bye.	Pro.
HIV-2	60.0%	67.3%	70.9%	81.8%	87.5%	90.9%	90.9%
HIV-1	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%
HIV-1/2	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%

Conclusion: Sera from HIV-2 infected individuals will be detected by HIV-1 ELISA at a rate ranging from 60.0% to 90.9%, depending on the test used. Screening the blood supply with HIV-1 ELISA will not detect all HIV-2 infected sera.

Diagnostic: contrôle de la qualité et techniques rapides

T.B.P.120

EVALUATION POUR TEST DE DETECTION RAPIDE DES SUIJETS SEROTIPIQUES HIV-2.
O. CATALAN, A. MILANOVIKOV, T.D. LEE, J. Pauline Alfred Ponsier - Paris

Objectif: Evaluer la sensibilité et la spécificité d'une technique ELISA rapide sur matériaux de sérotypisation, obtenus deux ans après de peptides recombinants à un sérotype de la O10 101 pour HIV 2.

Méthodes: Un groupe de patients sérotypés (technique ELISA Organon et Dupont de Nemours), confirmés par Western blot (Dow) puis Panzer sous (Dupont de Nemours) a été sélectionné puis les patients suivis pour sérotypisation (TCM, TCM, Beta-2-microglobuline, dosage des immunoglobulines, etc.) (14 patients) a permis d'évaluer la sensibilité.

L'autre groupe (16 patients) a été constitué de patients sérotypés par les techniques pédiatriques et succès de consensus d'origine. Des sérum de patients sérotypés ayant une infection HIV 2, soit, ont été faits. Le test a été effectué à partir de sérum séché sur nitrocellulose.

Résultats: 7 sérum, adressés pour sérotypation, ont été trouvés négatifs dans toutes les techniques. L'autre groupe, sérotypés, ont été trouvés positifs dans les 10 sérum HIV 2 et 2 ont été trouvés positifs dans les 16 sérum HIV 2. Les résultats ont été comparés à ceux des techniques pédiatriques et succès de consensus d'origine. Les sérum de patients sérotypés ayant une infection HIV 2, soit, ont été faits. Le test a été effectué à partir de sérum séché sur nitrocellulose.

Conclusion: Ce test rapide (cinq minutes), permet d'adapter à toutes les situations expérimentales, permet une sensibilité et spécificité excellentes, de peucis d'inférence HIV séro HIV 2, alors que dans une situation une grande homologie, tout au moins dans les premiers de ceux.

T.B.P-127 EVALUATION OF A RECOMBINANT HIV-1 ENZYME IMMUNOASSAY (EIA) IN PATIENTS ATTENDING AN EMERGENCY ROOM AND A SEXUALLY TRANSMITTED DISEASE CLINIC

Kim Richards¹, Kelen, G.D.², Hock, E.W., Brothers, T.A.², O'Sullivan, S.M.², Criss, J.
¹NIAID, NIH, Bethesda, Maryland; ²Johns Hopkins Medical Institutions, Baltimore, Maryland

Objective: To evaluate the reliability, sensitivity and specificity of the Syva Microtrak Recombinant HIV-1 EIA compared to a commercially licensed EIA and Western blot.
Methods: 2000 patients attending an emergency room and sexually transmitted disease clinic were tested for HIV-1 seropositivity using a recombinant HIV-1 EIA (Syva). This EIA was genetically engineered gp41 and gp120 and p24 gene products of HIV-1 expressed in *R. solis*. After purification, all immunologically detectable bacterial proteins were removed. All sera were also analyzed by EIA (Organon) and sera which were seropositive by either assay were confirmed by Western blot (DuPont).
Results: The Syva Microtrak HIV-1 EIA procedure was easy to perform with short incubation times and color-coding of reagents to lessen the chance of error. In assessing HIV-1 seropositivity in the two populations, the Organon EIA and Western blot detected 119 positive and 3 indeterminate samples. The Syva EIA detected all 119 positive samples with no false positive samples. Compared to Western blot, the assay had a sensitivity of 100% and specificity of 100%.
Conclusion: Use of the Syva Microtrak Recombinant HIV-1 EIA for detection of HIV-1 infection in these populations proved to be highly reliable with excellent sensitivity and specificity compared to a licensed EIA and Western blot.

T.B.P-129 USE OF A PEPTIDE-BASED, RAPID IMMUNOASSAY FOR THE DETECTION OF ANTIBODY TO HIV-1

Soni, R.L., Popoulos, S.P., Kiv, S., Hossain, M., Perera, C., Kojima, Madao, S.***
^{*}Chicago Laboratory, Lenexa, KA and ^{**}Genetic Systems Corporation, Seattle, WA, U.S.A.

Objective: To investigate the utility of a peptide-based, rapid immunoassay for detecting antibody to Human Immunodeficiency Virus Type 1 (HIV-1).
Methods: 1595 samples were tested by a rapid immunoassay based on a synthetic peptide found in the conserved region of the viral transmembrane glycoprotein, gp 41 and by a whole virus immunoassay. Repetibly reactive samples were also tested by Western blot (DuPont).

Results: Results of the sera were interpreted according to the package insert of each test.

Immunoassay	EIA	Western Blot	Number of Samples
Negative	Neg	Not Detected	1383
Positive	Positive	Positive	101
Negative	Positive	Indeterminate	86
Negative	Negative	Indeterminate	21
Positive	Negative	Indeterminate	3
Positive	Positive	Indeterminate	3

Conclusion: The sensitivity and specificity of enzyme immunoassays and blot kits marketed for detection of antibody to HIV are greater than 99%; however, when a low prevalence population is tested a high percentage of the reactive samples are false positive or blot indeterminate. Preliminary results indicate that a peptide-based test may be useful in distinguishing samples which are false positive by EIA or indeterminate by Western blot.

T.B.P-131 THE ANTI-HIV TESTING BY QUICK TESTS AND A COMPARISON WITH A STANDARD ELISA

Dea, P., de Vries, A.H., McHine, R.L.; Smit Sibinga, C.; Het Rod Cross Blood Center, Groningen-Drenthe, Groningen, The Netherlands.

To provide rapid but sensitive and anti-HIV specific testing we have compared HIV check (DuPont), gelatin particle agglutination (Pujarbio) tests with our routine enzyme immuno assay (EIA - Wellcome) used for routine testing of 50,000 donations per year.
Initial screening consists of 3 Western blot positive donor sera, 3 'tricky' samples (2/3 and/or 2/5 bands) and healthy donor sera (40). In the second phase 3 Western blot positive sera were diluted and run in parallel. All tests were carried out according to the manufacturers' instructions.
Results:

Initial screening	TESTS			
	HIV-check	HIV-check	Pujarbio	EIA
Tricky (n=5)	All neg	All pos	All pos	All pos
Normal (n=40)	All neg	All neg	All neg	All neg

In the rapid HIV check test all the positive samples were clearly identified and tricky sera remained negative. Pujarbio is at least 3-fold sensitive in and point immunoassay (14002 vs 2048 in EIA). HIV check is fairly quick (20') having a high sensitivity and specificity (1/40 initial non-specific reaction). Pujarbio showed very high specificity and sensitivity, and seems adapted to rapid testing.

T.B.P-128 DETECTION OF ANTI-HIV ANTIBODIES WITH SYNTHETIC PEPTIDES USING A 3 MINUTES RAPID TEST

Shaban, Rattimani, J. Martin, A., Herreweghe, P., Tardieu, C.,** Richeux, J.,** Pignatelli, G.,** Bismet, J.***
^{*}Clonon: 60 rue de Valenciennes - 75013 PARIS - FRANCE
^{**}V-Chem: PO Box 4, USA ^{**}Geno-SAN: DREUX, CA - USA

Objective: A 3 minutes immunoradiation ELISA device using synthetic peptides derived from the transmembrane glycoprotein of HIV1 and HIV2, was optimized for the detection and the distinction of anti-HIV antibodies in serum or whole blood samples.
Methods: The assay involved synthetic peptides coupled on a membrane with one spot of HIV1 peptide, one spot of HIV2 peptide and one uncoated control ring. A diluted specimen is filtered through the reactive membrane. Anti-human IgG peroxidase conjugate solution is added. The result is read visually. Results are recorded as positive if one or two bands and the peroxidase blue ring appear on the membrane. Results are recorded as negative if the blue ring appear only.
Results: 200 positive HIV1 peptide, 200 positive HIV2 peptide and 18 false HIV1 antibodies were tested. 276 were reactive with the HIV1 peptide (sensitivity = 98.9 %), 441 negative sera and 18 false positive sera in ELISA. 100% sensitivity and 100% specificity were achieved.
To evaluate HIV2 peptide, 66 anti-HIV1 sera were tested. All were reactive with this peptide (sensitivity = 100 %). 67 HIV2 negative and 18 false positive sera, no reaction was observed (specificity = 100 %).
Conclusion: Target HIV is a sensitive and specific rapid test which can be performed readily for the screening and the typing of HIV. We achieved 100% sensitivity and 100% specificity of 991 sera, the sensitivity of the test is 99.6% and the specificity is 100%. We thank Dr. J. P. Virelizier.

T.B.P-130 COMPARISON OF SERUM AND PAPER-ABSORBED FINGERSTICK BLOOD SAMPLES FOR DIAGNOSIS OF HIV INFECTION IN INTERMEDIATE DRUG USERS.

Offit, Edward, Sloger, K., Deutsch, G.,** Weiblen, B.,** Comella, L.,** and Williams, J.M.***
^{*}Massachusetts Department of Public Health, Center for Disease Control; ^{**}Boston City Hospital, Boston, Massachusetts, USA.

Objective: To determine whether the results of HIV ELISA and immunoblot (IB) assays on paper absorbed (PA) fingerstick blood are equivalent to that obtained with serum specimens.
Methods: Paired specimens of venous blood serum and fingerstick blood collected and dried onto SMC 803 collection paper were obtained with consent from 283 clients using a walk-in anonymous counseling and testing service for intravenous drug users. The paired serum and PA specimens were tested by ELISA (Genetic Systems) and the Miniblot® IB procedure.
Results: The same group of 66 IB-confirmed ELISA-positive clients was detected by examining the serum and the PA specimens. The IB band patterns in the 66 paired specimens were identical. By ELISA 100% of sera (72/72) and 100% of PA specimens (72/72) were repeatedly reactive, and the relative strength of ELISA reactivity in the paired specimens was virtually identical (p=0.84). A slightly higher ELISA mean background with PA specimens (45% of the cutoff vs 27% for serum) resulted in 10 non-IB confirmable ELISA positives in contrast to 8 for serum.
Conclusion: PA specimens, as compared to serum, provide for equivalent sensitivity and specificity to ELISA and IB assays for HIV antibodies. Moreover, the PA method is superior in convenience, safety, transport, and processing—all of which are advantages for serosurvey and screening programs, especially when volunteers are problematic.

T.B.P-132 A SIMILAROUS BRIDOR QUICK TEST FOR DETECTION OF HIV-ANTIBODY AND USE OF THIS TEST FOR RISK ASSESSMENT

Tardieu, E., Rattimani, J.,** Marty, J.,** Wilson, A.J.,** Schmitt, M.,** Yemine, F.,** Fournier, R.,******
^{*}Univ. São Paulo, Brazil; ^{**}Univ. Foundation for Medical Research, São Paulo, City, Utah, USA; ^{**}Univ. Ribeirão Preto, São Paulo, Brazil.

Objective: The developing countries are in urgent need of an easy and economical test for HIV-1. This test for use in parallel with other rapid tests in order to eliminate false negatives/positives. This test detects, at the same time, HIV-Ab and HBs-Ag using whole blood, plasma or sera.

Methods: HIV-Ab and HBs-Ag was spotted in each well of a 96-well test card. The card is placed in a tray. Add 1 drop of undiluted specimen to the well. Incubate at room temperature for 10 minutes. Wash the card with buffer shaking the tray for 10 seconds. Discharge the buffer and repeat operation for 3x. Add enough conjugate to the tray to completely immerse the card. Wait 10 minutes at room temperature. Pour off the conjugate and wash 3 x. Add color developer and incubate for 10 minutes. Pour off the solution and wash the card with water and read. The reaction is positive when the spot is colored.

Results: 480 clinical specimens of AIDS and hepatitis patients or suspected and normal donors were tested. Sensitivity was 99% and 100% of specificity when compared with western blot of the test - 99.3%.

Conclusion: This test is a very useful tool for screening, repetition or emergency situations.

T.B.P.133 FIELD EVALUATION OF IMMUNOASSAY AND AGGLUTINATION TESTS FOR HIV

Michélin, Ghislain*, Tubet, P.H.,**Houyou, S.,**Pirajac, J.,***
Lecroq, P.,**
*AIDS/CRF/Family Health International, North Carolina, USA, **Virus Re-
search Center, Nairobi, Kenya, ***Olivierie Charité Area Hosp, Baker,
Sengal, ****Chaga Medical School, Actra, Ghana.

Objective. To evaluate one rapid test as a screening test for HIV and two agglutination tests as supplemental tests for HIV in field laboratories in 3 countries in Africa.
Methods. The HIVCSSE (Dupont, USA) was evaluated as a screening test with the HEMO-ELISA (Fujiwara, Japan) and HEMOCHEL (Abbott, USA) being evaluated as supplemental tests. A total of 6,000 specimens were tested in 14 laboratories in Kenya, Ghana and Senegal. Through, standardized training in these techniques was provided to all technicians.
Results. Sensitivity and specificity of the tests will be determined and compared with those of ELISA and Western Blot. Inter and intra country differences in test performance will be assessed and reported.
Conclusion. With proper training the newly developed tests for HIV antibody can perform well in laboratories lacking sophisticated equipment. The use of these assays for screening and confirmation would facilitate blood donor screening in developing countries.

T.B.P.135 COMPARISON OF HIV INFECTION WITH A LINE DISKING ASSAY (DND-12A) USING NECKS BLOOD IMPROVED FILTER PAPER TESTS

Samaga, Jan*, Pollet, D.M.,** Clapen, M.,* Vandendriessche, M.* Peeters, D.M.,**
De Groot, G.*
*Institute of Tropical Medicine, ** Ziekenhuis Nijmegen, Nijmegen, Belgium.

Objective. To evaluate the use of whole blood collected on filter paper in the DND-12A, a newly developed "second generation" HIV antibody confirmation test, methods. From each of 40 HIV+ subjects blood samples were collected in 4 different ways and coagulated from capillary (C) and venous (V) whole blood as well as heparinized (H) whole blood were collected on Whatman 3MM Chr filter paper. In addition, capillary (C) and venous (V) whole blood were collected on "DND" paper. Blood impregnated filter papers were air dried, placed in a sealed plastic bag and stored at 4°C for at least 2 weeks prior to testing. Punched filter papers (5 mm) were obtained in 1 ml PBS applied with 100 microliters (100 µl) of saline and 100 µl of the same buffer was also used to dilute serum (S). The presence of antibodies against gag (p24 and p17), pol (reverse transcriptase), env HIV-1 (gp41) and env HIV-2 (gp120) was assessed in the DND-12A according to the instructions of the manufacturer.
Results. The three different methods of sample collection on filter paper gave identical results which accorded the results of a 1:100 dilution of serum. No selective loss of signals was observed with the paper discs as compared to the serum samples. Samples from patients with HIV-1 infection could easily be distinguished from subjects with HIV-2 infection and were in accordance with Western blot findings.
Conclusion. Whole blood impregnated filter paper can successfully be used to confirm infection with HIV when used in the DND-12A. This is of special interest in field studies where filter paper blood can easily be obtained and transported.

T.B.P.137 RAPID, MANUAL SCREENING TEST (HIVCHECK™) FOR ANTIBODIES AGAINST HIV-1 AND HIV-2

**Basig, N.*, Galtvis, J.R.*, Tirado, J.*,
Reed, D.**, Chu, P.R.,** Chu, A.R.,**
*The Pont de Nemours International S.A., Geneva, Switzerland, USA,
**Du Pont de Nemours International S.A., Geneva, Switzerland,
***Virus Laboratories, San Mateo, California, USA.**

Objective. To develop a simple assay test that would simultaneously screen for antibodies against both viruses. Ultimately, to facilitate screening in developing nations with small labs in developed countries.
Methods. A number of peptides and recombinant proteins have been evaluated to determine the widely accepted HIVCHECK™ assay to HIV-2 only sample. The sensitivity of the original HIVCHECK™ assay to HIV-2 only samples has increased from approximately 30% to 100% in the populations tested. In these HIV-2 populations, samples can be diluted and still detected as positive on this modified HIVCHECK™ assay. In a preliminary study in France and Portugal, the modified HIVCHECK™ assay correctly identified all 12 samples from patients known to be infected with HIV-2. Detailed data from more extensive evaluations now in progress in Europe and Africa will be presented.
Conclusion. Antibodies to both viruses can be simultaneously screened for when a proper selection of antigens is made. Sensitivity and specificity remain excellent. Use of antigens from the envelope regions of the viruses' genomes as the antibody capture reagents have provided an excellent method of achieving this sensitization.

T.B.P.134 USE OF AGGLUTINATION ASSAYS AS SUPPLEMENTAL TESTS FOR ANTIBODY TO HIV

Tsukamoto, K.*, Mizuhata, S.,** Symonog, J.,**
*Virus Research Center, Mitohi, Kenya, Africa, **Family Health International, Research Triangle Park, North Carolina, U.S.A., ***National Public Health Laboratory, Mitohi, Kenya.

Objective. To evaluate two agglutination assays for antibody to HIV as supplemental tests in field laboratories in Kenya.
Methods. A particle agglutination test SHERO-ELISA (Fujiwara, Japan) and a hemagglutination test HEMOCHEL (Abbott, USA) were evaluated for use as supplemental tests in comparison with the Western Blot. Seven laboratories in Kenya participated in the study. Serum from 2,000 blood donors, persons at high risk and suspected AIDS patients were initially screened by the HIVCHECK (Dupont, USA). All positive specimens and 10% of the negative were then tested by SHERO-ELISA and HEMOCHEL. At the reference laboratory, duplicate samples were tested by ELISA. All sample positive by any test were 100% positive when tested by Western Blot. Each test is being evaluated for sensitivity, specificity and usefulness in these field laboratories.
Results. With thorough training these tests can readily be performed in laboratories without sophisticated equipment. Data on sensitivity and specificity will be presented at the conference.
Conclusion. The agglutination tests do not require expensive equipment or highly trained staff and are more economical than the conventional supplemental tests used in HIV testing. These tests offer an alternative to the Western Blot technique as well as their intended use as screening tests.

T.B.P.136 A RAPID COLORMETRIC VIA FOR DETECTION OF ANTIBODY TO HIV-1

M. Shukla*, D. Maitra** (Mark White** Brian Dewar** and
Carole Ann**
*Virus Laboratory, Gorra, Georgia USA,
**Institute for Cancer Research, San Francisco, CA, USA.

Objective. To develop a rapid, sensitive and specific colorimetric assay necessary for the qualitative detection of antibody to HIV in specimens.
Methods. A simple, 10 minute colorimetric screening test was developed using Murax 3000 test cartridge and proprietary microfluidization H1A method. The test incorporates immunofluorescently purified HIV-1 antigen and synthetic peptide. A mixture of specificity and solid phase capture reagent is incubated 3 minutes at room temperature. Mixture is dispensed into a 3000 cartridge and substrate material is removed by addition of wash reagent to cartridge. Excess antibody conjugate is added to the cartridge and is allowed to incubate at room temperature for 3 minutes. Unbound conjugate is removed by addition of wash reagent to the cartridge. Following a 2 minute substrate development step, result is read from the bottom of cartridge. A distinct blue color indicates a positive test.
Results: Of 136 specimens examined, 646 were negative and 647 were positive. Observed sensitivity was 99.7%. Specificity was 100% and 99.7%, respectively. Positive predictive value was 99.7%. Negative predictive was 100%.
Conclusion. Murax 3000 HIV-1 antibody test provides an easy method for the detection of antibodies to HIV-1 and a total test time of approximately 10 minutes. Precision pipetting, specialized instrumentation and extensive training are not required.

T.B.P.138 MULTIPLE USE OF A SINGLE HIVCHECK™ DEVICE FOR SCREENING FOR HIV-1 ANTIBODIES

Basig, N.*, Galtvis, J.R.*, Tirado, J.*,
Chu, P.R.,** Chu, A.R.,** Tirado, J.,**
*The Pont de Nemours International S.A., Geneva, Switzerland, USA,
**Virus Laboratories, San Mateo, California, USA.

Objective. To provide developing nations with the capability of using HIVCHECK™ to screen for HIV-1 antibodies by reducing the cost/sample tested. Maintain the simplicity and ease-of-use of the assay technique.
Methods. Several techniques were evaluated to determine if the device was evaluated so that a device may be reused with several samples. In the preferred protocol, only one more reagent addition step is required to regenerate the device.
Results. As reported earlier, HIVCHECK™ is a very accurate, (sensitivity 100%, specificity 100%) rapid test for the detection of antibodies to HIV. To make the assay even more useful in developing nations, a HIVCHECK™ device can be regenerated after a negative sample has been assayed on a device. This is best performed by washing the device with an acid solution prior to performing the assay another time on the same device. A single device can be used with a negative sample and still detect a weak positive on the subsequent test. The acid wash will not eliminate a visibly detectable positive spot on a device with the first sample. Further detailed results will be provided.
Conclusions. By reusing a device several times, the cost/sample analyzed is significantly reduced thereby making the HIVCHECK™ assay significantly more affordable in developing nations. This regeneration of a device minimally impacts on the use of the HIVCHECK™ assay by clinicians.

T.B.P.139

A PARTICLE-AGGLUTINATION ASSAY FOR ANTI-HIV-1 IN DEVELOPING COUNTRIES

Richard, M.* (Machini), O.* (Munoz), M.* (Perez Bianco), R.* (Perez), J.M.* (Terra), Academia Nacional de Medicina, **Hospital Juan A. Fernandez, Buenos Aires, Argentina.

Objective: To evaluate the efficiency of a rapid and easy-to-use assay for HIV not requiring specialized equipment. There is an urgent need for this test in developing countries.

Methods: A particle-agglutination (PA) test (Serodia-HIV, Nippon Bio, Inc., Japan) was evaluated for screening of HIV antibodies in a panel of 504 frozen sera from high-risk individuals and in 250 blood donors. Results were compared with EIA (Abbott) and confirmed by W.R. (Dupont) and/or IP.

Results: Out of the 205 HIV-1-positive-confirmed sera, the PA detected 198. In 75 sera the reaction was equivalent (7) or less, as suggested by the manufacturer, it was scored positive. This gives a sensitivity of 100%. When we tested a panel of sera from blood donors, we observed a 95.1% specificity. The test had produced a considerable amount of false positive results.

Conclusion: In our hands, this assay showed to be very sensitive. Although specificity was not confirmed by the manufacturer, it seems that this test is suitable for its use in blood banks in developing countries. Still, we have some doubts about its use with frozen sera from high-risk groups. Repeatedly frozen sera could give false positive reactions which should be avoided.

T.B.P.140

EVALUATION OF A NEW RAPID SCREENING ASSAY FOR HIV ANTIBODIES

Richard, M.* (Machini), O.* (Munoz), M.* (Perez Bianco), R.* (Perez), J.M.* (Terra), Academia Nacional de Medicina, **Hospital Juan A. Fernandez, Buenos Aires, Argentina.

Objective: To describe the efficiency of a very rapid test (less than 15 minutes), suitable for use in developing countries.

Methods: The "HIVRUC" test (Dupont) was evaluated using 94 frozen sera from high-risk individuals and containing 56 sera HIV-1-positive by EIA (Abbott), confirmed by IP, HADAGE (Abbott) or W.R. (Dupont), and 38 HIV-1-negative sera. Fresh sera from 50 blood donors was also evaluated.

Results: Out of 56 frozen sera repeatedly positive by EIA, the new test only detected 53, which gave a sensitivity of 93.3% and a specificity of 98.7%. When fresh sera from 50 blood donors were excluded and we considered only fresh-blood sera, the sensitivity of the test was 100% and the specificity 98%. Although some sera were not correctly absorbed to the paper and considered undetermined, some fresh sera from the first and the 1-week-later assays. There were no doubtful results and all the sera absorbed perfectly well to the filter.

Conclusion: The "HIVRUC" is an excellent method to be used in developing countries where there is a need for a rapid and simple method with no additional costs. This is a preliminary report, but it seems this test works very well with fresh sera and, on the contrary, there is a lot of difficulties with sera that have been previously frozen. Apparently, sera can be shipped long distances unfrozen, at 4°C, without alteration of results.

T.B.P.141

EVALUATION OF LABORATORY PERFORMANCE OF ENZYME IMMUNOASSAY TESTS FOR HIV-1 ANTIBODY

Richard, M.* (Machini), O.* (Munoz), M.* (Perez Bianco), R.* (Perez), J.M.* (Terra), Academia Nacional de Medicina, **Hospital Juan A. Fernandez, Buenos Aires, Argentina.

Objective: To evaluate laboratory performance of human immunodeficiency virus type 1 (HIV-1) antibody enzyme immunoassay (EIA) tests, the screening test primarily used in the United States to detect infection by HIV-1.

Methods: A panel of 22 samples was mailed in May 1988 to 1,309 laboratories enrolled in the Centers for Disease Control's Model Performance Evaluation Program (MPEP) antibody testing in the specific application being used to develop this program. The panels consisted of both single donor and pooled donor samples. Not all laboratories received the same 22 samples; 23 different lots of samples were actually used. All samples were provided in blind duplicate.

The HIV-1 antibody reactivity levels varied from negative to weakly reactive to positive. In addition to providing sample analysis, laboratories also provided information describing their laboratory and testing practices.

Results: Enzyme immunoassay results were reported by 1,201 laboratories; 48 percent were hospital laboratories, 19 percent blood banks, 11 percent independent laboratories, and 22 percent public health laboratories. Most of the laboratories (80 percent) reported only EIA test results; that is, they did not perform confirmatory testing. By manufacturer, 63 percent of the percentage used a kit from Abbott; 9 percent used Genetic Systems; 9 percent, DuPont/Walton; 4 percent, Cetus; 4 percent, Ortho; and 4 percent, Electrochemica. For the sensitive samples, the percentage correctly interpreted ranged from 74 percent to 100 percent and for the strong positive samples, from 98 to 100 percent.

Conclusion: Screening for HIV-1 antibodies is performed well by most laboratories in a variety of settings. Nonetheless, small errors and weak HIV-1 antibody reactivity are the cause of some of the observed performance problems.

T.B.P.142

Results of CDC's Model Performance Evaluation Program for HIV-1 Antibody Testing

Richard, M.* (Machini), O.* (Munoz), M.* (Perez Bianco), R.* (Perez), J.M.* (Terra), Academia Nacional de Medicina, **Hospital Juan A. Fernandez, Buenos Aires, Argentina.

Objective: To track trends in testing, to characterize HIV-1 testing laboratories and evaluate their performance, to document changes in performance and impact on public health, to evaluate emerging technology, and to identify possible sources of error and intervention strategies.

Methods: A combination of comprehensive demographic questionnaires and performance evaluation surveys were used to obtain lab descriptive data and test results. Questionnaires requesting information on lab type, personnel, workload, and testing procedures were mailed to labs in May and October 1988. Shipments of 22 samples per lab were mailed in February, May, and September of 1988. Results were tabulated and analyzed. Summary reports were returned to the participants.

Results: About 1400 laboratories are enrolled in this voluntary program. Both lab descriptive data and test results were usually provided by a high percentage of the labs (typically >90%). Enzyme immunoassay (EIA) results were reported by about 1200 laboratories, Western blot (WB) by about 250, and immunofluorescence by about 70. Results were compared by method and test manufacturer. Problems were identified with some commercial EIA kits with some samples. Need for standardization of WB test was apparent.

Conclusion: No serious performance problems were detected. Data will be used to develop a profile of labs which perform high quality testing. Continued operation of the program is required to monitor rapidly changing technology and applications.

T.B.P.143

CENTERS FOR DISEASE CONTROL MODEL PERFORMANCE EVALUATION PROGRAM RESULTS OF THE WESTERN BLOT AND INDIAN IMMUNOFLUORESCENCE TESTS FOR DETECTION OF HIV-1 ANTIBODIES

Richard, M.* (Machini), O.* (Munoz), M.* (Perez Bianco), R.* (Perez), J.M.* (Terra), Academia Nacional de Medicina, **Hospital Juan A. Fernandez, Buenos Aires, Argentina.

Objective: To evaluate, through mailed sample panels, the performance of laboratories that test for human immunodeficiency virus type 1 (HIV-1) infection and to track changes or trends in Western blot (WB) and indirect immunofluorescence (IF) testing through three periodic performance evaluation programs.

Methods: Panels containing 22 serum samples obtained from confirmed HIV-1 antibody-positive and antibody-negative donors were sent in May and September 1988 to the approximately 1,400 laboratories enrolled in a voluntary performance evaluation program. Panels were sent to 1,212 laboratories that returned results after testing the May performance panel samples, 229 (18.9%) and 71 (5.7%) laboratories reported WB and IF results, respectively. Among the 1,125 laboratories that returned results after testing the September performance panel samples, 260 (23.1%) and 67 (5.9%) reported WB and IF results, respectively. Eleven WB kits (commercial and in-house) were used by the laboratories in both surveys; whereas, 77% of the results were reported with five commercial kits. Six IF kits (commercial and in-house) were used in both surveys. Little difficulty was demonstrated by the majority of the laboratories in reporting interpretations for the strong positive and true negative samples for the WB and IF. Some laboratories reported vital specific bands for true negative samples that otherwise often were reported as positive. Some laboratories reported results that contained weak specific bands. Some laboratories experienced difficulty in IF result interpretation for samples that showed low reactivity in the enzyme immunoassay.

Conclusion: While no specific trends in WB or IF were observed, the data suggested that fewer survey samples are needed for continued evaluation of laboratory performance.

T.B.P.144

QUALITY CONTROL FOR ANTI HIV TESTING: THE EXPERIENCE OF CHETUMAL, YUCATAN, MEXICO

Richard, M.* (Machini), O.* (Munoz), M.* (Perez Bianco), R.* (Perez), J.M.* (Terra), Academia Nacional de Medicina, **Hospital Juan A. Fernandez, Buenos Aires, Argentina.

Objective: The availability of various anti HIV commercial kits and the concern for valid results led to the establishment of a panel of well defined sera for assessment of the quality control panel.

Methods: A panel of sera was assigned for anti HIV using various kits in two laboratories. Results were compared by method and test manufacturer. Problems were identified with some commercial EIA kits with some samples. Need for standardization of WB test was apparent.

Conclusion: No serious performance problems were detected. Data will be used to develop a profile of labs which perform high quality testing. Continued operation of the program is required to monitor rapidly changing technology and applications.

T.B.P.145 PROBLEMS ENCOUNTERED IN HIV SEROLOGY Faktor, Gerald; McLaughlin, B. Ontario Ministry of Health, Toronto, Ontario, Canada.

Objective. With over 150,000 specimens submitted for HIV serology, we have encountered and described a number of difficult cases and situations which can lead to erroneous double and/or triple testing.

Method. The problems ranged from simple specimen misidentification to complex situations including: the contamination of a negative serum by a minute quantity of positive serum (by submerging laboratories) carryover from positive to negative wells in the test procedure, detection of passive antibodies due to the administration of HIV seropositive immune globulin; interpretation of indeterminate results; cases of apparent sero-reversion; and failure of standard procedures to detect HIV antibodies in infected individuals.

Results. Mechanisms have been installed to detect the above mentioned situations, including double verification of tube and reagent identification, requests for whole blood rather than serum samples, careful scrutiny of confirmatory test results for weakly reactive or unusual results, facilities with clinical and risk group information provided by physicians and requests for follow-up specimens. **Conclusion.** Laboratories must remain aware of the potential for erroneous results to occur and of the serious consequences of inaccurate results for the patient and the community at large.

T.B.P.147 MORTALITY IN CHILDREN WITH AIDS: AGE AT DIAGNOSIS AS RISK FACTOR Isaiah, Sylvia; Bant, M.; Stone, R.E.; Cronbach, D.S.; Hasenauer, E. New York Medical College, New York, N.Y.

Objective. To compare mortality in children diagnosed as AIDS in the first year of age (group I), vs those diagnosed above one year (group II). **Methods.** The study was performed at two public hospitals in New York City on sixty two patients with perinatal HIV infection, admitted from 1984-1988 and followed for 1-50 months (mean 18 mo). All mothers except three were intravenous drug abusers. The majority of patients in group (I) were symptomatic in the first six months of life. The G consisted of 42 patients, 14 blacks (3) and 28 Puerto Ricans (PB), 21 males (6) and 21 females (15). G II comprised 20 patients, 13 b and 7 Fb, 12 m and 8 f, ranging in age from 11.3 to 72 months (mean 17 mo).

Results. Mortality was significantly higher in GI vs GII: 42% vs 31%. **P=0.001.** No significant sex and race differences were found in GI (32% mortality in f, 33% in m, 50% in b and 39% in Fb), but mortality was higher in f than b (80% vs 33%). The majority of patients died of pneumocystis carinii pneumonia (PCP). In GI only 4% died. **Conclusion.** Infants with perinatal HIV infection who become asymptomatic at an early age have a high mortality rate and females seem more at risk. Long term follow-up is needed to establish mortality rates in older infants and children.

T.B.P.149 CUTANEOUS MANIFESTATIONS OF PEDIATRIC HUMAN IMMUNODEFICIENCY VIRUS INFECTION Frost, Neil S. State University of New York, Health Science Center at Brooklyn, Brooklyn, N.Y., U.S.A.

Objective. To describe the varied cutaneous manifestations of HIV infection in children.

Methods. One hundred and twenty-two children with HIV infection were examined as part of a dermatologic consultation service at three area hospitals. Skin biopsy and culture were performed as necessary.

Results. We have developed an overview of the various cutaneous manifestations of pediatric HIV infection, and of the natural history of these disorders. There is no single cutaneous disease that is pathognomonic for HIV infection during childhood. The cutaneous manifestations of HIV disease in children are primarily fungal, bacterial, and viral infections. These include recalcitrant oral and cutaneous candidiasis, cellulitis, severe herpes simplex and herpes zoster, and unusual dermatophytoses. All of these manifestations are distinguishable by their severity, frequency of recurrence, and poor treatment response. We have also seen patients with severe atopic dermatitis, widespread flat warts, drug eruptions, chronic varicella-zoster infection, and unusual patterns of bacterial and viral infections. **Conclusion.** Familiarity with both the common and unusual patterns of cutaneous disease in HIV-infected child can aid in early diagnosis, and in the treatment of opportunistic infections.

T.B.P.146 ENHANCED CARDIAC FUNCTION IN PEDIATRIC HIV INFECTION. Shaw, E. Lippitt, Stephen P. Saxon, Steven S. Cole, Kenneth McDonald, Children's Hospital, Boston, MA, USA.

Objective. Fifty four pediatric patients with HIV infection underwent serial echocardiographic evaluation (n=133) of cardiac function as part of a natural history study. **Methods.** The M-mode shortening fraction was used to assess left ventricular (LV) function, and systolic and aortic EDSWs to measure afterload, and the relation between rate-adjusted velocity of fiber shortening and EDSWs to evaluate contractility. This load-independent index allowed determination of contractility despite changing heart size and blood pressure. **Results.** At initial evaluation 50% of patients had hyperdynamic LV function, generally associated with enhanced contractility and reduced afterload. During follow-up of up to 57 months, function decreased to normal or subnormal in 69% of patients with hyperdynamic function initially. In contrast, function or contractility did not normalize in six patients with normal function and contractility. Hypodynamic LV function was noted on one or more exams in 36 patients. Irrespective of stage of disease or route of infection, this group (n=36) all patients with documented high-grade aortic (b/a), sudden unexplained death (s/u) and 4/5 patients with evidence for cardiac or organ mononuclear infiltrate at autopsy. A change to enhanced LV function was observed in patients with previously normal function who developed mononuclear infiltrative disease of other organ systems. Unusual heart rate and blood pressure variability as well as exaggerated heart rate and blood pressure responses to medications were seen in these patients. These findings as well as autonomic function testing in selected patients are consistent with enhanced sympathetic tone. **Conclusion.** Hyperdynamic LV function is a common finding in early pediatric HIV infection, often associated with autonomic instability and mononuclear infiltrative disease, and may be a marker for arrhythmias or sudden death.

T.B.P.140 ISOLATION OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) FROM CEREBRAL TISSUE AND CHARACTERIZATION OF ITS BIOLOGICAL PROPERTIES Dimitrov, D.R.; Geyer, F.; Spector, A.A.; Melsink, J.L.; Shearer, W. and Hollinger, F.; Blaine, R. Baylor College of Medicine, Houston, Texas, U.S.A.

Objective. To report the detection and isolation of HIV from the cerebral tissue of two clinically infected children, 2 and 3 years old, with neurologic dysfunction.

Methods. Electron microscopy (EM), histology, and cell culture. **Results.** Neuropathologic evaluation of both children revealed marked cerebral atrophy. At postmortem examination, both brains showed encephalopathy, cerebral atrophy and decreased myelin. EM examination of the white matter of the brain revealed areas with myelin and cell degeneration. In these areas, infection of oligodendrocytes with HIV was inferred based on the presence of typical viral core structure and HIV-1A particles in the endoplasmic reticulum of these cells. Occurrences of normal donor PBMCs with 1 x 10⁶ neural cells from these infected children yielded evidence of HIV infection as manifested by the expression of HIV p24 antigen in culture supernatants. These neural viral isolates readily infected T₄ B and monocyte cell lines, e.g. Jurkat, MT-2, Raji, U937, HL-60 and THP-1, as determined by the detection of HIV p24 antigen in culture supernatants. The neural viral isolates were not cytotoxic for these cell lines. **Conclusion.** These data suggest that HIV is associated with the neuropathology observed in the brain of infected children.

T.B.P.150 CLINICAL SPECTRUM OF HUMAN IMMUNODEFICIENCY INFECTION IN CHILDREN LESS THAN 4 MONTHS OF AGE. T. Schwartz, M.D., Leiby, A., Fine, S.J., Fallon, Boston City Hospital and Boston University School of Medicine, Boston, MA, U.S.A.

The early recognition of children with infection due to Human Immunodeficiency Virus (HIV) may permit intervention strategy such as nutritional supplementation, prophylactic antineoplastic therapy, or experimental antiretroviral chemotherapy. We report on 11 HIV-1A seropositive children (ages 1-4 months) who presented with clinical signs and symptoms before 4 mos. of age. The earliest at diagnosis was male at 10 weeks of age in a child with thrombocytopenia at birth, who developed hepatosplenomegaly (HSM). A additional child presented before 4 mos. of life; 2 with proven PCP requiring mechanical ventilation, and 3 with axillary adenopathy and poor weight gain. 2 of the 11 children had the diagnosis established before 3 mos. of age; 1 with failure to thrive requiring nightly nasogastric tube feeding and axillary adenopathy, and 1 with developmental delay and presumed PCP. A of the 11 children presented before 4 mos. of age: HSM and lymphadenopathy (1), recurrent sepsis (1), suspected PCP pneumonia (1) and adenopathy (1) were the presenting signs. Of the 11 cases, 10 had mucocutaneous candidiasis by exam or history prior to 3 mos. of age, and 7 of the 11 children had significant adenopathy at presentation. In 7 of the 10 children, IgG was already greater than normal. Ultrasonid in 1 child revealed echo densities in the basal ganglia in the absence of neurologic findings. Children have been followed for a median of 6 mos. (range 1-46) since diagnosis. 3 of the 11 children developed a progressive thrombocytopenia resulting in death. All 3 were Haitian; illness in 2 of the 3 was complicated by infection with CMV, and one of the 3 had significant adenopathy.

T.B.P.151 HIV ACTIVATION BY COFACTORS: P-24 ANTIGENEMIA AFTER INJECTIONS OF SOLUBLE ANTIGENS IN CHILDREN WITH AIDS

Santaloro, G., Charvet, J., Plouffe, C., Gagnon, M., Hôpital Ste-Justine, Université du Montréal, Montréal, Québec, Canada.

OBJECTIVES: To monitor P-24 antigenemia (Ag) following repeated KLN injections and to correlate with immunologic status of patients.
Methods: The study was conducted in HIV positive immunodeficient symptomatic children, asymptomatic adults, HIV negative children and adults. KLN was injected at 0 and 14 days. P-24 antigen (Abtest) was measured at 0, 14, 28 days and results were expressed after neutralization. Lymphocyte sub-populations, mitogen and KLN responses, anti-KLN antibodies by ELISA and PCR were measured at 0, 14, 28 days.

RESULTS: 25 individuals of which 13 were HIV positive were injected with KLN. Results of 7 remaining children developed P-24 Ag. All met criteria for pediatric AIDS and were immunologic (mean T-cell counts = 1946, CD4 = 462, CD8 = 1037 ± 656), had depressed mitogen responses and no significant antibody response to KLN. In asymptomatic HIV positive mothers, injections were associated with the appearance of P-24 Ag in 2 cases, and increase in P-24 Ag in 1 case. They had low normal T-cell count, low CD4 (59.7% ± 2.2) and CD8 (55.5% ± 3.1). Mitogen responses were generally normal, antibody response to KLN was partly abolished, no significant change in lymphocyte sub-populations was noted during the study.

CONCLUSION: Injection of soluble antigens may trigger P-24 antigenemia and this seems to be limited to asymptomatic moderately immunodeficient individuals. The clinical relevance of these findings requires further study.

T.B.P.152 NATURAL HISTORY OF LYMPHOCYTE IMMUNOLOGICAL DEFICIENCY (LID) IN PERINATAL HIV-1 INFECTION

GEIS, GONCALVES, SOUZA, G., CASTRO, A., BRADFORD, B.B., MESTRUCIO, M., PARKS, W. UNIVERSITY OF MIAMI SCHOOL OF MEDICINE, MIAMI, FL, U.S.A.

OBJECTIVE: To review the natural history of LID in pediatric AIDS focusing on the clinical, radiological and immunological parameters.
Methods: From January 1984 to February 1989, 48 cases of LIP were diagnosed among 172 cases of perinatally HIV-1 infected children. Charts were reviewed retrospectively. X-rays were reviewed by the same radiologist. 100% of the children were black.

Results: Radiologically, LIP developed at a mean age of 16 months. Chronic lung disease with oxygen dependency and clubbing occurred in 30%. The reticulonodular pattern on chest x-rays cleared in 64. Physical examination revealed lymphadenopathy 100%, hepatomegaly 90%, splenomegaly 60%, proctitis 78% and failure to thrive in 69%. Common infections included bacteremia 50%, bacteriuria 59%, recurrent otitis media 69% and recurrent diarrhea 59%. Opportunistic infections were less common. Mean level of IgG at onset of LIP was 4421 mg (20 patients). Acute levels at less than 1000/dg were seen in older patients at a mean age of 5 years.

Mean level at a mean age of 14 months. Those who died often had concurrent opportunistic infections and significantly elevated IgG mean 6124 mg. **Conclusions:** LIP is often associated with lymphadenopathy, hepatomegaly, failure to thrive, proctitis, bacteremia, bacteriuria and recurrent otitis media. Opportunistic infections are rarely associated. Mortality is significantly decreased as compared to overall Pediatric AIDS mortality of 57%.

T.B.P.153 PNEUMOCYSTIS CARinii PNEUMONITIS (PCP) IN CHILDREN WITH RENAL IMMUNODEFICIENCY Yaws (HIV-1) INFECTION

Sanchez, Bayes, J., Buitel, L., Rodriguez, M., A. and Parks, W. UNIVERSITY OF MIAMI SCHOOL OF MEDICINE, MIAMI, FL, U.S.A.

Objectives: To determine the clinical course and outcome of children with HIV-1 infection and PCP.

Methods: Hospital admission of 19 HIV-1 infected children diagnosed with PCP between January, 1983 and December, 1987 were retrospectively reviewed.

Results: Eighteen children had perinatally acquired HIV-1 infection and one acquired infection in the neonatal period through blood transfusion. There were eleven females and eight males. Seven of these children presented with PCP as their first manifestation of HIV infection. The median age at onset of PCP was 3-6 months with a range from 3-60 months. Diagnosis was made by demonstration of the organism in specimens from endotracheal aspirates (8), bronchoalveolar lavage (6), biopsy (4), and autopsy (1). Elevated IgG levels and depressed numbers of T helper cells were the most common immune abnormalities present at diagnosis of PCP. All children received oxygen therapy. Eight patients were intubated and received assisted ventilatory support for a mean time of 31 days. (Median survival post-PCP was 10 months (range 3-53 months) for patients not requiring intubation and 1 month (range 2-11 months) in intubated patients. All but one of the children have died.

Conclusion: The early age of onset and the high mortality and morbidity associated with PCP in children emphasize the importance of early recognition of infants at risk and indicates a role for PCP prophylaxis.

T.B.P.154 GENERAL DYSFUNCTION IN PERINATAL HIV

McCarthy, Ellen, Jones S, Raju, N, Rhee R, University of New York Medical College, White Plains, New York, N.Y.

OBJECTIVE: To study the hypothalamic-pituitary-adrenal axis in HIV-1 infected children. **Methods:** 12 patients aged 8 months to 9 years (median 3.5 years) with HIV-1 infection were studied. All others were HIV-1 negative. **Results:** All others were HIV-1 negative. **Conclusions:** LIP is often associated with lymphadenopathy, hepatomegaly, failure to thrive, proctitis, bacteremia, bacteriuria and recurrent otitis media. Opportunistic infections are rarely associated. Mortality is significantly decreased as compared to overall Pediatric AIDS mortality of 57%.

AGE (yr)	ACTH (pg/ml)	Baseline	Post-stress	Post-stress	Post-stress
		Basal	Basal	Basal	Basal
1	11.1	14.0	14.0	14.0	14.0
2	11.1	14.0	14.0	14.0	14.0
3	11.1	14.0	14.0	14.0	14.0
4	11.1	14.0	14.0	14.0	14.0
5	11.1	14.0	14.0	14.0	14.0
6	11.1	14.0	14.0	14.0	14.0
7	11.1	14.0	14.0	14.0	14.0
8	11.1	14.0	14.0	14.0	14.0
9	11.1	14.0	14.0	14.0	14.0
10	11.1	14.0	14.0	14.0	14.0
11	11.1	14.0	14.0	14.0	14.0
12	11.1	14.0	14.0	14.0	14.0

CONCLUSION: Though the majority of patients (72%) demonstrated normal adrenal function, a significant number (28%) had abnormal function manifested by a blunted response to ACTH. Abnormal hypothalamic-pituitary-adrenal axis was associated with elevated ACTH levels.

T.B.P.155 BRONCHO-ALVEOLAR LAVAGE TO EVALUATE PULMONARY STATUS IN THE HIV INFECTED CHILD

Sanchez, Bayes, J., Buitel, L., Rodriguez, M., A. and Parks, W. UNIVERSITY OF MIAMI SCHOOL OF MEDICINE, MIAMI, FL, U.S.A.

OBJECTIVE: To determine the clinical course and outcome of children with HIV-1 infection and PCP.

Methods: Hospital admission of 19 HIV-1 infected children diagnosed with PCP between January, 1983 and December, 1987 were retrospectively reviewed.

Results: Eighteen children had perinatally acquired HIV-1 infection and one acquired infection in the neonatal period through blood transfusion. There were eleven females and eight males. Seven of these children presented with PCP as their first manifestation of HIV infection. The median age at onset of PCP was 3-6 months with a range from 3-60 months. Diagnosis was made by demonstration of the organism in specimens from endotracheal aspirates (8), bronchoalveolar lavage (6), biopsy (4), and autopsy (1). Elevated IgG levels and depressed numbers of T helper cells were the most common immune abnormalities present at diagnosis of PCP. All children received oxygen therapy. Eight patients were intubated and received assisted ventilatory support for a mean time of 31 days. (Median survival post-PCP was 10 months (range 3-53 months) for patients not requiring intubation and 1 month (range 2-11 months) in intubated patients. All but one of the children have died.

Conclusion: The early age of onset and the high mortality and morbidity associated with PCP in children emphasize the importance of early recognition of infants at risk and indicates a role for PCP prophylaxis.

T.B.P.156 UNUSUAL MORTALITY FROM PNEUMOCYSTIS CARinii PNEUMONITIS (PCP)

Chow, Jean; Shah, K. A.; K. Gupta, A.; Chhabra, L.; Kaul, A.; Greenough, J. F. Department of Pediatrics, New York Medical College, New York, USA.

Objective: Is PCP in early infancy universally fatal if no, what are the differences in the onset, course, and mortality compared to older children?

Methods: From 1984 to 1989, over 110 infants and children with HIV have been seen at 3 hospitals. PCP was confirmed in 15 children, from tracheal washings (3), lung biopsy (12), or to autopsy (1).

Results: 13/15 children were 6 months or younger. 13 previously healthy infants were thriving well. Associated physical findings included oral thrush (12), hepatomegaly (10), generalized lymphadenopathy (7), and perianal fever (13). They presented with acute respiratory illness which rapidly progressed to respiratory failure. Course in older children was more protracted. Antimicrobial therapy with TMP/SMX and/or trimethoprim was initiated in 14/15 children. Despite early and aggressive therapy, 11/13 infants expired at first presentation. One surviving infant died at 11 months of age. Both of the older children are alive at 2 years after PCP. Interestingly, lung biopsies in both the older children also showed lymphocytic interstitial pneumonitis (LIP).

Conclusion: PCP in early infancy can be a rapid and invariably fatal illness. Primary infection, not reactivation of latent infection. Prospective studies of antimicrobial prophylaxis of PCP may show the greatest benefit in first year of life.

T.B.P.157

SEROEPIDEMIOLOGY OF HIV INFECTION IN AN URBAN PEDIATRIC POPULATION

Lalith Padmanab K, Joseph, S, Gerson, P, Gayle, H*

*Children's Hospital National Medical Center, George Washington University School of Medicine, Washington, DC and **Centers for Disease Control, Atlanta, Georgia, U.S.A.

Objective: To evaluate seroprevalence to HIV in children in a large, urban community with a high incidence of AIDS and drug abuse.

Methods: We conducted an anonymous, blind serosurvey on discarded blood samples from children aged 2-6 years who presented to outpatient and community-based outreach clinics served by our pediatric teaching hospital between 1/87 and 12/88. Demographic information from the surveillance study was compared to that obtained on age-matched seropositive, who were HIV tested for clinical indications. Parents of HIV seropositive children were contacted for consent for by limiting the enrollment age to 2-8 years, respectively.

Results: 4120 specimens were tested, 508 (2007) from males and 4013 (1763) from females. The overall sample had a mean age of 3.72 ± 2.53 years. All 8 seropositive were seropositive by EIA and 9 (2%) were repeatedly reactive. Western blots confirmed 6 of the 9 EIA for a seroprevalence of 1.57/1000. 3 were indeterminate. We suggest: 1) All HIV positive specimens were from black children, age 2.3-6.6 years (N = 524 ± 2.9), 1 male and 4 females from 5 clustered zip codes, while the 3 indeterminate were from black males with an average age 4.92 ± 1.8 years. Although the Emergency Room (ER) indicated for 50% of total specimens, 60% of positive or indeterminate specimens were from the ER. There were no positive specimens (0/51) among age-matched children tested for clinical indications during the same time interval.

Conclusion: HIV infection is present in 0.12% of urban children; a major source of identification is by presentation to the ER. Sequential analysis will define trends in the spread of HIV over time.

T.B.P.159

MATERNAL DRUG ABUSE AND PERINATAL HIV SEROPREVALENCE

Chechick, R.T., Hand I., Mignis, Andrew, Kim, M., Sobie, L., Tom, J. Albert Einstein College of Medicine, Bronx, N.Y. U.S.A.

Objective: Assess the prevalence of HIV seropositivity (+) in infants of drug abusing mothers (IDM) and HIV seropositive non-IDM (NIDM) mothers.

Methods: In a six month period in 1988, HIV antibody was studied by Elisa and confirmed by Western blot in 102 IDM with maternal consent. All infants were examined and maternal and neonatal data were compared in the IDM*, HIV+ infants and non-IDM control groups.

Results: In 1988, 3-15 of mothers were IDM (75/9437) compared to 12.85 (367/2866) in 1989, (p < 0.001). A 19.85% (30/151) incidence of HIV+ was higher than a 6.5 (5/78) in the non-IDM normal women (p < 0.1). As expected, the HIV (+) rate was higher in the 15 IV IDM than the 86 non IV IDM (50% vs 14%) (p < 0.001). There were no significant differences in race, maternal age or mode of delivery in the HIV+ and HIV- groups. Lack of prenatal care was similar as was the incidence of maternal syphilis. Maternal smoking, alcohol and drug use were also similar in these groups. Gestational age (37.5 vs 37.5) birth weight (3230 vs 3158), 12% rate (60/5 vs 23%) and 80% infants (30/3 vs 16%) and microcephaly (ECRDI: 205 vs 111%) were not significantly different in the above groups, though they differed from the general population (p < 0.001).

Conclusion: No neonatal factor were identified which could be attributed to HIV seropositivity. Decreased GA and BW and increased incidences of IUGR, OIA, and microcephaly may be due to maternal drug abuse, not HIV. Maternal IV drug abuse is a significant risk factor for HIV seropositivity. However, 60% of HIV mothers did not have any history of IV drug abuse. This suggests that heterosexual contact plays a significant role in the HIV transmission.

Pediatrics: Natural History

T.B.P.161

CLINICAL & HISTORICAL FEATURES ASSOCIATED WITH PERINATAL HIV INFECTION IN LOS ANGELES COUNTY, CALIF.

Friedland, Tom*, Smith, L.L., Bess, M., O'Connell, J., Reynolds, L.,**

Kovacs, A.,** et al.
*Los Angeles County Health Dept., Dept. of Health Services,
**University of California Los Angeles, L.A., Calif., U.S.A.

Objective: To gain insight into the clinical and immunologic spectrum of perinatal HIV infection using data from a Los Angeles County (LAC) active surveillance program.

Methods: An active surveillance system for perinatal HIV infection began in 1986. Birth, clinical and lab data from medical records, HIV infected children was classified using the latest CDC classification system and whether they had serologic or immunologic abnormalities.

Results: As of 12/20/89, LAC had 139 cases of perinatal HIV infection. HIV (+) had AIDS, 38 (27%) had symptoms but not AIDS, 33 (24%) were seropositive, and 18 (13%) were indeterminate (difficult to see without virologic evidence of infection). About half of these cases (excluding the indeterminate) had immunologic data available. AIDS and seropositive cases differed on all serologic features. Among the AIDS cases, 76% had a T cell count < 0.004³, 100% had a T4/T8 ratio < 1.0, 60% had a CD4/CD8 ratio < 0.016³, and 40% had total IgG levels less than 1.0 mg/dl. Among those seropositive, only sero-2/3 cases had abnormalities as well; 65% had abnormal T4/T8 ratios, 30% had increased immunoglobulins, 2% had abnormal IgG concentrations.

Conclusion: The spectrum of clinical, clinical and immunologic abnormalities among HIV infected children is great. Detailed serologic and clinical data will better define the natural history of HIV infection in children with regard to clinical and laboratory parameters.

T.B.P.158

HIV INFECTION AND PEDIATRIC AIDS IN SEMI-RURAL DAROU PROTESTANT HOSPITAL (DROY COAST)

* Protestant Hospital, Darou, Ivory Coast ** Pasteur Institute, Abidjan, Ivory Coast *** CNRS Lab Faculty of Medicine, Alexis Carrel, Lyon, France

Within a year (Feb 87-Jan 88), 793 suspected cases of pediatric AIDS based on Burchard criteria and/or with severe malnutrition were tested for HIV-1 and HIV-2 by ELISA and then western blot. 73 (23.6%) had confirmed antibodies to HIV; 43 (57.9%) exhibiting HIV-1 reactivity, 4 (14%) HIV-2 reactivity and 4 (2.7%) double reactivity. No difference in symptom frequency was observed between these sub-groups.

Mothers of 68 positive children were also tested. In 88 cases (78%), the child infection probably originated from seropositive mother; in further 10 cases the mothers were positive but the children were transfused, so the origin of infection remained problematic in 8 children, the origin of infection remained unknown as their mothers were seronegative and the children did not receive transfusion.

The study of 100 sequential cases of pediatric severe malnutrition showed 14 cases of HIV positivity: 11 HIV-1, 2 HIV-2 and 1 HIV-1+2. The testing of 93 corresponding mothers showed that 19 were positive (21 having a seropositive child but 7 a seronegative one). Two children with seronegative mothers had been contaminated by blood transfusion.

Among 83 HIV positive children, 11 died during hospitalization, 16 were moribund at their discharge from hospital and 19 could be follow-up. Among those, one died within 10 months after discharge, 8 had an unfavorable evolution, but 14 exhibited improvement during a follow-up period of 3 to 6 months.

T.B.P.160

DIFFICULTIES ENCOUNTERED IN INFORMING THE PARENTS OF SERODIAGNOSIS OF HIV TESTING RESULTS IN AN URBAN COMMUNITY.

Minton, Andrew, Gaffrey, BC, Chechick, R., Therpe, A., Daley, T., Casper, M.S. Bronx-Lebanon Hospital, Bronx, New York, U.S.A.

Objective: To evaluate maternal compliance in infants at risk for HIV.

Methods: Bronx-Lebanon is located in the South Bronx, an area highly endemic for HIV infection (4-3% of pregnant women are HIV infected). Maternal consent to routinely sought to screen newborn whose mothers had identified risk factors for HIV. An appointment is scheduled for two weeks later to discuss the test results. Missed appointments are pursued by telephone calls and certified letters. Older children at risk, identified during hospitalizations, will child care or from outside sources are also screened with parental consent. All identified children are to be followed in an immunology clinic.

Results: Appointments to receive testing results were attended by only 32 of 114 mothers. These include 29 (25%) of the 101 HIV negative newborns and 3 of 13 (23%) infants with positive HIV serology in spite of multiple attempts to contact these mothers. In contrast, 21 of 23 (91%) of the older HIV infected children have been compliant with medical follow-up.

Conclusion: In this urban community, the rate of success in communicating HIV testing results to mothers of neonates is poor once that infant is discharged in spite of the mothers granting informed consent. A more rapid reporting of results and informing the mother prior to discharge may improve compliance with medical follow-up.

T.B.P.162

NEONATAL PERINATAL GENETIC MUTUAL HISTORY PROGRESS REPORT.

Goodman, Ed.,* Schrock, M., Denny, T.,* Octay, M.,*Ott, C.F.,* Glesne, J.,* et al., Children's Hospital of NO at

Emory School, Emory Univ., Atlanta, Georgia, U.S.A.

OBJECTIVE: In 3/87 a study of infants (INF) born to HIV infected mothers (MO) at a large hospital in New York was initiated to define the rate of perinatal transmission of HIV and the natural history of these INF.

Methods: HIV-1 MO who delivered INF are invited to participate. INF are prospectively monitored every month until, then every 2nd mo. up to, and every 3rd mo. thereafter. Clinical, immunologic, serologic and virologic data are collected at specified intervals.

Results: Forty seven INF born to 44 HIV seropositive MO. Mean age of MO = 29.7 yr (16-38); 93% black, 8% Hispanic, 38 white; 80% were IV drug users and 20% acquired HIV by sexual contact. At delivery 84 were asymptomatic, 108 ANC and 108 AIDS. Mean gestational age of INF = 36.5 wk (33-40); 19 were OIA and 6 were SIA. There were 29 INF that were followed for > 9 mo. Five INF were considered HIV infected: 3/6 had HIV cultures, 2/3 had HIV symptoms and died at 247 mo, 3/3 had HIV IgG and +P 24 IgG; both are well and one had +PCR and 1 + PCR. Of the remaining 24 INF, 8 are considered re-infectants while 16 are well but indeterminate. One of these infants died at 2 mo of complications of prematurity. Seven of 8 PCR assays on this group were negative and one positive. All 8 re-infectants are 17 mo INF.

CONCLUSIONS: While it is premature to determine transmission rate, it is significant that 93% of INF in this study are asymptomatic and 87% are not symptomatic. In general there was concordance between PCR and other parameters of infection.

T.B.P-175 BEHAVIORAL CHANGES IN CHILDREN WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION. Lifshitz, Maria; Benson, C. Wilson, E. and Shaver, T.T., Baylor Coll. of Med., Houston, Tx, USA.
Objective: Common neurological manifestations in HIV-infected children include acquired microcephaly, developmental delay, and pyramidal tract signs. This is a report of behavioral changes in the HIV-infected girls.
Method: Longitudinal assessment includes immunological profile, head imaging by CT scan or MRI, and neurodevelopmental examinations.

Results:
Age last evaluation Patient #1 4/7/72 year 5/7/72 year
Source: HIV stage Transformation, P-I A Maternal, P-I A
Serology (+) EIA, W. Blot (-) EIA, W. Blot
Iq, ug/dl 2420 2850
Head imaging Normal Normal
McCarthy IQ score 97 90
The neurodevelopment of patient #1 was consistently average but she had onset of behavioral problems at age 31 yrs. A conduct disorder as per DSM-III R criteria was diagnosed based on fire-setting & deliberate destruction of other's property, and physical abuse to people. Patient #1 showed delayed development at 3 yrs., however, at 5/7/72 yr. intellectual functioning was low average with a deficit in visual-motor-perception. Distractibility was first noted at 3 yrs. and has progressed to attention deficit hyperactivity disorder (ADHD by DSM-III R) responsive to Ritalin.
Conclusion: Behavioral dysfunction in children with HIV infection may be a very early manifestation of CNS involvement. These preliminary observations may be relevant for treatment planning and indicate the need for inclusion of systematic behavioral along with neurodevelopmental assessment.

T.B.P-176 NEUROLOGIC FINDINGS AS THE INITIAL PRESENTATION OF HIV INFECTION IN PEDIATRIC PATIENTS

Yildirim, Zehra, F., Bask, H., Koc, S., Dalgic, D., Nariyari, R., Fischer, G.,** The Walter Reed Neurology Research Group, Walter Reed Army Medical Center, Washington, D.C., United States of America
*Uniformed Services University of Health Sciences, Bethesda, Maryland, USA.

Objective: To describe the variability in the acute presentation of neurologic disease in children with previously unrecognized HIV infection.
Methods: Retrospective review of all military-dependent children who were diagnosed with HIV at WMMC in the past 5 years.
Results: Twenty patients with HIV infection, 10-1 or 10-2, were seen at WMMC since 1987. Initial clinical presentation with neurologic symptoms as the presenting complaint occurred in 3 patients, as represented by the following 3 patients. One child with unrecognized perinatal HIV was diagnosed with stroke and CNS plaques at age 4 months, and was diagnosed as having CNS plaques. Another child with perinatal HIV had regression in developmental milestones within a year of the first, and was diagnosed with HIV seropositivity. Later, he developed rapidly progressive neurologic deterioration and died of HIV-induced primary CNS lymphoma. A third child with transfusion-acquired HIV was diagnosed well until age 4 years when he then began to develop ataxia, apathy, loss of speech and fine and gross motor skills, and regression of cognitive functions.
Conclusion: CNS manifestations of HIV disease in children may vary from already progressive encephalopathy to rapidly deteriorating processes that include opportunistic infections and CNS tumors. Physicians who care for children should consider HIV in the differential diagnosis of any child who presents with neurologic symptoms of undetermined etiology.

T.B.P-177 AIDS-RELATED PERIPHERAL NEUROPATHY IN CHILDREN AND YOUNG ADULTS: HEMOPHILICS
Kilgus, A., Whaley, A., Lewis, E., Beckman, D., Koenig, M., Wiersma, P., et al.
Neurology, "Pediatrics and Pediatric", University of California, San Francisco, CA USA.

Objective: To assess the occurrence of peripheral neuropathy in HIV positive children and young adult hemophiliacs.
Methods: A cross sectional study was conducted. Nineteen infants and children and 6 young adult hemophiliacs, all HIV positive were examined by a pediatric neurologist for clinical evidence of a peripheral neuropathy. Seven of the children, all on an ACT protocol, and 5 of the hemophiliacs had clinical AIDS.
Results: No clinical signs or symptoms of peripheral involvement were seen in any of the 27 patients. Additionally, electrodiagnostic studies (EMG/NCV) were performed on two of the children and were normal.
Conclusion: The absence of a peripheral neuropathy in children and young adult hemophiliacs contrasts greatly with its occurrence in 35% of adult hemophiliac AIDS patients. This lack of neuropathy correlates with the absence of a specific autoantibody described in patients with HIV-related peripheral neuropathy (accompanying abstract).

T.B.P-178 PSYCHIC DEVELOPMENT OF CHILDREN BORN TO HIV INFECTED PARENTS
A. Ostfeld, C. Ostfeld, F. Wiro, S. O'Neill, M. Shapiro, A.B. Lerman
Neuropsychiatry Service - Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, PA

Objective: To investigate the influence of environmental conditions quality of mother-child relationship and HIV infection status on psychic development of children born to HIV infected Italian mothers.
Methods: Psychic development (DQ) of children born to HIV positive mothers is evaluated 3-monthly using 1) development scales (Bayley-Scales, Bayley 2) psychometric observation of mother-child interaction. The development is considered altered when the difference between chronological and mental age is more than 3 months. The mother-child relationship was classified as "adequate", "partially adequate" or "inadequate" according to a qualitative scale. Social IQ data are evaluated with a special score. **Objective:** Inferiorly degree-determined children are identified according to the clinical course of the children (IQ criteria).
Results: 85 children were studied; 42 not infected, 43 infected, 18 HIV-infected. There is no significant correlation between infection status and development IQ (p<0.05). In both infected and not infected patients there is a correlation between a low IQ and inadequate mother-child relationship and a degree/unequal environment.
Conclusion: These findings suggest that the development of the children is more correlated to the socio-economic situation and to the quality of the relationship than to the clinical status.

T.B.P-179 NEUROPSYCHOLOGICAL PROFILE OF CHILDREN WITH SYMPTOMATIC HIV INFECTION PRIOR TO ANTI-RETROVIRAL TREATMENT.
Bismuth, Eric, Mose, H., Wolpert, P., Eddy, J., Pines, P. Pediatric Branch, National Cancer Institute, Bethesda, MD, USA.

Forty-one children with symptomatic HIV infection, ranging in age from 6 months to 18 years 10 months were evaluated with an age appropriate battery of neuropsychological tests at the Pediatric Branch, NCI. Children were tested when they were stable and free from acute illness. Twenty 12-18 year olds were tested through comprehensive tests of Motor Function (TRANS), Mean Clinical IQ, and Developmental Quotient (DQ) using the Wechsler Intelligence Scale (WISC-III) and the Bayley Scales (ages 6-17). Patients also completed a verbal memory test (WISC-III) and a nonverbal memory test (WISC-III). Although a somewhat higher incidence of abnormality was found in the HIV+ than in the HIV- group (60% vs 17%, p < .05, analysis of the verbal memory and IQ subtests), no significant differences in IQ (p > .10) between these groups. On the other hand, HIVCD patients had significantly lower IQs (p < .001) than the HIVACT patients. Most types of verbal memory and the TRANS group was associated by the different indices rate to neuropsychology. The WISC-III subtests profile in other patients revealed interactions when associated with Attention Deficit Disorder.

Analysis of the IQ subtests scores for all patients on the Wechsler Adult Intelligence Scale, a semi-structured interview administered to the child's parent or primary caregiver once more indicated an significant difference (p < .05) between the HIV+ and TRANS patients. After HIVCD patients had significantly lower IQ equivalent scores (p < .001) than HIVACT patients.
Correlations between cognitive variables and hematology, neurology, and immunologic measures indicated the relation between neurologic and cognitive tests and other variables comparing HIV+ to TRANS patients. One difference in age, different education level, and IQ score had to be administered to compare (TRANS as compared to other patients). Patients and family were assessed for participation in treatment protocols at NCI, which could lead to relative success. However, when the complete assessment, neurology, and immunologic measures were used, no differences were found of a more devastating effect of prenatally HIV infection on neuropsychological development.

T.B.P-180 NEURODEVELOPMENTAL ASSESSMENT OF CHILDREN WITH SYMPTOMATIC HIV INFECTION.
Hilakivi-Clayton, Pirita J., Gomez, N., Shover, F., SURT-SAC, Brooklyn, NY, U.S.A.

OBJECTIVE: To assess the neurodevelopmental outcome of 30 children with symptomatic HIV infection.
RESULTS: Thirty children attending Pediatric AIDS Clinic at University Hospital have received neurodevelopmental evaluation as part of their clinical care. Infants under 18 months of age were evaluated as the Bayley Scales; those over 30 months on the Stanford-Binet Intelligence Scales, the Peabody Motor Scales, and the Porteus Big Board. 10 Gordon Diagnostic Scales were used to test attention in children over 10.
RESULTS: The mean age of the children in this sample is 22.5 months with 20% being of the sample under 30 months of age. Ninety-three percent have been diagnosed as having AIDS. Only 3 or 10% are functioning within normal limits. All three are less than 18 months of age. However, all of the rest of the infants under 18 months of age were severely cognitively impaired. Thus being young with this disease does not preclude developmental disability. Over half the children were mentally retarded; 6% showed severe motor delays or a specific motor deficit. One-third of the children had a specific cognitive deficit, such as low IQ of intelligence. The two school-age children were in this range and had a learning disability.
CONCLUSION: Unlike the neurodevelopmental sequelae of HIV infection are severe, these children are living and entering school and will require special education.

T.B.P.181 DEVELOPMENTAL ABNORMALITIES AND SOCIAL BEHAVIOR OTHER CLINICAL MANIFESTATIONS OF PERINATALLY ACQUIRED HIV INFECTION IN RESPON- SIVE INFANTS

Kabagho, U.*; Mendenhall, R.*; Srinivasan, R.*; Elong, S.*; Duff, P.*; Mendenhall, R.*; Special AIDS Clinic, Johns Hopkins Univ. Sch. of Med., Baltimore, Md. 21205. **Objectives:** To prospectively evaluate cognitive, motor and neurologic development of infants with perinatal HIV infection. **Methods:** 21 children of HIV-infected mothers were followed up to age 12. Group I (n=11) had HIV-1 antibody positive mothers and HIV-1 antibody negative infants. Group II had HIV-1 antibody positive mothers. Group III had HIV-1 antibody negative mothers. Bilingual Bayley trials of Infant Development testing complemented monthly neurologic examinations. **Results:** Bayley Scores in children without AIDS signs/symptoms at the time of developmental testing

Group	1	2	3	Age 12 months	Age 18 months
Mean	77	81	87	84	87
SD	12	10	10	11	12
Group II	111	100	107	107	100
SD	11	10	10	10	10

(P)Psychometric Developmental Index; (M)Motor Developmental Index; (C)Cognitive Developmental Index. **Conclusions:** Developmental delay was not observed through the age of 18 months.

T.B.P.182 NEUROCOGNITIVE FUNCTIONING AMONG INFANTS EXPOSED PERINATALLY TO HIV

Staska, Thomas E.; Stone, G.B.; Cohen, D.L.; Carlson, R.G.; Park, A.D.; Parks, W.P. Department of Pediatrics and Neurology, University of Miami, Miami, Florida, U.S.A. **Objectives:** The impact of infant leukoencephalopathy (L) on neurocognitive functioning of later assessed neonates in high-risk populations, was assessed for in a prospective study exploring cognitive, perceptual, and neurological aspects of patients' HIV infection. This paper reports on our preliminary findings. **Methods:** The Pagen was administered cross-sectionally to 19 infants at either six, nine or twelve months of age, along with Bayley, neurological exam, and laboratory studies. Subjects were the offspring of HIV-infected mothers with no history of IV drug use. **Results:** The sample yielded a mean Pagen overall performance of 58.6% (SD=6.4). Two groups displayed abnormal patterns. Three infants were unable to maintain attention sufficiently to complete the test. Of those completing the test, four displayed abnormal recognition memory (overall < 54%). The results of the Pagen testing are outlined below.

Failed or incomplete Pagen	0	0	7
HIV+ Infected-mothers	0	0	7

Failed or incomplete Pagen: 1 1 10 12
The HIV-infected who failed the Pagen showed a consistent CNS involvement on the neurological exams and the Bayley. The one HIV-infected who passed the Pagen also had normal neurological and Bayley findings. However, 1 of the HIV-infected infants who failed the Pagen there was a lack of other abnormalities, with the exception of one infant who had a repeat Bayley. **Conclusions:** Three of four infants who potentially acquired HIV infection exhibited abnormal cognitive functioning as assessed with the Pagen, and consistent deficits in neurological and developmental examinations. Further descriptive studies based upon infant behavior, memory and cognitive functioning are warranted.

T.B.P.183 NEURODEVELOPMENT IN CHILDREN WITH HIV INFECTION ACQUIRED FROM DONORIAL BLOOD TRANSFUSION

Cohen, Sarah*.; Rudy, T.*.; Karasick, B.*.; Ward, J.*.; *Walla School of Medicine, *Cedars-Sinai Medical Center, Los Angeles, Ca. **AIDS Program, Cedars-Sinai Medical Center, Los Angeles, Ca.

Objectives: The purpose of this report is to examine the neurodevelopmental course of children who acquired HIV infection as neonatal transfusion recipients. **Methods:** Neuropsychological batteries were administered to 16 HIV positive children and to a control group of 33 HIV negative children who also received neonatal blood transfusion. Serial assessments were conducted 8 months apart by a psychologist who was uninformed as to the HIV status. **Results:** Scores on two batteries indicated that the HIV positive children were similar on most neuropsychological measures to the HIV negative group as long as 4-5 years after transfusion. The two groups did not differ in their overall intelligence. Deficits were observed in the HIV positive group in measures of school achievement, memory, and fine motor performance. There were no neurodevelopmental differences between the clinically asymptomatic, P1 (n=11) and the asymptomatic, P2 (n=5) groups. **Conclusions:** A high level of cognitive functioning may be maintained in children who acquired HIV infection as neonatal transfusion recipients. Neurophysiological deterioration observed was primarily in memory, attention, and fine motor behavior. Subtle differences in cognitive functioning may be an early manifestation of encephalopathy in HIV infected children.

T.B.P.184 DIVERGENCE OF ONSET OF NEUROLOGIC AND IMMUNOLOGIC IMPAIRMENT IN INFANTS EXPOSE TO HIV SERONEGATIVE MOTHERS

Calvello, Theresa*.; Bellino, A.*.; Burti, C.*.; Ombino, M.*.; *Albert Einstein College of Medicine, Bronx, N.Y., U.S.A.; **NYU at Stony Brook, Stony Brook, N.Y., U.S.A.

Objectives: To compare the onset of neurologic impairment with the onset of immunologic dysfunction in a prospective study of perinatally infected infants. **Methods:** Peripheral blood lymphocytes from 16 infants born to HIV-infected mothers were obtained during serial follow-up visits. HIV antibody was determined by ELISA and Western Blot. Seropositive subjects were determined by flow cytometric analysis of dual-color stained samples using whole-blood lysate methodology. Standard neurologic examinations were conducted at 3 month intervals. **Results:** Three of 16 infants were born neurologically and immunologically normal through 2-7 months follow-up. Of 8 infants with neurologic impairment ranging from mild developmental delay to severe cognitive and motor deficits, 3 showed early immune dysfunction indicated as early increasing CD4/T8 ratios and low total T cell counts. Two of 3 infants with mild neurologic dysfunction not accompanied by immune defects, developed immune abnormalities later. Five infants had normal neurologic exams, but showed immune dysfunction, including hypogammaglobulinemia, decreased total T cells, increased B cells, and decreasing CD4/T8 ratios. Three infants remain immunologically negative at 18-26 months, including the hypogammaglobulinemic child. **Conclusions:** Neurologic dysfunction can precede, or occur in the absence of, immunologic impairment in infants born to HIV-infected mothers. Conversely, immune can show severe immune dysfunction with totally normal neurologic exams.

T.B.P.185 ONSET OF NEUROLOGICAL ABNORMALITIES IN INFANTS AT RISK FROM DONORIAL BLOOD TRANSFUSION

Marcus, Joseph C.*; Butler, Ch.*; Hittelman, Jim.; Mendes, H.; Goedert, J.P.; Hilligoss, R.* et al. *MCH-MSD, Balyle, NY *MCH/MSD, Bethesda, MD, U.S.A.

Objectives: To determine the nature of neurological abnormalities in infants at risk of developing AIDS. **Methods:** The offspring of women at risk of developing AIDS—drug-abusers and prostitutes—were examined neurologically at birth, then prospectively in the first year of life and 6-monthly thereafter, by 2 neurologists blinded to their serological status. Twenty-three with persistent abnormalities were found. **Results:** Twenty-two infants showed varying degrees of speech delay, from 9 months to 2 years of age. Fourteen had abnormal hand function over 6 months to 18-2 years of age. Eleven had persistent primitive responses, 6 being cross reflexes. Of the 23, 6 are definitely infected, 7 have seroconverted, while 10 have HIV-negative mothers. The abnormal findings were noted in all 3 groups.

	Speech	Manual	Persistent Primitive Responses	Develop-mental Delay	Cross/Reflex Responses
Infected	6	4	4	4	5
Seroconverted	6	5	3	3	3
HIV-negative	10	6	6	6	6

Conclusions: It has been possible to establish a pattern of neurological abnormalities in infants at risk of developing AIDS, compared to their controls, not in those with any difference in the type of onset. However, at far, only one child has shown any deterioration or loss of established functions.

T.B.P.186 NEUROLOGIC IMPAIRMENTS IN PERINATALLY HIV INFECTED CHILDREN. A PROSPECTIVE STUDY

A. Iannone, J., Ed. Metro A., *Naples, K., *Raga, E., *Bastello F., et al. Department of Pediatrics, "Gaetano Capone" University of Palermo, Italy.

Objectives: To study the neurological manifestations in children born to HIV positive mothers. **Methods:** All children born to HIV positive mothers in high risk groups are clinically and neurologically evaluated at birth and at 3 monthly intervals. The Brunet-Leslie scale is administered to all children at 30 of age and Bayley Revised test to the other patients every 3 months. The infected children only undergo CT scan, EEG, CT study every year of writer if clinically suspec-

Results: Currently 15 children (median age 10.5, range 3-10 months) are infected, 42 are not infected (median age 24, range 0-30 months) in an intermediate (median age 6.0, range 1-13). 4 of the infected children died of AIDS; 2 without any sign of neurological involvement, 1 had progressive encephalopathy and 1 primary brain lymphoma. Included "early" neurological signs (spasticity, rigidity, sensory deficit, unilateral pupillary dysfunction, tremor) were found in 5 out of the other 11 children and in 11 every 10 of 42 not infected ones (X², p<0.05). None of the infected patients had CT scan abnormalities nor developed macrocephaly. We also compared the developmental score obtained at the last evaluation in infected and not infected children. The mean score in the infected was 61.52 and in the not infected 61.52 (p<0.05 Mann-Whitney test). **Conclusions:** Our preliminary results suggest that neurological and developmental abnormalities do not occur early in the course of vertical HIV infection.

T.B.P.216

SOFTY DETECTION OF HIV INFECTION IN CHILDREN.
Salleh, I., Muzaffar, M., Husein, M., Saeed, F., Yusof, F., Zeman, S., & Corbett, V.
*Hospital Unit, Fencotek Hospital, 8, Anson Road, Singapore 1100. *Hospital, Institut La Paz, Madrid, Spain.

It is unclear the feasibility of the anti-HIV detection in children of HIV-seropositive mothers, as the maternal antibodies and the p24 antigen (p24Ag) remain in children for a mean time of 8-10 months. For this reason it is necessary to develop new diagnostic techniques for the early identification of the parent HIV infection in these children. With this purpose we have studied the presence of anti-HIV IgM in 17 children less than 1 year old (14: 1 male) born to 15 mothers born from anti-HIV positive mothers, and we have compared it with the anti-HIV detection in blood-serum and with HIVAg by ELISA. HIVAg was detected in 14 of total DNA isolated from the PBMC, by slot-blot hybridization using a p18-300-20 probe.

Anti-HIV was found in 15/17 (88%) of the children, circulating HIVAg was present in 2/18 (11%) and HIV-DNA in 4/17 (23%) of them. Out of the 14 HIV-DNA positive cases, 2 children (13 months old) presented anti-HIV in the HIVAg was undetectable, 1 child had anti-HIV and also HIVAg positive, while in the remaining child (15 months) these markers were negative. All of them were seropositive.

In conclusion: 1) The absence of HIVAg in children under 1 year old could indicate that these children do not have HIV infection and the anti-HIV antibodies are from their mother. 2) HIV-DNA detection allows the early diagnosis of HIV infection in asymptomatic children even without other viral markers. However, these preliminary results will be completed with a dynamic study in a wider population.

This work was supported by the Comité Activo de Madrid.

T.B.P.218

IGM SERUM-LAGS CONCENTRATIONS AND ANTIBODY LEVELS TO MATERNAL TORCHES IN CHILDREN WITH HUMAN DEFICIENCY VIRUS (HIV) INFECTION.
McLennan, S., Hunter, R., Dwyer, S., Vines, B., Wainwright, P., Fletcher, M., Alvarez, S., Belmont, D., Hershkov, S., Nordberg, A., & O'Brien, J. W. (CNS Laboratory, Frankfurt (Main) FRG)

Infection with HIV results in a combined immunodeficiency. As a result of serological B-cell activation there is a significant increase in the serum immunoglobulin levels. The specific humoral immune response is, however, usually impaired. We have investigated to what extent the levels of IgG subclasses undergo change as a result of HIV-infection. In the period from January of 1987 to January 89 we carried out an investigation of immunoglobulin subclasses in a total of 27 children exposed to HIV. Of these children 14 had proven HIV-infection, 13 (aged over 18 months), who had been previously HIV-antibody positive, have remained negative up till the present time and have shown no clinical and immunological signs of HIV-infection. No patient was given intravenous IgG therapy before or during the investigation. The immunoglobulin, alpha-1 and lambda antibody levels of our patients were compared to a healthy control group of 150 children of different ages. IgG subclasses were also noted in a random immunoglobulin, antibody levels to tetanus (TT) and diphtheria (DT) toxoids by enzyme immuno assay. Levels below 1:100 are considered not to be protective for both - in this group of 13 previously HIV-antibody positive children (10 HIV-antibody negative, normal IgG antibody levels were found. In contrast, 13 of 14 HIV-positive children showed a significant increase in serum IgG and IgG1; 3 of whom additionally showed elevated IgG2 levels. 8 of 10 HIV-positive children showed protective antibody levels to TT and 8 of 10 HIV-IG. All non-infected children had protective antibody levels to TT, but antibody levels to DT were not protective in 4.

We conclude that IgG subclass serum profiles are a frequent finding in HIV-infected children especially a polyclonal increase in IgG1 and IgG2. Longitudinal observation is necessary to determine whether the development of an IgG2 subclass deficiency is an additional indication for intercurrent immunodeficiency. Supported by Ministry of Health (BMFG), BRG.

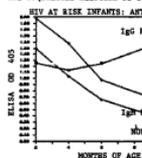

T.B.P.220

SEROLOGIC RESPONSE TO HIV INFECTION IN INFANTS.
Johnson, John P., Davis, K., Shinsberry, R., and Hair, P.
UNIVERSITY OF Maryland School of Medicine, Baltimore, MD, USA

Objective: To document the antibody response to HIV infection in neonates. Methods: Blood was obtained from 35 children born to seropositive women at 2, 4, 6, and 12 months. Serum was assayed using the DuPont HIV ELISA and P24 antigen and IgG antibody tests. HIV RNA was detected using Strip Gene-Technica and sequential addition of biotinylated anti-IgG (M1) or IgG1 or IgG2 followed by biotin-avidin HRP, and then DAB.

Results: Children showed increasing anti-HIV IgG, and P24 antigen was detected in 7 children. The IgG1, anti-p120 IgM and anti-p24 IgM were found in 5, 2 and 4 cord blood specimens respectively. Paired sera from 3 mothers showed weakly positive anti-p120 IgM and anti-p24 IgM bands. At 2-month follow-up, 2 infants developed additional anti-p120 IgM bands. One infant has been followed for over 8 months. Her anti-HIV IgM bands disappeared and was replaced by weakly positive anti-p120 IgG.

Conclusion: The kinetics of loss of maternal antibody and the class specific anti-HIV antibody positive infants demonstrated in neonates.

T.B.P.217

DETECTION OF SPECIFIC IGM ANTIBODY BY RADIOIMMUNOPRECIPITATION ASSAY FOR EARLY DIAGNOSIS OF HIV INFECTION IN INFANTS
Zhou, Y., Michelson, J., Lacombe, C., Clinebarr, J., Suman, S., and M. Lapointe**

*Laboratoire de santé publique du Québec, **Institut Armand-Frappier, Université, Michelson, J., Lacombe, C., Clinebarr, J., Suman, S., and M. Lapointe**

Objective: To evaluate Igm-specific HIV antibody (Ab) by radioimmuno-precipitation assay (RIA) in infants born to seropositive mothers as a tool for early diagnosis.

Methods: Sequential sera from 5 HIV-infected infants were analyzed by standard RIA with protein-A-Sepharose and by RIA-IgM. For the latter, CMI-activated Sepharose 4B was coupled with purified monoclonal Ab to human p24-IgM. Samples were incubated with anti-sepharose beads and washed. (125I)-HIV antigen was then added. Bound proteins were separated by SDS-PAGE and revealed by autoradiography. Specificity of Igm reactions was tested after serum adsorption on IgG-coated beads or with anti-IgM IgG.

Results: Igm Ab to pp 120/120 and p24 were detected in 15/21 sera from all 5 infants. Comparison of Ab patterns observed with standard RIA and RIA-IgM revealed that anti-HIV Igm appeared at 2 to 13 months of age. After disappearance of maternal Ab and parallel to p24Ag synthesis, Igm Ab persisted for 26-30 months in 3 children. RIA-IgM reactivity was still observed after removal of rheumatoid factor or IgG.

Conclusion: Detection of Igm-Ab did not allow early diagnosis of HIV infection in the first 6 months of life. Further studies are required to determine the specificity of Igm reaction in older infants.

T.B.P.219

WESTERN-BLOT QUANTITATIVE : HIVI DES MOUVEMENTS-DES VIH SEROPOSITIFS
Schivini S., Paul Jacquelin, Rousseau A., Gaye-Margelle C., Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE

Objective: Etudier la cinétique des différentes spécificités Ac anti-VIH avec le Western-blot (WB) quantitatif chez un enfant né de mère séropositive.
Méthode: Nous avons étudié une enfant née le 10.11.87 de mère séropositive, et qui a été de 2 ans et 2 mois toujours asymptomatique. Le WB quantitatif (Du Pont de Nemours) consiste en une lecture densitométrique des bandes réactives, perceptible par l'obtention d'une courbe une quantification précise de chaque p24 et p31; les résultats sont exprimés en intégrales représentatives de la surface des différents pics. Les titres d'Ac totaux (Epreuve Diagnostique Pasteur) sont déterminés par comparaison de la densité optique de l'échantillon à celle d'une gamme étalon.

Résultats:

Titres Ac	gp120	gp120	p26	p55	p31	p31	p31	p24	p17
20.00.87	30000	4110	1214	2258	7859	1763	12778	15217	18530
22.05.87	3000	3721	1938	859	604	1012	7171	3044	2829
16.11.87	500	1950	276	276	0	0	0	0	881
10.01.88	100	531	0	0	0	0	0	0	0
22.09.88	100	0	0	0	0	0	0	0	0

De la 1e au 2e mois, le réactif des toutes les spécificités Ac distinctes, parallèlement à la diminution des anticorps anti-VIH1 totaux. A 1 an 11 mois anti-VIH (ELISA) sont nuls; seuls en WB quantitatif, les Ac gp120 persistent.

Conclusion: Ces données confirment la grande sensibilité de WB quantitatif.

T.B.P.221

THE USE OF ANTI-HIV IGM IMMUNOLOGY IN THE DIAGNOSIS OF NEONATAL HIV INFECTION : A REPORT OF 5 CASES.
Pantova, Vajana, Sivichikova, S., Chanderpedarek, S., Likhonina, S. and Panchal, B.

Chulalongkorn University Hospital, Bangkok, Thailand.

Objective: To evaluate the reliability of anti-HIV Igm immunology in the diagnosis of HIV infection in babies of HIV-infected mothers.

Methods: Paired maternal and cord blood from 5 babies at Chulalongkorn University Hospital from HIV-infected intravenous heroin abusing mothers were studied. Anti-HIV Igm immunoblot was modified from Pasteur commercial kits by changing the enzyme conjugates to rabbit anti-human Igm, followed by peroxidase labeled avidin-biotinylated goat anti-rabbit Igm.

Results: All newborns were anti-HIV positive at birth due to the transplacental transfer of Igm antibodies as evidenced by the identical patterns on Igm immunoblot. Using commercial ELISA kits from diagnostic Pasteur could not be detected in any mothers or babies at birth. Anti-p160 anti-gp120 Igm and anti-p24 Igm were found in 2, 2 and 4 cord blood specimens respectively. Paired sera from 3 mothers showed weakly positive anti-gp120 and anti-p24 Igm bands. At 2-month follow-up, 2 infants developed additional anti-gp120 Igm bands. One infant has been followed for over 8 months. Her anti-HIV Igm bands disappeared and was replaced by weakly positive anti-gp120 Igm.

Conclusion: Our preliminary study indicates that immunoblot can be successfully used anti-HIV Igm to detect early HIV infection in newborns. Our results indicate that transplacental HIV infection has occurred in all 5 babies studied.

Aspects cliniques Clinical Aspects of AIDS

T.B.P.222 IS THE IgM ANTIBODIES STATUS A USEFUL MARKER TO ASSESS THE IMMEDIATE CONTAMINATION BY HIV-1 ?

Guyot-Besauge, J., Dal, Jacqueline, Tricore, J., Rousseau, A.
Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE.

Objective. Realisation of an early diagnosis of congenital or neonatal transmission in order to initiate an immediate therapy against HIV-1.
Methods. We tested IgM antibodies in 53 neonates born to intravenous drug abusers (MAD) heterosexually contaminated (M7) and "unknown" mothers (M2) using the Western-blot assay (Du Pont ELISA-III Western blot IgM). The test was performed at birth and/or during the clinical and biological follow-up of the neonates (mean 14,5 months). The test was considered positive when antibodies neonates (mean 14,5 months) were present. The results of the test were compared with the infants' parameters (clinical status, p24 antigenemia, anti p24 antibodies titers and HIV antibodies persistence beyond 18 months) and the mothers' parameters (clinical status and HIV-1 antibodies titers at the delivery).

Results. We could form 3 groups : the first included 28 children who were always IgM negative, the second group included 15 IgM positive children at a given time, and the third, 10 children with borderline results of the test at a given time. In the IgM positive group 9 children were diseased (class P2), 4 children had clinical signs and 6 were healthy. Nevertheless, statistically significant difference was present between the mother of IgM positive and IgM negative diseased children ($p < 0.05$ with Fisher-Fisher Test).
Conclusion. The results indicate that the IgM screening may be useful as a supplementary marker in the assessment of the children contamination by the HIV-1.

T.B.P.223 EXAMINATION OF PERIPHERAL BLOOD ANTIBODY-SECRETING CELLS AS A DIAGNOSTIC AID FOR HIV INFECTION IN CHILDREN

Neuhoff, A., Lee, J., Hehner, A., De, C., Walter, J., and Side, B. Depts. of Pediatrics and Pathology, Emory University, Atlanta, GA, USA

Objective: To evaluate the enzyme-linked immunospot (ELISPOT) for diagnosis of HIV infection in asymptomatic children and infants born to seropos. mothers.
Methods: The ELISPOT, using anti-HIV-1 p24 antigen protein, was applied to peripheral blood mononuclear cells (PBMC) obtained from 31 negative children, 28 children with ARC/AIDS, and 27 infants born to seropos. mothers between 1985 and 1988; 18 IgM and p24 antigen assays were also obtained.

Results:

	tested	anti HIV ASC*	+ HIV ASC
A Children with ARC/AIDS	28	20 (71%)	8 (1 with agamma.)
B Infants born to seropos. mothers	27	6 (22%)	2
C Control children	31	0	31 (100%)

HIV ASC positivity ranged from 8 to 22 per 1 million PBMC. Of the 8 ASC children born to seropos. women (all still alive), one was ASC positive at 1 1/2 yrs of age, the earliest time of ELISPOT testing in all groups (A-C), when repeated in 3 infants, the assay was positive in all three, who are now asymptomatic. In four ASC asymptomatic infant had virus pos. amniotic fluid in utero. Of the 21 ASC- children, 15 have been repeatedly ASC- and 6 are no longer alive. All infants in group B have been p24 antigen negative.
Conclusion: This rapid (24 hr.) assay, which can be performed on archived or frozen cells, appears to be specific, although its sensitivity could be enhanced by methods under current study. The HIV ELISPOT could prove particularly helpful in the early diagnosis of HIV infection in children.

T.B.P.224 RECOVERY OF HIV FROM LYMPHOCYTES AND MONOCYTES

OF EPIDEMIOLOGIC HIV INFECTED CHILDREN. **Lindau, Alan, J.†**
Chicago, Ill., U.S.A. and **Chandler, Robert, M.†**
Medical Center, Chicago, Ill., U.S.A. and **Childs, Memorial Hospital,**
Northwestern University, Chicago, Ill., U.S.A.

Objective. Correlation of immunologic and virologic findings with clinical status in perinatally HIV-infected children.

Methods. HIV antibody (Ab) and antigen (Ag) status was determined by commercial ELISA procedures. CD4 and CD8 lymphocyte analysis was performed by a whole blood lysis procedure and analyzed by dual parameter flow cytometry. HIV co-cultures were performed by adding peripheral blood mononuclear cells (PBMC), purified lymphocytes, or purified monocytes to PHA-stimulated lymphocytes from HIV negative donors or allogeneic monocytes. Viral growth was detected by an antigen capture assay.

Results. Ten symptomatic children (3P2A, 7 P2B-7) ranging in age from 1.5 to 9.5 years were evaluated. Nine of ten were Ab+ and seven of ten were serum Ag+. Five of the ten patients had <1000 CD4 cells/mm³ while the CD8/CD4 ratio in nine of ten children was >0.5. Eight of ten individuals were culture positive by day three in the BSC as well as in purified lymphocytes. In contrast, co-cultures of purified monocytes and allogeneic monocytes was still negative at 14 days.

Conclusions. Viral cultures were positive in the majority of symptomatic children with perinatal infections. The clinical stage of disease and immunological parameters did not correlate with viral isolation. It seems that at least in the early phase of culture, HIV grows more readily from lymphocytes.

T.B.P.225 NEOPTERIN - POTENTIAL EARLY MARKER OF PERINATAL HIV INFECTION

Lindner, Harold M.† **Reagers, Dm.†** **Kaplan, Sh.†** **Treanor, CD,†**
Shandley, Lm.† **Levine, David A.†** **Christophers, Betsy for Childs,**
Philadelphia, PA.† **Ortiz de la Cruz, M.†** **De, New Jersey, Camden, NJ, USA.**

Objective. To test the hypothesis that neopterin (N) levels can differentiate infected from non-infected infants and children infected with HIV in mothers.
Methods. N was determined by 125I radioimmunoassay (DGE, Berlin) in 58 serum and/or EDTA plasma specimens from 40 children of HIV-infected mothers 1 to 39 mo of age and control specimens. N/B was taken as >2 SD above adult mean.
Results: Mean N levels in uMol/l are shown by CDC diagnostic class as follows:

	N ± SD	n	with Ab
Probably not infected (HIV antibody negative)	6.3 ± 2.1	17	0
CDC P0 (asymptomatic - HIV cultures pending)	9.9 ± 4.4	15	15 (3 3 ug)
CDC P1A or B (infected - asymptomatic)	19 ± 4	2	2 (all Ab)
CDC P2A (infected - "ARC")	8 ± 3	4	1 (11 ug/ml)
CDC P2B, C, and/or B (infected - "AIDS")	37 ± 19	7	7

N levels in replicate specimens obtained 3 to 9 months apart were usually in 11 of 18 pairs within one SD range (1.1 ug/ml) of replicate assays on the same specimen. In 4 HIV-infected infants and one infected 3 yr old, rises of 5 to 19 ug/ml were observed. In 2 infants, low antibody negative, falls of 6 to 8 ug/ml were observed. In levels were high (24 ± 11) in presumably normal, uninfected cord sera, but appeared to reach adult levels by 1 mo of age.

Urine N levels appeared to be less discriminatory than plasma levels.
Conclusion: The pilot data support the hypothesis for asymptomatic infants only, suggest that N levels may be useful in staging perinatal HIV infection, and indicate that a hypothesis (Ciba Annual Newsletter 9:159, 1988) that N release occurs in primary HIV infection deserves investigation in infants.

T.B.P.226 HIGH PREVALENCE OF HIV-SPECIFIC IgM AND IgG-SPECIFIC IgM ANTIBODIES IN MONOES OF HIV-POSITIVE MOTHERS

Schubert, G.† **Wunderli, V.†** **Isid, C.†** **Serafin, K.†**
Stumpfiger, A.† **Tomasik, K.†**

* Swiss National Centre for HIV Research, Institute of Immunology and Virology, University of Zurich, Zurich, Switzerland

† Institute of Immunology, University of Zurich, Zurich, Switzerland

** Swiss Neonatal HIV Study Group, Department of Neonatology, Kantonsspital, St. Gallen, Switzerland

Objective. To analyze the specificity of Western blot (WB)-reactive IgM and IgG in cord blood.

Methods. Cord blood of 21 babies of HIV+ mothers was tested for HIV-specific IgM or IgA by WB. Prescreenings of IgG with immobilized protein A or G were done to determine whether reactions were mediated by HIV-specific IgG or IgA, or by other antibodies bound to HIV-reactive IgG of maternal origin.

Results. Initial IgM reaction was present in 15 sera (71%). Removal of IgG showed that 80% of these IgM were directed against maternal HIV-specific IgG. IgA reaction was present in 10 sera (48%) absorption of IgG indicated HIV specificity in 8 (80%). Most IgA reaction was seen only after removal of bulk IgG. Absorption with immobilized protein G was better than with protein A. Antigen was present in 10 in a case negative for IgM or IgA.
Conclusion. Most HIV-WB-reactive IgA are indeed HIV-specific; most HIV WB-reactive IgG are specific not for HIV, but maternal IgG.

T.B.P.227 PROSPECTIVE STUDY OF POLYMERASE CHAIN REACTION FOR

EARLY DETECTION OF HIV INFECTION IN INFANTS BORN TO HIV

ANTIBODY POSITIVE WOMEN

Weisbuch, P. Ulrich, F. Edwards, J. Ramsey, C. Vyas, G. Gowan, Morlan, et al.

University of California, San Francisco, California, USA

Objective. To determine the applicability of polymerase chain reaction (PCR) for early diagnosis of HIV infection in high-risk infants.

Methods. All infants referred for prospective evaluation who were 35 months of age and in HIV antibody positive women were studied. HIV-1 RNA was amplified using a 2 distinct gag specific primer pairs were performed on crude PBMC (frames for 35 cycles. Hybridization in solution to a P22-derived oligonucleotide probe was followed by ethylenediamine gel electrophoresis and autoradiography. Specimens were tested at least twice with each primer pair. HIV cultures were performed on all specimens by standard co-culture technique.

Results. Thirteen infants were tested at a mean age of one month. Three infants were positive by PCR for every amplification. Only 2 of these were HIV culture positive. Three infants were equivocal by PCR (<100% positive amplification). All 5 were HIV culture negative. All 7 PCR negative infants were also HIV culture negative. No patient was HIV culture positive and PCR negative. All patients are well (mean age 6 months) and being followed.

Conclusions. PCR is applicable for the early detection of HIV infection in high-risk infant and appears to be more sensitive than standard co-culture technique. Long-term follow-up is essential to determine if PCR positive and equivocal infants who are culture negative are truly infected or represent lack of specificity.

T.B.P.228 HIV p24 ANTIGEN ASSAY AS A DIAGNOSTIC/PROGNOSTIC TEST IN PEDIATRIC HIV INFECTION. Silve, Tso, J. Olson, S., Simpson, B.J., Andiman, R.L. Yale University School of Medicine, New Haven, CT, USA

Objective: To learn if HIV p24 antigen (Ag) detection tests can be used to diagnose infection in children or to select mother at risk of transmitting infection.
Methods: We examined sera from a group of children born to HIV seropositive (HIV) women as part of an ongoing prospective study of pediatric AIDS. We used a commercially available p24 capture immunoassay (Abbott) to screen 109 serum samples from 66 children and from 48 of their mothers were also examined. "Infection" was defined by CDC criteria.
Results: Five of 66 children of HIV women and 3 mothers were Ag+. Seven of 8 infected children were Ag+, but only 12 of 19 individual samples were Ag+. One of 41 seronegative children was Ag+. Upon the incidence of anti-p24 in mothers and children was compared we found that 92 of Ag+ mothers had Ag+ children and that only 1 of 6 children who met CDC criteria for infection had an Ag+ mother. Only 2 of 9 instances the inverse relationship between Ag and p24 antibody detected by Western blot did not exist. Antigenemia occurred at a higher rate in seronegative/infected than in seropositive/uninfected children. The p24 Ag assay failed to identify 1 of 8 children with symptomatic disease. The p24 Ag assay was positive; in 2 cases, serial tests may be needed to identify an Ag patient.
Conclusions: The clinical utility of a single negative p24 test is low. It does not classify a child as uninfected and it does not predict a more benign disease course. A negative Ag test in a mother does not accurately indicate that her child will be Ag+.

T.B.P.229 SERUMELISA IN PERINATAL STUDY OF HIV INFECTED MOTHERS AND THEIR CHILDREN SINCE THE NEONATAL PERIOD AGE. PÉREZ ALVAREZ, M.D., GARRIDO, M., GARCÍA, M., GONZÁLEZ-SANFELIX, J.A., VILLALBA, A. INSTITUTO DE SALUD CUBANA, HOSPITAL GENERAL PEDAGÓGICO INFORMATIVO, HAVANA, CUBA

Objective: Serological follow up of HIV antibodies in mother-child pairs since birth and the analysis of the evolution of the bands against the different viral proteins by WB technique.
Study of the potential usefulness of the P-24 Ag analysis as a supportive marker of neonatal infection.
Methods: Since January 1988 we have studied 10 pairs mother-child (average 3-6 months since the first course of life. Serum samples were tested by different EIA methods: IgA and Western Blot, and P-24 antigen was detected by ELISA. Infection has been attempted by co-culturing peripheral blood lymphocytes.
Results: All the mothers are intravenous drug addicts and HIV-All the children are asymptomatic in PO stage. In relation with the sequential analysis until now, 4 children turned seronegative but in other 4 there was a gradual development of the bands detected by WB. The final and complete data will be available at the end of the study now in progress. P-24 Ag was detected only in one mother whose child turned seronegative at the age of 12 months. Until now the virus isolation has been negative in all cases.
Conclusions: It would be possible to confirm the presence of HIV infection in the early 13 months period by the serial analysis with WB of the sera of children of mothers HIV- and the detection of P-24 Ag, although the final diagnosis at this age involve the virus detection, re... It is very useful the virus isolation from lymphocytes and the DNA detection.

T.B.P.230 COMPARISON OF THE ORTHO HIV RECOMBINANT ANTIGEN NEUTRALIZATION ASSAY AND DUPONT WESTERN BLOT FOR CONFIRMATION OF ELISA REACTIVE SERA FROM CHILDREN. Frost, Anna*, Mahla, C.†, Luban, N.† and Cannon, J.† *George Washington University Hospital, Washington, DC, USA, **Children's Hospital National Medical Center, Washington, DC, USA.

Objective: To compare the performance of the HIV Recombinant Antigen Neutralization Assay (RANA) (Ortho Diagnostic Systems, Raritan, NJ, USA) and the HIV Western Blot Kit (WB) (Dupont Company, Wilmington, DE, USA) as confirmatory test of HIV ELISA repeatedly reactive sera from high-risk children.
Methods: RANA uses a pool of recombinant core (G24), polymerase (G31) and envelope (Gp12) antigens for neutralization of HIV antibodies in ELISA positive sera. Dilutions of these sera were added to the antigen mixture and incubated for 16-18 hours at 37°C. The ELISA reactivity (Urbant HIV EIA, Abbott Laboratories, North Chicago, IL, USA) of each recombinant serum was determined and compared to an unrecombinated control. A reduction in absorbance by ≥40% constituted a positive test. WB was performed and interpreted according to the manufacturer's instructions.
Results: All 34 study sera were positive by RANA (mean neutralization 72%), and 25 (74%) were positive by WB. Nine sera (26%) yielded indeterminate WB results. Of the nine, 6 were tested for HIV antigen (Orbont HIV II Antigen EIA) and 4 were positive. None of the HIV ELISA repeatedly reactive sera collected from our high-risk population during the study period was RANA or WB negative.
Conclusions: RANA is a sensitive, objectively interpreted confirmatory test of HIV ELISA seropositivity in high-risk children.

T.B.P.231 A NOVEL HIV I EIA DETECTS IgG AND IgM ANTIBODIES IN INFANTS AND NEONATES. Baccard-Longere, M.†, Blanc, Sylvie**†, Genoulas, C*†, Giroud, M†, Seignourin, J.M*†

*Département de virologie, A. Michallon Hospital, BP 217 X, 38043 Grenoble Cedex France. **Hellice Diagnostics, 15000 Paris Cedex 12, FRANCE.
Objective: To study the utility of the HelliceWise HIV Recombinant EIA in HIV diagnosis, and in particular its ability to detect IgM antibodies in infants.
Methods: The EIA was initially evaluated on 4000 sera and 500 positive samples, including 12 sera from individuals at the beginning of sero-conversion. IgM antibodies were isolated by sucrose gradient centrifugation and their presence confirmed by Western Blotting.
Results: The assay's specificity is near 100%. No false positives were detected. In the negative samples, nor in 25 samples known to give falsely positive results in other EIA, all the positives samples were detected, including those from sero-conversion whose blots would not yet have been declared positive. Presence of antibodies to P24 and GP160 or indeterminate, and a specimen in early sero-conversion for HIV 2. IgM was detected in 25/35 samples, and in the stored samples 1 of 2. Infants known to have been infected perinatally (cord blood was IgM negative) but not in non-infected of infants of sero-positive mothers.
Conclusion: This EIA is specific and sensitive - useful for routine detection of early sero-conversion in adults and neonates as well as for routine screening.

T.B.P.232 IgM MAY BE DETECTED TO CONTEMPORANEOUSLY BEFORE EARLY IN SEROCONVERSION TO HIV. Robert, Gagner*, Math, G*, O'Keefe, Bethesda, NY *McGraw-Hill, Inc., Health Research, CT, USA.

Objective: To determine if the apparent insensitivity of a whole virus immunoblot (WB) to early anti-HIV IgM in seroconversion is due to a function of cross-reactivity available in that assay.
Methods: Anti-HIV detection by WB (DuPont) and a recombinant gp120, gp41 (Orbont) were compared using class-specific anti-human IgM conjugates. Parallel assays were performed with a EIA using native or S26, S26-detached proteins coated in equal amounts to 96-well plates.
Results:

Subject	DuPont WB status		MaxGenWB status	
	Anti-HIV	Anti-IgM	Anti-HIV	Anti-IgM
1	NEG	POS	NEG	POS
2	NEG	POS	NEG	POS
3	NEG	POS	NEG	POS
4	NEG	POS	NEG	POS

In seven O.D. values were lower for duPont than for native EIA. In seven bleeds of 3/4 subjects, the values actually fell below cut-off. **Conclusions:** We demonstrated increased reactivity of the WB to the WB due to improved detection of early IgM responses with dual-length reagent recombinant proteins were so low (less than 0.6). The parallel EIA study clearly showed that duPontation reduced signal strength. These results suggest that conventional assays may be important for IgM detection; therefore that are lost in WB format. These observations may be important in improving early antibody detection and in evaluating vaccines.

T.B.P.233 HYPERGAMMAGLOBULINEMIA AND HYPOGAMMAGLOBULINEMIA AS MARKERS OF HIV DISEASE IN PERINATALLY INFECTED CHILDREN. Calvello, Thomas; Steinhauser, R.; Nathan, R.; Dwyer, V.; Narasain, L. and Binneman, A. Albert Einstein College of Medicine, Bronx, New York, U.S.A.

Objective: Diagnosis of HIV infection in children born to HIV positive mothers can be complicated as a result of infant's B cell dysfunction seen after disappearance of maternal antibody in our experience, 8% of children presenting with seropositivity consistent with HIV infection show negative or equivocal ELISA and Western blots.
Methods: To ascertain whether the absence of reactivity in HIV antibody tests in HIV infected infants was due to (1) an inability to produce immunoglobulin, or (2) an inability to form specific antibody response, serum from each child was assayed for IgG concentration. Standard rapid immunofixation assay was employed.
Results: Eight of 20 HIV infected but serologically negative children were found to be hypogammaglobulinemic. None of these yielded an unequivocal positive specific HIV antibody test on multiple drawings through 1 year of follow up. Thirty percent were found to have normal serum IgG concentration, and 19% were low normal; of these, 1 eventually seroconverted. Three were hypergammaglobulinemic. None of these were seroconverted for as long as 1 year of follow-up (up to 3 years of age).
Conclusions: Negative or equivocal antibody tests in children who are perinatally infected with HIV can be the result of at least 2 distinct manifestations of B cell dysfunction. Some children, despite their ability to produce IgG, are unable to mount a specific antibody response to HIV; others may also be hypogammaglobulinemic.

Aspects cliniques Clinical Aspects AIDS

T.B.P.234 ASSOCIATION BETWEEN PLASMA HUMAN IMMUNODEFICIENCY VIRUS TYPE-1 (HIV) VIREMIA AND CLINICAL CLASS OF PEDIATRIC HIV INFECTION
Buzich, S., Goebel, R., Chaloupek, E., Stanescu, J., Wilson, C., Corey, L., St. Et. University of Washington, Seattle, WA, USA.

Objective: To develop sensitive virologic markers predictive of asymptomatic and symptomatic pediatric HIV infection.

Methods: Sequentially obtained samples from 12 HIV infected children as they progressed from CDC classification P1 to P2 and from 13 P0 children were analyzed. Plasma or peripheral blood mononuclear cells (PBMC) from 3 ml of blood were cultured CH_4 d. P24 antigen (Ag) in culture supernatants or in plasma/serum was determined by ELISA antigen-capture (Abbott).

	Quart 1 Diagnosis		Quart 2 Diagnosis	
	Partial	Transfusion	Partial	Transfusion
n	4	4	4	4
Age mean (mo.)	0-18	96	12	82
PMBC range	0-18	2-36	0-36	84
FBMC	4/5	4/5	5/5	2/2
Plasma	0/4	0/5	5/5	2/2
Ag	2/4	2/4	5/5	1/1

All P0 children remained asymptomatic. FBMC culture neg. and Ag neg. **Conclusion:** HIV PBMC culture and Ag were highly sensitive (98%) for detecting infection. While Ag was associated with both P1 and P2 infection (pmW), HIV plasma viremia was only associated with P2 infection (p<0.003). The association between plasma viremia and asymptomatic stage of infection suggests there is an increased amount of replicating HIV associated with advanced clinical disease. Plasma viremia is a potential endpoint for evaluating both progression of disease and antiviral therapy in the pediatric population.

T.B.P.236 LYMPHOKINE AND IMMUNOGLOBULIN PRODUCTION IN VITRO IN NEONATES AND INFANTS WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION
Petro, Cecilia; Herson, I.C., Herson, T.A. and Snaver, K.T. Baylor College of Medicine, Texas Children's Hospital, Houston, TX, USA.

Objective: To assess early immune parameters in HIV neonates and infants. **Methods:** Interleukin-2 (IL-2) was measured using an IL-2 dependent cell line (C11) after stimulation with PHA and augmentation with recombinant IL-2 in placental (Con 1) and infant (Con 2) controls and HIV neonates and infants. Immunoglobulin production after PHA stimulation and 7 day incubation was measured in affected children and described controls.

Results: HIV infants studied were Group 1, < 6 weeks (asymptomatic) [+], infected with cytomegalovirus (CMV) [-] and Group 2, > 1 year [-] [+]. IL-2 results are reported as units/ml (mean±standard error).

	Group 1 (n=6)	Group 1 (n=2)	Group 2 (n=3)	Group 2 (n=2)
PHA [50ug/ml]	0.11±	0.01	0.17±	0.14±
	0.08	0.05*	0.08	0.12*
IL-2 [5000u/ml]	1.32±	None	1.97±	1.34±
	0.68*		1.49	1.49

* p less than 0.05

IgG production after PHA and PHM-IL-2 stimulation was negligible in Groups 1 and 2 and Con 1 compared to adult controls. IgG production was high in 3 infants in Group 2 alone.

Conclusion: IgG production in vitro for HIV neonates and infants is not different than expected neonatal results. IL-2 production was decreased except in those infants with concurrent CMV. Monitoring IL-2 production with clinical correlation may detect subtle immune changes in HIV children.

T.B.P.238 DETECTION OF SECRETORY ANTIBODIES TO HIV IN NEONATES
Azzolini, S., Davis, E. & Johnson, S. University of Maryland at Baltimore, Baltimore, MD, U.S.A.

Viral-specific, non-maternally derived secretory IgA (sIgA) antibodies have been demonstrated soon after birth in certain infections. sIgA to HIV antigens has been detected in infected adults. We collected serum and saliva from 21 children (ages 7 to 48 months) born to women at risk for HIV infection to investigate the presence of HIV-specific salivary IgA. sIgA was ascertained by one or more of the following: a rise overtime in serum ELISA titre, development overtime of IgG antibodies to new HIV antigens, positive p24 antigen or PBW culture, or demonstration of serum IgA by Western Blot (WB) to 2 or more different classes of HIV antigens. Salivary samples were obtained by passive droplet collection using a modified WB. Saliva from 7 of 10 infected children, including one aged 6 months, demonstrated IgA class antibodies to HIV envelope antigens; 4 of the 7 also showed sIgA antibodies to other HIV antigens. The 3 sIgA negative infected children all demonstrated decreasing or absent serum IgA and IgG responses to HIV at the time of saliva sampling. Six of 6 children born to healthy mothers were IgA negative. Five children (3 to 6 months) with indeterminate HIV status, born to infected mothers, showed no virus-specific sIgA. We did they show serologic evidence of HIV infection. HIV-specific sIgA was detectable at 2 months of age and may prove to be valuable in the diagnosis of HIV infection in children born to infected mothers.

T.B.P.235 DETECTION OF HIV SEQUENCES IN CHILDREN BORN TO SEROPOSITIVE MOTHERS.

Sorghi, F., Vanni, Selleri**, L., Lavi*, G., Frigieri**, G. De Rienzo*, B., Torricelli*, G.
Department of Infectious Diseases, Dept. of Internal Medicine and Hematology** Dept. of Pediatrics***, University of Modena, Modena, Italy.

Purpose: Early detection of HIV infection in children born to seropositive mothers is now possible utilizing the polymerase chain reaction (PCR). **Methods:** PCR was performed on DNA extracted from PBMCs of children born to seropositive mothers as described by Saiki et al. using the SK 68 - SK 69 primers and the SK 70 primer, homologous to the HIV envelope. Clinical condition of the children were assessed following the criteria of Brunetti-Lazini and Bayley, and by immunological and virological tests.

Results: 13 children have been followed from birth, all were born to seropositive HIV mothers. All children were seronegative at the moment of DNA extraction. The loss of maternal anti-HIV Ab IgG occurred in 10-19 months after birth. None of the children was clinically or immunologically immunocompromised. The PCR was performed in 4 children (age 12-36 months) apparently healthy. Age of onset of the enzyme (measured by the SK 68 and SK 69 primers) occurred in all 4 cases.

Discussion: The PCR is an early diagnostic test for HIV infection in children and it can offer a precious tool as serological diagnosis is not possible in newborn children for several months after birth.

T.B.P.237 EARLY DETECTION OF HIV-1 SEROCONVERSION IN INFANTS OF SEROPOSITIVE MOTHERS USING SERIAL DILUTIONS IN WESTERN BLOTTING.
Bernstein, P., Alexander, G. P., Young, M., Giordano, L., Mank, H.**, and Frederick, W.*** Howard University Hospital, Washington, DC. U.S.A. *Johns Hopkins Laboratories, Baltimore, Maryland, U.S.A.

Objective: To determine if serial dilutions in Western blot (WB) assay can distinguish HIV-1 seroconversion from passively transferred maternal antibody (Ab) in infants born to seropositive mothers.

Methods: Sequential serum samples collected at 3-month intervals on 17 male and 9 female infants were tested by standard ELISA (EIA). Samples were also tested for HIV-1 Ab using serial dilutions of 1:100, 1:500 and 1:1000 in a standard WB assay (Biochem), and for p24 antigen (Ag) by EIA (Abbott). Polymerase chain reaction (PCR) was performed on lymphocytes from 12 infants.

Results: All infants were seropositive at birth by EIA and WB assays. Among infants who later became seronegative (8), the mean age from birth to non-reactivity was 9.8 mos. Serial serum dilutions in WB demonstrated disappearance of significant maternal Ab with emergence of infant Ab patterns typical of seroconversion in 10/16 infants at a mean age of 7.4 mos. At this age no difference was observed in Ab reactivity using standard EIA and WB assays between the 7 seroconverters and the remaining 19 infants whose sera were still reactive by standard WB assay (1:1000 dilution), but who later became Ab. Among the seroconverters, p24 Ag was detected just prior to seroconversion in 4 infants. PCR was positive in only 3. Currently 1/7 has AIDS; 2/7 have AIDS.

Conclusions: Serial serum dilutions in WB assay detected seroconversion in infants of seropositive mothers at an earlier age than standard EIA and WB assays. P24 antigenemia preceded HIV seroconversion. PCR positivity did not correlate strongly with seroconversion in our study.

T.B.P.239 ANEMIA AND HYPERBILIRUBINEMIA IN INFANTS WITH PEDIATRIC HIV INFECTION
Nahly, Gregory; Barton, N. and Madlin, J. Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, Maryland, U.S.A.

Objective: To determine whether hematologic abnormalities or hypochromic microcytosis are early indicators of HIV infection in infants born to HIV infected mothers.

Methods: Complete blood counts and immunologic concentrations were obtained from 20 five to nine month old infants born to HIV infected mothers and who were either seropositive or had nonspecific clinical signs and symptoms. These laboratory values, as well as aspects of the clinical history, were compared between the 8 infants who eventually met CDC criteria for HIV infection and the 12 infants who seroconverted.

Results: A significantly lower mean hematocrit value (32.8) was found for the infants who later met CDC criteria for pediatric HIV infection compared to the infants who seroconverted (37.0). Elevated mean immunologic levels were also noted in infected infants (infected IgG = 2840, IgA = 309, IgM = 268; seroconverted IgG = 491, IgA = 27.3, IgM = 43).

No aspect of the history could explain these differences. **Conclusion:** Unexplained anemia or hyperbilirubinemia in an infant with indeterminate CDC class P-0 HIV status strongly suggests the presence of HIV infection.

Session d'affichage Poster Session

T.B.P.240 ELISA (E) AND WESTERN BLOT (WB) RESPONSES AND A POSSIBLE SOURCE OF ANTIBODIES IN INFANTS BORN TO SEROPOSITIVE (SP) MOTHERS.

Hendes, Hecmaro, S.**, Madsen, J.**, Weiberg, J.**, Skiffing, K., Landeman, S.**, et al.***, SUN-HOBI, Copenhagen, N.D., *New York State Lab, Albany, N.Y., **HUSK, Bethesda, Maryland, USA.

OBJECTIVE: To describe HIV serological responses and to identify predictors of infection or HB in infants born to SP mothers.

METHOD: Pre and post-partum maternal sera, and infant sera collected at birth and at 3 months intervals, were frozen and later tested by E (Dupont) and WB (Cisprison-Pentlabs) against known controls.

RESULTS: Sera from 32 mother-infant pairs (infants' mean age: 10.3 mos; 6.9 specimens per child) were available. Generally, the infants' initial WB patterns reflected the mothers' pattern. By clinical and lab criteria, 9/28 infants were infected; 9/9 had serially positive (D) E, 1/9 became non reactive (NB) before developing AIDS. WB of infected infants showed fading of bands with subsequent increased reactivity and appearance of new bands. In 23 of the remaining 23 infants a WB E preceded a WB NB mainly due to fading but persistent anti-p24. In 4/23 (ages 15, 20, 20, and 20 mos) WB was equivocal; seroconversion occurred in 14/19 before 15 mos, and 5/19 after 15 mos of age. Once E and WB became negative all infants remained negative. An anti-glyco band was present in the maternal serum and the infant's first WB in 14/19 (74%) seroconverters and in 2/9 (22%) infected infants (p<0.001).

CONCLUSION: The presence of anti-glyco detected late in pregnancy and in the newborn, may be a marker of subsequent seroconversion.

T.B.P.242 EVALUATION OF THE WESTERN-BLOT IgM TECHNIQUE SPECIFICITY Duret-Mengelle C., Rousseau A., Paul Jacquelin Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE

Objective: Evaluation of the western blot IgM technique specificity.

METHOD: During the clinical screening of seropositive drug abusers women (N=67) and infants born to seropositive mothers (N=20) we investigated the IgM status by the Western blot assay (Du Pont HTLV-III Western blot IgM). The test was considered positive when the presence of antibodies against the p24 protein could be detected. When the IgM antibodies were present, the specificity of the reaction was checked by comparing the results before and after elimination of the rheumatoid factor by the "RF Sorbent" (Behring Laboratory) and after the IgG-IgM separation by elution through DEAE cellulose micro-columns.

Results: Although IgM antibodies were detected in 35 serum specimens, the specificity could be tested upon 24 sera only. In all cases the obtained results were identical. In 13 cases the results were dissociated: 3 sera were negative after the elimination of the rheumatoid factor that could give a false positive result with the two first techniques. 9 sera were negative after elution through the micro-column. The dilution of the specimens during this treatment could explain this negativity. 1 serum was negative after both: the result obtained for the serum before treatment could probably represent a false positivity.

Conclusion: IgM antibodies were really present in 20 sera. Thus the specificity of the Western-blot technique is high (83,33 %) and it can be a useful test in the neonates follow-up.

T.B.P.244 EARLY DIAGNOSIS OF HIV-INFECTION IN CHILDREN BORN TO SEROPOSITIVE MOTHERS-ORITICAL EVALUATION OF NEW DIAGNOSTIC APPROACHES.

De Biasi A., Madori A., Diavataio G., De Mistro A., Mammone F., Zaccarello F., DiCorleone R., et al.

*Institute of Oncology, Dept. of Pediatrics, University of Padova, Padova, Italy

Objective: Develop a protocol for early diagnosis in children born to HIV seropositive mothers. Correlation between diagnostic results and HIV infection status.

Methods: Children born to seropositive mothers were studied at birth and/or to the first months of life for the following parameters: 1) In vitro production of antibody, 2) antipneumonia in sera, 3) virus culture assays, and 4) DNA amplification by polymerase chain reaction using specific primers for gag and env HIV genes.

Results: In a series of 101 children, 64 were repeatedly negative for all parameters and 18 were constantly positive; in 19 cases the results were discordant among different tests. Nine than one year follow-up of the negative children later confirmed that all, but one who developed AIDS at 6 mos. of age, were not infected. 10 of the 18 positive children developed AIDS or AIDS related states. Among the discordant cases, several patterns were observed, and the 4 parameters were variately positive and negative, in different combinations.

Conclusions: Analysis of the data provided the limits of the simple diagnostic procedures, and also reflected the different status of HIV infection; interestingly, 2 asymptomatic seronegative, but HIV infected children, were identified.

T.B.P.241 SEQUENTIAL WESTERN BLOT PATTERNS IN CONFIRMED HIV SEROPOSITIVE INFANTS

Laban, Naomi L.; Criss, V.C.; Joseph, S.; Mohla, C.; and Campos, J.M. Children's Hospital National Medical Center, George Washington University School of Medicine, Washington, DC, USA.

Objective: To follow western blot patterns over time in confirmed HIV seropositive infants and compare loss of specific bands with the Centers for Disease Control classification of disease.

Methods: One hundred eighty-five serial serum specimens were collected at approximately 3 month intervals from 37 confirmed seropositive infants (<24 months of age) and tested for ELISA reactivity (Abbott HIV EIA, Abbott Laboratories, North Chicago, IL, USA), western blot (DHY Western Blot kit, Dupont Company, Wilmington, DE, USA) and HIV antigen (Abbott HTLV III Antigen EIA). Each infant also was evaluated according to the Centers for Disease Control classification scheme for pediatric AIDS.

Results: Eight of the 37 infants (21.6%) became western blot negative during the study period, at a mean age of 16 months (range 12-23 months). Nine of the infants remained western blot positive; 3 of the 9 were HIV antigen positive. Twenty of the infants became western blot indeterminate; 6 of the 10 had class P2 disease, and 5 of the 6 were HIV antigen positive. Inconsistent western blot patterns were observed in these 5 infants over time and among siblings.

Conclusions: Western blot indetermination patterns are common in infants with HIV disease. Resembling and/or disappearance of specific bands in serial western blot from confirmed HIV seropositive infants are not as prognostically useful as reported in adults. The definition of "indeterminate" may need to be redefined in infants with potentially acquired HIV.

T.B.P.243 MONITORING OF HIV ANTIBODY PROFILES BY RIFA AS A MEANS OF DIAGNOSING INFECTION IN INFANTS

Laboulaye M., Lapostolle J., Masmouni J., Delagrèe G., Delagrèe N., Bouchevarot, C.

*Laboratoire de santé publique du Québec, **Hôpital Ste-Justine, Montréal, Québec.

Objective: In an ongoing prospective study of HIV perinatal infection, radioimmuno-precipitation assay (RIPA) was evaluated for its ability to differentiate de novo synthesis from passively transferred antibody (Ab). RIPA was also compared with virus isolation and HIV antigen (Ag) detection for early diagnosis.

Methods: Fifty-two sera obtained at each visit from 9 asymptomatic mothers and 6 infants were tested for HIV-Ab by RIPA and for HIV-Ag with a commercial EIA. Isolation was carried out by co-cultivation of PHL with cord blood lymphocytes and was monitored by RT activity and HIV-Ag detection. **Results:** Sera of 6/9 mothers revealed Ab profiles against all labeled HIV polypeptides by RIPA. Virus was isolated in 4/7 women. HIV-Ag was demonstrated in only one. Initial sera from infants did not show Ab profiles different from those of their mothers. Analysis of sequential sera obtained up to 9 months of age revealed decreased reactivity to selected polypeptides, indicating loss of maternal Ab. Virus was isolated from 3 symptomatic infants (at 14, 4, 2 and 5 mo), but not from 3 asymptomatic ones. HIV seropositivity was observed in only one asymptomatic infant.

Conclusion: Our preliminary results suggest that virus isolation is a more sensitive indicator of HIV infection than Ab or Ag detection. Comparison of Ab profiles in sera of women at birth and their offspring did not allow early diagnosis of HIV infection in infants.

T.B.P.245 INTÉRIEUR DE LA MISE EN CULTURE SYSTÉMATIQUE DU VIH CHEZ LES ENFANTS NÉS DE MÈRES INFECTÉES

Fleury, Hervé J.A.; Delord, B.; Douard, D.; Perel, Y.***

*Laboratoire de Virologie, CHU de Bordeaux et Université de Bordeaux II, Bordeaux, France, **Services de Pédiatrie et Néonatalogie, CHU de Bordeaux, Bordeaux, France, *** Service de Pédiatrie, Centre Hospitalier de la Côte Basque, Bayonne, France.

Objective: Comparer les résultats de la mise en culture systématique du VIH sur sérum d'enfants biologiques et cliniques dans une cohorte prospective de mères infectées.

Méthodes: Les cellules mononucléées du sang circulant d'enfants nés de mères infectées par le VIH 1 ont été systématiquement mises en culture et le virus VIH 1 éventuellement produit a été détecté par son activité RT et la présence de l'antigène de Core p24. Les résultats de l'isolement ont été comparés aux données de l'antipneumonie TCD4, de la cinétique des anticorps anti-VIH 1 (ELISA et WB), de la numération des lymphocytes TCD4, du dosage sérique des immunoglobulines et de l'état clinique.

Résultats: Nous distinguons deux groupes: 1) Un où l'isolement viral est négatif et dont les autres données biologiques et cliniques indiquent qu'il s'agit d'un cas d'infection virale; 2) L'autre (3/30 des enfants) où l'isolement est positif et corrélié par un ou plusieurs paramètres pédiatriques (antipneumonie élevée, augmentation des immunoglobulines, signes cliniques... etc.). **Conclusion:** L'isolement systématique du VIH chez les enfants nés de mères infectées demeure une technique de base indispensable à l'établissement d'un pronostic.

T.B.P.258

EXPERIENCE WITH CENTRAL VENOUS CATHETERS IN PEDIATRIC AIDS

OBJECTIVE: Children with AIDS are at high risk for infection and malnutrition. Frequently receiving intravenous fluids for antibiotics and nutritional support. We undertook this study to determine the course and complication rate of central venous catheters (CVCs) when used in a pediatric AIDS population.

Methods: Retrospective chart review of 289 HIV infected children in Newark, NJ (1982-88).

Results: 2126 children who received catheters had charts available for review and received 35 catheters. All 28 and 68 CVC defined AIDS (EBS with CD4 <400). Mean age at insertion was 28 mo. (10 w. - 11 yr.). Mean duration of placement was 115 d (28-400) for a cumulative total of 4846 days. In 2373 courses, children were able to go home, with family training and nursing support, for a mean duration of 72 d. There were no catheter related deaths. Sixteen catheters were removed for technical problems. Of all failed attempts (15) evaluated during catheter placement, 21 documented catheter related infections occurred. Ten bacterial episodes were successfully treated with catheters remaining Organisms: 4 staph, 3 strep, 3 gram neg. Eight catheters were removed because of inability to clear the infection (organisms: 3 candida, 3 staph, 3 strep, 3 gram neg.). Of 3 local infections, one local infection was successfully treated and 2 catheters were removed for exit site infections with pseudomonas. These 16 bacteremic episodes represent 4.3/1000 days of catheter use.

Conclusion: Our infection rate with bacteria in children with AIDS (4.3/1000) compares favorably with previously documented infection rates in pediatric oncology patients (1.3-7.3/1000). Catheters can be safely used at home for outpatient antibiotic and nutritional therapy in this high risk population.

T.B.P.259

NEOPLASTIC DISEASE IN CHILDREN WITH AIDS. S. K. Goyal, M. D., M. Comer, F. Starita, L. S. Epstein, S. M. Blinn. Departments of Clinical Pathology and Pediatrics, The Children's Hospital, University School of Medicine, Newark, NJ, and Children's Hospital of New Jersey, New Jersey Medical School, Newark, NJ, USA.

Objective: To describe the incidence and types of neoplastic diseases (ND) in children with AIDS.

Methods: Ninety (35 cases) male/female (18 cases) material from 102 HIV infected children.

Results: Seven cases showed ND. The risk factor in five of the cases was parental IV drug use. In 2 cases HIV was ascertained via transmission of blood or blood products. In 2 cases, ND was the first major evidence of HIV infection. In 1 it was part of a complicated course and in 2 it was found at autopsy. Following types of ND were observed: 1) peripheral neuroangioma (2 cases); 2) lymphoproliferative disorder (PLD) characterized by involvement of lymph nodes, spleen, adenoids, liver and parotid gland (brain lesion was not involved) case; 3) testis represented progression of pulmonary lymphoma; hyperplastic lymphoid interstitial pneumonitis; PLD in intercostal space; interstitial in biologic behavior between benign and malignant lymphoproliferation; 2) multiple lymphoma involving only the brain in 2 cases; 4) squamous carcinoma of gastrointestinal tract (4) primary tumors extending from stomach to colon, with metastasis to lymph nodes, brain and liver in one case; 4) epiphyseal sarcoma of skin of arm, nose and prostate in a child with metastatic squamous cell infection.

Conclusion: HIV associated ND may be more common than previously reported and may occur at any point in the symptomatic course.

T.B.P.260

SAFETY AND EFFICACY OF CENTRAL VENOUS CATHETERS IN PEDIATRIC AIDS PATIENTS

OBJECTIVE: Children with AIDS are at high risk for infection and malnutrition. Frequently receiving intravenous fluids for antibiotics and nutritional support. We undertook this study to determine the course and complication rate of central venous catheters (CVCs) when used in a pediatric AIDS population.

Methods: Retrospective chart review of children with CDC-defined AIDS (P2D) who had CVC placed due to inadequate venous access.

Results: The medical records of 11 pts (7 males, 4 female), ages 3 mos to 12 1/2 yrs (mean=7 mos) were reviewed. Risk factors included blood transfusions in 10, perinatal exposure in 6 pts. Mean absolute granulocyte count (AGC) at the time of CVC placement was 3083/mm³, with 3 pts having an AGC of <1000/mm³. Mean CD4 cell %s were 24.3%, with 10 pts having CD4 <4500/mm³. No morbidity or mortality was associated with the CVC operative procedures. Thirteen CVCs double lumen, 1 single, 3 totally implanted were placed for a total of 1812 CVC days (mean=164 days/CVC). The 13 CVCs were used for the following: parenteral nutrition-12; IVIG-1; blood products-12; other medicines-11; blood draws-11. Four episodes of CVC-related sepsis (3 pts) occurred; 22 infections (100 CVC days) resulting in removal of 3 CVCs. Klebsiella, Enterobacter species and S. Eptidermidis were isolated from individual CVCs. Three CVC occlusions (radiographically confirmed) occurred, 2 of which spontaneously resolved, 1 which required operative CVC revision.

Conclusion: The ease and types of CVC infection in children with profound HIV related CD4+ cell deficiency approximates that seen in pediatric oncology pts. CVCs proved valuable in pts requiring multiple therapeutic interventions.

T.B.P.261

HIV INFECTION (HIV) IN PATIENTS (PTS) TREATED FOR LEUKEMIA OR SOLID TUMOR. A. Pediatric Oncology Group (POG) Study

OBJECTIVE: To determine the incidence and sequelae of HIV infection in patients treated for leukemia or solid tumors.

Methods: A retrospective chart review of children with CDC-defined AIDS (P2D) who had CVC placed due to inadequate venous access.

Results: Ten of 74 responding institutions reported a total of 19 HIV infected pts (14 leukemias, 5 solid tumors; 12 boys, 7 girls; age 10 mos-20 yrs.). Thirteen pts were diagnosed off-therapy, 6 pts on therapy. Sixteen pts acquired HIV post-transfusion. Three pts with congenital AIDS developed B-cell leukemia before the age of two. A correlation exists between number of cases by institution and geographic HIV seroprevalence. The median interval between transfusion and diagnosis of HIV was 20 mos (range 5 wks-6 yrs.) between transfusion and death was 30 mos (range 2 mos-18 yrs.). 18/19 HIV pts developed AIDS, one remains asymptomatic. 12/19 have died (CD4 < 80). Two pts are being treated with ZV or AZT.

Conclusion: (1) No true seroprevalence was available; (2) A correlation existed between HIV, geographic area and number of transfusions; (3) HIV status appeared not to affect tolerance of chemotherapy; (4) the natural history was different from lymphomas but similar to other transfused pts; (5) Testing with consent form, counseling, follow-up and therapeutic guidelines is recommended for pts transfused in high seroprevalence areas.

T.B.P.262

VERY LATE ONSET OF GROUP B STREPTOCOCCAL SEPSIS IN INFANTS WITH HIV INFECTION.

OBJECTIVE: To describe characteristics of Group B streptococcal (GBS) disease in HIV infected children.

Methods: GBS disease (documented in 2/200 (1-8) of HIV infected children diagnosed at the University of Maryland and NY Medical Center. Charts were reviewed to describe clinical features, course, and outcome of GBS disease.

Results: GBS patients were 2, 5, 8 and 5 months of age respectively. Each had evidence of HIV infection as well as immunologic dysfunction including low T-cell counts and poor mitogen responses. All had fever > 100F, elevated WBC's ranging from 10,000 - 20,000, and marked left shift. Two presented as meningitis with bulging fontanelle, irritability, and seizures. Both had CSF pleocytosis and + CSF cultures for GBS. One presented with tachypnea, rales, apnea, and radiographic evidence of bilateral pneumonia. The course of each patient was unusually complicated. All 3 responded to IV beta-lactams.

Conclusion: GBS disease (meningitis and pneumonia) occurred beyond the usual age of onset in HIV infected children. Despite immunologic dysfunction and severe GBS disease these patients mounted PNH cell responses and improved with beta-lactam antibiotics.

T.B.P.263

DIARRHEA AND ITS CONSEQUENCES IN HIV-INFECTED CHILDREN.

OBJECTIVE: To determine the incidence, etiology, and sequelae of diarrhea in children with HIV infection.

Methods: Children with AIDS and AIC (16) were prospectively enrolled and serially evaluated. When a physician was made for diarrhea, a whole stool or rectal swab was examined for bacterial enteropathogens, protozoa (with special media), mycobacteria, viruses, and Clostridium difficile toxin.

Results: During the first 11 months of therapy, the incidence of diarrhea was 0.13 episodes per child-year, which is 2.6 times the incidence we observed in seronegative children born to HIV-infected or high risk women (mean age 7.2 > 6.2 months). Four cases were hospitalized because of diarrhea, and one case with salmonellosis died. Two cases had recurrent (> 3) episodes/year and one had persistent (> 14 days) diarrhea. Wasting (weight for height < 5th percentile) was seen in 4 children.

Conclusions: Diarrhea is a major cause of morbidity in HIV-infected children and occurs at a rate that is 2.7 times higher than the reported incidence in uninfected children. A potentially treatable infectious etiology can be detected in almost all children.

BRUNETT LYMANNA IS AN HIV-INFECTED CHILD.
R. Cassill, R. Aziz, J. Deina*, E. Michelson*, A. Rescardou, P. Lescarot*
Dept. Pediatrics, *Infectious Diseases, University of Paris, Italy

HIV infection in children is infrequently complicated with malignancy: Kaposi sarcoma (KS) then TB, a few cases of malignant brain lymphoma, an case of Burkitt lymphoma (BL) are reported. We describe B. in a 2-year-old white female, born to drug abuse seropositive mother, uninfected because of fever, anorexia, interstitial pneumo. HIV seropositivity, failure to thrive, enlarged lymphnodes, liver and spleen above evident than 3-month-old. Persistent interstitial pneumonia until the age of 18 months. During the next 6 months pallidness, hyperpneumothorax, recurrent CNS and HIV seropositivity persisted (positive according to CDC). In admission she was febrile, poorly nourished with dyspnea and generalized lymphadenopathy; her abdomen was protuberant and tender. Liver margin at 11 cm, spleen 9 cm. WBC 13,700/ml (85% NE, 10% LY, 5% MO, 1% E), IgM 1010 µg/ml, IgG 1110 µg/ml, IgA 100 µg/ml, CD4-78%, CD8-28%, CD4:CD8 ratio near HIV antibodies in ELISA and R. blast (12/23-33-35-65), qc 102-216). CMV was isolated from body fluids. Necrosis for brain scan (normal) caused severe hyperpnea. CT scanning: moderately ventricled enlarged paraventricular (4.2 cm) and subcortical lymphomas. Coexistence of biopsy specimens of skin lesions changes consistent with K. combination chemotherapy (KS, CMC, PDR, Imit 102) was started. Dramatic clinical improvement was evident within two weeks: mediastinal circumference decreased by 11 cm and TB scan showed disappearance of mediastinal nodes. In case of massive mediastinal distention in HIV infected children, even if one year after the onset of signs of illness, opportunistic lymphoproliferative neoplasms should be ruled out. If detected, it can be symptomatically treated with specific chemotherapy with some advantage.

T.B.P.266

OPPORTUNISTIC INFECTIONS AND MORTALITY IN AN URBAN PEDIATRIC POPULATION INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV)
Hassan, J., Collins, Rosenblatt, M.M. and Shearer, W.L. Baylor College of Medicine's Hospital, Houston, Texas, U.S.A.

Objective: To define opportunistic infections (OI) that were most prevalent and linked with the highest mortality rates in an urban pediatric population.
Methods: 73 pediatric HIV patients followed up to 7 years (mean 2 years) were reviewed for evidence of OI (Center for Disease Control, stage B-1).
Results: As in the adult population, pneumocystis carinii pneumonia (PCP) was the most frequently reported opportunistic organism with a high mortality rate linked to both a) clinical presentation with acute respiratory failure and b) co-infection with cytomegalovirus (CMV). CMV infection had the highest mortality rate with documented pneumonitis (3/5), hepatitis (1/5) and retinitis (1/5). Bacterial infections were not as common as in other reports.

OI	# of Patients	Mortality	Recovery
PCP	108	100%	No
CMV	6	100%	No
HIV intracellularly	5	100%	No
Salmonella	2	0%	Yes
E. Coli	1	100%	No
Strep. pneumoniae	1	0%	Yes
Candida esophagitis	0/2	0%	Yes

Conclusion: The incidence of OI was 25% (18/73) with mortality high for PCP, CMV and gram negative sepsis (averaging 90%). Attention should be focused on early detection and intervention for OI. Protocol's defining and standardizing therapeutic approaches to OI in children must be designed and implemented.

AZT SK/Thrombocytopenie et autres traitements AZT KS/Thrombocytopenia and Other RX

T.B.P.268

NEUTROPHILIC EFFECTS AND COURSE OF ZIDOVUDINE (AZT) THERAPY.
Schibler, Walter*, Marrier, G.* and Johnston, B.*
*Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, Canada

Objective: To describe the hematologic effects and outcomes of zidovudine (AZT) therapy in CDC group III and group IV HIV-infected patients (pts).
Methods: 29 AIDS and group III (n=24) pts were treated with AZT. Hematologic parameters studied included hemoglobin count (Hb c), platelet count (PLT c), hemoglobin (Hgb), mean corpuscular volume (MCV), and lymphocyte (CD4) cell counts.
Results: Of 34 pts enrolled, 7 are dead, 12 are off Rx, and 14 remain on Rx. Deaths were due to disseminated TB (1); recurrent PCP (2); progressive dementia (1); leishmaniasis (1) and lymphoma (3). Disseminated CMV (2), PML (1) and stage IV lymphoma have developed in 4 pts continuing Rx. Serial CD4 cts demonstrated significant increases in 8/24 pts able to take 1200 mg/day of AZT. Pts. with CD4 cts <100 cts/mm³ did not show increases to >100 cts/mm³. Progressive thrombocytopenia was seen in 12/24 pts. Pts. with starting Hgb <14 g/dl were more likely to have significant decreases in Hgb on Rx (p<0.05). OC cts varied but increases were noted when OC cts were low at start. P/E cts remained stable or increased slightly.
Conclusions: Zidovudine causes predictable thrombocytopenia and unpredictable anemia. OC and P/E cts may improve with suppression of active HIV infection. Opportunistic infections and malignancies continue to develop in patients taking zidovudine.

T.B.P.265

CHRONIC MUCOCUTANEOUS CANDIDIASIS IN PEDIATRIC AIDS
Jombik, Sylvia; Meiji, M.; Stoner, K.R.; Gromlich, D.D.; Marmorstein, V.
New York Medical College, New York, USA

Objective: To compare the incidence of persistent mucocutaneous candidiasis in patients diagnosed as AIDS in the first year of life (group I) to those diagnosed later (group II).
Methods: The study was performed at two public hospitals in New York City on 81 HIV-2 patients with perinatal HIV infection admitted from 1984-1988 and followed for 1-50 months (mean 18 mo.). All mothers except three were intravenous drug abusers. The majority of patients in group (I) became symptomatic in the first six months of life. The C consisted of 42 patients: 44 blanche (3) and 28 Puerto Rican (9) 21 males (4) and 21 females (1). G I comprised 20 patients (13 and 7 P) 12 m and 8 f, ranging in age from 12.5 months to 72 months (mean 37 mo.).
Results: Chronic mucocutaneous candidiasis was significantly more frequent in G I (n=21) (50% vs 10%, p<0.006). There were no significant race or sex differences between groups, but in G I 5 were more often afflicted than P (2 (60% vs 31%). Also in G I candidiasis was the sole initial manifestation in 9 patients (28%) and 3 of those (60%) died by four months of age. In G II candidiasis was found only in PR with no significant sex differences (2/8 in 6 m vs 2/8 in 12 m).
Conclusions: In the very young infant with perinatal HIV infection, chronic mucocutaneous candidiasis may predict early and severe morbidity. Long term follow-up is needed to elucidate its prognostic value in older infants and children.

T.B.P.267

SPECTRUM OF INFECTIONS IDENTIFIED AT AUTOPSY IN PEDIATRIC AIDS
Rosa, Lawrence A.; Wong, K.K.; Gowers, E.D.; Rinaldo, A.L. and Church, J. Childrens Hospital of Los Angeles and U.S.C. School of Medicine, Los Angeles, California, U.S.A.

Objective: To identify the spectrum and sites of infection in children dying of AIDS. **Methods:** 33 children with AIDS of Los Angeles and U.S.C. School of Childrens Hospital of Los Angeles; 22 have expired; 12 postmortem examinations revealed the following:

ORGANISM	# of Pts	SOURCE	CLINICAL CORRELATES
P. carinii	7	lung(1)	pneumonia(P)
Candida Spp.	5	l. pharynx, heart(3); blood(3); kidney, bladder, esophagus	P. thrush, esophagitis, endocarditis, disseminated disease(D)
Cytomegalovirus	4	l. brain, pancreas, adrenal glands, thyroid, brain(4)	P. HD, virecemia, enterocolitis, encephalitis(E)
H. avium complex	2	l. b.	P. sepsis(S)
Adenovirus	1	l. l., P, tr	DD, P, E
P. aeruginosa	1	l. b., l.	S, P
H. coli	1	l. b., l., peritonium	P, S, peritonitis
P. pneumoniae	1	l. meningis	P, meningitis
HSV	1	l.	P

Conclusion: Multiple infectious agents may be responsible for a fatal outcome in children with AIDS. This indicates the need for a wide range of improved antimicrobial therapy for these children.

T.B.P.269

THROMBOCYTOSIS IN HIV INFECTION
Suzil, Singsap*, Jardi, F.*; Awati, R.M.*; Falestin, R.*; Stallard, R.* and Basillat, S.*

Objective: To describe the incidence of thrombocytosis in HIV positive pts, to assess the severe lesions and the prognostic significance of thrombocytosis in the AIDS condition.
Methods: on Dec. 21, 1988, eighty-eight cases of thrombocytosis were observed with a population of about 1000 HIV positive pts. at the 1st Division of Infectious Diseases Follow-up Study, with results before with an average 11-month observation. Nine narrow bligies from 23 thrombocytotic anti-HIV positive pts. were observed at light and electron microscopy. The 19 Ppt. and the 21 group III pts. (CDC 1985) were initially all free from opportunistic involvement and remained so until death. Platelets were initially all free from opportunistic involvement. We evidence of granuloses or acid fast organisms was found. These data suggest a probable mechanism destroying light platelets particularly in the absence of bone marrow endoprothetion. In the present follow-up only two pts. undergoing a bone marrow biopsy, evolved to follow-up.
Conclusions: 1) 8% of the HIV positive population presents thrombocytosis as a clinical sign of early bone marrow involvement. 2) The main bone marrow alterations are characterized by an increased number of megakaryocytes with hyperplastic and plasmacytic. 3) Thrombocytosis has no inferable prognostic meaning in the relation to AIDS.

Thérapie et évaluation clinique : ribavirine et autres médicaments Therapy and Clinical Evaluation, HIV Ribavirin and Other Drugs

T.B.P.294 COMPARISON OF RIBAVIRIN VERSUS PLACEBO FOR PREVENTING THE PROGRESSION OF HIV INFECTED SUBJECTS FROM CDC STAGE III TO STAGE IV.

Spanish Ribavirin Study Group. Barcelona, Madrid, Bilbao, San Sebastian, Spain.

OBJECTIVE: To compare the efficacy of ribavirin versus placebo to prevent the progression of infected patients from CDC stage III to stage IV.

METHODS: 131 HIV-infected patients (209 homosexual, 468 drug addicts) on CDC stage III, and a CD4 cell count between 300 and 500 per mm³ were included in a double blind multicentric trial and randomly allocated to receive ribavirin (15 mg/kg) or placebo. The planned duration of the study was 18 months with an interim analysis at 6 months without opening the codes unless a significant difference in efficacy or toxicity were detected. The Student's t-test, the Chi-square test, life-table analysis and the Mantel-Cox test were used in the statistical analysis.

RESULTS: The 63 patients included in the study group B and the 68 included in group A had a similar age, sex, race, white and CD4 blood cell counts. In the interim analysis at 6 months of the 63 patients of group A progressed stage IV or to stage IV-C1 to 10-6 and 5 to IV-C1 versus 11 (18%) of the 68 patients of group B to stage IV-C1 to 10-6 and 5 to IV-C1. The difference was not statistically significant pooling together all patients progressing to stage IV or performing a separate analysis for those reaching the CDC stage IV-C1. Side effects were irrelevant in both study groups.

CONCLUSION: At the interim analysis after 6 months both ribavirin (15 mg/kg per day) and placebo were well tolerated but the progression rate stage IV was not statistically different. The results of the final analysis at 18 months will be presented in the Conference.

T.B.P.296 RIBAVIRIN DOES ESCALATING PHASE I TRIAL IN PATIENTS WITH AIDS AND ACD

Chomont, D., Cohen P., Paarlant, J.M., Paarlant, G., Valentine P., Mills J., and Spector R. Beth Israel Hospital, Boston, MA *WHO, New York, *San Francisco General, *San Diego, and *HIV/AIDS-Bethesda, MD, U.S.A.

OBJECTIVE: To carry out an increasing dose phase I trial to find maximum tolerated dose of Ribavirin (RBV).

Methods: Patients to 3 arms, 1) AIDS no previous treatment; 2) ACD; 3) AIDS, ACD failures; were enrolled in a 6 month trial of RBV 600, 1200, 1600, or 2000 mg/d with a goal of 26 patients per dose regimen. Patients all had serum p24 > 70 pg/ml at entry. Clinical status, serum p24, HIV culture, total CD4⁺ cells were assessed in all patients at 4 weekly intervals.

Pharmacokinetic values were measured in plasma and RBC by radioimmunoassay. **Results:** As of 2/1/89, 28 patients were enrolled in the trial. All were in dose range 800 and 1200mg/d. Patients with AIDS no previous treatment (10), severe ACD (10), and ACD failures (8) are receiving RBV. Main side effect has been a pruritic rash at 1200mg/d requiring lowering dosage in 4 patients. In 100 patients mouth 2 episodes of ROP, 1 HSV, 1 CMV and 1 candida infection have occurred. No mononucleosis or granulocytopenia requiring transfusion has occurred. Serum p24 levels have decreased in 3 patients, but trends of all serum p24 values increase with time. CD4⁺ cells have increased in 2 patients, but trend of all values is a decrease with time. Pharmacokinetic data on 100mg/d reveal a steady state plasma level of 10-12 µg/ml.

Conclusion: RBV at 800 and 1200mg/d is well tolerated and is less than MTD. No severe granulocytopenia, mononucleosis or neurotoxicity has occurred. Patients are having few opportunistic infections but CD3 progresses. Patients are continuing to be followed for CD4⁺ cell changes.

T.B.P.298 EVALUATION OF PROGESTERONE ACETATE TREATMENT IN AIDS

Sidd, S., O'Connell, J., and G. S. Alkhatib (eds). AIDS Centre, Sydney Hospital, Sydney, Australia.

Objective: To evaluate the components of weight gain associated with progestin acetate therapy in late stage HIV disease.

Methods: Ten males with a weight loss of 15-20% of usual weight due to late stage HIV disease were treated with norgestrel acetate (10 mg, three times a day). Subjects were treated as out-patients. All patients were on zalcitabine therapy. ACT (ACT prophylaxis). Baseline data obtained pre-treatment included blood biochemistry and hematology, and food intake diary. Subject had an anthropometric assessment as well as body composition analysis by bioelectrical impedance. Subjects were requested to complete questionnaires regarding quality of life assessment, and factors affecting food intake.

Results: Results for a 6 week period of 12 weeks therapy per subject will be discussed. In addition results of weight gain and more specific indicators of body composition are presented to indicate exactly how norgestrel acetate affects nutritional status.

T.B.P.295 DEXTRAN SULFATE IS POORLY ABSORBED AFTER ORAL ADMINISTRATION LACERANAL, R.C.***; Mendrix, C.***; Collins, J.***; Kishi, R.***; Pridy, R.***; Lieberman, M.A.***; S. H. Lieman, M.A.***

*Johns Hopkins University, Baltimore, MD; **U.S. Food and Drug Administration, Rockville, MD; ***University of Colorado, Denver, CO, USA.

Objective: To determine whether dextran sulfate, a synthetic analogue of heparin with anti-human immunodeficiency virus activity in vitro, is absorbed after oral administration.

Methods: Volunteers were given an 1800 mg oral dose followed forty-eight hours later by a 225 mg intravenous infusion of dextran sulfate. Because dextran sulfate is an anticoagulant and the activated partial thromboplastin time (APTT) is a sensitive measure of its anticoagulant activity we measured changes in the APTT after each dose. We also measured plasma lipase activity because dextran sulfate causes the release of lipase into the plasma.

Results: After the oral dose the APTT^a were indistinguishable from the normal variability of this assay over time. In contrast the mean peak APTT was prolonged 160 seconds after the intravenous dose. Because we have observed a linear relationship between the log APTT and the plasma concentration of dextran sulfate in vitro, we used this assay to calculate plasma dextran sulfate concentrations, and we used these values to determine the absorption concentration of this drug. The mean bioavailability was 0.7% (range 0-2.2%), this small percentage could not be distinguished from 0. In lipase activities increased to 2.3 X baseline after the oral dose and >400 X (range 10-1000) after the intravenous dose.

Conclusion: We conclude that dextran sulfate is very poorly absorbed after oral administration.

T.B.P.297 PHASE I STUDY OF 2', 3' DIDEOXYINOSINE (ddI) GIVEN ONLY DAILY TO PATIENTS WITH AIDS OR ACD

Conley, T.J., Fischl, I., Saunders, C., J. Parkin, J.C., McCaffery, R.P.,** McEldowney, C.T., Lieberman, M.A.,** Boston University School of Medicine, Boston, MA, USA; ** Bristol-Myers Company, Wallingford, CT, USA.

Objective: To determine maximum tolerated dose (MTD), pharmacokinetics (PK) and efficacy of iv and oral ddI given once daily. **Methods:** To date, 9 patients (6 men, 2 women) with AIDS (4) or ACD (5) were treated. Plasma and urine were collected after initial iv infusion and at steady state doses of 0.8 (1), 2 (5), 3.5 (2) mg/kg/d and after initial po dose and steady state doses of 1.6 (1), 4 (4), and 7 (2) mg/kg/d. Serial T4 lymphocytes (T4L) and p24 antigen were studied.

Results: Pre-dddI T4L mean = 106/mm³, mean = 2-390/mm³. After 16 days of iv dddI, T4L rose in 4 pts, mean rise = 28/mm³, range 10-57/mm³. After 2-16 weeks of po dddI, T4L rose in 3 pts, mean rise = 90/mm³, range 20-150/mm³. Pre-dddI p24 all positive; no change on iv dddI; 1 on po dddI became p24 all negative. PK data to follow. Heavy leukopenia resolved in 2. Dose limiting toxicity: grade 1 cutaneous (1) and grade 2 hepatic (1). ddI was discontinued in 1 pt with HIV cardiomyopathy and ECG changes.

Conclusion: Daily ddI is well-tolerated in pts with AIDS and ACD with minimal toxicity. The MTD has yet to be established. Preliminary data suggest efficacy with increase in T4L. PE protocol continues with further dose escalations.

T.B.P.299 RECOMBINANT GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR (GM-CSF): LACK OF NEUROLOGICAL TOXICITY

Eng, R.,** Kralj, J.,** J. Parkin, J.C.,** Kram, S.F.,** Anselmo, W.,** Birnbaun, J.,** Sigittis, J.P.,** Price, N.B.,** Bonnen, E.M.,** Memorial Sloan-Kettering Cancer Center, NY and *Schering Corporation, Kenilworth, NJ.

Objective: To assess the possibility of neurological toxicity of GM-CSF in neurologically compromised AIDS patients without disease.

Methods: Patients enrolled in a phase I trial of GM-CSF as treatment for AIDS-related neutropenia were evaluated by quantitative neurological and neuropsychological assessment before and after each treatment cycle. GM-CSF was given by daily sc. injection for 10 days followed by an 18 day period. Subsequent treatments were in 28 day cycles. Four patients were receiving concomitant zalcitabine (AZT). Patients with AIDS Dementia Complex (ADC) (Stage 1, 0, or greater) were excluded.

Results: Nine patients were evaluated: 5 were seen three times and one patient was seen twice, four, five and six times. All patients at baseline had after neurological signs such as eye movement abnormalities and slowing of limb movements (ADC Stage 0.5). None had cognitive complaints. No significant changes were seen in either the neurological or neuropsychological impairment scores.

Conclusions: Theoretical concerns have been expressed that GM-CSF might activate latent HIV-1 infection in macrophages and thereby lead to brain infection and ADC. However, this initial study found no evidence that GM-CSF exacerbated the clinical ADC-related neurological signs present at baseline, or led to ADC. These findings provide a basis for subsequent studies of GM-CSF and AZT in patients with ADC whose neutropenia precludes AZT.

T.B.P.300 OCCUPATIONAL THERAPY FOR PEOPLE WITH AIDS

Authors: Lebowitz, V. Center for Special Services, New York, NY, USA.

Objective: To maintain or improve functional independence and quality of life for HIV/AIDS patients and their families. To be cost effective by decreasing frequency and length of hospital admissions and hours of home health care needed. **Methods:** Occupational therapy as a component of Rehabilitation Medicine, assists the psychologically and physically disabled individual/family in achieving independence and quality of life, via a variety of modalities. These include but are not limited to: 1) Contemporary strategies for performing Activities of Daily Living (ADL) (ie- one-handed techniques, adapted equipment, ADL for the blind). 2) Ordering of bathroom equipment to assist family members in maintaining safety and ease of transfers. 3) Recommendation of wheelchair and positioning devices. 4) Building functional strength and endurance. 5) Teaching entry/exit techniques for the car (push and pull). 6) Instruction in stress management skills. 7) Conversation to the patient with short-term and long-term goals. 8) Instruction in social engagement skills. 9) Teaching letters skills to increase productive use of time. Patients are seen weekly at an inpatient center or as inpatients as needed, and alternated with therapist and psychiatrist. **Results:** Based on formal written evaluations, documented in the medical charts: Patients and families demonstrate an increased independence in ADL's as a result of increased knowledge and adaptive equipment as needed. Through such devices an adaptive pillow chair, patients no longer require a home health aide to assist or supervise medications. They were found success in creative projects. Families learn to monitor well and paralyzed patient safety. **Conclusions:** Occupational therapy as a discipline of rehabilitation medicine, helps people with AIDS and their families achieve quality of life and a greater level of independence. This service is cost effective as it decreases the need for home health care services and, instead, empowers the individual.

T.B.P.302 LONG TERM ZIDOVUDINE TREATMENT

Authors: Sz. Lendvay, J. Ujhelyi, E. P. Patai, Gy. Hidy, J. V. Vernal, P. Kivertó for Institute of Tropical Diseases, Postgraduate Medical School, National Institute for Hematology and Blood Transfusion, Budapest, Hungary.

Objective: To evaluate clinical efficacy, safety and tolerance of long term Zidovudine treatment.

Methods: Four patients (pts) /stage III-3 stage IV/A-1/ were treated with 600 mg/day zidovudine orally. Number and ratio of CD4+ and CD8+ lymphocytes, serum levels of immunoglobulins, antibodies and HIV p24 antigen were determined monthly as well as clinical assessments, clinical chemistry, haematology, parasitology and bacteriology were investigated.

Results: Three pts were treated for 24 one for 13 months. In overall conditions of the pts improved, no serious infection of opportunistic disease were observed (The AIDS p24 cryptosporidial diarrhea stopped) however oral hairy leukoplakia developed in two pts. CD4+ cell count and ratio stabilized in 3 pts and significantly elevated in one. Two pts had been and remained positive, one pt became HIV p24 antigen positive after 12 months and one pt was negative. The pts tolerated zidovudine treatment extremely well, no side effects, nor even anaemia were observed.

Conclusion: Zidovudine might be of use in the long term treatment of pts in stage III. Neither adverse reaction, nor side effects have been observed.

T.B.P.304 ESSAI RANDOMISÉ CONTRE PLACÉBO DE FORTES DOSES

AUTRES LES PATIENTS HIV CHAUVYET, J. AND S. MALEY, J. WALDOR, A. BUSSON, M. BILLETIER, P. PORTIER II. Service des Maladies Infectieuses, Hôpital de la Croix-Rouge, 12018 Lyon, France.

Le but de cette étude était d'étudier l'influence de fortes doses d'AZV sur la progression de la maladie HIV de patients qui ne présentent aucun symptôme ou dont les infections opportunistes ne sont à risque de graves complications. Les patients ont été randomisés en deux groupes: un groupe recevant le placebo et un groupe recevant des fortes doses d'AZV (300 mg/kg) à raison d'une fois par semaine pendant 12 semaines.

Methodes: 20 patients (C20) ou III. 21 hommes, 9 femmes, âgés de 17 à 60 ans ont été randomisés en 2 groupes parallèles, et ont reçu pendant 12 semaines une injection par semaine associée à 1 g de placebo ou à 1 g d'AZV 300 mg/kg soit du placebo ou du zidovudine. Les résultats sont exposés dans le tableau I.

T-lymphocytes	T-suppr/lym	T-h/7s	beta2 mg/l	p-0.07
avant après	avant après	avant après	avant après	**p-0.25
placebo 576 756	746 786	1.25 1.07	2.3 1.1	**p-0.15
ACT 747 778	848 797**	1.86 1.55	3.25 3.5	

Conclusions: AZV à 300 mg/kg 1 fois/semaine, bien toléré, semble ralentir la progression de plusieurs marqueurs de la maladie HIV: baisse des T4 et augmentation des T8. Ces résultats incitent à poursuivre les études en utilisant le didanosine. En effet, sans préjudice de l'AZV bien toléré par voie orale depuis des concentrations sériques importantes.

T.B.P.301 SUPERVISED PHYSICAL EXERCISE LEADS TO PSYCHOLOGICAL AND IMMUNOLOGICAL IMPROVEMENT IN PRE-AIDS PATIENTS.

Authors: Collins, C., Jager, H., Flower, H., Harnett, G., and Popescu, M. University of Heidelberg, Heidelberg, FRG, *AGS Study Group, Schwabinger Kreisstrasse, Munich, FRG.

Objective: The immunological and psychological effects of therapeutically supervised physical exercise in HIV-AB positive individuals were investigated in a randomized controlled prospective study.

Methods: Twenty-eight HIV-AB positive patients were stratified according to the Walter-Reading-Strating-Classification (Stages 1 through 4 were included). Fifteen subjects were randomly assigned to participate in one-hour physical exercise sessions twice a week over a period of 8 weeks. The exercise program was designed to develop endurance beyond threshold values of 4 renal lactate. The control group of 13 patients did not receive exercise treatment.

Results: Within the first 4 weeks the number of CD4+ cells increased in 67% of subjects receiving therapy, as compared to 6% of the control group. CD4+/CD8+ ratio of the last group increased from 0.48 to 0.47 while the ratio in control subjects decreased from 0.48 to 0.42. In addition delayed cutaneous hypersensitivity reactions measured by roval antigens (Plantain Mercurio) increased from 15.2/2 to 18.2/2. There was a clear psychological benefit concerning reduction of anxiety and depression as well as build up of a group feeling. PCMG, a psychological symptoms inventory, showed decrease, but strong correlation with changes in the immunological parameters.

Conclusions: These results demonstrate that carefully directed physical exercise can improve both immunological and psychological parameters in HIV-infected patients.

T.B.P.303 A PHASE I STUDY OF THE SAFETY AND PHARMACOKINETICS OF SOLUBLE RECOMBINANT CD4 (rCD4) IN PATIENTS WITH AIDS AND ARC.

Authors: J. Davies, J. Kahn, J.P. Dodge, T. Sherwin, S.M. Volberding, P.M. and Grossman, J.P. *New England Deaconess Hospital, Boston, MA; **San Francisco General Hospital, San Francisco, CA; ***Greenwich, Inc., South San Francisco, CA, U.S.A.

Objective: To determine the safety and maximal tolerated dose of rCD4 and preliminary indications of antiviral effects of rCD4 in patients with AIDS and ARC. **Methods:** A 2 center, phase I study with dose escalation and monitoring of the safety, pharmacokinetics, and clinical effects of rCD4 in 30 patients with AIDS or ARC. Six patients were enrolled at each dose level of 1,10,100, and 300 µg/kg rCD4 was administered by a single intravenous (IV) infusion on day 1, followed by a 3 day wash out, then infusions 3 times weekly for 8 weeks (11 was total).

Results: No significant adverse effects have been noted in clinical, hematologic, or serum chemistry parameters. One patient developed borderline evidence of anti-rCD4 antibodies on day 37 that were not detected on subsequent determinations. No other instances of anti-rCD4 antibody have been detected thus far. In those patients for whom follow up data is available the total T4 count was 115/50 at entry and 131/41 at 11 weeks of therapy. One individual exhibited a consistent sustained increase or decrease in total T4 count. Approximately 23% of individuals were p24 Ag(+) at entry. Follow up analysis of p24 Ag and viral isolation data are not complete.

Conclusion: IV administration of soluble rCD4 appeared to be well tolerated over the course of this study. Preliminary analysis has not indicated a significant change in total T4 count. Studies are being conducted with long term maintenance IV therapy as well as SC and IM administration.

T.B.P.311 **ROLE OF P24-40 TESTING IN PATIENTS ON ZIDOVUDINE**
 Ross JONES, David J. Myles, A. Donald McMillan, Greg Lamacz, R. Patricia Infectious Diseases Assoc., Melbourne, Victoria, Australia.

Objective: To examine the role of regular measurement of serum p24 antigen (p24) in the management of HIV infected patients (Pz) on zidovudine (AZT).
Methods: From 1 June 1985, 95 p24 and 56 ABC have received AZT for 6-18 months, reviewed 2-4 weeks. 27 patients had monthly serum p24 measurements, measured by a solid phase sandwich immunoassay (Abbott Laboratories). Results: At entry, there were 39 p24 positive (40 ABC, 14 ABC) and 56 p24 negative (56 p24) (34 AIDS, 22 ABC). The follow-up period was a mean 56.1±13.7 weeks for p24 positive and 54.1±13.3 weeks for p24 negative. Twelve p24 positive became p24 negative on AZT, while 27 remained p24 positive. Twenty-five p24 negative became p24 positive on AZT while 31 remained p24 negative. There were 17 deaths and no significant difference in mortality between p24 positive and p24 negative. Thirty-three of the 39 p24 positive p24 developed further opportunistic infections. Results: 11 ABC with 11 of the 56 p24 positive p24 had a further OI (23 AIDS, 16 ABC). There were significantly less OI in the p24 negative group for AZT treatment periods up to 12 months. After 12 months there is no difference in OI between p24 positive and p24 negative patients. Eleven p24 positive (6 AIDS, 5 ABC) and 20 p24 negative (15 AIDS, 5 ABC) entered final dose AZT (>1000ng/ml). Eight of the 11 p24 positive and 11 of the 20 p24 negative developed further OI. On reduced dose AZT, 10 patients, 25±2 p24 positive and 31 of 36 p24 negative p24 developed further OI. Eighteen of the initially p24 positive p24 became p24 negative on full dose AZT. The presence of serum p24 as a predictor of outcome in patients treated with AZT for less than 12 months. Neither the predictive value of p24 nor the benefits of AZT persist beyond 12 months.

T.B.P.313 **USE OF MULTIPARAMETRIC FLOW CYTOMETRY (LYMPHOCTE SUBSET ANALYSIS) TO EVALUATE AZDOXYTHIMIDINE THERAPY**
 Chignon-Villain, Betsy M.*; Cory, J.M.*; Keefer, H.A.*; Eyster, M.E.*; Rapoport, F.*; Landay, A.L.*; et al.
 M.E. Hersey, Montclair State University, State Univ., Hersey, PA; *Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL, USA.

Objective: To evaluate in a cross-sectional study the effect of azidothymidine (AZT) treatment on levels of active HIV-1 infection in AIDS patients.
Methods: A new test, lymphocyte p24-IFA, based on multiparametric flow cytometry, was used to quantitate active HIV-1 infection of peripheral blood lymphocytes in 245. Results were expressed as % p24 positive cells. The assay is based on binding of monoclonal antibody specific for p24 core protein; therefore, only cells with actively replicating HIV were detected. Viral infection was by standard coculture methods. Other work has shown a correlation between viral culture positivity and samples with >1.0% positive lymphocytes. Results: AIDS patients receiving AZT were compared to untreated AIDS patients using lymphocyte p24-IFA. Patients receiving AZT had a mean lymphocyte p24-IFA of 0.3% (I=20) (range <0.1-1.7) whereas untreated patients had values of 0.5, 1.7 and 18.4% (mean = 6.1%). One patient for whom treatment was discontinued increased from 0.19 to 0.9% in one month.
Conclusion: Use of a rapid, quantitative test confirmed reduction of active HIV infection by AZT in a small study. Lymphocyte p24-IFA should be considered for new studies evaluating antiretroviral agents.
 (Supported by USA NIH HL35, NCI-HB-67023 Project #221924 and AIG5915).

T.B.P.315 **THIS EFFECT OF TREATMENT WITH ZIDOVUDINE ON IMMUNE SYSTEM IN THE EARLY IN COURSE OF HIV INFECTION**
 Ricker, William M. Clinch, P.J. Center for Special Immunology, Ft. Lauderdale, FL, USA.

Objective: To study the immune system effects and toxicity of zidovudine in patients with HIV infection and T4 lymphocyte counts between 200 and 400 cells/cm³.
Methods: Patients were further evaluated by determination of HIV p24 antigen level, lymphocyte Naugensin counts with the inclusion of P1A, beta-2 microglobulin level, CD4, chemistries and zidovudine level. Therapy was initiated with zidovudine, 200mg q4H. Laboratory studies were obtained every 3 months. Results: In these patients were compared with patients who initially presented with T4 lymphocyte counts below 200 cells/cm³. No other antiretroviral medications were administered. Results: 38 patients were in the early treatment group. 74 mean was 285 cells/cm³ mean baseline, 388 at 3M and 405 at 6M. Stimulation index with P1A mean was 34 baseline, 97 at 3M and 76 at 6M. HIV p24 antigen mean was 132 pg/ml baseline, 46 at 3M and 56 at 6M. Hct mean was 42.2% baseline, 39.0 at 3M and 40.7 at 6M. 1 patient received a transfusion. There were 28 patients in the late treatment group. 74 mean was 97 baseline, 136 at 3M and 98 at 6M. Stimulation index mean was 25 baseline, 53 at 3M and 51 at 6M. HIV p24 antigen mean was 121 baseline, 77 at 3M and 117 at 6M. Hct mean was 37.5 baseline, 34.7 at 3M and 37.6 at 6M, 9 patients received transfusions.
Conclusion: Earlier treatment of HIV infection before advanced damage to the immune system occurred, resulted in less improvement of the immune system defects studied without the development of clinical disease or significant toxicity. Patients for whom therapy was initiated later in the course of infection did not show this improvement. Earlier initiation of anti-viral therapy with zidovudine may halt the progressive immune destruction and improve defects in immune function in patients with HIV infection.

T.B.P.312 **CHANGE IN BETA-2 MICROGLOBULIN (B2M) DURING ZIDOVUDINE (ZDV) THERAPY (RT) PREDICTS CLINICAL OUTCOME**
 Jacobson, Mark A.; Abram, D.; Mocchetti, P.; Kocourek, R.; Wilber, J.V.; Moss, A.B.; Hiestand, H.C.; et al. Center for HIV Public Health Dept., San Francisco, CA; *Immunodiagnostic Laboratory Inc., San Leandro, CA and AIDS Clinical Trials Group, NIAID, Bethesda, MD, USA.

Objective: Determine if changes during ZDV Rx in CD4 lymphocyte number or any of a serologic markers of HIV activity predict clinical outcome.
Methods: Whole blood CD4 lymphocytes (CD4) and serum p24 antigen (p24 Ag), beta-2 microglobulin (B2M), neopterin (NPT) and p24 antibody (p24 Ab) were measured pre- and serially during ZDV Rx in 38 AIDS and ABC patients (pts). We examined the association between change from baseline values of these markers during the first 6-18 months of ZDV Rx and clinical outcome 14-18 months (mo) after ZDV Rx was initiated.
Results: Among pts whose serum B2M increased during the first 6-12 mo of ZDV Rx, 9/11 had 1 or more serious events (SE) occur (death, life-threatening opportunistic infection, lymphoma) during 14-18 mo of follow-up while among those whose B2M decreased, 10/10 had SE (p<0.01, odds ratio [OR] 10:1). Neither increase in p24 Ag nor NPT, nor decrease in CD4 nor p24 Ab predicted SE (OR=1.0:1). Mean control for underlying diagnosis (AIDS vs. ABC), B2M increase was still predictive of SE by bivariate logistic regression analysis (p<0.01). Also, serum p24 Ab rose in the normal range at 6M & 8M of ZDV Rx. 8/11 were seroconverted (seroconversion status < 60) or died at 14-18 mo compared with 16/28 whose 6M B2M was elevated (p<0.01).
Conclusion: Decrease in B2M normalization in B2M during the first 6-12 mo of ZDV Rx was predictive of stable clinical status 14-18 mo after starting ZDV.

T.B.P.314 **The inhibitory effects of AZT on HIV replication as determined by DNA content analysis**
 Hsu, H.C.; Chang, S.H.; Lajtha, M.; Weinberg, J.; Ruedy, J.; Landay, A.L.; Fleming, J.; et al.
 1 - Federal Center for AIDS, Ottawa, 2 - McGill University, Montreal, 3 - St. Paul's Hospital, Vancouver and 4 - University of Toronto, Toronto, Canada.

A Canadian multicenter study assessed the possible toxic effects of AZT (zidovudine) in 72 HIV-1 infected individuals. In this dose-escalating study, the patients were initially treated with 600 mg of drug/day for 10 weeks, 900 mg/day for another 9 weeks and 1200 mg/day for another 9 weeks. A "washout" period of 6 weeks followed after which the drug was restarted at 1200 mg/day. During this study, both the levels of HIV p24 antigen detected by non-commercial kits and the recovery of HIV-1 from cultured peripheral blood lymphocytes were measured. Twenty-two patients were HIV-1 p24 antigen positive during the study. Treatment with AZT over the 600 mg/day period reduced the levels of circulating p24. In patients that were p24 antigen positive upon entry, treatment with the drug resulted in a sharp decrease in the levels of antigen which persisted for the treatment duration. During the 6 week washout the levels of p24 antigen rose. Drug was reintroduced at 42 weeks and the patients are being monitored to assess the effect of the washout/reintroduction on HIV p24. In those patients in which the level of p24 antigen rose during AZT treatment, there was an accompanying alteration in their antibody profile. The level of antibody to p24 relative to that of gp41 decreased as the p24 antigen increased. There was agreement between these observations and increasing physical condition.

T.B.P.316 **COMBINATION THERAPY TO PREVENT ORAL CHERMOPHILIN (OP-90) IN THE TREATMENT OF PHARYNGEAL CANDIDA PNEUMONIA (PCP)**
 Ricker, William M.; Clinch, P.J.; Howe, R.; Hillman, S.; and Pillsbury, R.A.; Ft. Lauderdale, FL, USA; *Center for Special Immunology, Ft. Lauderdale, FL, USA.

Objective: To evaluate the prevalence, clinical morphology and course of oropharyngeal to PCP in the treatment of HIV-associated PCP.
Methods: Prospective clinical and serological examination for oropharyngeal reactions in the treatment of 16 consecutive episodes of PCP in 6 patients (5 first manifestations). 2 episodes with OP (2nd episode) (OP) (200mg q4H) were included in the analysis. Results: Patients with first OP-episodes (group I) showed outcome rates in 2/4 (12.5%). Patients with recurrent OP (group II) and the same therapy regimen in 5/6 (14/27). Oropharyngeal eruptions (oropharynx) occurred 20.7 days after the onset of therapy in group I and recurrently earlier (mean 7.5 days) in group II. In typical cases there was no skin itching erythema. Injuncting in the patients from, extending in craniocaudal direction 3-4 days prior to smothering. In 7/8 washouts consisted of discontinuing oral and analgesic with confusion and pyrexia. 1 patient developed a mild conjunctivitis, 2 an uveitis and another 2 another 2 mycotic infections (1 patient with progression to Herpes-zoster syndrome). OP-90 therapy was not to be stopped unless patients with oropharyngeal reactions. **Conclusions:** Oropharyngeal eruptions in the treatment of PCP with OP-90 are very frequent but not dangerous. Patients probably toxic reactions (fever, malaise, myalgia, erythema) are common. Oropharyngeal eruptions and severe oropharyngeal mycotic eruptions do not force us to stop therapy when high doses of zidovudine are given. However, when patients with oropharyngeal eruptions, toxic eruptions, and severe oropharyngeal therapy has to be stopped.

Aspects Cliniques Clinical Aspects of AIDS

T.B.P.317 PRELIMINARY OBSERVATIONS ABOUT THE ADVERSE EFFECTS OF PEGLOSSICIN IN THE TREATMENT OF SALMONELLA BACTEREMIA IN PATIENTS WITH AIDS

Levi, Danilo Carlos; Medeiros, S.A.S.; Mendonça, J.S.; da; e Carvalho, M.C.S. 747 - Rua E.T.V. Fioravanti, 8. Serviço de Medicinas Infecciosas, Hospital do Servidor Público Estadual - São Paulo, Brazil.

We treated 3 patients with AIDS and positive blood cultures for *Salmonella* sp. in 2 cases of typhoid fever and, in one, of dysentery. They received pefloxacin orally, 800 mg/day, in 2 divided doses. They had a fast clinical and microbiological response, with disappearance of fever in few days and normalization of the blood cultures. Unfortunately, they also developed severe side effects. The patient developed Stevens-Johnson syndrome on the seventh day of treatment. One presented generalized maculopapular rash on the fourth day, and the third had to interrupt treatment on the fifteenth day due to severe headache and insomnia. All side-effects reversed soon after stopping pefloxacin.

These preliminary observations suggest that the use of quinolones may cause in AIDS patients, as also describe before with other drugs, increased and severe adverse effects, and call our attention to the necessity of extreme prudence in further studies with their use in patients with HIV infections.

T.B.P.318 SEVERE ACUTE TRINITROBENZENE-SULFAMETHOXAZOLE (T-S) REACTION INDICED IN AIDS PATIENTS

Johnson, Michael P.; Goodson, R.D.**; Shands, Jr., J.M.*. Colleges of Medicine* and Pharmacy**, University of Florida, Gainesville, Florida, USA.

Objective: To describe a severe, acute syndrome of fever, hypotension, and primary infiltrates in HIV infected patients receiving T-S.

Methods: We present the cases of two patients that we have seen and the four cases reported in the literature to describe this new syndrome.

Results: The clinical features occurred within hours of T-S therapy.

Patient: Fever New infiltrates Chest X-ray Pneumocystis Prior T-S

1 39 Yes 15 mm/Hg No Infiltrates Not Detected by Unknown

2 39 Yes 65 mm/Hg No Infiltrates Not Detected by Unknown

3 40 Yes 60 mm/Hg New Infiltrates Previously Treated Yes

4 40 Yes 70 mm/Hg New Infiltrates Previously Treated Yes

5 40 Yes "low" Not Described Previously Treated Yes

6 41 Not Described Not Described Previously Treated Yes

All patients improved following discontinuation of T-S.

Conclusion: An unusual syndrome of high fever, hypotension, and pulmonary infiltrates may follow T-S administration to HIV infected individuals with proven or suspected *Pneumocystis carinii* pneumonia. This syndrome, unreported in non-HIV infected patients and rare in HIV positive patients, is acute, severe, and may be difficult to distinguish from sepsis.

* Case reports obtained by literature search.

T.B.P.319 HYPOGLYCEMIE ET DIABETE DUS AU

RESERVE EN GLUCOSE DU SIDA.
PARDONNE, Christian; Briceau, F.; Lepout, C.; Assan D.; Assan R.*
Hôpital Claude-Bernard, 75018 Paris, France.

Objectif: Analyser la glycémie de 18 SIDA (pneumocystoses) traités par méplaté de pentamidine (P), 4 mg/kg/j en i.v.

Méthode: Des glycémies (hors perfusion) à 3,2 mmol/l

définissant l'hypoglycémie et à 15 mmol/l le diabète.

Résultats: 8 malades ont un trouble glycémique à 4 des

hypoglycémies, 3 une hypoglycémie puis un diabète et 1 un

diabète d'emblée (3/8 d'hypoglycémies, 2/8 de diabète). Les

hypoglycémies (9,1±0,7 mmol/l) étaient précoces (5^e jour

après le début de P) avec 2 comas prolongés. Le diabète

(glycémie 26,5±2,2 mmol/l) survint après 41±4 jours, était

insulinodépendant chez tous. La dose totale de P était

1941±218 mg en cas de trouble et 1170±152 mg en leur

absence. Le créatininémie sous P était 194±15 µmol/l

(hypoglycémie seule), 236±52 µmol/l (hypoglycémie + diabète)

et 116±14 µmol/l (absence de trouble) (p < 0,01).

Conclusion: Des doses élevées et instancieuses de pentamidine favorisent

l'accumulation de P et les troubles glycémiques. Avec le

méplaté, la fréquence des hypoglycémies (3/8) et surtout du

diabète (2/8) est supérieure qu'avec l'isothionate de P (2/8

d'hypoglycémies, 0/8 de diabète) (Smith-Bayliss C.M. et al. Clin Pharmacol Ther, 1986, 39, 271-5).

T.B.P.320 ORAL DEMONSTRATION TO SULFADIAZINE AND TRINITROBENZENE-SULFAMETHOXAZOLE (TSP-SM) IN 4 PATIENTS WITH ACQUIRED IMMUNODEFICIENCY SYNDROME

Nickola, Jose H.; and Maggio, C.M., University of Miami School of Medicine, Miami, Florida, USA. Jackson Memorial Hospital, Pharmacy Department, Miami, Florida, USA.

Objective: To develop and evaluate an abbreviated oral desensitization program for patients with AIDS allergic to sulfadiazine and/or TSP-SM.

Methods: Four patients with prior allergic reactions to sulfadiazine (3) and TSP-SM (1) were identified. Allergic reactions included a severe generalized

erythematous rash with pruritus. Sulfadiazine oral suspension was compounded

at a concentration of 1 mg/ml. An initial dose of 1 ml was given and

subsequent dose concentrations were doubled every 15 minutes to achieve a

total dose of 1 gm within 2.5 hours. TSP-SM suspension, serially diluted to

10 mg/ml (5% concentration), was administered in aliquots of 1/2, 1, 2 and 4

ml every 15 minutes to achieve a total dose of approximately 800mg of SM after 2

hours.

Results: One patient had mild rash and pruritus at 400 mg of SM component.

Desensitization was interrupted for 48 hours and restarted with successful

completion. With long-term follow-up, one patient has demonstrated a

phenomenon of *in-vitro* re-sensitization and sulfadiazine was discontinued temporarily.

Conclusion: Oral sulfadiazine and TSP-SM desensitization should be

considered in patients with sulfadiazine-allergy. Compared to current

literature values, an abbreviated desensitization program, as described, may

be useful.

T.B.P.321 A METHOD FOR RAPID ORAL DEMONSTRATION OF PATIENTS ALLERGIC TO AZT

MacDuff, D.L. Toronto Western Hospital, University of Toronto, Toronto, Ontario, Canada.

Patients with HIV infection experience an increasing frequency of allergic reactions to antiretroviral drugs with approximately 18 experiencing sufficiently severe reaction to AZT to warrant discontinuation of the drug. In a population of 200 patients treated with AZT, 12 patients with a history of any sensitivity developed a rash with AZT. Two subsequent re-challenges were attempted in 3 patients and resulted in reappearance of the rash at 12 and 2 hours respectively.

Method: In an attempt to desensitize 3 patients, AZT was given orally at increasing doses according to the following schedule: 1, 10, 20, 50, 100, 200 and 500 mg every 15 minutes; 1, 2, 5, 10, 20, 50 mg hourly and 200 mg every 4 hours thereafter.

Results: All 3 patients tolerated AZT desensitization without adverse clinical, hematological or immunological effects. One patient underwent 2 successful desensitizations following AZT withdrawal for intercurrent illness.

Conclusion: Intolerance to AZT resulting in severe rash can be treated with a simple, rapid oral desensitization. Repeated desensitizations may be performed with little risk of adverse reactions.

T.B.P.322 RECOMBINANT INTERFERON- β_2 PROTECTS AGAINST ZIDOVUDINE-INDUCED GENETIC DAMAGE IN AIDS PATIENTS

Shafiq, Nazam*; Notta, M. and Hallard, R.B. *Department of Chemical, Environmental and Occupational Medicine, University of New South Wales, Sydney, Australia; **Department of Medicine, The University of Texas Medical Branch, Galveston, Texas, USA.

This study was conducted to evaluate the *in vivo* gene-toxicity of zidovudine (ZDV) in patients with AIDS. AIDS patients (n=10) were non-smokers and on ZDV (1500 mg/day) as a sole medication for at least 6 months.

The study. AIDS and AHC patients prior to receiving any therapy served as a negative control. Whole blood cultures were initiated by conventional methods with PMA 1:50 dilution. For each study subject each experiment consisted of an untreated control and recombinant Interferon- β_2 (rIFN- β_2) experimen-

tal group cultures received 10, 100, 1000, 10,000 units of rIFN- β_2 for the entire incubation period. Cells were harvested at 72 hours and stained with the fluorescence plus Giemsa method which enables the determination of number of division cycles a cell has completed. One hundred metaphases from first division cells were scored from each culture for

chromosome aberrations that were mainly from the chromosome-type, i.e. chromatid, chromosome, and isochromatid breaks. The frequency of breaks in the study and negative control group was 5.1±1.2 and 5.0±1.2, respectively (p > 0.05). Cultures receiving 100 and 1000 units of rIFN- β_2 however, showed a frequency of 2.1±0.3 and 0.7±0.37 respectively,

which was significantly lower than the untreated cultures (p < 0.05), using paired t-test. At the highest dose of rIFN- β_2 no aberrations were detected. We conclude that rIFN- β_2 protects against ZDV induced genetic damage.

Aspects cliniques Clinical Aspects of AIDS

T.B.P.323 MEGALOBLASTIC CHANGES IN THE BONE MARROW OF AIT TREATED AIDS-PATIENTS AS A PROGNOSTIC MARKER FOR NEED OF BLOOD TRANSFUSION.

Roy, Leonard, Van Den Burg-Wolf, M, Pistersz, R, Van Veen, J, Bessink H, Verweyling voor Bloedovernameking Prinsengracht, Amsterdam, The Netherlands.

Objective: to study the effects of one year azidothymidine (AZT) treatment on the erythropoiesis of AIDS-patients.

Patients and methods: twenty three male patients, classified as having AIDS underwent serial bone marrow aspirations during AZT treatment (6 x 200 mg qd).

Results: After one month AZT 12/23 (52%) of the patients exhibited moderate megaloblastic changes in the bone marrow, whereas the other 11 remained normoblastic. Sixteen patients were available for follow up after 12 months AZT therapy. 8 from the megaloblastic group and 8 from the normoblastic. Vitamin B12 and folic acid levels were not significantly different in both groups during AZT treatment. In the group with megaloblastic changes the patients needed a significantly higher number of red cell concentrates than in the normoblastic group, i.e. 42 units versus 6 units (p < 0.05).

Conclusion: Megaloblastosis of the bone marrow early in the treatment with AZT may be a prognostic marker for the need of blood transfusion in AIDS-patients.

T.B.P.325 HOME TRANSFUSION FOR AIDS PATIENTS ON ZIDOVUDINE

HE, HAN, KAZANZAKI, A, K, Jevancic, S, I Gilson *
*Nightingale Nurses Association, Milwaukee, WI, USA, **Department of Pediatrics, University of Wisconsin Medical School (Milwaukee Clinical Campus), Milwaukee, WI, USA

Objective: To describe a home blood transfusion (HBT) program for AIDS patients (pts) on zidovudine (ZDV) therapy.
Methods: AIDS pts with transfused anemia (Hgb < 8 gm) were contacted. HBT by home care nurses as an alternative to hospital transfusions (ht), usually at 2 units of HBC-poor packed RBC under supervision of the primary MD. Most pts were ambulatory and all were hemodynamically stable. All were required to have a consent present after HT.
Results: 8 AIDS pts on ZDV were given 178 U HBC-poor packed RBC over mean 13 mo (range 7-18). US u were HT and 42 u were hospital outpatient or inpatient. 15 pts are presently alive (5 still on ZDV). 2 expired from opportunistic infections. One pt had an unusual reaction to HT which responded to antihistamines. One pt had a delayed hemolytic reaction to blood given as an inpatient, several minor febrile reactions to HT did not require treatment. Cost for 2 units HT = \$182, cost for 2 units in hospital = \$ 699. HT reduced total cost by 31%, saving an average of \$196/pt/yr. No pt had to permanently stop ZDV because of anemia, and all pts continue to prefer HT.
Conclusion: HT is feasible, safe, cost-effective, and facilitates long-term ZDV therapy in the home environment.

T.B.P.327 POLYMYOSITIS DURING ZIDOVUDINE THERAPY

Therrien, Thomas, Kaiser Foundation Hospital, Oakland, California

Objective: To determine the incidence of polymyositis during zidovudine (AZT) therapy.

Methods: A 12 month prospective followup of a cohort of 10 patients (pts) taking AZT. Creatine phosphokinase (CKP) was routinely monitored during visits and in pts with symptoms of polymyositis.

Results: Eight pts (40%) were found to have elevated CKP over the period of observation. Onset of lab abnormality was from 10 days to 17 months (mean 7.8 months) after starting AZT. Most pts had mild Quadriceps muscle weakness and fatigue on exertion; 1 pt had acute onset Quadriceps tenderness and weakness which resolved in 1 week; 1 pt had chronic weakness limiting ability to ambulate. Most pts either resolved (9/8) or remained stable (4/pts) despite continued AZT in all patients from 3 to 13 months (mean 4.6) after onset of polymyositis.

Peak CKP ranged from 418 to 894 IU/L (n = 200). Duration of elevation varied from 1 to 5 months. No correlation between dose of AZT and severity of polymyositis was found.

Conclusion: Mild polymyositis is common during zidovudine therapy but usually resolves or remains stable during continued zidovudine therapy.

T.B.P.324 THE EFFECTS OF PCP PROPHYLACTIC AGENTS ON ZIDOVUDINE-INDUCED ANEMIAS

Rodgers, P., Craig Egge, Marie, C, Wolbert, J, Kelly, J, Kibbe, D, Ballinger Hospital Center, Community Health Project, St. St. USA.

Objective: To review transfusion requirements in PCP prophylaxis receiving zidovudine. **Method:** Through chart review, transfusion requirements for 169 patients on zidovudine therapy for a median of 22 weeks were compared by type of absence of PCP prophylaxis. Eighty-eight patients received DMG/ Sulfa, 59 patients received aerosolized Pentamidine and 22 patients received no PCP prophylaxis. Hematocrit (Hct) were recorded at onset of zidovudine therapy and at time of transfusion. Length of time from initiation of zidovudine to time of transfusion was recorded. Hematocrit 54 patients required transfusion: 28 (32%) on DMG/Sulfa, 10 (17%) on aerosolized Pentamidine and 11 (50%) without prophylaxis. The DMG/Sulfa and Pentamidine groups were not statistically different with respect to pre-zidovudine Hct or time to transfusion. However, in the non-prophylaxed group the pre-zidovudine Hct was significantly lower (31.17 vs. 30.85, p less than .01) and the most of transfusion-dependent anemia significantly sooner (82 days vs. 103 days, p less than .01). **Conclusion:** The use of DMG/Sulfa as a PCP prophylactic agent as compared to aerosolized Pentamidine is associated with a significant increase in the incidence of transfusion-dependent anemia. Randomized, controlled studies are indicated.

T.B.P.326 THE TOXICITY OF ZIDOVUDINE IN THE TREATMENT OF PATIENTS WITH AIDS-RELATED COMPLEX (ARC) AND AIDS

Geared, K. St. Elizabeth's Hospital, Lowell, Massachusetts

Objective: To evaluate zidovudine toxicity over a two year period of its clinical use in HIV patients.

Methods: Zidovudine-treated 351 ARC and AIDS patients, on 100mg 4-hourly oral regimen, have been monitored fortnightly for up to two years.
Results: Over a median follow-up of 8.3 months (range 1 - 23) zidovudine was stopped/discontinued because of death (51), drug toxicity (48), other toxic treatments (23) or patient's request (27). The dose was lowered in 50 patients due to toxicity. Anemia or hypoproteinaemia accounted for drug cessation and lowering of dose in 74 and leucopenia alone in 16 cases. Of 15 patients with thrombocytopenia, the platelets rose to normal level in 11 but this was not sustained for longer than 3 months in 5 patients. 182 (52) subjects received at least one blood transfusion. Of 110 patients who were on zidovudine for more than one year in 66 (60%) drug had been discontinued. Bone marrow aspirates in 13 patients with median follow-up of 8 months showed hypercellularity to 6 and hypocellular erythropoiesis in 6 patients. In 8 patients with a 3-fold rise in CPK, zidovudine was stopped in a median follow-up of 11 months; in 4 the levels didn't change significantly, in 2 fell substantially and in 2 normalized. Muscle biopsy in 7 of these 8 patients with a rise associated peripheral muscle atrophy, was normal.
Conclusions: Zidovudine treatment in ARC and AIDS patients cause severe hematological toxicity and possibly effects muscle metabolism. In one year 60% of treated patients needed to be taken off zidovudine.

T.B.P.328 NEUTROPHILIA IN HIV INFECTED PATIENTS UNDER ZIDOVUDINE THERAPY.

Palmer, Peter, J, Morgan, JG, O'Neil, GJ, Adams G, and Nyrop, M. Tulane University, New Orleans, LA, USA

Objective: To evaluate neutrophilia in patients with symptomatic HIV infection before and during Zidovudine (ZDV) therapy.

Methods: Forty nine individuals with late ARC or AIDS who had negative serology for pretreatment were studied. The natural history of neutrophilia, and absolute numbers of neutrophils and lymphocytes, could be followed in 47 of these during ZDV treatment. Neutrophil (NOS) percentages (N) were the differential, absolute NOS count was derived from the value and the WBC. Geographic controls established the normal range.

Results: Twenty two individuals (45%) had NOS I (> 42). Absolute NOS count (> 450) were elevated in 9/40 (18%) subjects. Following treatment with ZDV (median duration = 22 weeks, range 2 - 24), 28 had raised N and 12 had elevated absolute NOS count. For the entire population, there were significant reductions in NOS T, numbers, and total lymphocyte numbers (p < 0.05). Overall, neutrophils were unchanged. In a subset of patients (n=16) with neutrophil toxicity (mean time of appearance = 5.3 ± 1.1 weeks), both NOS T and absolute count decreased. When dose reduction of ZDV resulted in a raise in neutrophil numbers there was a concomitant increase in both T and absolute NOS count.

Conclusions: Increased NOS T seen in symptomatic HIV infected patients are frequent and associated with elevated absolute counts. Thus, there appears to be a true rise in NOS T in many HIV-infected patients. When ZDV treatment induces neutrophil toxicity, NOS are usually reduced in line, suggesting that ZDV can be toxic for NOS, as well as neutrophils.

T.B.P.329

ACT: DOUBLE EDGED SWORD
RITA L. HARRIS, Deborah L. University of California School of Medicine, San Francisco, CA, U.S.A.

Objective: To provide information about patients' stressors as well as positive perceptions regarding AZT that may influence their decision to take AZT, cooperate with treatment, and possibly their treatment outcome.
Method: 100 seropositive homosexual men with at least one HIV-related symptom were recruited from the UCSF AIDS Clinic and administered an in-depth, semi-structured interview at 4 time points approximately 6 months apart. The interview was designed to elicit symptoms, coping strategies, and both positive and negative perceptions in such areas as HIV testing, symptom recognition, clinical diagnosis, illness episodes, and treatment.
Results: 60.8% spontaneously raised 39 concerns about AZT and 26 positive perceptions. The number of 39 who mentioned these concerns, which we categorized, were: 39--toxicity side-effects; 30--cost and financing; 18--future decisions about the number of 39 who mentioned these concerns, which we categorized, were: 18--AZT as a negative symbol of the reality of AIDS/AIDS; 17--negative physician interactions with health care providers; 10--lifestyle modifications; 9--effectiveness of AZT; 7--drug study protocols; 7--lack of funding/availability of drugs; 6--telling others; 6--going off AZT; 4--time limitations; 4--availability of social support; 2--peer pressure to choose AZT; 10--peer pressure to choose an alternative; By the Time 2 interview, 20.6% had been on AZT, 30.0% were in addition to 4 on study protocols. A total of 32 subjects experienced negative side effects they attributed to AZT. **Conclusions:** For every 100 patients, AZT has been a means of promoting survival and reducing the severity and frequency of opportunistic infections. For many of the AIDS patients in our study, however, AZT also involved a number of physical and psychosocial stressors.

T.B.P.331

PHASE I STUDY OF INTERFERON ALPHA-2b (INTRON), ZIDOVUDINE AND ZINC-FP IN PATIENTS WITH AIDS-ASSOCIATED BACTERIAL INFECTIONS
Richard M. Schoenbach, S. O'Keefe, P. Thompson, G. and Santiago, S. University of Miami, Miami, Florida, U.S.A.

Objective: To evaluate the efficacy and safety of ZINC-FP in combination with Intron and zidovudine in patients with AIDS-associated bacterial infections (ABIs).
Method: Patients with 30 and no active infections were enrolled. Intron was given as 12 mg 3x daily and zidovudine 200mg orally every 4 hrs for 16 wks. Patients received placebo or ZINC-FP, 5-10 mg/kg 5x daily for 16 wks. **Results:** 12 patients have been enrolled. Mean length of time on study is 8.0 weeks. All have completed 16 wks. Change in mean hematology parameters were:
Wbc (x10⁶/mm³) 4.5 4.7 8.9 9.0 4.0 5.9 4.3
(range) 2.5-7.5/3.0-12.7/1.8-28.2/2.8-28.0/2.0-21.6/2.0-10.4
Neutrophils(%) 2428 2852 2823 5280 6323 3820 2114
Platelet Ct (x10⁹) 203 158 168 150 174 174 210
CD4 cells/mm³ 225 N/A 260 N/A N/A 330 253
pH (log) 4 N/A 1 N/A N/A
One patient developed severe hypoxemia and died. Nephritis, fatigue, anorexia, weight loss, headache, arthralgia, myalgia and fevers were seen during the first 4 wks of therapy. 2 patients had bone pain, 1 patient had a complete anti-tumor response; the remainder had a partial anti-tumor response.
Conclusion: ZINC-FP resulted in dramatic and sustained increases in the WBC count and neutrophil count in patients receiving Intron and zidovudine. Doses of 4-5mg/kg of ZINC-FP may be useful. Adverse reactions were minimal. Early data do not suggest negative or synergistic ZINC-FP anti-HIV activity.

T.B.P.333

UPDATE ON PROGRAM STANDARDIZATION AMONG PUBLIC HEALTH LABORATORIES IN THE U.S.A. PERFORMING TESTS FOR HUMAN RETROVIRUSES
Margaret Billings, J. J. Bilalov, A. M. Joseph, J. M. and Gethal, J. M. Institute Hygienic Laboratories, Administration, (Sb)

Objective: To promote uniformity and assure quality of testing for HIV and other human retroviruses.
Method: A survey of the fifty-four member laboratories of the Association of State and Territorial Public Health Laboratory Directors seeking information and data on human retroviruses in the U.S.A. have established an effective system for program standardization. Other countries have expressed interest in the program and some have established similar consensus building structures.

T.B.P.330

PARASITIS IN HIV AS POSITIVE DRUG ABUSERS
Marco Masini, A. Petrucci, A. M. Costa, A. Ricciardi, F. Castellani, F. Chiodo, Istituto di Clinica Dermatologica, *Istituto Malattie Infettive Università di Bologna, Bologna, ITALY.

Objective: To describe the onset of parasitosis during HIV infection in drug abusing patients.
Results: We report on 5 Italian patients, aged between 22 and 34 years, who all had been drug abusers for more than 2 years. They have never been affected by parasitosis before diagnosis of HIV infection was made, and three of them have developed A.I.B.S. within the following 12 months. All patients presented small periorificial lesions which covered less than 25% of the body surface. The lesions didn't worsen as in the three patients in which opportunistic infections occurred as in a syphilis free patient. In only one case, a small PML granuloma was observed in a generalized flare of extradermal parasitosis, which however responded to therapy with topical corticosteroids. Parasitosis is a disease of unknown etiology, but it is generally suggested that infectious may play a role of stimulus in a genetically predisposed patient, and that parasitosis is described as a typical example of this event. Patients in whom HIV infection is associated with parasitosis have not frequently been reported. The Authors generally presented small periorificial lesions which covered less than 25% of the body surface under treatment and parasitosis often became uncontrollable when immune response was depressed during opportunistic infections. The clinical course and infectious background of drug abusers can be explain the different aspect of the disease in this patients.

T.B.P.332

A NEW MORE SENSITIVE AND HIGHLY SPECIFIC ANTI HIV-1 ASSAY BASED ON RECOMBINANT PROTEIN.

Richard M. Schoenbach, S. O'Keefe, P. Thompson, G. and Santiago, S. University of Miami, Miami, Florida, U.S.A.
Objective: To replace tissue culture based HIV-1 assays with a sensitive and recombinant antigen in the Wellcozyme Monoclonal test and to further improve on the specificity seen in Wellcozyme competitive assays.
Method: A recombinant DNA produced fusion protein containing the immunodominant regions of HIV-1 envelope and core proteins replaced whole viable lysate grown in CD4 cells. Chemically inactivated herdsmenish peroxidase was included in the assay procedure and its effect on the rate of false positive reactions was determined.
Results: All of the 348 confirmed HIV-1 positive sera from AIDS, ARC and seropositive donors reacted (100% sensitivity) in the test. In 4 out of 5 serial samples taken from donors during seroconversion the assay detected HIV antibodies earlier than the Wellcozyme Monoclonal test. The assay was used to 10 fold more sensitive on end point dilutions of weakly reactive sera and had similar sensitivity with strongly reactive sera. None of 11542 negatives (9509 sera, 2034 plasma) were reactive (100% specificity), although one sample was close to cut-off.
Conclusion: The use of recombinant antigens has improved the sensitivity with weak samples and the inclusion of peroxidase in the assay procedure has increased specificity. The majority of false positive reactions seen in previous tests of this type were caused by an inhibitory anti-peroxidase activity present in some serum samples.

T.B.P.334

THE "INTERNAL IMAGE"-BEARING ANTIBODIES IN SERA OF PATIENTS WITH HIV-1 INFECTION
Schedel, Ingrid; Winkelmann, P.; Dreihausman, U.; Wink, J. and Deitler, M. Department of Internal Medicine, Division of Immunology, *Institute of Virology, Medical School Hannover

Human immunodeficiency virus (HIV)-neutralizing antibodies could be detected in HIV-infected individuals by different groups. Obviously, the infection of the target-cell for HIV takes place by specific binding of the viral surface glycoprotein (gp120) with cellular CD4-receptor. This binding site is conserved in different isolates of HIV and lineage to CD4 as well as specific binding to gp120 could be blocked by monoclonal antibodies reacting with the gp120-epitope.
Sera from patients with HIV-infection (n=103) and sera of an HIV-negative control group (n=50) were tested for antibodies reacting with the gp120-recognizing region of monoclonal antibodies in an ELISA-system. The HIV-positive sera showed significantly elevated binding activities in comparison with the sera of the control group (p<0.0001). In the multiple regression analysis we determined a correlation of 0.38 (p<0.01) between binding activity and linear combination of the following parameters: stage (seroconversion), IgG-absolute, IgM-absolute, IgA/IgG-ratio, Mif-test, Mif-test-optimized, public health laboratory in the U.S.A. have established an effective system for program standardization. Other countries have expressed interest in the program and some have established similar consensus building structures.

T.B.P.335 EVALUATION OF DIFFERENT ANTI-HIV REAGENTS THAT ARE AVAILABLE IN MEXICO
 Dominguez J., Morales C., Moreno M.* and Cruz M.*
 Centro Nacional de la Transfusión Sanguínea, México, D.F.

Objective.

To get to know percentage of sensitivity, specificity, false positive, false negatives of the reagents that are used in the Mexican health care system.

Method.

5 Traditional Elisa, 3 recombinant Elisa, 3 agglutination and 2 quick technology Elisa were evaluated with a known panel of 160 samples with aids, asymptomatic seropositives, healthy/donors. Other infections samples and blood donors samples.

Results:

The percentage of sensitivity was between 100 and 62.5% specificity between 98.3 to 82.5% false positive index turned out to be between 4.76 and 41.17% and the false negative index was from 37.5 to 0%.

Conclusion.

We found that two types of reagents. One of agglutination technology and the other one Elisa quick technology were not suitable for its use. The rest of the reagents turned out to be suitable for their use.

T.B.P.336 WHICH IS THE BEST LABORATORY MARKER WHEN FOLLOWING HIV-POSITIVE PERSON?
 Reis. M.*; Sprinz, E.**; Kronfeld, M.**; Azevedo, M.*; Saadi, C.*; GRAVBE, M.* et al.
 *Laboratório Welmann de Porto Alegre
 **Hospital de Clínicas de Porto Alegre

Objective. Establish the best laboratory marker when following HIV-positive patients.

Methods. It were analyzed 60 ambulatory patients and 19 hospital HIV-positive patients. The following tests were executed: Western-blot (WB-Dupont), Envsacor HIV (ELISA-Abbott) and the presence of viral circulating antigen (HIV-Ag).

Results. The patients were segregated in 3 groups as follows:
 I: positive WB 24, positive EC 24, negative HIV-Ag (40 ambulatory patients)

II: positive WB 24, negative EC 24, negative HIV-Ag (4 hospitalized and 5 ambulatory patients)

III: positive WB 24, negative EC 24, positive HIV-Ag (8 hospitalized and 10 ambulatory patients)

IV: positive WB 24, positive EC 24, positive HIV-Ag (1 hospitalized and 5 ambulatory patients)

CONCLUSION. The best relation with anti-p24 antibody drop, antigenemia and clinical criteria of AIDS progression was obtained with EC-Abbott. Surprisingly, we did not find the WB-Dupont controllable as a marker of AIDS progression.

T.B.P.337 COMPARISON OF COMMERCIAL AVAILABLE TEST FOR HIV ANTIBODIES USING LAMBIAN SERA

Loz N.P., Hira S.S., Sityambang J.P., Khabibi R.P., Chipoke L.*
 Macwanwa*, *University Teaching Hospital, Lusaka, Zambia.

OBJECTIVE. To compare the available test, the first generation, and confirmatory test with a view to decide the best screening test and confirmatory test in Zambia.

METHOD. 3 Panels of sera were set. Each panel of sera was screened for HIV antibodies using a set of test from the first generation and new generation. Positives were confirmed using the standard confirmatory test like Western blots and immunofluorescent as well as using another ELISA as a confirmatory test.

RESULTS. Some of the first generation ELISA gave a very high false positive rate while the second generation were more reliable. Use of second ELISA as a confirmatory test was found to be as good as using the standard confirmatory i.e. Western blots.

CONCLUSION. Use of one of two other ELISA can be used as a confirmatory test. Immunofluorescent test was the other alternative to confirmatory test.

T.B.P.338 COMPARISON OF TWO HIV IMMUNOLOGY TECHNIQUES.
 MURRAY E., MATRA G.²

1. Mayo Medical Research Institute
 2. University of Nairobi, Microbiology Dept.

OBJECTIVE: To investigate the pattern of bands in strips of two electroforetic immunology techniques to same sera.

METHOD: 72 adult sera, 51 positive for HIV-1 and 21 seronegative were tested with an DUPONT and ANKEX Western blot electroforetic techniques.

RESULTS: Comparison of tests with DUPONT as reference test. (Positive tests)

	GENERAL	P15	P17	P24	P33	P41	P55	P64	P66	P160
a) No of sera observed:	51	20	32	48	50	50	51	41	46	46
b) % of sera seen for:										
both tests:	76	82	60	78	70	66	51	49	38	39
c) Sensitivity:	95	100	90	75	99	94	95	84	53	53
d) Specificity:	92	100	43	73	80	65	92	46	61	61

No sp 120 was found in ANKEX, but was present in 51% of DUPONT strips

CONCLUSION: Despite the high level of correspondence present when combinations of protein bands are considered, great variation was present on regarding individual proteins and glycoproteins in the two techniques.

T.B.P.339 LABORATORY TESTING FOR HIV-1 ANTIBODY TESTING IN CALIFORNIA: ANALYSIS OF CURRENT PRACTICES AND IMPROVEMENT STRATEGIES

Wang, S.H., Hira S.S., Sityambang J.P., Khabibi R.P., Chipoke L.*
 *San Diego State University, San Diego, California, USA.

San Diego State University, San Diego, California, USA.
 *California West and Southern States Laboratory, Berkeley, California, USA.

Objective. This program uses HIV antibody testing as a model to develop and evaluate methods of optimizing and improving laboratory quality.

Method. Using a "blind" protocol laboratory testing, serum samples with known HIV content were submitted as clinical specimens by physicians, clinicians and health-care workers to their usual sources of testing. Currently 20 HIV laboratories and 11 confirmatory laboratories in five states were included. An open proficiency test and a written survey to a sample of 10 HIV laboratories in California has also been completed in order to profile HIV testing practices and plan future improvement activities.

Results. Performance on HIV screen tests has been excellent with fewer than 2% incorrect results. Western blot confirmatory tests are more problematic with commercial laboratories reporting a high proportion of indeterminate results, while public health laboratories in California use a well standardized laboratory protocol. Commercial reference laboratories use both licensed and unlicensed Western blot reagents with a variety of interpretation criteria for seronegativity testing. Seropositivity testing, many reports were obtained without a written consent of the patient and physician. There is no consensus on the use of a "blind" protocol of HIV testing. Seropositivity testing, many reports were obtained without a written consent of the patient and physician. There is no consensus on the use of a "blind" protocol of HIV testing.

Conclusions. HIV antibody testing has the potential to be a highly sensitive and specific assay. However, there was no consensus on what was clinically important bands.

Conclusions. HIV antibody testing has the potential to be a highly sensitive and specific assay. However, there was no consensus on what was clinically important bands. Seropositivity testing, many reports were obtained without a written consent of the patient and physician. There is no consensus on the use of a "blind" protocol of HIV testing. T.B.P.340 CROSS-REACTIVITY BETWEEN HIV-1 FOR DETECTION OF HIV-1 AND HIV-2

Reis, M.*; Sprinz, E.**; Kronfeld, M.**; Azevedo, M.*; Saadi, C.*; GRAVBE, M.* et al.
 *Laboratório Welmann de Porto Alegre
 **Hospital de Clínicas de Porto Alegre

Objective. To study the cross-reactivity of HIV-1 and HIV-2 in ELISA assays.

Methods. Sixty sera from hemophiliacs were tested for antibodies HIV-1 (HIV-1 IgG) and HIV-2 (HIV-2 IgG) and confirmed by means of DNA/RNA (Abbott) and RIPA. In all the sera, HIV-2 antibodies were determined using a commercial available anti-HIV-2 ELISA test (ELAVIA 2) (Diagnostica Pasteur).

Results. HIV-2 ELISA reactivity was observed in only 1 out of the 27 HIV-1-negative samples, but HIV-2 reactivity was found in 27 out of the 33 HIV-1-positive sera. All the HIV-2 samples positive by ELISA were negative by RIPA, which difference was statistically significant (p<0.05). No significant differences were observed between the presence or absence of HIV-1 core proteins and HIV-2.

Conclusion. These results confirm the high degree of serologic cross-reactivity between gene products of HIV-1 and HIV-2 (ELISA).

(Supported by a grant from Fundação Boomer).

T.B.P.341 FAILURE OF ELISA AND ME TESTING TO DETECT HIV INFECTED SUBJECTS

Remolina, M.†; Ispolito, G.***; Nicolai, M.***; Mirolo, M.†; Remolina, R.***; Angelini, P.†
 *Istituto Red Cross, National Center for Blood Transfusion, **Lazaro Spallanzani Hospital for Infectious Diseases, ***University of Rome-Italy

Objective: To assess the efficacy of ELISA and ME test routinely used in laboratory setting to detect HIV infected subjects.

Methods: 411 plasma portions of seropositive blood donors were tested by ELISA and ME; most negative for anti-HIV were in situ hybridized (ISH) with an ISHA plasmid containing the nine-alkaline NcoI-draI viral insert. 17 donors were tested by inserting an antigenic surface group into cytosine of the deuterated DNA.

Results: Studied population was: 27 partners (3 males and 24 females) of 27 seropositive blood donors (20 males and 2 females); the distribution by risk group was: homosexual activity 3.7%, bisexual male 11.1%, intravenous drug addict 16.5%, heterosexual contacts 22.2%, not known 7.6%.

In 3 cases the partner, belonging to risk group, was the source of class I HLA specificities represented, eliminated antibodies to the A, B and C-2 of the HLA system. Testing in the panel of T-lymphocytes was carried out to determine the degree of serum purification of HLA-A, B, C antibodies.

Conclusion: In false-positive individuals after seropositivity by the serologic antigen the sera in ELISA became negative; this was confirmed in the panel of T-cells. It can be concluded that false-positive results of ELISA may be due to antibodies to class I antigens of the HLA system.

T.B.P.342 CORRECTION OF FALSE-POSITIVE RESULTS OF ELISA OF IMMUNOELECTROPHORESIS

Kabatals, E.†, Schovay, A.**, Svrtkova, J., Burstin, J.**, Shif, B.**, Denkova, A.**, *Kriga, M.†
 *Kriga Institute of Microbiology, Latvian SSR Acad.Sci., ** Rigas Medical Institute

Summary: A near-real serotyping of various subpopulations in sera of HIV infected demonstrated that ELISA is a most widespread method of examination, and, irrespective of its high specificity, yields false-positive results in a definite percent of cases.

Methods: Serological testing for the presence of antibodies to AIDS virus was carried out by ELISA with lower-potential and imported test-systems. The obtained results were confirmed by immunoelectrophoresis.

Results: The results of ELISA were corrected by the following: adsorption of sera (the test and control sera) by the pool of trophoblastic antigen, screening of the sera under study prior to and after treatment with the trophoblastic antigen in the panel of T-lymphocytes of test-donors with the known spectrum of HLA-antigens, adsorption by the pool of trophoblastic antigen, with only class I HLA specificities represented, eliminated antibodies to the A, B and C-2 of the HLA system. Testing in the panel of T-lymphocytes was carried out to determine the degree of serum purification of HLA-A, B, C antibodies.

Conclusion: In false-positive individuals after seropositivity by the serologic antigen the sera in ELISA became negative; this was confirmed in the panel of T-cells. It can be concluded that false-positive results of ELISA may be due to antibodies to class I antigens of the HLA system.

Donneurs et receveurs de sang et de produits sanguins Recipients and Donors of Blood and Blood Products

T.B.P.343 SEROSURVEY OF WOMEN IN A MATERNITY WARD

A. Santos Pinto, W. Canas Ferreira, E. Prieto, R.A. Sousa-Institute of Hygiene and Tropical Medicine, Ministry of Health, Cape Verde.

Objective: - To study the prevalence of hepatitis B markers and HIV antibodies in parturients receiving clinical care at a hospital in a Cape Verde Island (West Africa).

Methods: - During January and May 1988 serosurvey of the vertical transmission of hepatitis B virus was performed on 336 parturients and their babies. Specimens were analyzed also for anti-HIV antibodies. Elisa and Western blot was the methods employed.

Results: - 224 (17%) of the mothers were HBe Ag positive and 78 (11.7%) were HBe Ab positive. Study of HIV prevalence is in progress. The results will be presented and discussed at the Conference.

T.B.P.344 LOOKBACK: AN UPDATE ON THE NEW YORK EXPERIENCE

George, Eugene, Kessler, S., Moore, S., Berger, P., Drivalla, C.; New York Blood Center, New York, NY, USA.

Objective: To evaluate results and assess costs of the Lookback Program. **Methods:** A lookback of previous donations from 158 anti-HIV positive blood donors identified since April, 1985 has been carried out. 303 hospitals in the greater New York region have been notified of receipt of 247 components back to May, 1989.

Results: To date, 1627 reports have been received from hospitals (68% response rate); 1462 or 90% of components were transfused. Of these recipients, 1079 or 74% are deceased. Recipients known to have been discharged equal 326. Of these, 237 or 72% have been tested; 90 or 42% are HIV antibody positive. The positivity rate was highest in patients transfused in 1984; 46 patients or 61% of those tested were seropositive.

In 1989, 16 patients (52%) were positive. There were no positive recipients in 1989. There are 95 recipients (70%) between 18 and 70, which may be a surrogate measure of sexual activity and potential transmission. 8643,440, including 975,000 in grant support or approximately \$6,500 per positive recipient located. This figure does not include hospital costs which are substantial, nor does it include the cost of Lookback-generated lawsuits.

Conclusion: The 95 seropositive Lookback recipients identified constitute only a small fraction of the total estimated HIV infected population in the country. Despite its impact on public health risk, Lookback notifies our obligation to notify about information of significance to another's health.

T.B.P.345 THE ITALIAN HEMOPHILIC REGISTER AND NATURAL HISTORY OF HIV INFECTION

Schiappa, Nicola†; Ghisardini, A.***; Valderaci, C.†; Gringoli, A.***; Martelli, G.††† and Remolina, P.M.***
 * Istituto Superiore di Sanita, Roma, ** University of Rome, *** University of Milano, (Steering Committee of the Scientific and Medical Board of "Preparations all'uso interno")

Objective: To present the results of a nationwide survey of all population affected by congenital congenital disorders, with the aim to evaluate the time-trend of the incidence of HIV seropositivity and AIDS in the Italian Hemophilia population through a retrospective national cohort study.

Methods: This project is divided up into two phases: 1. the set up of the Register (National Hemophilia Survey), and 2. the evaluation of the spread of HIV infection. The National Hemophilia Survey carried out between September and November 1988 was performed by a standard questionnaire, with an individual code to ensure confidentiality sent to all the Hemophilia Centers to collect demographic and clinical information. Data have been analyzed using a database program.

Results: As of 15 January 1989, 21 Hemophilia Centers had replied. At this the information regarding 859 subjects were collected. On the whole a prevalence of HIV-Ab positivity of 21% was found.

Conclusions: This National Hemophilia Survey has been the first comprehensive evaluation of the Italian population affected by congenital congenital diseases. The Hemophilia Centers participate enthusiastically to this cooperative project. From this Nation Survey, through the analysis of the data it is still incomplete, a prevalence of HIV-Ab positivity of 21% was shown.

T.B.P.346 TRANSFUSION-ASSOCIATED (T-A) AIDS CASES

Schiappa, Nicola, Valderaci, C., Istituto Superiore di Sanita, Roma, Italy.

Objective: To present an update of the patients with AIDS due to blood transfusion, and to discuss the importance of an active surveillance system of T-A AIDS within the overall AIDS surveillance. The peculiarities of this specific surveillance will also be discussed.

Methods: A database has been created including all the subjects for whom the only associated risk factor was the reception of blood transfusion. It has been derived from the National AIDS Register, including other pieces of information collected by means of a special standardized form. The analysis has been carried out using different BMDP programs. **Results:** As of 31 December 1988, 53/3008 (1.8%) patients were reported with T-A AIDS, 5 of which were below 14 years of age (9.4%). At the same date, the case-fatality rate was 41.5%. Clinical and epidemiologic information will be presented, as well as the mean lag time between infection and the development of full-blown AIDS.

Conclusions: At the end of 1988, the relative proportion of T-A AIDS was slightly lower than at the end of 1987; in Italy, the case-fatality rate is also less for this subgroup of patients than for all the other AIDS subjects. The standard reporting form for AIDS has proved indispensable to describe both the pattern and the natural history of the syndrome in T-A patients. Nor have the reporting physicians provided enough data, as a result of an investigation carried out early in 1988. Thus a revised out national AIDS unit, the reporting physicians, the unit(s) where the blood was administered, and the blood bank to being implemented.

T.B.P.347 HIV-1 HIV ANTIBODY SCREENING OF BLOOD DONORS IN LOCALITIES WITH HIGH HIV-1 ANTIBODY PREVALENCE

Transmission Study Group* represented by Hugh Elliott**

* Participating laboratories: San Francisco, CA, Miami, Florida, San Francisco, and Los Angeles, CA.
** Donor Blood Centers and Division of California, San Francisco, California, USA.

Objective: To assess the frequency of HIV-1 p24 antigen (p24) positivity among male donors in high anti-HIV-1 prevalence areas in the city of San Francisco (SF) during a period with a high rate of HIV seroconversions. **Method:** The SF component of the TEMUDA (Transmission Study) Group has collected in total 106 weekly 100 ml before anti-HIV-1 screening blood. Overall prevalence of anti-HIV-1 among these specimens was 5.3%. A subset of 2,297 cases was selected among males aged 18-64 years with addresses in SF by code barling one or more anti-HIV-1(p24) positivity results. The anti-HIV-1 prevalence of the subset by prior barling was 1.041. HIV-1 p24 by barling and Abbott's ELISA and neutralization (confirmatory) requests; if initially p24 reactive, anti-HIV-1 was reassayed (Genzyme, Inc.).

Results:

anti-HIV-1 Status	HIV-1 p24 antigen Barling	Index (1)	Neutralized
Positive	25	3 (12%)	3 (12%)
Negative	2,272	0 (0.41%)	0 (0%)

* San Francisco within the HIV CI of a Pulse Field defined HIV-1 sero of 1.
Conclusion: In HIV-1 p24 antigen positive blood donors from areas 2,272 anti-HIV-1(p24) prevalence in a population that yielded 25 anti-HIV-1(p24) results. Given the present anti-HIV-1 prevalence of 0.023 in the SF donors, over 20,000 seronegative donations would be needed for a similar situation of the anti-HIV-1(p24) results (assayed by Centers J 93-84-7002 and 93-84-7003 of the National Heart Lung and Blood Institute).

T.B.P.349 MULTICENTER EVALUATION OF A RECOMBINANT BASED HIV-1/HIV-2 COMBINATION SCREENING ENZYME IMMUNOASSAY.

F. Aviner, L. Gaudier, M. Juler-Jankovik, S. Riang, P. Sued, F. Simon, D. Sording, H. Haem, P. Schauer, H. Tzoumas, M. H. Tzoumas, * European Clinical Study Group, ** Abbott Laboratories, Wiesbaden-Deinhausen, Federal Republic of Germany (FRG).

OBJECTIVE: To evaluate a newly developed screening assay which utilizes HIV-1 and HIV-2 recombinant proteins. A significant number of HIV-2 infected individuals would not be detected with current HIV-1 screening assays.

METHOD: An enzyme immunoassay (EIA) was developed which utilizes both HIV-1 recombinant antigens and HIV-2 antigens and a recombinant HIV-2 envelope protein on the solid phase. The sensitivity and specificity of the EIA was evaluated on serum or plasma from normal blood donors and from individuals infected with HIV-1 or HIV-2. Results were compared to the current recombinant-based HIV-1 EIA.

RESULTS:

Type of Specimen	No. Tested	No. Positively Reacted (%)	
		HIV-1/EIA	HIV-1/HIV-2/EIA
Blood Donors	5029	5 (0.10)	8 (0.16)
HIV-1 Seropositive	288	288 (100)	288 (100)
HIV-2 Seropositive	202	154 (76.2)	201 (99.5)

Both assays had a specificity of 99.8% and detected 100% of the HIV-1/HIV-1 specimens. The sensitivity of HIV-1 EIA and HIV-1/HIV-2 EIA for detecting HIV-2 seropositives was 76.2% and 99.5% respectively.

CONCLUSION: The addition of HIV-2 envelope proteins to HIV-1 proteins already on the solid phase improved the performance of the HIV-1 EIA and significantly improved the detection of HIV-2 antibodies.

T.B.P.351 USE OF RAPID ASSAYS FOR ANTIBODY TO HIV IN BLOOD DONORS, PERSONS PRACTICING HIGH RISK BEHAVIORS AND SUSPECTED AIDS CASES IN GHANA

Mingis, Julius, Mitchell, S.W., Osei-Dwamena*,
**Wagdy Memorial Institute for Medical Research, Accra, Ghana, Africa;
***Wagdy Memorial International, Research Triangle Park, North Carolina, USA.

Objective: To evaluate three tests for antibody to HIV which do not require specialized equipment in three different populations in Ghana.

Method: Seven laboratories in Ghana participated in the study. Two thousand specimens from 3 populations were tested with RIVELISA, SEROITA and Retrotest. The 3 populations were blood donors, persons practicing high risk behaviors and suspected AIDS cases. Each specimen was also tested by ELISA for antibody to HIV-1 and HIV-2. All positivities were confirmed by Western Blot.

Results: Analysis is currently being performed to determine sensitivity, specificity, and predictive values of the tests in each of the populations tested. These results will be reported.

Conclusion: Many laboratories in developing countries are not equipped to perform the standard tests for HIV antibody, ELISA and Western Blot. Although the newly developed tests for HIV were designed primarily for screening blood donors, many of these tests will be asked to test suspected AIDS patients and persons thought to be at high risk of acquiring HIV. These tests have been evaluated for use in these populations under true field conditions.

T.B.P.346 HIV INFECTION IN WESTERN BLOT INDETERMINATE BLOOD DONORS

Richard Bonatti*,
H.H. Jurek**, MacDonnell***, Kunk 5***, Stramer****, Baifour****,
HIV Laboratory, North Chicago, IL, USA, *Cruz Cross, St. Paul, MN, USA,
****Memorial Blood Center, Minneapolis, MN, USA, ****Cruz Cross, Eneryville, CA, USA,
*****University of Minnesota, Minneapolis, MN, USA,
*****Minnesota Dept. of Health, Minneapolis, MN, USA

Objective: To determine whether U.S. Upper Midwest blood donors with indeterminate HIV-1 Western blot results are HIV-1 infected.

Methods: 187 volunteer blood donors who had tested reactively positive by enzyme immunoassay (EIA) and had at least one HIV-1 characteristic band on Western blot (but not positive) were asked to return for an interview and blood testing. We obtained information regarding HIV risk factors and peripheral blood specimens for the following tests: HIV-1 antibody (two different EIAs) and a PCR analysis using an HIV-1 gag primer pair. EIA, HIV-1 serum antigen, HIV-1 culture using both RT and HIV-1 antigen detection assays, HIV-1 J antibody EIA, and PCR analysis using an HIV-1 gag primer pair. Results: 100 of 187 (53%) blood donors agreed to participate. There was no significant difference between the blood donor participants and nonparticipants in terms of age, sex, or Western blot band pattern. 65 of 100 were still repeatedly reactive for HIV-1 antibody by at least one HIV-1 EIA. All 100 tested risk factors for HIV-1 infection. 92 of 100 were still indeterminate by Western blot and 8 were negative after 1-6 month follow-up. None were positive by HIV-1 Western blot, HIV-1 serum antigen EIA, HIV-2 antibody EIA, HIV-1 culture, or HIV-1 J antibody EIA. HIV-1 PCR analysis results are pending.

Conclusion: These data indicate that blood donors who are indeterminate by HIV-1 Western blot and lack risk factors for HIV infection are not infected with HIV-1.

T.B.P.358 HUMAN IMMUNODEFICIENCY VIRUS ANTIBODY SCREENING OF BLOOD DONORS - AN INTERNATIONAL SURVEY.

BURBALL, S.L., MANHART, S.J. AND ADATA, A.,
The Canadian Red Cross Society, Ottawa, Canada

BETWEEN OCTOBER 1985 AND MARCH 1988, THE CANADIAN RED CROSS SOCIETY (CRCS) CONDUCTED THREE SURVEYS ON INTERNATIONAL PRACTICES OF SCREENING BLOOD DONORS FOR ANTI-HIV. DURING THIS PERIOD, THE REPORTED CASES OF AIDS PER 100,000 POPULATION INCREASED FROM 12 IN 1985 TO 61X IN 1988. AT THE SAME TIME, THE MORTALITY RATE DUE TO AIDS ALSO INCREASED FROM 1/100,000 IN 1985 TO 4/100,000 IN 1988. THE NUMBER OF BLOOD TRANSFUSION ASSOCIATED AIDS CASES INCREASED FROM 1-85 IN 1985 TO 3-68 IN 1988. IN 1985, 17/22 COUNTRIES SURVEYED WERE SCREENING THE BLOOD DONORS FOR ANTI-HIV, WHEREAS, IN 1988, 31/33 COUNTRIES WERE SCREENING BLOOD DONORS. OF THE 19 COUNTRIES FROM WHICH INFORMATION WAS AVAILABLE, 17 COUNTRIES REPORTED A DECREASING TREND IN THE ANTI-HIV SEROPREVALENCE RATE, FIVE COUNTRIES REPORTED A STABLE TREND AND THE REMAINING ONE REPORTED AN INCREASING TREND. THE CONFIRMED POSITIVE ANTI-HIV RATE IN 1988 VARIED FROM 0% TO 0.64X WITH THE MAJORITY OF COUNTRIES REPORTING THE PREVALENCE RATE BELOW 0.05%. IN 1988, THE MAJORITY OF COUNTRIES HAD ALREADY IMPLEMENTED SELF-EXCLUSION PROGRAMME AND PROVIDED ALTERNATE TEST SITES. MOST OF THE COUNTRIES WERE ALSO REPORTING ANTIMONY STATUS TO THE DONORS AND MAINTAINING CONFIDENTIALITY OF THEIR TEST RESULTS. BY 1988, OF THE 33 COUNTRIES SURVEYED, 22 HAD ALREADY STARTED SCREENING DONORS FOR ANTI-HIV-2 AND ADDITIONALLY, 14 COUNTRIES WERE CONDUCTING FEASIBILITY STUDIES. ADDITIONAL INFORMATION BASED ON THE SURVEY PLANNED FOR MARCH 1989, WILL ALSO BE PRESENTED.

T.B.P.352 'THE GIFT RELATIONSHIP REVISITED': HIV SEROPREVALENCE IN BLOOD DONORS AND OTHER LOW-RISK GROUPS IN AFRICA

DIXLEY, Barbara Rozita, Halligan, R. and Wey, F.,
Bureau of the Census, Washington, DC, U.S.A.

Objective: HIV survey data from 22 African countries reinforces the conclusion of Temuda's "The Gift Relationship" that the quality of donated blood varies considerably.

Method: Compared HIV seroprevalence estimates from non-random sample surveys of blood donors and other low-risk groups (i.e., pregnant women) in the same year and location. Data from small sample sizes and from small differences in seroprevalence (the significance of which is tested) are discarded.

Results: HIV seroprevalence for urban blood donors and other low-risk groups in 10 of the 22 countries was similar; in 3 countries, donor seroprevalence was lower; but in 9 countries it was higher (6 of which achieved $p < 0.02$).

In regions outside the capital, the relationship is reversed. In 7 of the 10 regions, the HIV seroprevalence of donors is lower than other low-risk groups. In all 9 countries with data on gender of blood donors, male donors outnumber females; in 7 of the 9 countries, the female HIV seroprevalence rate was higher than males. Longitudinal data, available on blood donors in 9 countries, suggest that 3 countries have shown no seroprevalence change, 2 have shown a modest decrease, and 2 have shown an increase.

Conclusion: Data suggest that blood donors and other low-risk groups are not a random population apparently, and their higher HIV seroprevalence, especially for women, is troubling. Blood banking procedures should be reevaluated in light of this HIV data, as should the gift relationship itself.

T.B.P.353 THE IMPACT OF AIDS ON BLOOD TRANSFUSION SERVICES AT THE UNIVERSITY TEACHING HOSPITAL, LUSAKA

Dr. Abraham Mulla, University Teaching Hospital (UTH), Lusaka, Zambia

Objective: To describe the impact of AIDS on the Blood Transfusion services by the UTH.

Method: The data was obtained from annual records and my full participation in the recruitment of blood donors.

Results: The number of blood units discarded on account of HIV positivity is rising and thus making it more difficult for the blood bank to meet the ever increasing hospital demands.

Year	No. of Donors	No. of HIV+ve	%
1987	7457	478	8
1988	5505	1037	18.8

Conclusion: The AIDS pandemic relentlessly continues to be a colossal challenge to the meagre blood transfusion services offered by the UTH.

T.B.P.355 IMPROVED HIV-1 WESTERN BLOT RESULTS IN BLOOD DONORS: A MONITOR OF IMPROVEMENT TO RECIPIENTS OF BLOOD

Van Der Pijl, Ooms, Lalle, N., Nass, Hainin, H.; Ethlers, P., Bokker, E., Willemse, M.,**

* Ned Cross Blood Transf. Serv., ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.

Objective: To investigate if donor blood with indeterminate test results in HIV-1 Western Blot (WB) transmit HIV-1 to recipients.

Method: Serum samples from blood donors (n=130) and recipients (n=382), who participated in a prospective study for posttransfusion hepatitis, were tested for HIV-1 antibodies with a commercially available ELISA. The recipients were followed-up for 6 months. Repeatedly ELISA reactive samples were tested for confirmation with commercially available WB strips, and ³²P-RIPA developed in our institute.

Donors	n	ELISA reactive		Western Blot		125-P-RIPA	
		initially	repeatedly	pos	indef.	pos	indef.
5,332	109	12 (2.047)	19 (17.384)	0	0	0	0
352	5	1 (1.288)	1 (17.288)	0	0	0	0

The 6 recipients who received blood products from 6 donors with indeterminate HIV-1 WB, were non-reactive in HIV-1 WB and ³²P-RIPA, with serum samples obtained 0, 3 and 6 months after transfusion.

Conclusions: Blood products from donors with indeterminate results in HIV-1 Western Blot, do not transmit HIV-1 to recipients.

T.B.P.357 A CLINICAL AND SEROLOGICAL FOLLOW-UP OF HIV 2 - POSITIVE PATIENTS FROM GUINEA-BISSAU (WEST AFRICA)

Celestino Costa, Vanda F. Caneva Ferreira, J. Chappellinaud, Kamal Marinho, A. Santos Figueira, Francisco Siqueira, Paulo Mendes, Augusto P. Silva, E. Prieto, J.L. Baptista, C. Araújo, J. Baptista Marques, J. Brandão, Rita Albuquerque Sousa-Instituto de Higiene and Tropical Medicine-Dep Microbiology and Dep. Clinical Tropical Medicine-Ministry of Health, Guinea-Bissau.

OBJECTIVE: - To establish the clinical and laboratorial features of HIV 2 infection and to determine parameters of these infection related to disease progression in people from Guinea-Bissau.

METHODS: - 39 asymptomatic persons with documented (serological) HIV 2 infection in 1986 were re-evaluated in 1989 by their medical clinical, physical examination and laboratory tests. The serological HIV profile was determined and compared by ELISA and by monoclonal antibodies to healthy HIV negative persons were enrolled as a control group.

RESULTS: - The parameters of HIV 2 were associated with disease progression. Higher relative and absolute number of CD4 and CD8 cells were associated with disease progression. No direct relationship was seen between CD4 and HIV serological status. More results, statistics and conclusion will be presented.

T.B.P.354 HIV ANTIBODY TESTS AMONGST NEW BLOOD DONORS

Day, P.C.; de Vries, A.R.; McBride, R.L.; Butt, Sibinga, C.T.H. Red Cross Blood Bank Groningen-Drenthe, Groningen, Nl.

A "window-period" (3-12 weeks) may exist following HIV infection when no antibody can be demonstrable but HIV antigen may appear in the blood. We have tested this possibility in first time (new) blood donors, since in our blood bank 40,000 annual donations have been followed over 3 years without additional seroconversion amongst repeat donors.

Included also in this study are 4 donors who have stopped donating because of the "risk factors": 3 W. blot positive donor sera and 3 "risky sera" (only P24/P55) detected by a first generation test during 1985. Antigen assay is based on enzyme immuno assay system (Vironostika, Organon). All samples are tested in parallel by routine antibody assay (Wellcome).

TESTS	NEW DONORS		HIV antibody positive		Donor with risky factors		risky	
	pos	neg	pos	neg	pos	neg	pos	neg
Antigen (Organon)	2	pos	neg	neg	neg	neg	neg	neg
Antibody (Wellcome)	157	pos	neg	neg	neg	neg	neg	neg

Our results indicate Vironostika did not show any reactivity in the "risky sera" and to antibody containing sera, suggesting its specificity. 2/157 donor sera showed initial reactivity, but not reproducible. However, application of the test may be profitable in risk groups and in patients where anti-genesis has prognostic and therapeutic significance.

T.B.P.356 "SAFE" CONTROL IN HIV SEROPOSITIVITY IN SERIALIZED PATIENTS* A.

Maleno, R., Anttila, S., Sarna, J., Maleno, J.A., Lonn, L.A., Henna, Sanna, Helsinki University of Medicine and Dentistry, Helsinki, Finland, Helsinki, Finland

To investigate the extent of HIV infection among dialysis patients, an unselected 117 patients of the hemodialysis unit of the Juntala Institute Hospital, eastern part of the Pacific, city, was tested anti-HIV and Western Blot. Immunological status, exposure to blood transfusion and the use of hemodialysis. Twelve patients were positive with the ELISA method and 4 (37%) were confirmed by Western Blot. Risk factors were that blood transfusion were ruled out in all 8 patients, heavy transfusion was necessary in 2 controls tested for ser. The mean number of visits of hemodialysis was 28.2 and 27.2 months, respectively for cases and controls. Seven of the patients who had chronic hemodialysis, all the cases had no clinical symptoms associated to HIV infection at that time. The risk of HIV infection was neither associated to the number of blood units transfused nor to the time on hemodialysis. Seropositive rate was 4% in all study included patients. After 13 months, 3 out of 4 died, and 1 developed AIDS. The others have been asymptomatic. No investigations show any more infection by HIV, who is also asymptomatic. The prevalence of HIV infection observed in this study is rather high. This finding stresses the need for the dialysis units personnel to carefully with recommended preventive measures.

T.B.P.358 LATEX AGGLUTINATION TESTING OF WHOLE BLOOD FOR HIV-1 IN THE FIELD.

Muganyizi, S. M.; Bilyahahaho, B. M.; Ojwaya, S. M.; Kijumu, J. M.; Downing, R. M.; Sempala, S. M.; Mwangi, S. M. New York, USA * Uganda Virus Research Institute, Entebbe, Uganda. ** WHO, Entebbe, Uganda.

OBJECTIVE: To determine the reliability and practicability of using a Latex Agglutination (L.A.) test (RECOGNIBEN donated by Cambridge Biocentec) to test for HIV antibodies in a field serosurvey in Rakai, District, a highly endemic area of Uganda.

METHODS: RECOGNIBEN L.A. is a rapid (5 min) visually scored test for antibody to recombinant gp 120 and 41. The test was performed on finger prick or venipuncture whole blood samples. Immediately after samples were obtained in the subjects' home in a community based survey, 145 subjects were tested by both L.A. and serum ELISA (RECOGNIBEN antibody to HIV-1).

RESULTS: Technical staff expressed satisfaction with the ease and readability of the method. Sensitivity was 100% but specificity only 84% compared to the ELISA. Positive predictive value was 36%.

CONCLUSION: Despite ease of use and high sensitivity, the low specificity of the RECOGNIBEN L.A. test in this setting indicates that further development may be needed for use in the field. Reasons for the high rate of false positives are being investigated.

Aspects cliniques Clinical Aspects of AIDS

Infections liées au SIDA : syphilis AIDS Related infection: Syphilis

W.B.P.49 ATYPICAL SECONDARY SYPHILIS IN HIV-SEROPOSITIVE PATIENTS Cases: E., Janier Michel*, Jansen P., Rybojad A., Julien J., et al.

* Department of Dermatology and ** STD Clinic, Hôpital Saint-Louis, Paris, France.

Objective: to describe secondary syphilis in 8 HIV-seropositive patients. **Methods:** serological of venereal, serological, bacteriological and histopathological data in 8 consecutive patients (HIV+) seen in our department from 1989 to 1989 for a secondary syphilis. **Result:** Patients: 8 males (mean age: 36.8 ± 10.2 years old), 7 homosexual, 1 drug addict, 2 with AIDS, 2 with the lymphadenopathy associated syndrome and 4 with asymptomatic HIV infection, 3 of them had a previous treated syphilis and only one had a history of chancre before the eruption. Clinical presentation was similar in 5: one trépano-cervical of the trunk, two palmoplantar keratodermas, two malignant ulcerative syphilis. The 3 others had a classical presentation (roséolae or papular syphilis). Diagnosis was made on serology (high titers of antibody in R, darkfield examination in 1, histopathology (numerous plasma cells) in 5, all were cured with classical recommended Penicillin therapy for early syphilis. **Conclusion:** Clinical presentation of secondary syphilis during HIV infection was atypical in 5/8 patients, syphilis is more than ever "the great imitator". On the other hand, the serological and histological data were typical of secondary syphilis and led to an easy diagnosis.

W.B.P.51 STYLETIC MELOPHYIA WITH HUMAN IMMUNODEFICIENCY VIRUS: A TREATABLE CASE OF SPINAL CORD DISEASE

Joseph B. Szary, M.D., G. Sawyer, M.D., L. Moskowitz, M.D.,
From the Departments of Neurology, Internal Medicine, and Pathology,
the University of Miami School of Medicine, and the Department of
Pathology, Baptist Hospital, Florida, U.S.A.

Three individuals with syphilitic myelopathy occurring in association with human immunodeficiency virus (HIV) infection are described. One patient responded dramatically to high dose intravenous penicillin therapy. In the other two patients, syphilitic spinal cord involvement was confirmed at autopsy by the presence of infectious fibrous leptomeningitis, chronic perivascularitis, and microglial infiltrates of the spinal cord. Both also exhibited radiculitis. One patient had clinical features of cervical radiculopathy, paraparesis, and double incontinence. The other was treated for neurosyphilis three months before death when she presented with an altered mental state, acute left hemiparesis, and hemiparesis with postural syphilis syndrome.

Syphilis needs to be considered in the differential diagnosis of any patient developing a myelopathy in association with HIV infection. Because of the diverse nature in which syphilis may affect the spinal cord, any HIV-seropositive patient with a progressive, unexplained myelopathy and a positive serum RPR-Ab should be considered for therapy with intravenous aqueous penicillin, 12 to 24 million units daily for a minimum of 10 days, even in the absence of a positive cerebrospinal fluid RPR.

Supported in part by National Institutes of Neurological Diseases and Stroke's Program Project P01-NS1556

W.B.P.53 AN ASSOCIATION OF STYLETIC EPISODES AND HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION OR SEROALLY TRANSMITTED VIRUSES (STV) INFECTIONS IN LOS ANGELES COUNTY

Norm. Thayer, D. M. Ford, W. W. Ruppel, P. W. Miller, L. W. Gorman, I. **
* Los Angeles County Health Department, Los Angeles, California, U.S.A.

*Centers for Disease Control, Atlanta, Georgia, USA.
Objective: to determine if an association exists between a history of syphilis episodes and HIV seropositivity.
Methods: Clients participating in confidential HIV testing in Los Angeles County STD clinics between July 1 and December 31, 1989, were interviewed by pretest counselors about their history of STDs and high risk behaviors such as number of sex partners, drug use, and prostitution.
Results: Having a history of at least one episode of syphilis appears to be strongly associated with HIV seropositivity (p<.0001). For those clients testing HIV positive, 57.8% (26/45) reported an episode of syphilis in contrast to 26.8% of those testing HIV negative (128/473). Upon further examination of drug and sex-related risk factors, contrary to our theory of drug use and intravenous drug use since 1978 were all strongly associated with having had at least one syphilis episode (p<.001). These associations were consistent within two groups (black and Hispanic) and among those who were interviewed by pretest counselors independently associated with being HIV positive (p<.0001). **Conclusions:** Syphilis appears to be a risk factor for HIV infection independent of any confounding effect of intravenous drug use unless drugs are exchanged for sex. Syphilis in Los Angeles County may predispose an individual to HIV infection.

W.B.P.56 NEUROSYPHILIS IN HIV-INFECTED PATIENTS: EVIDENCE OF UNRELIABLE SEROLOGICAL RESPONSES

Rolf Malassa*, H. Babay*, H. Birkenshaw*,
J. Blinck**, G. Schwedenmann*
Dept. of Neurology, **Geriatrics, University Clinic Essen,
**Dept. of Neurology, University Clinic Aachen, FRG.
Objective and Rationale: The combined infection with Treponema pallidum and HIV by unknown interaction leads to an atypical presentation of Neurosyphilis (NS), but remain and treponemal antibody tests have remained the cornerstones of diagnosis. We report on 4 HIV-infected men (CDC group II and III) with NS (one meningovascular, two meningal, 1 go production). The TPPA-serum/CSF-quotient was calculated. In 3 patients the relative concentrations of HIV-antibodies in serum and CSF were determined by serial dilutions in an anti-HIV ELISA (Abbott, Dublin). CSF was examined for cell count, protein content, oligoclonal bands and intrathecal IgG production. **Results:** There was serologic evidence for a previous syphilitic infection in all patients, but the serologic indicators of active NS, the cardiolipin reaction and the IgM-TPA in CSF, were negative. In addition, three of the patients showed no serologic signs of active syphilis in serum. One patient developed a relapse of NS despite an adequately high dose antibiotic therapy.

W.B.P.52 HISTORY OF AND CONVENTIONAL TESTS FOR SYPHILIS IN HIV-1 SEROPOSITIVE HOMOSEXUAL MEN IN BALTIMORE MDC

Almond Hays, Fox R. Hook E., Marlar Jr, Starkey D.

Sean A. The Johns Hopkins Medical Institutions, Baltimore, MD, USA

Objective: To determine the validity of syphilis testing in HIV-1 seropositive homosexual men with reported history of syphilis. **Methods:** Sixty HIV-1 seropositive Rapid Plasma Reagin (RPR)-men in the Baltimore MDC were stratified by self-reported history of syphilis and tested for evidence of past or present infection using the Fluorescent Antibody Absorbed (FTA) assay. 50/60 men had lumbar punctures performed using Venereal Disease Research Laboratory (VDRL) analysis of cerebrospinal fluid (CSF).

Results: Fifteen men reported history of syphilis, all before 1984. FTA tests were reactive in 13/15 (86.7% sensitivity - 88%). CSF-VDRL analysis was available in 8/15 of these men and were all nonreactive. In 45 men with no history of syphilis, the FTA was reactive in 2 (specificity - 4.4%). CSF-VDRL evaluation was negative in 31 of those tested including one participant with FTA and negative history.

Conclusion: Both sensitivity and specificity of reported lifetime history of syphilis are high compared to FTA testing in this small highly screened HIV-1 seropositive population. The 4% (2/45) of FTA men without reported history may be the result of recall error, false positive results, or inadvertent treatment of asymptomatic disease. These data suggest that the accuracy of self-reported serological testing for syphilis in HIV-1 seropositive homosexual men with negative RPR is high and the yield of further testing is low.

W.B.P.54 "SEROREVERSION" OF TRYPANOMAL TESTS DURING HIV INFECTION

Alma Jannari, R. Dillan, D. L. Iversen, D. M. Clement, W. Hoan M.,
San Francisco General Hospital & UCSF, SF, CA, Department
of Public Health, SF, CA, **Centers for Disease Control, Atlanta, GA, U.S.A.

Objective: To evaluate the sensitivity of trypomonal tests (i.e. FTA-ABS and/or RPR) for syphilis in individuals with a documented history of syphilis. **Methods:** Sub/ject=110 homosexual men with a documented history of syphilis, who enrolled in a longitudinal cohort between 1982-86. Syphilis serology done on entry into cohort was compared to results of serology confirmed on stored serum samples. **Study design-retrospective review.**
Results: None of the HIV-negative individuals in the cohort "seroreverted," whereas 7.2% of those who were HIV-seropositive but asymptomatic, 42.9% of those with AIDS, and 35.7% of those with AIDS had loss of reactivity of a trypomonal test. The relative risk of "seroreversion" for those with AIDS was 14; (p<.02), and for those with AIDS 10.5 (p<.02). Characteristics of those with "seroreversion" and those with persistent reactivity include:

14 count (n=17)	14 count (n=8)	14 count (n=8)
74/78 ratio	80/1 (21.6-80.1)	86.4 (21.6-80.1)
	4/5 (0.8-0.9)	4/5 (0.8-1)
	1.8 (1.0-3.0)	1.8 (1.0-3.0)

all men reported an mean (17- 85K contact person interval). **Conclusions:** Individuals with asymptomatic HIV infection and a documented history of syphilis lose reactivity of a trypomonal test for those with AIDS to be related to the decline of total T4 count and 14/78 ratio. These findings raise questions about the sensitivity of trypomonal tests in HIV-infected individuals, and suggest that a history of syphilis cannot be relied upon for negative trypomonal tests.

W.B.P.43 EFFICACITE DE LA SOMATOSTATINE LONGUE ACTION (SMS 201 905) DANS LE TRAITEMENT DES DIARRHEES ET NANTES LES CYTOMERES DE DEUX MALADES AFFECTES DE SIDA

Buty JP*, Latrelle J*, Pomeroy D*, Rochech J*, Dons M*, Beaulieu R*.
Hémocentrique* et maladies infectieuses* Hôpital Bichat-Montparnasse, Hôpital de la Santé Université de Paris 7.
Le SIDA parent est symptomatique chez 2 patients. Nous avons observé chez ces deux résultats liés associés à une correction de la cytométrie chez 2 SIDA.
Obs.1 : un homosexual de 32 ans avec sarcose de Kaposi et pneumocystose présentait une diarrhée localisée avec une éruption et une perte de 8 kilos en 4 semaines. Après 14 jours de tous les traitements symptomatiques et antibiotiques larges un traitement par SMS à la dose de 100 mg par s/c q8 heures a arrêté la diarrhée. Au 15ème Jour nous avons stoppé la SMS avec une récidive de la diarrhée. La coproculture des selles a été positive à *Micobacterium Avium* uniquement. Le traitement par Rifampicine et l'administration de pus acidifiés dans les selles. Les globules blancs avant et après traitement (15^{e} jour) passaient de 9000 à 5600. Les CD4 de 5/83 à 54. Les plaquettes de 47000 à 290000; l'hémoglobine resta stable. Le patient a gagné de 8 kilos en 10 semaines.
Obs.2 : un hétérosexuel de 28 ans présentant une pneumocystose avec cachexie. 12 selles liquides/jour. L'examen des selles (bactères, parasites, champignons) fut négatif. Après traitement de 300 mg 3 fois/jour, arrêt de sa diarrhée. De la cessation du traitement, récidive de la diarrhée et contrôle à la reprise de SMS à la dose de 100 mg par s/c q8 heures. Le 15ème jour passaient de 800 à 1100/m3, les plaquettes de 40000 à 110000. La SMS semble être un traitement symptomatique de la diarrhée du SIDA et a permis la correction de la cytométrie. Une étude est nécessaire pour en comprendre les mécanismes.

W.B.P.44 GASTRIC LEISHMANIASIS IN AN AIDS-PATIENT.

Pinco A.M.I., Virel H., Taillan M., Benin-Paul M.C., Marty, J., Le Fournier J., Chastagnat J.P., C.H.R.U. Nice, France.
Visceral leishmaniasis has been previously described in HIV seropositive patients and even proposed as a new opportunistic disease.
A 26-year-old patient, seropositive for HIV, followed since 1985, was admitted for weight loss, epigastric pain. Two years ago, he had developed cerebral toxoplasmosis. Since June 1987, he received trimoprim therapy, which was stopped in August 1988 for hematological toxicity. On admission, blood cells count was: 1.4, 10.9/1 leucocytes, 3.58, 10.1/1 erythrocytes, 34, 10.9/1 platelets, hemoglobin level was 116 g/l. Hematocrit was normal at proddal dosage. CD4 positive blood cells were <10/mm³. Endoscopic examination showed an ulcer on cardiac. Gastroenterologic examination revealed a gastric localization of leishmaniasis. Histologic examination and specific culture were positive. Specific serology was negative. There was no any parasite on skin and blood examination. Clinical status was dramatically improved by specific therapy of ulcers and sodium stibogluconate (Pentostam®) (600 mg/day during 3 weeks). At the end of the first cure, we noted: 5.5, 10.5/1 leucocytes, 37, 10.9/1 platelets and hemoglobin level was 120 g/l. Severe lymphopenia was persistent. Second cure was started again. At our knowledge, gastric localization of leishmaniasis in AIDS patient was not previously described, since intestinal involvement is well known. It would be a possible outline for the "opportunistic" character of leishmaniasis in AIDS-patients. Research of visceral leishmaniasis seems to be necessary in endemic area, in HIV seropositive patients with lymphopenia, mainly with hematological abnormalities.

W.B.P.45 SUCCESSFUL USE OF REFINEMENT BOVINE COLONOSIS TO TREAT CRYPTOSPORIDIUM INFECTION IN AN AIDS PATIENT

Woods, R.H.*, Ward, J.M. and O'Brien, C. A.
*Uniformed Services University of the Health Sciences, Bethesda, MD, USA,
**United States Department of Agriculture, Beltsville, MD, USA

Cryptosporidium is a protozoan parasite of the human gastrointestinal tract which can cause life-threatening diarrhea in immunodeficient patients. Although colic to slightly agents have been tried with occasional anecdotal success, treatment remains primarily limited to hydration. We describe a 36-year-old homosexual male with antibody to human immunodeficiency virus and *Cryptosporidium*-related diarrhea. The patient excreted 6 to 12 liters of stool per day for at least three months. In hospital, repeat stool examinations identified no bacterial or parasitic pathogen other than *Cryptosporidium*. Trials with more than six anti-diarrheal medications, including loperamide, were ineffective and the patient finally received bovine colostrum hyperimmune to *Cryptosporidium* by direct buccal infusion. The colostrum was produced by pasteurized *Escherichia coli* immunized with oocysts into pregnant dairy cows; resulting colostrum had $>1,200,000$ titers of specific bovine anti-*Cryptosporidium* IgG-1, IgM and IgM. During infusion, the patient's fecal output decreased to less than 2 liters per day and 48 hours after treatment, stools were fully formed and oocysts to *Cryptosporidium* could not be found. The patient remains asymptomatic 3 months later. Hyperimmune bovine colostrum offers an exciting possible new treatment for cryptosporidiosis: the active factor(s) and mechanism of action should be characterized.

W.B.P.46 A COMPARISON OF ELECTRON MICROSCOPY (EM) AND LIGHT MICROSCOPY (LM) IN THE DIAGNOSIS OF CRYPTOSPORIDIUM BLASTOCYSTIS INFECTION

Connolly, C.M., Dewey, G.J., Gazzard, B.C., St. Stephen's Hospital, London, UNITED KINGDOM

Objective: To assess the value of I/M and E/M in the identification of apparent cryptosporidial infection.
Methods: Rectal biopsy and stool specimens were examined by I/M and E/M from 40 AIDS patients with diarrhoea (at least 3 liquid stools/day for longer than one month).
Results: I/M confirmed the presence of cryptosporidium in 4 of 11 patients identified by I/M and in no patients where this organism had not been seen. The 4 patients had typical cryptosporidial infection with mean weight loss 14.6kg, and large volume diarrhoea (mean 1.96/day). They all died 3, 7, 9 and 24 months after diagnosis. In the other 7 patients, an alternative diagnosis was suggested at E/M (blastocystis 6 and dead cysts of giardia in 1). Four of the 6 patients with blastocystis are still alive 9, 12, 12, and 21 months after diagnosis. They had lost little weight at presentation (mean 4.3kg) and had low stool volumes (mean 0.7/day). A subsequent E/M diagnosis has been made in 3 of these 4 patients.
Conclusion: Light microscopy can confirm blastocystis and cryptosporidial infection. The former has a better prognosis, is not a feature of AIDS and presents with fewer clinical symptoms.

W.B.P.47 TREATMENT OF CRYPTOSPORIDIUM INFECTION WITH RECOMBINANT INTERFERON-2 (rIF-2)

Connolly, C.M., Dewey, G.J., Hawkins, D.A., Gazzard, B.C., St. Stephen's Hospital, London, England, UNITED KINGDOM

Objective: To assess the response of cryptosporidial diarrhoea to rIF-2.
Methods: Three patients with cryptosporidial diarrhoea (present in 3 stool specimens and rectal biopsy) were treated for four days with rIF-2 at 100 mg and seven days after a course of intravenous rIF-2 (400ug over 2 hours daily for 14 days). A patient with severe right upper quadrant pain, sclerotic conjunctivitis, iritis and cryptosporidiosis and *Cryptosporidium* on rectal biopsy was treated similarly.
Results: In all four patient cryptosporidium was not found in stools or rectal biopsy after treatment. In two of three patients with diarrhoea the average daily stool volumes fell from 1.8 and 1.5 litres per day to 0.75 and 0.3 litres per day. Remission was maintained for two weeks in one patient who died of pneumonia and for two months in another patient who died of CMV colitis. The third patient had visceral Kaposi's sarcoma and no reduction in stool volumes and died within two months. After starting a course of rIF-2 in one patient with sclerotic conjunctivitis and abdominal pain was markedly reduced but treatment was discontinued after seven days because of marked hypotension, pyrexia and haematuria from which he recovered. He subsequently received Posaconazole for CMV colitis and remission well four months later. Three of the four were febrile in response to rIF-2 and the alkaline phosphatase was significantly raised in two during treatment.
Conclusion: rIF-2 is an effective treatment for cryptosporidial diarrhoea but may cause severe reactions.

W.B.P.48 GASTROINTESTINAL CRYPTOSPORIDIOSIS IN RIO GRANDE DO SUL (RS) STATE: THE HIGHEST INCIDENCE

Barth, A.T., Pardini, L.A., Lemos, J., Araujo, M.J., Capobianco, M., Universidade Federal do Rio Grande do Sul, Porto Alegre, Brasil

Objetivo: Estabelecer a incidência de gastrointestinais cryptosporidiosis em AIDS patients in RS.
Métodos: 48 casos confirmados, 48 pacientes, 50 registros de AIDS (positivos à PCR) entre julho e novembro 1988. 8 casos were excluded because they did not meet the inclusion criteria (at least 4 stool analysis for cryptosporidium sp. in an acid-fast smear).
Resultados: 52,4% (n=22) were positive, and 47,6% (n=20) were negative for cryptosporidium sp.
Conclusão: Gastrointestinal cryptosporidiosis in RS is one of the highest incidence in the world. Therefore, it is important to consider this disease when dealing with an AIDS patient coming from RS.

W.B.P.37

BLASTOCYSTIS HOMINIS INFECTION IN AIDS PATIENTS.
E. Klinger, S. DeLigas, The University of Texas M. D. Anderson Cancer Center, Houston, Texas, U.S.A.

Although associated with some instances of human gastrointestinal disease, the pathogenicity of *Blastocystis hominis* is still under question. Objective - to evaluate the pathogenic potential of *B. hominis* in AIDS patients.

Methods - The records of HIV-infected individuals whose stool specimens contained *B. hominis* (5 per 400x field) were reviewed.

Results - Seven such patients were seen at our institution. All had significant diarrhea (4 bowel evacuations per day) nausea, abdominal cramping, fever and weight loss. Stool specimens of 3 patients contained only *B. hominis*. The remaining 4 had other potential intestinal pathogens (*Entamoeba histolytica*, *Giardia lamblia*) which have been implicated as copathogens with *B. hominis*. All seven patients responded to therapy (metronidazole or *Trimethoprim/Amphotericin*) with resolution of symptoms and eradication of organisms from stool. No relapses occurred (follow-up - 4 months). No other causes for their diarrhea were found.

Conclusions - *B. hominis* should be considered a potential pathogen in AIDS patients and may be associated with other intestinal pathogens. Specific therapy usually results in resolution of the infection. Relapses are rare. In patients who do not respond, other causes of diarrhea should be investigated.

W.B.P.38

VARIABLE LOCALIZATION OF INTESTINAL CRYPTOSPORIDIOSIS IN AIDS.

Heiner, Todd D. Therapy, AR, Kotler, DP, St Luke's Roosevelt Hospital Center, Columbia University, New York, NY, USA.

Objective: To examine the localization of cryptosporidial (Crypto) infections in the gastrointestinal tracts of patients with AIDS.

Methods: In a retrospective review of biopsies from 25 AIDS patients with Crypto, the small intestine was the primary site of involvement in 16 patients, the colon was the primary site of involvement in 9 patients, and no patient had severe disease in both sites. The influence of disease localization was studied prospectively in 8 patients with jejunal Crypto and in 5 patients with colonic Crypto. Studies of coxist excretion, small intestinal structure, and the absorption of sugar (xylose) acid fat (sterols) were performed.

Results: Diarrhea was more severe in patients with jejunal Crypto and was associated with greater xyst excretion, more jejunal injury and more xylose malabsorption. The malabsorption was abnormal in both groups.

Discussion: Cryptosporidial (Crypto) infections in AIDS patients may have different localizations. Jejunal involvement is associated with more severe diarrhea and malabsorption. The localization of Crypto may be related to the site of infection.

Conclusions: Crypto has a variable localization in the intestine. Intestinal structural and functional abnormalities correlate strongly with the localization of Crypto.

W.B.P.39

COLONOSCOPIC ETIOLOGICAL DIAGNOSIS OF DIARRHEA IN AIDS
Souza de Lima, Dirceu, Jrado, E.; Favoreto, C.; Treibman, M.; RESENDE, R.

Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brasil.

From August 1985 to September 1986, 18 patients were studied by the same physicians at the Department of Infectious Diseases and private clinic. They presented diarrhea for more than 30 days. Among them were 14 homosexual men, 2 blood receivers and 2 women married with bisexual men. After negative labo- ratorial investigation for common intestinal parasites in AIDS, colonoscopies with biopsies from caecum through rectum (flexocolonoscopy ACM and video-colonoscopy Welch Allip) were performed in 16 patients. The examination showed: normal mucosa (6 cases), swollen and edematous mucosa without friability (6 cases) and sick mucosa with multiple ulcerations (6 cases). The histopathology showed *Cytomegalovirus* colitis (5 cases), cryptosporidiosis (1 case) and nonspecific colitis (10 cases) at the remaining ones.

There were two patients not submitted to colonoscopy which presented *Cytomegalovirus* colitis. One of them had peritonitis due to a left colon ulcer perforation found at surgery and the other at post mortem examination. The diagnosis were made by histopathology of the surgical specimen and autopsy respectively.

After given anti-viral therapy, the patients with *Cytomegalovirus* colitis remained with diarrhoea. One of them had cryptosporidiosis and the other *Shigella flexneri* in the stool culture.

W.B.P.40

INCIDENCE OF INFECTIONS GASTROENTERITIS IN SPANISH AIDS PATIENTS

Jorge, Millares; Moreno A, Niro JM, Gattell JM, Laborde J, Barcelona, Barcelona, Spain.

Soriano E. Infectious Diseases Unit, Hospital Clinic, University of Barcelona, Barcelona, Spain.

Objective: To describe the characteristics of the infectious gastroenteritis (IG) in 226 Spanish AIDS cases.

Methods: Since 1984, all patients who fulfilled the CDC criteria for AIDS case definition were prospectively followed. Seventy four (32%) were male and 50 (22%) were female. All patients were followed up to death or to the end of the study.

Results: Fifty nine episodes of IG (defined as the isolation of one (44 episodes) or more (15 episodes) microorganisms in the feces or in the intestinal mucosa) were identified in 44 of the 226 AIDS cases (20.3%). All but 2 were males and the mean age was 36 (range 20-59) twenty seven were men (61%) and 17 (34%) were women (39%). The IG alone or associated with other opportunistic infection was present at the moment of performing the diagnosis of AIDS in 30 of the 46 cases (63%). The microorganisms were: *Cryptosporidium* (19), *E. lamblia* (18), *Entamoeba coli* (8), *L. belli* (7), *Cytomegalovirus* (7) (postmortem diagnosis), *Salmoneella* sp. (7) (five with opportunistic bacteremia), *C. jejuni* (5), *S. flexneri* (5), *E. nana* (2), and *NAI*, *V. enterocolitica* and *S. typhimurium* in one case each. All episodes of IG, but 4, caused by cryptosporidium, were self-limited or responded to treatment. The IG was the main or an associated cause of death in 5 of the 25 patients who have already died.

Conclusion: IG is very common among Spanish AIDS patients (mainly among HWG) and often are the first manifestation of AIDS. The most frequent microorganism was *Cryptosporidium*.

W.B.P.41

GASTROINTESTINAL MULTIFUNCTION IN AIDS PATIENT: A CASE REPORT

Spinella, Rosalind Springs, C*-
*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil
*Hospital de Clínicas de Porto Alegre (HCPA), Rio Grande do Sul, Brazil

Objective: Report a gastrointestinal multifunction in AIDS patient in Rio Grande do Sul (RS) state.

Case Report: A 29 years old white, drug addict and promiscuous was hospitalized with a copious, explosive, bloody diarrhea.

First stool analysis revealed *Stromboloides* trophozoites and *Shigella flexneri* bacteremia. *Trimethoprim* and *Amphotericin* were started without great improvement. Her stool culture yielded *Shigella flexneri* and *Cryptosporidium* was initiated with improvement of the diarrhea. Another stool analysis showed *Candida* sp. and *Cryptosporidium* sp.. *Amphotericin* B was added and a great improvement has been noticed. She was discharged after 20 days with 2 diarrheal episodes per day. Her stool analysis was negative, except for the presence of *Cryptosporidium* sp..

Conclusion: When treating AIDS patients, is important to know that infections are very simple, and to report it as a perfect example of the transformations going on gastrointestinal system of these patients.

W.B.P.42

ROTAVIRUS AS A DIARRHEAL AGENT IN ADULT AIDS PATIENTS.

Blum, Jihad*, Deluca, P., Ferris, G., Shah, J., Deluca, A. Saint Michael's Medical Center, Newark, New Jersey, U.S.A.

Objective: To determine incidence and importance of rotavirus as a cause of diarrhea in AIDS patients.

Methods: Stool samples were assayed by latex agglutination and ELISA technique for the presence of rotavirus. These stool samples were collected from 12/88 through 1/78 when the incidence of rotavirus was at its highest in the corresponding pediatric population. The medical charts of these patients were reviewed for symptoms.

Results: Eighteen patients had stool samples sent for study. Eight of these patients had symptoms of diarrhea and one of these had rotavirus detected by ELISA. *Mycobacterium Avium* Intracellular was the most common cause of diarrhea among the virus detected in their stools.

Conclusions: Rotavirus was not found to be a significant cause of diarrhea in adult AIDS patients. Detection of this agent also may not explain the diarrheal syndrome even when found.

W.B.P.31 THERAPEUTIC OF TOXOPLASMIC ENCEPHALITIS IN AIDS PATIENTS

BRONKHORST, G.O., LONO, I.M.F., STEFANI, H.N., BIANCOLANI, M.T., RODRIGUES, G.A. and LEVI, G.C.

Serviço de Moléstias Infecciosas, Hospital do Servidor Público Estadual, São Paulo, Brazil.

Seventeen patients with AIDS and toxoplasmic encephalitis were studied regarding therapeutic response and adverse effects, diagnosis being established on clinical and tomographic basis. All patients had positive specific serological tests; IgM was always negative and IgG was always $> 1/256$; median CD4 count was 222 cells/mm³. Pyrimethamine, sulfadiazine, and clindamycin were used in various combinations \forall , in few cases, due to allergic or toxic reactions to the other drugs, as monotherapy. The same drugs and Fansidar were used as suppressive therapy. Thirteen patients were cured and four died (three of them before completing 10 days of treatment). Relapse was observed in 50% of the cases, and the mean survival time was 161 days.

Overall there was a trend towards the favourable therapeutic response even when monotherapy with clindamycin was used, and the high incidence of side effects of therapeutics and relapse of the disease in spite of suppressive therapy.

W.B.P.32 IN VITRO INHIBITION OF TOXOPLASMA SPECIFIC ANTIBODIES BY PERIPHERAL BLOOD CELLS FROM HIV INFECTED SUBJECTS.

VENDRILLO, P. J., BIANCHI, G., FERRARI, G.***, SUPPET, R. F.**, CANALI, A., BERRE, A.**,

* Laboratorio d'Immunologia, Ospedale Leprosario, *** service

Malattie infettive, Ospedale S. Maria, Milano.

INTRODUCTION. Severe cerebral complications of Toxoplasma occur in 10 to 20% of AIDS patients. Serology is no great help for their diagnosis which relies on clinical and scanner arguments. We wondered whether specific B cells could not be present in the blood stream at earlier stages of active toxoplasmosis infection together with the HIV-secreting cells.

METHODS. PBMc culture supernatants from 43 HIV seropositive and 24 seronegative subjects were incubated in wells of Behring or Parke-Davis antibody kits. To elicit a seropositive complex we used to reveal the in vitro secreted and fixed antibodies.

RESULTS. In vitro production of Toxoplasma antibodies was detected in 10 of the 36 HIV and "Toxo seropositive" and in 60% of the HIV "seronegative" but "Toxo seronegative" subjects. Although 20 of the 24 HIV "seronegative" subjects were "Toxo seropositive" none of them gave positive results in the in vitro Toxo test. Of scanner and clinical evidence of cerebral toxoplasmosis was found in only 7 of the 17 HIV and "Toxo positive" subjects and isolated neurological symptoms in only 7 others. In a specific and selective inhibition of the Toxo in vitro test (and not of the HIV test) was observed after preincubation on the PBMc with Toxoplasma antigens (kindly provided by Dr Capron, Milan).

CONCLUSION. Toxoplasma antibody secreting cells are present in the blood stream of some but not all HIV infected subjects. Their detection could provide a tool for the diagnosis and the early treatment of active Toxoplasmosis.

W.B.P.33 THE VALUE OF PYRIMETHAMIN/ALFADOXIN (PFA) IN THE PREVENTION OF CNS-TOXOPLASMA IN AIDS PATIENTS

BILIR, THOMAS, MATHIAS, A., JAFFAR, S., JAGANNATHAN, S., SANKAR, S. and STEINER, J.S. *

*Neurological and *Neurological Department of Klinikum Steglitz, Freie Universität Berlin, FEDERAL REPUBLIC OF GERMANY

OBJECTIVE: To evaluate (1) the value of PFA for prevention of CNS-toxoplasmosis (CNS) in AIDS-patients (AIDS)

Methods: Retrospective analysis of 18 pts. treated for CNS between 1984 and 1988.

Results: Fifteen human immunodeficiency virus seropositive pts with acute CNS (clinical intracranial lesions in 86.6% of cases) were treated with pyrimethamine (PM) and/or Fansidar in combination with either cotrimoxazole (COT) or clindamycin (CL). 1,8-2,400 mg of one of both effects. 4 of these pts. developed their CNS disease secondary long term prevention of CNS with 160 (80mg/160mg), 14/18 pts. (77.8%) showed complete (CR) or partial (PR) response (partial was better or neurological defect), 2 pts. died. Treatment was continued as long term therapy with 160 (80mg/160mg) in 4 pts., 80 mg in 2 pts., 40 mg in 2 pts. (1,8-2,400 mg). None of the 18 pts with complete response developed a relapse. 18 pts. with partial response, but of them 14 pts. relapsed long term therapy with 160 and 80 mg. with PFA. Thus, 4/16 pts. (25%) developed CNS disease secondary to acquired acute CNS while under long term therapy with Fansidar.

Conclusions: These retrospective data indicate that (1) Fansidar is a drug of 160 mg PM / 1,60 mg 80 mg of cotrimoxazole for the primary or secondary prevention of CNS in AIDS-pats, and (2) that partial relapse of CNS seemed to be a major risk factor for CNS relapse.

W.B.P.34 TREATMENT OF CNS TOXOPLASMOSES IN AIDS PATIENTS. RESULTS OF PROSPECTIVE STUDIES USING PYRIMETHAMINE AND MACROLIDE ANTIBIOTICS.

Ruf, Bernhard *, Pöhl, H.D. * and Iglesias, J.R. **

* Departments of Internal Medicine and ** Neuropathology, Rudolf Virchow University Hospital (Wedding), Freie Universität Berlin, FRG

For treatment of cerebral toxoplasmosis pyrimethamine in combination with sulfadiazine is commonly used. In our study the sulfadiazine component was replaced by macrolide antibiotics. The results of treatment with pyrimethamine and with one or two macrolides were compared: with clindamycin and spiramycin (three drug regimen) and with clindamycin (two drug regimen). For maintenance therapy the effectiveness of pyrimethamine/alfadoxin was studied.

Dosages: 1.5 mg pyrimethamine/kg body weight/0.24 g clindamycin/d and 9 Mill. IU spiramycin for 3 weeks. Prophylaxis after acute therapy: 50 mg pyrimethamine and 1000 mg sulfadiazine in 2 tablets Fansidar® once a week.

Three drug regimen therapy was effective in 22/35 cases. Relapse occurred in 11/19 cases under maintenance treatment but in all six patients who had omitted the prophylaxis. Two drug regimen therapy was effective in 12/13 cases. Two of 13 patients developed a relapse under prophylaxis. Hematologic side effects were mild for both regimens, but could be controlled by folic acid given from the start of therapy in most cases. Skin rashes were observed in 10 cases.

Therapy regimen with pyrimethamine and macrolide antibiotic and maintenance treatment were proven to be effective. Relapses are mainly due to discontinuation of the prophylaxis.

W.B.P.35 LOCALIZATIONS OF THE TOXOPLASMOSES DANS LE TUBE DIGESTIF (T.D.) AU STADE AVANCÉ DES SIDA. ÉTUDE ANATOMO-CLINIQUE

MARCO, C.; MORALES RUBIN, C.; CLAIR, B.; TROPHEAN, B.; FROSTIER, J.; NICHOU, A.G.

Hôpital Richier-Clair, Paris, France.

Objectif: Evaluer la fréquence de la toxoplasmose digestive et préciser ses aspects anatomo-cliniques.

Méthodes: Étude macroscopique et histologique systématique de T.D. de 150 patients (Pa) atteints de SIDA, corrélatée avec les données cliniques.

Résultats: Le T.D. est atteint 7 fois (5 homoseksuels européens, 1 saoudien, 1 indonésien). Age moyen 37 ans ± 6 ans (écart interquartile 1-30 ans). Sexe

INTERFÉRENCE 2 fois tout le tube digestif, 1 fois la grêle et le colon, 4 fois seulement l'oesophage (n = 1), la grêle (n = 1) ou le colon (n = 2). L'aspect macroscopique est local (œdème, pétéchiales) dans 2 cas; 2 aspects de type gastrique diffuse (1 cas) et de recto-colite hémorragique (1 cas).

Toxoplasmose généralisée (T.G.) peut infecter tous les types cellulaires. Types et topographies lésés sont en évidence sur toute l'épaisseur de la paroi, dans des lésions inflammatoires et/ou adhésives, nodulaires ou diffuses.

Dans 2 cas T.G. est le seul agent pathogène; 2 fois il est associé à des cryptosporidies (n = 1) et à une infection par *Opisthorchis viverrini* et *Hyocysternum* dans l'intestin terminal.

La toxoplasmose digestive est la 1^{re} cause de douleurs abdominales et s'étend au moins une autre localisation viscérale. La clinique se résume à une diarrhée profuse (5 fois) et/ou à des douleurs abdominales (3 fois).

Conclusion: La toxoplasmose digestive est la 1^{re} cause de douleurs abdominales systémiquement sur les biopsies digestives, au moins par immunoperoxidase.

Infections liées au SIDA : diarrhée

AIDS Related Infection: Diarrhea

W.B.P.36 ANOXYGENES ISOLE DU TUBE DIGESTIF CHEZ 20 PATIENTS SIDA. UNILÉVELLE IDENTIFICATION CLINIQUE

BALLET, R., MULLIGAN, J., LEPORT, C., GUER, J., LEPORT C., BRICOURT, F., VILIS, J.L. Hôpital Claude-Bernard, Paris, France.

OBJECTIF: Définir le rôle des adénovirus au cours du SIDA.

Méthodes: Étude rétrospective des diarrées chez 20 patients (pts) SIDA chez lesquels un adénovirus a été isolé des selles ou des biopsies coliques entre août 1987 et septembre 1988.

Résultats: Tous avaient des signes digestifs : diarrhée (n=18), douleurs abdominales (n=7), traie pts avaient une ulcération anale. La coloscopie

révéla des lésions chez 8/18 pts et normales chez 10/18 pts. Les

ulcéraires chez 10/18 (5/1) avec histologiquement des lésions

compatibles avec une infection à CMV (n=1), des cryptosporidies (n=1) et

aucun autre agent pathogène chez 1 adénovirus (n=1). Un adénovirus était

isolé des selles (n=1), des biopsies rectales (n=2) et/ou caecales (n=8)

ou de l'ulcération anale (n=7). Les structures de 4 autres études

étaient 1/8, 1/2, 2/2 et 2/2. Les recherches d'adénovirus étaient réalisées à

4 fois dans selles et biopsies chez 10 pts; elles étaient positives aux

deux niveaux chez 6 pts (6/7) à positive seulement dans les selles chez

4 pts (4/4) et 6 sur 6 pts (6/6) à positive seulement dans les selles et

colite adhésive chez 1 pt. Les virus CMV étaient présents chez 0/8 pts (0/8), et

8 sur 8 pts (4/2) avec une localisation vésiculaire à CMV.

Conclusion: Ces résultats (1) suggèrent la possible responsabilité de

adénovirus dans certaines manifestations digestives courtes du SIDA, (2)

évaluent la question des relations entre CMV et adénovirus au niveau du

tube digestif chez ces pts.

W.B.P.13

LE "FLUCONAZOLE" DANS LE TRAITEMENT DE LA CRYPTOCOCCOSE MÊNINGÉE CHEZ LES PATIENTS ATTEINTS DE SIDA.

NAVERNE KALAMBAYILI, MD et DEHRET P.***
*CITROUDES Universitaires de Kinshasa, **Labo de Mycologie, Zaire.

OBJECTIF: Étudier cliniquement l'efficacité du Flucanazole dans le traitement de la cryptococcose méningée chez les SIDAiens.
PATIENTS: 12 SIDAiens* cas HIV (11 et 12) avec Cryptococcose méningée confirmée par culture (Sabouraud) et par seroélectrophorèse (IEM) ont été traités de façon randomisée soit par flucanazole soit par association Amphotéricin B + 5 Fluorocytosine.
RÉSULTATS: Les symptômes cliniques disparaissent et guérison mycologique est obtenue dans la culture du liquide céphalo-rachidien (LCR) devenant négative après 8 contrôles successifs.

RÉSULTATS: 17 malades ont eu le flucanazole (groupe A) et 17 l'association amphotéricin B/5 fluorocytosine (groupe B).

DURÉE DES SYMPTÔMES	Gr. A	Gr. B	p=0.7
Ag Crypt. dans le sang	1/25(38)	1/14(47)	p=0.6
Ag Crypt. dans le LCR	1/18(4)	1/20(5)	p=0.2
Guérison clin.	11/17	20/21	p=0.8
Guérison myc.	11/17	20/21	

CONCLUSION: Le flucanazole a une efficacité comparable à celle de l'association amphotéricin B + 5 fluorocytosine.

W.B.P.14

LA CRYPTOCOCCOSE AU MAROC

FACH JACQ-ROBERT, ROYER S., LAMOURI S., KAMRER W.,
*Centre Hospitalier Universitaire de Rabat, MAROC.

OBJECTIF: Analyser l'importance de la meningite à cryptococques dans le SIDA et l'évolution de son traitement par le Flucanazole.

METHODES: - Étude de 37 cas de meningites à cryptococques observées en 32 mois et 17 cas de son traitement par le Flucanazole.

- Diagnostic clinique et diagnostic biologique reposant sur le mise en évidence de lésions typiques de Cryptococcus méningococci sur smears microscopiques direct du L.C.R., sous scap ou culture systématique sur milieu de Sabouraud, suivi d'une identification mycologique précise. - Traitement appliqué au cours de l'étude: a) association amphotéricin B et 5-Fluorocytosine - ou du FLUCANAZOLE.

RÉSULTATS: - Prévalence de la cryptococcose dans le SIDA: 2/3 des cas
- Importance clinique: meningite méningococcale dans 80 % des cas
- Traitement par FLUCANAZOLE: 17 patients, 17 fois, bien toléré, facile à administrer

CONCLUSIONS: - La Meningite à Cryptococcus méningococci survient souvent au stade du SIDA au Maroc, son diagnostic est facile, le traitement par le FLUCANAZOLE est bien toléré, efficace, d'administration facile, bien toléré, bien adapté aux pays à revenu autochtono sous-développés.

W.B.P.15 CRYPTOCOCCAL MENINGITIS AND HIV INFECTION IN NORTH CAROLINA

NEWMAN, BARRY, BARRETT, J.A. and COLLINS, M.D.
Duke University Medical Center, Durham, North Carolina, USA

Objective: Evaluate characteristics of cryptococcal disease among persons with human immunodeficiency virus infection in rural, southeastern USA.

Methods: A retrospective review of clinical and laboratory records.

Results: From 1983 through 1989, the proportion of patients with cryptococcal disease who also had HIV infection tripled:

1985-24 (53%), 1986-29 (31%), 1987-67 (10%), 1988-73 (11%)

We compared the 29 HIV patients to the 33 HIV patients diagnosed with disseminated or meningeal cryptococcosis. HIV-infected patients were more likely to have cryptococcal meningitis, had rapid conversion of serum antigen titers from negative to positive, and had higher cryptococcal antigen titers at the time of initial diagnosis.

A review of survival trends of the HIV-infected cohort (n=29) indicated that 12-month survival following diagnosis has increased from 13% (1/8) in 1985-1986 to 67% (6/9) in 1987-1989. The magnitude of titrable antigen (by latex fixation) at the time of diagnosis was not predictive of long-term response.

One of the 7 long-term survivors had initial CSF antigen titers greater than 1:100; one patient had a CSF titer greater than 1:1000,000.

In all patients, a decline in cryptococcal antigen titer did occur following initiation of therapy and was associated with a positive response. Subsequent increase or plateau of antigen levels was associated with relapse. All long-term survivors required maintenance therapy.

Conclusion: The diagnosis of cryptococcosis in HIV-infected patients should not center a dismal prognosis.

W.B.P.16 CRYPTOCOCCAL MENINGITIS IN PATIENTS WITH AIDS. DIAGNOSTIC FEATURES AND OUTCOME IN 8 CASES.

ANTONELLI, G., VIGARIANO, P., JESSELLI, G., BIANCHI, B., BORDI, R., & SILELLI, M., SILELLI, M.D.

Sanatorio Spallanzani Hospital for Infectious Diseases, Rome, Italy

Objective: To study clinical and laboratory features of cryptococcal meningitis (CM) in patients (pts) with AIDS.

Methods: Investigations involved clinical manifestations, tests on blood, CSF, sputum, brain and tissues, CT brain scans and/or cranial MRI.

Results: Among 101 patients with AIDS observed from 1984 to 1988, 8 (1.9%) had CM. Four of them had also antineoplastic involvement. CM was the first diagnosed opportunistic disease in 4 pts. Fever and headache were present respectively in 6/8 and 7/8 of the patients.

Initial status, meningismus and vomiting occurred in 6/8, 3/8, and 2/8 respectively. The symptoms duration before diagnosis ranged from 8 to 20 days.

The diagnosis of CM was based on CSF studies in 8 cases and on autopsy findings in one. The CSF protein was 25-172 mg/dl, the glucose range was 16-64 mg/dl and the white blood cell count in 7 cases in only 1 of 7 pts (range 1-60 cells/dl).

The CSF culture was positive in 4 pts, Indian ink preparation in 6 of 7 pts and the cryptococcal antigen titer was positive in all pts. Brain scans and/or MRI revealed abnormal results in 4 pts.

Therapeutic regimen included amphotericin B 0.1 mg/kg plus fluconazole 150 mg/d for 8 pts. Two of the 7 pts were cured.

Conclusions: The authors point out that CM may present in an insidious manner in pts with AIDS, the high mortality rate in spite of an early diagnosis and the recommended therapeutic regimen.

W.B.P.17 THE LIMITED VALUE OF ROUTINE SERUM ANTIGEN SCREENING FOR CRYPTOCOCCAL INFECTION.

NEWMAN, BARRY S., SMITH, D.A., HAWKINS, D., SHANKER, D., REED, C., SILELLI, M.D. & STERNBERG, RICHARD, M.D., NEW YORK, ENGLAND.

Objective: To assess the routine serum cryptococcal antigen as a screening procedure for diagnosis of cryptococcal infection.

Methods: All HIV antibody positive patients over a three year period who had pyrexia of unknown origin or meningitis underwent screening by serum cryptococcal antigen latex agglutination tests. All patients with a positive titre or signs of meningitis had a lumbar puncture. In those patients with a positive serum antigen, a further antigen was performed on serum saved prior to diagnosis.

Results: Only 15 of 808 serum cryptococcal antigens were positive, 15 of whom had meningitis and had cryptococcal meningitis confirmed at lumbar puncture. The other 8 patients had pyrexia of unknown origin without meningitis and had no CSF abnormalities. One was retained well for over one year. The other had a tubercula which responded to conventional therapy and is well at six months.

A saved sera was available on 8 of the patients with positive serum antigen within 3 months prior to diagnosis (range 20-90 days; mean 60 days). All were well at time of testing. None of the sera were positive.

Conclusion: Cryptococcal antigen testing is not of value as a screening test for patients with a pyrexia of unknown origin or in predicting which well patients may develop this infection. It does predict which patients with meningitis have cryptococcal infection.

W.B.P.18 CRYPTOCOCCUS MENINGITIS PULMONARY INFECTION IN 17 HIV INFECTED PATIENTS

Chak, Ananda*, Grew, D., Valente, G., and Hyslop, N.*.
*Dallas/LSD ACTV, New Orleans, USA

Objective: To review the presentation and clinical course of Cryptococcus meningitis (CM) pulmonary infections in HIV infected (HIV+) patients.

Methods: Hospital records and chest X-rays of HIV+ patients known to have CM pulmonary infection either by positive respiratory cultures or histopathologic evidence were retrospectively reviewed. All patients were seen at Charity Hospital of New Orleans, Veterans Administration Medical Center, or Tulane Medical Center between January 1, 1985 and December 1, 1988.

Results: Of 17 patients, all were male; most were white (15), and homosexual (12), with an average age of 33 (± 6) years. The most frequent presenting symptoms were fever (15) and cough or dyspnea (5). Although chest X-ray patterns included cavity lesions (2), nodules (2), and a solitary lower infiltrate (1), the most common finding was bilateral interstitial infiltrates (7), of which 3 had coexistent cytologically proven PCP. Positive simultaneous extrapulmonary cultures, CSF (8/15) and blood (4/10), were found in 8 patients. Two patients with no extrapulmonary infection with a mean length of survival of 16 (± 6) weeks and 6 patients with concomitant CNS involvement died with a mean length of survival of 4 (± 5) weeks.

Conclusions: Chest X-ray findings in HIV+ patients with CM pulmonary infections can be unusual. Features and differentiations from PCP may be difficult. The mortality rate is high in HIV+ patients with CM symptoms and may be influenced by the presence of CNS involvement.

Aspects cliniques Clinical Aspects of AIDS

W.B.P.85 MEASUREMENT OF β_2 -MICROGLOBULIN (EM) BY RAGE EPIDEMIOLOGIC ASSISTED IN BLOOD FROM AIDS INFECTED
Shyam-Bashi, J. Johnson, M. Chen, F. J. and Miller, J. Clinical Lab., T.F. General Hospital and Dept. Lab Med., UCSF, San Francisco CA, U.S.A.

Objective: EM content of blood, CD4 T-cell count, hemoglobin and social and behavioral risk factors have been proposed as prognostic indicators in AIDS/ARC patients. We developed a method to measure EM by immunonephelometry (INA).

Methods: We used the Beckman ICS nephelometer and commercially available anti-EM. We mixed 50 μ l of serum or plasma with 1.50 ml of 9% polyethylene glycol (PEG) and 84 μ l of anti-EM. EM from human urine was used as standard.

Results: Analytical sensitivity and linearity were 1.0 mg/L and 7.7 mg/L. Inter-assay CV's were 7.2% for 5.6 mg/L and 4.8% for 2.6 mg/L. Intra-assay CV's were 3.9% for 4.7 mg/L and 4.8% for 2.1 mg/L. EM content by assay (CV) and EM were highly correlated: $r = 0.926$. Serum from 45 AIDS and ARC patients had a mean EM of 3.7 ± 1.4 mg/L. Sera from 22 healthy subjects had a mean EM of 1.7 ± 0.5 mg/L. Lipemic specimens were cleared by ultracentrifugation. Specimens kept at -70°C up to 6 months are suitable for this assay.

Conclusion: This assay procedure is easily adaptable to routine clinical laboratory operation, is less expensive and is less labor-intensive than is ELISA and RIA. Further, the AIDS/ARC EM show significant elevation over healthy subjects studied at UCSF.

We wish to acknowledge Dr. A. Ross for providing AIDS/ARC samples.

W.B.P.87 QUEST FOR PROGNOSTIC MARKERS IN HIV INFECTED HAEMOPHILIC CHILDREN

Susan Shidmore*, M Williams**, SJ Mason* & PDH Hill**

*Regional Virus Laboratory, East Birmingham Hospital, Birmingham, UK
**Department of Haematology, Birmingham Children's Hospital, Birmingham, UK

Objective: To assess the predictive value of laboratory markers in progression of HIV infection in a cohort of haemophilic boys.

Methods: Assays for anti-HIV, anti-CD4, anti-CD8, anti-CD4/CD8, anti-interferon, neopterin and β_2 -microglobulin were bought in kit form and carried out according to the manufacturer's instruction.

Patients: Since the introduction of HIV screening, HIV seroconversion has been shown in 34 haemophilic boys attending a large paediatric haemophilia centre. It has been possible to document that seroconversion occurred as early as 1981 but the majority in 1983 to 1985 with seroconversion precisely identified within a three month period in at least a third of the patients.

Sequential samples including one pre-seroconversion are available on all patients (mean number 13 per patient).

Results: Among this cohort one boy has persistent 4-7% of an upsurge of pneumococcal carinii pneumonia 2 years ago, but is currently well on no treatment. Although a further 7 boys have one or more altered markers, all remain well and are asymptomatic, one after 6 years of follow up. These results will be presented in relation to the time from seroconversion.

Conclusion: Results from marker studies in haemophilic children should be interpreted independently. Data from studies in adults cannot be used to predict the course of infection in children. It seems likely that age will prove a contributory factor in the development of the infection in this group of patients.

W.B.P.89 NEOPTERIN IS A RELIABLE DIAGNOSTIC MARKER IN HIV-INFECTION.

E. Reisinger*, P. Kern*, S. Schneider*, A. Borchmann*, M. Ernst*, D. Bartzke* & H. B. Fiedl*, R. Dietrich*

* Clin. Dept. and ** Dept. of Virology, Bernhard-Nocht-Inst. for Tropical Med., Hamburg, FRG.

* Forchungsanstalt Borstel, FRG

* B. Dept. of Borstel, Inst. for Virology, Hamburg, FRG

Objective: Neopterin is produced by macrophages stimulated with endotoxins. We report on the correlation of serum-neopterin with the course of HIV-infection during a prospective randomized double blind treatment study. Methods: 84 patients were examined in 6-week intervals and the neopterin levels were correlated with known prognostic markers for HIV-infection. In the IIA we are using the known normal limit is 20 nmol/L. Results: In the asymptomatic stage of the HIV-infection the neopterin levels are normal in most cases. In early asymptomatic stages of infection (CDC III) the neopterin levels are elevated statistically (10-20 nmol/L). The levels tend to increase with progression in CDC, Walter-Reed and Holtz-Peters in the case of AIDS. In the case of AIDS, the neopterin level is also highly correlated with progression parameters as CD4 count, lymphocytes, CD4/CD8 ratio, and HA-1-20 pg. lymphocytes.

Conclusion: Neopterin is produced by macrophages stimulated with endotoxins. We report on the correlation of serum-neopterin with the course of HIV-infection during a prospective randomized double blind treatment study. Methods: 84 patients were examined in 6-week intervals and the neopterin levels were correlated with known prognostic markers for HIV-infection. In the IIA we are using the known normal limit is 20 nmol/L. Results: In the asymptomatic stage of the HIV-infection the neopterin levels are normal in most cases. In early asymptomatic stages of infection (CDC III) the neopterin levels are elevated statistically (10-20 nmol/L). The levels tend to increase with progression in CDC, Walter-Reed and Holtz-Peters in the case of AIDS. In the case of AIDS, the neopterin level is also highly correlated with progression parameters as CD4 count, lymphocytes, CD4/CD8 ratio, and HA-1-20 pg. lymphocytes.

Conclusion: Neopterin is produced by macrophages stimulated with endotoxins. We report on the correlation of serum-neopterin with the course of HIV-infection during a prospective randomized double blind treatment study. Methods: 84 patients were examined in 6-week intervals and the neopterin levels were correlated with known prognostic markers for HIV-infection. In the case of AIDS, the neopterin level is also highly correlated with progression parameters as CD4 count, lymphocytes, CD4/CD8 ratio, and HA-1-20 pg. lymphocytes.

W.B.P.86 THE CLASSIFICATION OF HIV DISEASE: CORRELATION OF BETA-2-MICROGLOBULIN (B-2-M) AND ERYTHROCYTE SEDIMENTATION RATE (ESR).
Kilborn, J; Fisher, E; Elym, J; Markowitz, N. and Saravolatz, L.D. Henry Ford Hospital, Detroit, Michigan, USA.

Objective: To identify the role of beta-2-microglobulin, erythrocyte sedimentation rate, and hemoglobin (Hb) as predictive indicators of CDC-HIV stages.

Methods: At the time of initial medical assessment, 70 HIV(+) men were classified according to CDC clinical stage and had serum B-2-M, ESR, Hb and CD2, CD4, and CD8 T-lymphocytes subsets determined. CD2 groups were then compared by analysis of variance.

Results: Mean values \pm standard deviations are indicated for each parameter. CD2 group M (n=10) B-2-M (mg/dl) Hb (g/dl) CD4 (cells/mm³) CD8 (cells/mm³)
I 15 12.581(7.1) 2.65(0.7) 2972(81) 26.9(12.4) 0.87(0.27)
II 43 15.2(15.4) 2.44(0.5) 5172(589) 27.4(11.0) 0.66(0.26)
III 12 63.0(44.3) 3.9(2.2) 15.7(2.2) 296(180) 17.0(7.9) 0.36(0.22)

P value 0.0002 0.003 0.02 0.03 0.02 0.05
When analyzed by disease stage, none of the above parameters differed between I and II; all were significantly different between groups III and IV. Among T-cell measures, CD4 correlated best with group, however, ESR, B-2-M and Hb were each a more sensitive predictor of Stage IV than CD4.

Conclusion: The B-2-microglobulin and ESR may be more sensitive than the T-cell markers and a less expensive means in monitoring HIV disease.

W.B.P.88 ROUTINE LABORATORY TESTS WHICH CORRELATE WITH HIV-1 INFECTION PRIOR TO ONSET OF AIDS

William D'Arcy*, T. Hooton*, S. and Sacks, H.S. *Foundation for Research on Sexually Transmitted Diseases, NY, USA; *New York City Department of Health, NY, NY, USA, and **Mount Sinai School of Medicine, NY, NY, USA

Objective: To identify routine laboratory tests whose results can correlate with HIV-1 infection in asymptomatic people.

Methods: A group of 110 apparently healthy, formerly drug addicted women was evaluated during 1983-1985. The relationship of routine laboratory tests to anti-HIV-1 antibody presence was evaluated by univariate and multivariate analysis. HIV-1 testing by ELISA with confirmation by Western blot method found 46 of these women to be positive for anti-HIV-1 antibodies. None had AIDS or ARC at the time of evaluation.

Results: Even in the asymptomatic stages of the disease process, there is evidence of statistically significant values (p<0.05) in increased globulin (Glb), and decreased albumin (Alb) and albumin/globulin ratio (Alb/Glb), leucocytosis (Leu), white blood count (WBC), lymphocytes (Lym), cholesterol (Chol), sodium (Na), iron (Fe) and calcium (Ca) levels in the anti-HIV-1 positive women (values expressed as Means with Standard Deviations).

Stats	n	Glb	Alb	Alb/Glb	Leu	WBC	Lym	Chol	Na	Fe	Ca
Anti-HIV-1	46	7.4	3.92	1.089	10.26	5.531	2.004	156.89	135.53	74.93	8.86
Non-Infected	64	6.02	4.11	1.396	10.24	5.004	1.917	154.82	130.65	68.20	8.93
SD		0.72	0.34	0.227	3.57	1.477	0.579	39.78	3.83	27.16	0.39
Chi-Sq		3.57	0.23	0.207	3.58	1.948	1.815	30.04	2.69	18.24	1.03

Conclusion: This profile of results is indicative of the pattern of early seroconversion common to ARC and AIDS. The clinician can be alerted to suspect HIV-1 infection in these early stages, prior to the onset of ARC, by detecting this pattern of high globulin with "low normal" chemistries and blood counts. This pattern needs to be confirmed in other populations.

W.B.P.90 THE USE OF SERUM MONOCLONAL ANTIBODIES TO MONITOR THE COURSE OF HIV-INFECTION.

Panayiotou, Nicholas*, and Cosello, R.*

*National Institutes of Health, Bethesda, Maryland, USA.

Objective: To use oligoclonal bands as markers to follow the course of HIV-infection.

Methods: The increased sensitivity of our antigen-capture technique to determine serum proteins demonstrates discrete oligoclonal immunoglobulin bands (OIB) with an intense diffuse γ -globulin zone. Originally OIB were found in the serum of HIV-antibody carriers. Subsequently the serum OIB were identified with HIV-antigen. Presence of OIB in the serum of HIV-antibody carriers indicates a specific immune response of the host to HIV infection. This electrophoretic technique is used to monitor OIB in serum samples of asymptomatic HIV-antibody carriers. Testing is done every six months to correlate persistence and disappearance of OIB with progression of HIV infection to AIDS.

Results: Serial analysis of serum samples from 18 HIV-antibody carriers was performed for three years. During this period in 14 of 68 carriers (20%) disappearance or absence of OIB was associated with the development of clinical AIDS.

Conclusion: Millions of people worldwide are infected with HIV. Little is known about the factors the influence progression of infection to AIDS. Determination of OIB at defined time intervals serves as a useful marker to follow the clinical course of the infection in its progression to clinical AIDS.

Aspects cliniques Clinical Aspects of AIDS

W.B.P.91 CSF NEOPTERIN IN HIV-1 INFECTION AND AS A FUNCTION OF AIDS DEMENTIA COMPLEX (ADC) SEVERITY
 Bross, Bruce J.; Balla, R.; Schwartz, W.; Price, R.W. Memorial Sloan-Kettering Cancer Center, New York, NY USA

Objectives: To determine the clinical significance of elevated concentrations of neopterin in the cerebrospinal fluid (CSF) of HIV-infected individuals and assess the value of CSF neopterin as a marker of ADC.
Methods: 50 samples of CSF and serum from 44 neurologically symptomatic patients at various stages of HIV infection were analyzed by radioimmunoassay (a gift from Kallestad) for neopterin and albumin (CSF and serum). All patients had been assessed by a neurologist and staged according to the presence and severity of ADC.

Results:

Neurological	#	CSF Neopterin (pmol/l)	Serum Neopterin (nmol/l)	Albumin (g/dl)
Normal	15	54.3 ± 27.1	37.3 ± 29.1	29.8 ± 3.4
Mild Dementia	4	71.7 ± 59.3	78.8 ± 5.4	32.2 ± 3.0
Severe Dementia	21	29.8 ± 15.0	32.2 ± 3.0	27.0 ± 25.3

In the CSF only patients, CSF neopterin correlated with ADC severity ($p < .001$) but not albumin ratio.
Conclusions: CSF neopterin is frequently elevated in HIV-infected individuals and is at such a non-specific. In those patients with ADC without other confounding illnesses, CSF neopterin correlated with ADC severity and seemed to be independent of blood-brain barrier dysfunction. As such, it may prove useful as a marker of ADC when other confounding illnesses are absent.

Diagnosis: HIV

W.B.P.93 EFFICIENT SCREENING FOR HIV 1- AND HIV 2-ANTIBODIES WITH A 3RD GENERATION ASSAY
 Knapp, Ulrich; Rasmussen, J.; Jullien, Th.; Engels, R. Institut für Virologie, 3550 Marburg, FRG

Objective: To describe the features of a new ELISA ("Enzygost-Anti-HIV 1+2") based on synthetic peptides corresponding to env-proteins of HIV 1 and HIV 2.
Methods: 50 µl undiluted specimen are added to 50 µl diluent into each well of microtiter plates coated with a cocktail of 4 synthetic peptides. After an incubation for 20' at 37 °C and 4 washings, 100 µl of peroxidase labeled Anti human IgG are added and incubated for another 30' at 37 °C. Colour development was allowed after 4 washings for 30' at RT using TMB.
Results: Of 708 Anti HIV 1-sera and 198 Anti HIV 2-sera all specimens reacted positive, whereby the majority of about 95 % showed O.D. values greater than 2.0. Compared to 2nd generation assays an improved efficiency was found by clear cut positive results of 12 Anti HIV 1-seroconvertors and 5 samples from early stages of HIV 2-infections. By testing 789 sera from healthy blood donors and 5000 plasma as well as 758 "risky" specimens an overall specificity of 99.98 % was calculated. No false positive reactivity could be observed after the treatment or freeze-thawing of sera and plasma specimens.
Conclusions: These results and the ease of handling make this new assay most suited for the reliable screening for both Anti HIV 1 and Anti HIV 2.

W.B.P.95 A SEMIAUTOMATED DOT BLOT IMMUNOASSAY FOR THE CONFIRMATION OF HIV SEROPOSITIVITY
 Knapp, Ulrich; Rasmussen, J.; Kapslak, W.; Schöler, J.; Stephens, et al. Abbott Laboratories, North Chicago, IL, USA

Objective: To develop an HIV confirmatory assay which is more sensitive and specific than Western Blot.
Methods: Purified recombinant proteins of HIV-1 and HIV-2 are immobilized on nitrocellulose. The assay is conducted in a 35 C incubator surrounded for timed incubations, sample removal, washing, drying, and reflexion reading. A digital print-out records the intensities of the color reaction. The assay requires less than 3 hours to perform and utilizes an alkaline phosphatase detection system. The detection of antibodies to the HIV-1 ENV antigens in addition to either the GAG or POL antigens is used as the criteria for HIV-1 antibody confirmation. The detection of antibodies to the HIV-2 ENV is the criteria for HIV-2 antibody diagnosis.
Results: This assay, based on testing of dilution panels, is 8 to 16-fold more sensitive than the current commercially available Western Blot assays for HIV-1 or HIV-2. In a population of 50 AIDS-, 50 ARC and 50 seropositive individuals, all were detected by both the dot blot and Western Blot. One hundred percent correlation was found, with Western Blot, on a population of 75 normal blood donors.
Conclusion: This semiautomated dot blot immunoassay offers enhanced performance over the Western Blot with the additional advantage of a non-subjective instrument readout.

W.B.P.92 PREDICTIVE VALUE OF NEOPTERIN, β₂-MICROGLOBULIN AND THYMIDYLKINASE IN HIV INFECTION
 Bross, Bruce J.; Balla, R.; Schwartz, R.; Fowler, H.S.; Bogner, J.R.; Med. Poliklinik Universität München, FRG

OBJECTIVE: To determine the predictive value of β₂-microglobulin (β₂), Neopterin (Npt), and Thymidylkinase (TK) in patients (pts) with or without progression of HIV disease.
METHODS: 60 HIV-AB pos. pts in 4 groups with different clinical deterioration within 2 years (group I: progression III; group II: WR 6; III: WR 1 to WR 5; IV: WR 1 unchanged) were tested for lymphocyte subsets, β₂, Npt and TK.
RESULTS: Significant differences between all stages of WR were observed for CD4/E ratio (ratio) and β₂ for Npt only beginning with WR 3, for TK only between WR 1 and WR 6. Within group IV a significant increase of β₂ and decrease of the ratio were seen after 2 years despite unchanged classification in WR 1. Comparing WR 1 in group I and WR 1 in group IV revealed significantly higher values of β₂ and Npt, lower values for the ratio in group I.

CONCLUSION: Even in case of stable WR classification changes of β₂ and Npt, though unspecific, and ratio are highly predictive and indicate progressive disease. TK does not seem to have similar prognostic value.

W.B.P.94 The use of the N-terminal portion of the transmembrane protein for the early detection and discrimination of HIV 1 and HIV 2 infection

Yonkers, R.; Hirsiger, M.; Hesel-Schickel, H.; Nott, M.; Rothacker, R.; Wenzel, A.; Wolf, P.; Sommer, H.-H.; Beyer, G. Research Dept., Offenhof, FRG; 2 Geneva, Vetsuisse Institut, München, FRG; 3 Theodor-Kocher-Institut, Bern, Switzerland

Objective: To determine the usefulness of the transmembrane proteins for early discrimination of HIV 1 and HIV 2 infections.

Methods: A DNA-fragment coding for the N-terminal region of the transmembrane protein of HIV 1 and the corresponding sequence of HIV 2 which has been chemically synthesized were cloned and expressed in E. coli. The recombinant antigens were purified and further evaluated in ELISA-experiments.

Results: Both antigens could be efficiently expressed in E. coli and purified to homogeneity. The purity of antigens were well documented by SDS-PAGE, electrophoresis and Western Blot. In ELISA-experiments all sera obtained from HIV 1 and HIV 2 infected persons reacted with one of the recombinant antigens. Although a lot of sera reacted with both antigens a discrimination between HIV 1 and HIV 2 infection was possible.

Conclusion: The transmembrane proteins are very useful antigens for detection and discrimination of HIV 1 and HIV 2 infection.

W.B.P.96 Title : Improvement of anti-HIV-2 reactivity of Vironomax anti-HIV-III

Authors : E. D. Sprockens, P. Ten Kortenaar, J.A. Hallings, H.J. Thunnissen, J. Ariens, J. van Duyn, Diagnostics Research Lab., Organon International B.V., P.O. Box 200, 5340 BH, Oss, The Netherlands

HIV-2 has been described as a second causative agent of AIDS. Therefore anti-HIV-screening assays should be fully sensitive to both anti-HIV-1 and anti-HIV-2 antibodies.
 The existing competitive anti-HIV-1 EIA's have a sensitivity of 28-51% for anti-HIV-2 sera, existing indirect EIA's have a sensitivity of 70-93% for anti-HIV-2 sera. Anti-HIV-2 reactivity of anti-HIV-1 EIA's is mainly due to immunologic cross-reactivity of GAG and POL gene products of HIV-1 and HIV-2. We describe a new screening assay, the Vironomax anti-HIV 1+2, with a combination of HIV-1 viral lysate and HIV-2 synthetic peptides as antigens coated to microtiter plates. This combination of antigen results in an increased reactivity with anti-HIV-2 antibodies, without any loss of anti-HIV-1 reactivity. In a preliminary study of 22 anti-HIV-2 sera the sensitivity of the Vironomax anti-HIV 1+2 was 100%, compared to only 36% of the Vironomax anti-HIV-III, which is based on HIV-1 viral lysate only.

W.B.P.97

"DEVELOPMENT OF TWO DIAGNOSTIC SYSTEMS FOR HIV SEROCONVERSION USING TWO RECOMBINANT ANTIGENS"
 Authors: Bonifazi, J., Novoa, L. I., Machado, J. A., Garcia, J., Padr, G., Herrera, L., et al
 Center of Genetic Engineering and Biotechnology, C.Habana, Cuba

Objective: to develop two alternative diagnostic systems for HIV-antibodies detection using two recombinant antigens.

Methods: The recent development of second-generation tests based on simple and manual procedures for rapid diagnosis of HIV antibodies are said to be so reliable and easy to use, they could allow future application not only for clinical diagnosis - under elemental laboratory conditions, but also for their use in the undeveloped countries in order to eliminate the AIDS transmission by blood transfusion.

Two systems for HIV1 seroconversion were developed. An indirect sandwich type enzyme immunoassay and a visual test based on a membrane capture assay with detection of antibodies with a protein A-gold conjugated, both using two recombinant antigens - expression products of representative regions of the genes coding for the transmembrane gp-41 and the major core gp 24 - HIV-1 proteins.

W.B.P.98

CROSS REACTION BETWEEN HIV-1 AND HIV-2 OR DOUBLE INFECTION.
 R. Schuster (1,2), F. Gschmidt (1,2), Z. Mayer (1), J. Witterter (3), F. Benekovic (3), T. F. Schulz (4), M. Rieder (4), Department of Virology of the Hospital of Linz, Vienna, Austria (1), Ludwig Boltzmann Institute for Dermatovenerological Serodiagnosis, Vienna, Austria (2), Österreichische AIDS-Hilfe (3), Institute for Hygiene and Ludwig Boltzmann Institute for AIDS Research, Innsbruck, Austria (4).

HIV-1 and HIV-2 viruses exhibit a high degree of sequence homology, in particular in the core proteins. Antibodies to HIV-2 core proteins might cross-react with HIV-1 and vice versa, whereas envelope proteins are antigenically distinct. Distinction between antibodies to HIV-1 and HIV-2 thus is usually attempted on the basis of reactivity with envelope derived bands of HIV-1 and HIV-2 on Western Blots.

In the present study an ELISA-test system was established using recombinant HIV-2 envelope antigen corresponding to amino acids (E197) derived from core protein or extracted into the transmembrane proteins. This system recognized 17 out of 18 HIV-2 infected patients (one patient was in terminal disease and did not further produce antibodies), 12 sera, both reactive to HIV-1 (immunofluorescence and Western Blot) and conventional HIV-2 ELISA (Pastorex), were used for the experiments. 5 of these sera clearly stained the 10S IgG envelope band of HIV-2. However, none of them reacted with the recombinant HIV-2 envelope derived antigen. This study shows that antigenic cross reactivity between envelope proteins of HIV-1 and HIV-2 does exist and strict care should be taken in interpreting respective results.

W.B.P.99

EVALUATION OF HIV-1 AND HIV-2 ELISA BASED ON SYNTHETIC PEPTIDES OF gp41

Kura, C., Meins, F. K., and Parkhede, U. **
 * Institute of Virology, Vienna, Austria, **
 Pharcacia Diagnostica AB, Uppsala, Sweden.

Objective: Assessment of peptide-based enzyme-immunoassays for the detection of antibodies against HIV.

Methods: Three different tests were used: an HIV-1 assay based on a peptide from gp41, an HIV-2 assay based on the corresponding peptide from gp36, and a control-test which contains both the HIV-1 and the HIV-2 peptides.

Results: These tests were evaluated using two panels of sera. Panel A consisted of 700 HIV-1-positive sera which were all confirmed positive by Western blotting. Panel B consisted of 300 sera which had yielded false positive results upon screening in either the Organon ELISA or the Abbott Reagent ELISA but were Western blot-negative. All truly HIV-positive sera were also recognized as positive in the HIV-1 peptide- and in the control-test. About 20 percent of the HIV-1 positive sera were also reactive in the HIV-2 peptide ELISA. The absence values, however, were always lower than those obtained in the HIV-1 peptide ELISA and rapidly dropped off upon titration. With respect to specificity, the control-test-assy revealed a very low rate of false positive results. Only 16 out of 700 sera that had yielded a false positive result in other HIV assays were also repeatedly positive in the control-assay.

Conclusion: Due to its specificity and sensitivity the peptide-based ELISA seems to be suited as a routine diagnostic assay.

W.B.P.100

APTITUDE D'UN TEST RAPIDE POUR HIV1 ET DE TESTS D'AGGLUTINATION A DETECTER DES ANTICORPS ANTI-HIV1 AU SENGAL.

M. Boup, A. Sallamane*, Sankali, J. L., Kabeye, C. M.**, Diakhane, L.**, Thiam, D.**, Ndiaye, S.***
 *Bactériovirologie/Université de Dakar, Sénégal. **Projet SIDA/Kinshasa, Zaïre. ***Centre National de Transfusion Sanguine/Dakar, Sénégal. ****ADTBCEP/Family Health International, USA.

Objectif: Evaluer l'efficacité de tests d'immunoanalyse sur membrane (DOT-Blot) et d'agglutination coqueux pour HIV1 au Sénégal, pays en cours à la fin HIV1 et HIV2.

Méthodes: 2000 prélèvements sanguins de diagnostic de sang, de personnes à haut risque, et de patients suspects de SIDA ont été testés par HIVCHECK (Dipon, USA). Tous les positifs, les indécidés et 10% des négatifs ont été testés en double en RIFOROLL (Abbott) et en SERODIA-HIV (Purijapan, Japon). Tous les sérum ont aussi été testés par ELISA on HIV1 et HIV2, puis les positifs par Western-Blot HIV1 et HIV2.

Résultats: Cette étude est en cours et sera achevée en Janvier. Les résultats et la spécificité des 3 tests pour la détection de HIV2 seront étudiés.

Les résultats préliminaires sont les suivants:

CONTRIBUTION OF SYNTHETIC PEPTIDES (SPV) TO THE SEROLOGICAL DIAGNOSIS OF HIV-1 AND HIV-2 REACTIVITY.

Escilla, Guadalupe, Barrena, J.M., Gil, M.P., Bayo, A., Gattell, J.M., and Casado, R. Blood Bank and Infectious Dept. Hosp. Aol. Central, Barcelona, Spain.

Objective: To determine the extent of HIV-2 infection in high risk populations and its relationship with HIV-1 infection.

Methods: HIV-1 and HIV-2 antibodies were studied in sera of 218 individuals at risk, 22 out of the seropositive individuals HIV-1 Western Blot, and 70 (Venezuela) and HIV-2 (Ivoria). The positive results were confirmed by Western Blotting. Panel B consisted of 300 sera which had yielded false positive results upon screening in either the Organon ELISA or the Abbott Reagent ELISA but were Western blot-negative. All truly HIV-positive sera were also recognized as positive in the HIV-1 peptide- and in the control-test. About 20 percent of the HIV-1 positive sera were also reactive in the HIV-2 peptide ELISA. The absence values, however, were always lower than those obtained in the HIV-1 peptide ELISA and rapidly dropped off upon titration. With respect to specificity, the control-test-assy revealed a very low rate of false positive results. Only 16 out of 700 sera that had yielded a false positive result in other HIV assays were also repeatedly positive in the control-assay.

Conclusion: Due to its specificity and sensitivity the peptide-based ELISA seems to be suited as a routine diagnostic assay.

W.B.P.102

TYPE SPECIFICITY OF THE HIGHLY IMMUNOREACTIVE EPITOPES OF HIV-1 AND HIV-2

M. Boup, A. Sallamane*, Narváez, A.**, Kontin, S.**, Rescaudini R.**, Viacanti, M.**, Ndiaye, S.***
 *Laboratory Research/Laboratoire, Helsinki, Finland; **Laboratorio Microbiologia, Ospedale Nona, Monza, Italy; Department of Clinical Microbiology, Ospedale San Carlo, Genova, Italy.

We have developed sensitive EIA's to detect human serum antibodies elicited against HIV-1 and HIV-2. EIA's are based on synthetic peptides derived from transmembrane protein gp41 and gp36 respectively. These peptides share 20% homology with each other. In our earlier studies we have compared the HIV-1 specific gnp peptide EIA to other antibody assays, while specificity of HIV-1 and HIV-2 gnp peptides by using HIV-1 positive human sera from North-Italy and HIV-2 positive sera from West-Africa. In the case of 100 HIV-1 positive sera all reacted with HIV-1 gnp peptide, 20% of them reacted with HIV-2 gnp peptide. 25% of HIV-2 positive sera reacted with HIV-1 gnp peptide. HIV-1 and HIV-2 gnp peptides reacted with the mixture of HIV-1 and HIV-2 peptides. In the case of cross-reactivity, it remains open if the reaction is based on sequence homology or if these cases are true double infections. In order to solve this question, seroconversion panels from patients infected with HIV-1, two of these cases can be detected earlier in HIV-1 gnp peptide EIA than in HIV-2 gnp peptide EIA, the rest are detected parallel with whole virus EIA (Narváez et al., J. Med. Virol. 26:171-178, 1988). [Part of this work was conducted with J. Med. Virol. 26:171-178, 1988]. [Part of this work was conducted with International].

W.B.P.121 TESTPACK HIV-1 RAPID ASSAYS CAPABLE OF DETECTING ANTIBODIES TO HIV ANTIGEN IN SERUM, PLASMA, AND

Rachelle A. Wain, J.M. Pennington, K.M. Keig, J.M. Staller, L.A. Provorovsky, A. Marwaha, Abbott Laboratories, North Chicago, IL and Howard Brown Memorial Clinic, Chicago, IL, USA

Objective: To develop rapid, visual immunoassays to detect antibodies to Human Immunodeficiency Virus 1 and 2. These assays require minimal sample preparation, minimal technical expertise, no sophisticated equipment and provide easily interpretable results.

Methods: These tests utilize full length recombinant antigens gp24 and gp41 from HIV-1 either alone or in combination with gp41 from HIV-2. An internal control is incorporated to alert the user to procedural errors. Assays can be completed in 10 minutes, using whole blood, serum or plasma, with results read visually as a plus (+) or minus (-) sign.

Results: Study sera and 133 ELISA positive, Western blot confirmed HIV-1 samples were tested with the HIV-1 and HIV-1/HIV-2 assays, respectively. Each sample contained whole blood and matched serum or plasma. Both assays detected 100% of the samples from 98% on HIV-1/HIV-2 to 99% on HIV-1. Whole blood, obtained via fingerstick from 15 normal blood donors, was negative in both assays. The presence of the autoantigenes B2A, hepatitis and sodium chloride did not interfere with the performance of either assay.

Conclusions: These rapid assays demonstrate high sensitivity and specificity and are ideal for use in situations which preclude the use of conventional ELISA tests, e.g., appropriate for use in situations which preclude the use of conventional ELISA tests and small blood transfusions, emergency rooms, organ transplant, physician offices and small laboratories.

W.B.P.122 UNIQUE IMMUNOREACTIVITY OF A NORMAL HUMAN SERUM WITH RECOMBINANT HIV-1 *env* GENE PRODUCTS

John, James J. Demaree, J. J. Frankl, T. Terry, P. P., Roncazio, D., Lodi, M., et al. Transfusion Medicine, NIH, Bethesda, MD, Roche Diagnostic System, Nutley, NJ, USA.

Objective: To assess an anti-HIV-1 ELISA test based on recombinant products *env* to identify the specificity and significance of the immunoreactivity between the serum of a normal blood donor and recombinant HIV-1 envelope proteins.

Methods: Clones containing different regions of HIV-1 *env* were constructed and recombinant protein were produced and used as antigen in enzyme linked immunosorbent assay. Sensitivity for the detection of anti-HIV-1 was assessed with a panel of known positive specimens. To assess the specificity and the significance of this immunoreactivity, recombinant profiles of urine or overlapping sequences from different sections of *env* gene were also produced and used as antigen.

Results: Cross-reactivity in detection of anti-HIV-1 by recombinant products was observed with a panel of known positive sera in comparison with commercial tests made of viral culture products. A strong anti correlation reaction between protein of normal donor serum with recombinant products was observed. Serum from this donor was not reactive in any currently available commercial anti-HIV-1 ELISA tests, Western blot or radioimmuno precipitation assay. **Conclusions:** A specific immunoreactivity between a blood donor serum with a specific region of HIV-1 envelope protein *env* was identified with recombinant products. This immunoreactivity was unique and its biological significance remained to be assessed.

W.B.P.123 IMPROVED *in situ* DETECTION OF HIV NUCLEIC ACID WITH FLUORESCENT PROBES AND LASER EXCITATION.

Hart, L. Donagan, Biontech Research Wf, and Golden Eye, California, Davis, California, U.S.A.

Objective: To develop more sensitive instrumentation to detect and quantitate HIV infected cells in culture and in clinical specimens using nonradioactive *in situ* hybridization.

Methods: Acetylaminofluorene (AAF) HIV DNA probes were made and reacted by *in situ* hybridization with HIV infected CEM cell lines. The AAF-labeled probes were detected using rabbit antibodies to AAF, followed by an antirabbit antibody that was labeled with fluorescein. Samples were excited at 488 nm using either a 40 mW argon ion laser, or using a conventional 100 W mercury arc source. The fluorescent emission was detected through a 530 nm using a CCD video camera. The percentage of cells stained and their fluorescent staining intensity was quantified using a semi-automated computerized image analysis system and computer programs developed by us.

Results: Comparison of the numbers and intensity of cells stained *in situ* using the laser and mercury source showed that the laser had: 1) a 10 fold increase in fluorescence signal intensity and 2) improvement in the signal to noise ratio to avoid auto fluorescence.

Conclusions: *In situ* detection of HIV nucleic acid using fluorescent probes and an argon ion laser excitation source is more sensitive and has a higher signal to noise ratio than a mercury excitation source.

W.B.P.124 DETECTION OF HIV IN Hematopoietic Cells from Patients with AIDS and AIDS-related Complex (ARC).

Sun, Hsueh-Su, L. Hsu, H-T, Conrad, A., Shapshak, P., Bell, G., and Isajawa D.

Harbor-UCLA Medical Center, Torrance, CA, U.S.A. and *Marsden W.A. Medical Center, Los Angeles, CA, U.S.A.

Objective: To test the hypothesis that hematologic abnormalities in patients (G1) with ARC and AIDS were related to direct and persistent HIV infection of the hematopoietic precursors in the bone marrow.

Method: We used ³²P-labelled cDNA probe and *in situ* hybridization (ISH) method to detect the presence of HIV nucleic acids in formalin-fixed, paraffin-embedded bone marrow sections from ARC and AIDS (ten in each group) and five non-HIV-infected pts. **Results:** Positive cells were found in all ten ARC and eight AIDS pts, but none in two AIDS and five non-infected pts. Most positive cells were mononucleated, resembling lymphocytes and histiocytes. Endothelial cells, interdigitating reticulum cells, erythrocytes, nucleated red cells and immature myeloid cells also labeled with radioactive material in some instances. Positive cells were usually few and far between in each specimen. Megakaryocytes, epithelial histiocytes, fibroblasts, fibrocytes, osteoblasts, osteocytes, and osteocytes were consistently negative.

Conclusions: (1) ISH is a useful tool for identification and localization of HIV in tissues. (2) HIV is capable of infecting cells which do not have CD₄ receptors, and may become symbiotic with the host cells and cause latent persistent infection. (3) Hematologic manifestations in ARC and AIDS pts are at least partly caused by direct HIV infection.

W.B.P.125 SEROCONVERSION FOLLOWED BY RECOMBINANT- AND SYNTHETIC PEPTIDE BASED ANTIBODY ANALYSIS

Lauzinger, Robert J. Peterson, C., Vejlgaard, G.L., Lindhards, B., Black, F., Bernal, P., et al.

*Statens Serum Institut, Copenhagen, Denmark, **HIV Center, Copenhagen, Denmark, ***Fibiger Institute, Copenhagen, Denmark, ****Statens Serum Institut, Aarhus, Denmark, *****Sahlgrenska sjukhuset, Göteborg, Sweden

Objective: To define the sensitivity of recombinant- and synthetic peptide based anti-HIV ELISA tests.

Methods: A total of 290 sera, which were collected during the weeks and months of seroconversion, from 75 patients were studied with anti-HIV tests. The 28 patients had acute symptoms, while 47 patients did not report any symptoms connected to seroconversion. For 5 patients the time of exposure was reported. The sera were tested by two different anti-HIV peptide ELISA tests based on synthetic peptides (Pharmacia), recombinant DNA based anti-HIV test (DuPont), and immunoblotting (western blotting) (DuPont).

Results: Second generation anti-HIV analysis with recombinant- and synthetic peptide antigens showed specific antibody detection within 5 weeks from exposure to HIV. - the anti-HIV test appeared no later than 4 weeks from onset of symptoms, and most were within the first weeks after exposure. The immunoblotting test and the second generation ELISA tests were positive either simultaneously, or positive test results were only removed one sample from each other.

Conclusion: The serological "window" of acute HIV infection can be reduced by 3-5 weeks by recombinant- and synthetic peptide based anti-HIV assays.

W.B.P.126 HIV-1 POL synthetic peptides

E.D. Sranzanas, J.J. Schalken, J.A. Hellings and R. v. Sprang.

Diagnostica Research Lab, Organ International B.V., P.O. BOX 20, 5340 RH, Oss, The Netherlands

The HIV-1 POL amino-acid sequence was analysed for antigenic epitopes by the epitope-prediction programmes such as Hopp and Woods. Of the epitopes predicted by this method 14, partially overlapping, peptides were synthesized by solid phase methodology. The peptides were cloned to microtiter plates and analyzed for reactivity with anti-HIV-1 sera. We identified 3 anti-HIV-1 reactive peptides: AA 230-244 (IKKDKSTKWRLLVDF), AA 945-959 (TKGNFRVYRDRSN) and AA 975-994 (AVVQDQNSDKVYRRAKQ). The reactivity of these peptides could be increased by conjugation of the peptides to bovine serum albumin.

Immunosays, based on a single one of these POL-peptides as antigen, however, did not yield 100% sensitivity with P65/51 and P31 western blot positive anti-HIV-1 sera.

W.B.P.139 CHARACTERIZATION AND CLINICAL SIGNIFICANCE OF HIV p24 ANTIBODY

Melan Rosen*, Thya R. Fico, R.*, Falk, L.* and Allain, J.-P.*
*Abbot Laboratories, Abbott Park, IL, USA

Objective: Detect and quantitate p24 antibody (p24 Ab) to monitor natural history and therapy of HIV antigen (HIV Ag) negative individuals.

Methods: Solid phase was coated with recombinant p24 antigen to capture specific antibody. The same antigen labeled with HRP^o was used as a probe. Titer and slope of p24 Ab were obtained by plotting the optical density (OD) of 5 dilutions of each sample and extrapolating the intercept at a cutoff of 0.1 OD. These parameters were correlated with HIV Ag level and clinical condition.

Results: A wide range of slopes ($n = 61$; $n > 10$) reflected the variability of p24 Ab affinity and prevented use of a reference curve for quantitation. The distribution of HIV p24 Ab and Ag in seropositive persons stratified according to clinical condition is shown in the Table. Mean p24 Ab titer was lower in patients with AIDS (432) than AIC (841) or asymptomatic (1637). All but 1 p24 Ab negative sample were HIV Ag positive; in 15.3% of samples, p24 Ag and Ab were not detectable.

Clinical Condition	Number of positive HIV p24 Ab titers	Number of HIV Ag positive	Serial samples from anti-p24 Ab titers	Serial samples from anti-p24 Ag	Asymptomatic homosexual males
AIDS	122 (3)	317 (7)	197 (43.5)	21 (6)	Lower 2-3 years showed either a decline (48%) or no change (52%)
AIC	1 (50)	1 (60)	9 (24)	1 (12)	Stable
AIDS	1 (60)	2 (30)	40 (50)	1 (24)	Receiving antiviral therapy, only those treated with zalcitabine AZT-did. recovered p24 Ab after disappearance of HIV Ag.

Conclusions: Indicate quantitative p24 antibody provides information on the natural history, the clinical prognosis and the efficacy of anti-viral therapy in HIV infected persons.

W.B.P.141

HIV-1 SEROPOSITIVE INDIVIDUALS RECOGNIZE DIFFERENT EPITOPES OF P17: POTENTIAL FOR STAGING DISEASE

Paul H. Ravitt*, George A. Goldstein*, G. Simmonds*, P.S. Barlow*, S.S. Wang*, *The George Washington University, Washington, DC; **NIH, Bethesda, MD; **Westral Technologies Inc., Washington, D.C.; ***A.A. Qianqian, Development of an ELISA method to quantitate the levels of antibody to specific epitopes of HIV p17.

Methods: Synthetic peptides of 12 to 20 amino acids in length, representing the entire HIV p17 protein were synthesized. The presence of antibodies in serum to the peptides was determined using an ELISA procedure. Enhanced reactivity and lower backgrounds were achieved using peptide-BSA conjugates.

Results: Individuals who are seropositive for HIV p17 were found to recognize different epitopes on p17 as defined by the synthetic peptides. The peptide representing the C-terminal appeared to be more immunogenic while the N-terminal was least immunogenic. Antibodies to the p17 peptide representing the p17 candidate AIDS vaccine epitope (HIV-30) i.e., amino acids 85 to 115, (Taylor et al., 1985-88, 1987) were seen by antibodies from a subset (~30%) of seropositive individuals.

Conclusions: Recent observations indicate that a decline in antibodies to antibodies to p17 (Lange et al., AIDS 1, 155, 1987). These studies with p17 may provide a more diagnostic assay to stage clinical disease progression, and identify *in vivo* epitopes for inclusion in an HIV vaccine.

W.B.P.143 SIMPLE EASY TO USE HIV-1 RECOMBINANT ANTIBODY BLOOD ANTIBODY TEST

Richard Howard, M. Mtns., I. Genderson, A.G. Weiss, T., Heigh, V., Gufford, T.
Calypte Biomedical Company, Berkeley, CA, USA

Objective: Calypte Biomedical Company (CBC) has developed a simple and easy to use dipstick assay for HIV-1 antibodies. In this study, we evaluate the detection of antibodies to HIV-1 in the blood serum of patients with HIV-1 infection.

Methods: A dipstick format with recombinant HIV-1 envelope and core proteins was used to detect antibodies to HIV-1. 100 µl of blood or 100 µl of serum is added to the first tube containing the antigen. The E1 buffer is formulated to reduce background contamination. The dipstick is added, incubated for 30 minutes at ambient temperature, washed, incubated in conjugate and washed. Substrate is added to each of the wells and stopped after 10 minutes. Results are read as presence of color (positive) or no color (negative). Samples were taken from proficiency panels supplied by Massachusetts General Hospital, New York University, Center for Disease Control, Boston Biomedical and San Francisco Bay Area physicians.

Results: The proficiency panels taken together show: 1) the CBC E1 test was more sensitive than FDA licensed HIV-1 antibody test formats, 2) no false positives were observed and 3) there was 100% correlation of 43 observations with respect to positive and negative responses.

Conclusions: The CBC E1 HIV-1 antibody test is simple and easy to use. We have validated the efficacy of the E1 blocking buffer with respect to false positive samples (originally identified by FDA licensed tests). The test also accurately identified known effluent sample types such as sera that are hemolytic, lipemic, icteric or from patients with rheumatoid factor or rheumatic lupus erythematosus.

W.B.P.140 EVALUATION OF THE WELLOCORRE RECOMBINANT ENZYME IMMUNOASSAY

Quintanilla, P.J., Jimenez A., Conroy, D.A.
*Centre for Immunology, St. Vincent's Hospital, Sydney, Australia
**The National Health and Medical Research Council Special Unit in AIDS Epidemiology and Clinical Research, The University of New South Wales, Sydney, Australia

Objective: To evaluate the performance of the Wellocorre HIV-1 Recombinant Enzyme Immunoassay (EIA) in a clinical laboratory.

Methods: 1821 serum samples collected from patients with AIDS, ARC or Asymptomatic HIV infection and 36 serial serum samples from 2 seroconverting subjects were tested by the Wellocorre enzyme assay. 5 other commercial EIAs were tested on the seroconversion panel and level of detection were compared.

Results: 1821 out of 1821 samples from known anti-HIV positive patients were correctly identified by the Wellocorre assay indicating a sensitivity of 100% in this population. There was total agreement between the Wellocorre and the Wellocorre Physical assay and the Genetic Systems LAV EIA which had also been tested to test these sera. The Recombinant assay detected anti-HIV in 70% of samples collected in the seroconverting panel, compared with 50% detected anti-HIV in 70% of samples collected in the seroconverting assay which detected 20% in samples collected in the following two weeks the Wellocorre assay detected anti-HIV in 100% of seroconverting samples. No seroconversion was seen in any of the first week but onset of symptoms. In a multicentre random blood donor trial conducted by the Australian Red Cross Blood Transfusion Service on 2007 samples, no sample was repeatedly negative by the Recombinant assay, indicating a specificity of 100%.

Conclusions: The Wellocorre Recombinant assay (based on recombinant envelope and core antigens specifically captured onto microtitre wells to ensure monoclonal antibody and anti-HIV) is a sensitive and specific test well suited to a clinical laboratory.

W.B.P.142 DETECTION OF HIV-1 ANTIBODIES IN URINES OF ASYMPTOMATIC AND ARC AIDS PATIENTS

Quintanilla, P.J., Genderson, A.G., Wang, J., Fagan, B., Conroy, D.A., Cas, W., Gufford, T., Heigh, V., *Calypte Biomedical Company, Berkeley, CA, **New York University, New York, NY, USA

Objective: We (APC, NY) have reported detection of antibodies to HIV-1 in the urine of HIV-1 seropositive (infected) individuals using FDA licensed tests. In this study, we use a recombinant protein dipstick format, we evaluate the detection of antibodies to HIV-1 in the urine of HIV-1 individuals.

Methods: Immunologic recombinant HIV-1 envelope protein on a dipstick (Calypte Biomedical Company) (CBC) E1 test format was used to detect antibodies to HIV-1 in uncentrifuged urine. The test was carried out at room temperature. Urines tested were random samples collected from 30 HIV-1 seropositive and 3 ARC/AIDS patients and 20 HIV-1 seronegative (50) individuals. Results were read by 5 different observers as positive or negative to the presence of blue color in 10.

Results: All urines from HIV-1 individuals tested negative. Positive and negative controls reacted appropriately in all 50 urine samples.

Conclusions: There was a high correlation between reactivity of urine to HIV-1 recombinant envelope protein and serum reactivity in FDA licensed HIV-1 antibody blood tests for both positive (20/20) and negative (20/20) urine samples. These data suggest that blood of urine can be used as a sample source for the detection of HIV-1 or antibodies. There is a lower risk for false care workers testing for HIV-1 antibodies in urine rather than blood due to 1) substantially lower incidence of infectious HIV-1 virus in urine and 2) minimizing venipuncture and exposure to blood. The CBC dipstick test format used at room temperature allows to testing in nonclinical laboratory situations.

W.B.P.144 MULTIPLEXED RESPONSE TO HELIX AND RECOMBILANT-ADSORBED AID ANTIBIOTIC

Quintanilla, P.J., Jimenez A., Conroy, D.A., Fagan, B., Conroy, D.A., Cas, W., Gufford, T., Heigh, V., *Calypte Biomedical Company, Berkeley, CA, **New York University, New York, NY, USA

Objective: To evaluate the ability of recombinant immunity to a used synthetic peptide, to elicit a specific immune response in HIV-1 infected individuals.

Methods: Peripheral blood mononuclear cells (PBMC) obtained from 10 HIV-1 patients (5 AIDS, 5 ARC) were cultured in 96-well plates in triplicate for 4 days with different concentrations of a viral synthetic peptide (10, 100, 1000, 10,000, 100,000, 1000,000, 100,000,000) and added to the culture wells. The cells were harvested and analyzed for the presence of antibodies to the synthetic peptide.

Results: HIV-1 infected individuals were tested under the same experimental conditions a minimum time of 1720 of contact with peptide was completed as positive results. Specific T cell proliferative response was triggered by the synthetic form of the peptide. In contrast, the adherent factor elicited a significant humoral transformation in 2 out of 5 AIDS patients, 4 ARC and 1 control. No response was found in AIDS patients 10 and 2 control, respectively. In AIDS subjects a seropositivity effect of the adherent antigen on the proliferative response was observed. In all but one control donor, no significant anti-HIV recombinant proliferation was observed.

Conclusions: The results indicate that 4000 peptide epitopes to HIV envelope glycoprotein can be recognized by distinct synthetic peptides, under the suitable form, does not elicit HIV proliferative response. The data set show that synthetic HIV-1 peptides. The results indicate that the synthetic peptide response time, a cross-reactivity to used structures are seropositive in HIV-1 individuals. The specific cell delivery to HIV in AIDS patients are contrasts to the autologous immune response.

W.B.P.157 APPLICATION OF VIRUS CULTURE AND PCR FOR HIV DETECTION IN BLOOD DONORS WITH PERSISTENT ANTI-p24 REACTIVITY IN WESTERN BLOT

Van Der Poel, C.M.*; Wester, M.**; Roessink, H.*; Vermeulen, H.P.F.; Beutels, E.*; Buisson, L.**
* Red Cross Blood Bank, Amsterdam, ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.

Objective. To investigate the presence of HIV in blood donors with persistent indeterminate anti-p24 reactivity in HIV Western Blot.
Methods. PB1 from 11 blood donors with persistent anti-p24 in HIV WB, previously described as non infective to recipients of blood (Lancet 1986;i:752-53) and HIV positive cells were co-cultivated with PHA stimulated PB1 from HIV negative donors, and cultured for 30 days. HIV expression was monitored and p24 enzyme assay. After culturing PB1-DNA was isolated and applied in PCR. The PCR was performed with 2 primer sets for pol and gag. Positive amplifies were confirmed on Southern Blot using internal oligonucleotides with 40% by specific for pol and gag respectively, radio labeled with ³²P.
Results. None of 11 donors with persistent anti-p24 reactivity in WB were found positive in culture. The results of PCR analysis will be presented.
Conclusions. Will be discussed.

W.B.P.159 DETECTION OF HIV-1 SPECIFIC ANTIBODIES AND NEUTRALISING ACTIVITY (NC ACT) IN THE URINE OF SEROPOSITIVE PERSONS.

Dietrich, D.*; 4 Friedman-Zim, A.B.*; *New York University Med. Center, NY, NY; McGill School of Medicine, Cedars-Sinai Med. Center, Los Angeles, CA, U.S.A.

Objective. To detect antibodies to HIV-1, including neutralizing antibodies in urine samples from 56 HIV-1 seropositive individuals.
Methods. Fifty-six persons including 17 patients with AIDS-2, 16 with AIDS-1, 8 with ARC and 23 asymptomatic seropositive homosexual men were tested for HIV-1 specific antibodies in both serum and urine (concentrated 100-200X) by ELISA, Western blot (WB), and RIFA. HIV-1 RT act. was determined using a neutralization assay performed with the 89 clone as target cells and HIV-1 RNA as the viral inoculum.

Sample	No. reactive (N)		No. reactive (K)		NT
	By WB	By RIFA	By WB	By RIFA	
Serum ELISA	52/54	52/54	52/54	52/54	52/54
Urine	43	34	36	35/46	41/46
NC ACT	100.0 (40.4)	76.4 (28.4)	100.0 (37.6)	89.1 (32.7)	100.0 (41.1)
Urine	35	41	36	30/46	32/46
RT act.	39.2 (14.3)	37.3 (13.8)	30.0 (11.1)	48.3 (17.6)	33.3 (12.3)

The titers of the HIV-1 antibodies and HIV-1 RT act. found in the urine corresponded to the titers of the antibodies to HIV-1 and RT act. in the serum.
Conclusions. 1) Specific antibodies to HIV-1 were detected in urine of HIV-1 seropositive individuals. 2) HIV-1 RT act. was shown in 30% concentrated urine from those who were HIV-1 antibody positive in both serum and urine. 3) The anti-HIV-1 antibodies in the urine may be derived from the serum.

W.B.P.161 The Use of Recombinant HIV ELISA Kits as a Secondary Supplement for Serological Laboratory Tests have made the serological diagnosis of HIV infection far more reliable in recent years.

Improvements in the sensitivity and specificity of HIV ELISA kits and in the performance of Western Blot (WB) serological tests have made the serological diagnosis of HIV infection far more reliable in recent years.

We initiated a study involving over 3000 sera to evaluate the performance of a Recombinant HIV ELISA kit from Cambridge Bioclines (CBC), which employs 96 well microtitre plates coated with recombinants proteins from the gag and env gene products of HIV. In an initial analysis, 333 blot indeterminate, 362 blot positive and 321 blot negative samples were retested using the CBC test. The samples were retested in that all were submitted for reference analyses were tested by the CBC procedure. All immunoblot positive sera were positive by CBC while 23 of the 333 blot indeterminate sera were positive using this recombinant test. One of the 511 blot negative samples was positive by the CBC test and could represent a false positive result. This preliminary evaluation indicates recombinant protein-based kits may be extremely useful adjuncts in HIV testing especially when used as supplemental tests.

W.B.P.158 ANTI-NEF ANTIBODIES IN BLOODDONORS WITH PERSISTENT ANTI-p24 REACTIVITY IN HIV WESTERN BLOT, AND CHARACTERIZATION WITH RECOMBINANT p24 IN IMMUNOBLOTTING, BLIT AND ELISA.

Van Der Poel, C.M.*; Wester, M.**; Roessink, H.*; Buisson, L.**
* Red Cross Blood Bank, Amsterdam, The Netherlands ** Diagnostics Pasteur, Marne-la-Coquette, France.

Objective. To investigate the presence of anti-Nef antibodies as a marker of HIV infection in blood donors with indeterminate anti-p24 HIV Western Blot reactions, and to further characterize this reactivity employing recombinant p24 as antigen.
Methods. Serum samples of 11 blood donors with persistent isolated anti-p24 reactivity in HIV Western Blot, previously described as being non-infective to recipients of blood (Lancet 1986;i:752-53) and 10 anti-Nef antibody-diagnostic Pasteur) employing recombinant Nef protein (Transgene), diagnostic Pasteur), obtained native from E. coli as an antigen. Recombinant p24 and ELISA with recombinant p24 protein (Transgene, diagnostic Pasteur), and afterwards transferred to a nitrocellulose membrane. Immunoblotting was performed by electrophoresis according to electric current in a gel gradient and in second dimension by molecular weight with SDS-PAGE, and afterwards transferred to a nitrocellulose membrane.
Results. In recombinant p24 ELISA 5/11 sera were repeatedly positive and 1/11 was borderline positive. In immunoblotting blot 3/9 sera were positive, and 1/5 gave an indeterminate result. Results of anti-Nef testing will be presented.
Conclusions. Will be discussed.

W.B.P.160 COMPARISON OF WESTERN BLOT (WB) INTERPRETIVE CRITERIA FOR HIV-1 ANTIBODY

Shackelford, S.M.; George, J.; Phillips, S.; and Scholten, G.

Centers for Disease Control, Atlanta, GA, USA.

Objective. To ensure the four methods proposed for interpretations for their ability to confirm HIV-1 infection.

Methods. Proposed criteria include: 1) Amer State Terr Public Health Lab Directors (ASTPBL), 2) Centorize Hain Serol Base (CHS), 3) HIV American Red Cross (RC), 4) Doorn-PAH (Doorn PAH) WB. We evaluated each criteria by testing sera from 406 randomly selected patients as follows: AIDS (n=66), ARC (n=46), EA (n=46), asymptomatic homosexual men (n=88), and EA (n=46) positive volunteer blood donors (n=20). Each serum was tested by the PAH Doorn-PAH Western blot kit and the results were scored as positive (P), negative (N) or indeterminate (I) according to the four definitions.

Results. The data presented indicate that the ASTPBL criteria were the most sensitive and specific of the four criteria analyzed.

	ASTPBL		CHS		RC		DP
	SP	SN	SP	SN	SP	SN	
AIDS	83/90	81/81	74/80	81/81	74/80	81/81	80/72
ARC	39/37	1/3	38/39	1/3	38/39	1/3	34/35
EA	40/38	31/31	41/38	31/31	41/31	31/31	36/31

The most restrictive criteria (requiring the presence of IgG, IgM, and IgA, and Doorn-PAH paired-epher numbers of indeterminate, usually due to a lack of IgM/IgG antibody in AIDS patients).

Conclusions. The ASTPBL criteria have the most number of indeterminate in all categories.

This study was accurate interpretations with indeterminate results which may be followed by further serologic examinations. We would, however, after the negative statement for an viral specific bands present to be hands present.

W.B.P.162 LABORATORY IDENTIFICATION OF RECENT HIV SEROCONVERSION: THE UTILITY OF EARLY REPEAT SPECIMENS AND COORDINATION WITH THE COUSOUNING TEAM. JUSTIN C. WILSON*, B. LOUIS*, E. BONGAY*, A. LACK*, A. BRICKMAN*, A. LACK*, M. SAN FRANCISCO DEPARTMENT OF PUBLIC HEALTH, *UNIVERSITY OF CALIFORNIA AIDS HEALTH PROJECT, SAN FRANCISCO, CA, USA.

Objective. To study the collection of follow-up specimens when there are apparent indeterminate results in a high risk population. The objective was to determine serologic patterns consistent with early seroconversion, minimize time of uncertainty for clients with indeterminate results, and communicate these findings to the counseling and education teams.

Methods. Low level of antibody was defined as 1) EIA ratio 20.8 and (2) 2.5 immunofluorescence (IFA) titer (116) and 3) 1-3 viral bands on Western blot (WB). A second specimen was obtained 2-4 wk later (median 14 d, mean 15.6 d) by requesting a new blood draw at the time of the results reporting and counseling. It was possible to maintain anonymity and the link between the 2 specimens by including the previous specimen number on the new lab slip.

Results. Of 54,000 specimens tested 1985-1989, 92 were defined as low positive. In 13 of 20 cases where a second specimen was obtained, the EIA absorbance, the IFA titer, and the number of bands on WB increased, suggesting that these were early seroconverters. The WB patterns commonly contained 1-3 bands (usually only weak gp160) on the 1st specimen; the second specimens showing gp120 and other gag and pol bands.

Conclusions. Certain serologic responses may be indicative of early seroconversion, which can be confirmed on follow-up specimens taken 2-4 weeks later. Identification of such recent seroconverters may be valuable for planning and evaluation of prevention and education efforts.

W.B.P.163 THE D-MANNOSE-SPECIFIC LECTIN FROM *GIBBERIA SAKABAYI* BLOCKS BINDING OF HIV-1 TO H9 CELLS *IN VITRO*

Müller, W. Gertl, B. Weuter, P., Rennelien, K., Schröder, H. C., Institut für Physiologische Chemie, Universität, Duesenberg 6, 5500 Mainz, West Germany.

Objective: To describe that lectins can be used as a tool to inhibit HIV infection *in vitro*. **Methods:** Human T₄ cells (H9), infected with HIV-1 have been used for the studies. **Results:** The new (alpha-1->2)-mannose specific lectin from *Gibberia sakabayi* is shown to prevent infection of H9 cells with HIV-1 *in vitro*. At 0.2 µM a complete protection was achieved. Moreover, the lectin inhibits syncytia formation in the HIV-1/H9-Jurkat cell system to 100% at 0.2 µM. This effect was abolished by addition of D-mannose at a stoichiometric ratio of lectin to sugar of 1:500. In addition it is shown that the lectin reacts with the oligosaccharide side chains of HIV-1 gp120 *in vitro* molecules, after desialylation of the gp120, the resulting 58-60 kDa form did not react with the lectin. **Conclusion:** The lectin allows the development of assays (1) to screen for compounds that interfere with the gp120-CD4 interaction and (2) to detect viral antigens in patient sera. **Refs.:** K. Müller, A. Europe, et al. *Biochem. J.* 199, 5 (1987); Müller et al., J. Acquired Immune Def. Syndr. (1989), in press. Supported by grants from the Bundesgesundheitsamt.

W.B.P.165 IS THERE A LONG 'LATENT' PERIOD BEFORE ANTI-HIV-1 SERUM ANTIBODIES APPEAR IN HIV-1 INFECTION?

Plé, Jean, S. Lued, R. Soudes, J. G. Ferras, T. Usson, J. University of Antilles, Antilles, F.W.I.

Asahi et al. have suggested that a period as long as 6 months can pass since HIV-1 infection is acquired to anti-HIV-1 serum antibodies appearance. If a seroconversion test (antibody EIA (EIA)) is used to test them. However, if a recombinant, sensitive EIA (EIA) or a Western-Blot analysis (WB) are employed, antibodies to the HIV-1 core proteins are able to be detected during this 'latent' period.

Objective: To get more knowledge on the HIV-1 serology during this period of HIV-1 infection. **Methods:** We tested 1000 sera sequentially taken from 107 subjects (6 homosexual men, 1 homosexual, 2 intravenous drug abusers and the spouses of an infected man) who seroconverted for anti-HIV-1. 37 of these patients suffered from an acute, self-limited, febrile illness. The samples were collected between 3 and 12 months before they developed anti-HIV-1. Seroreversion (SR) was defined as the appearance of anti-HIV-1 antibodies tested by a recombinant test in a sample taken from a subject who previously had been proved to be seronegative. Results: All of the samples collected before SR were found to be negative for anti-HIV-1 when tested by both EIA and WB. The patients were anti-HIV-1 positive earlier when tested by recombinant EIA than when a seroconversion test was used. Four of the 17 subjects tested out to be positive for HIV-1 EIA 3 months before SR. **Conclusion:** There does seem to be a long 'latent' period before SR for anti-HIV-1. It is highly sensitive EIA to be used to test this marker. However, this seems to be the case may vary in the risk group and the clinical picture of acute HIV-1 infection.

Asahi et al. Long latency precedes acute seroconversion in sexually transmitted human immunodeficiency virus infection. *Lancet* 1987; 1: 148-501.

W.B.P.167 NEGATIVE RESULTS OF *IN VITRO* TESTS FOR HIV ANTIBODY PRODUCTION BY WESTERN BLOOD CELLS IN 12 CASES OF ISOLATED GAG-INDUCED PROTEIN POSITIVITY.

Wong, Jacques,*, Mendrala, J.P.,***, Reynes, J.,***, Dupont, M.,***, Connot, A.,***, Metz, A.,***,***, Laboratoire d'Immunologie, Hôpital Lapeyronie,*** Service Maladies Infectieuses, Hôpital St Etienne, MONTPELLIER, FRANCE.**

OBJECTIVE: To provide a help for the interpretation of ambiguous results observed in the course of systematic serologic tests for HIV seropositivity of ELISA tests. **Methods:** Together with isolated bands of p24 (or other gag-encodes/protein) bands with no gp bands probably correspond to HIV-1 'false positivity' and not to a very early stage of HIV seroconversion. The interpretation of such results is however difficult and screening.

RESULTS: P24 from 12 cases of isolated gag-encodes protein positivity and in the wells of classical antigenic HIV seropositivity were incubated: a) in the 12 cases of isolated ELISA like; the *in vitro* secreted HIV antibodies were revealed by the use of an amplification immunoenzymatic complex in antigen-free plates; the supernatants were then used for Western blot analysis on strips of the Western blot, thus allowing a comparison of secreted and equivalent Western blot profiles.

RESULTS: HIV in vitro ELISA and equivalent Western blot tests, positive in all HIV infected subjects even at very early stages of seroconversion were consistently and repeatedly negative in the 12 cases of isolated gag-encodes positivity.

CONCLUSION: Since circulating IgG-like have been shown to secrete HIV antibodies in vitro during the whole course of HIV infection, the absence of such cells should help to eliminate the diagnosis of HIV infection in these ambiguous cases.

W.B.P.164 EARLY SEROLOGIC EVIDENCE OF INFECTION WITH HUMAN IMMUNODEFICIENCY VIRUS-TYPE 1 (HIV-1)

Reich, John, Crisler, J., Hagler, R., Wang, L. Bart, D. and Crisler, J., Northwestern University Medical School and Howard Ross Memorial Clinic, Chicago, Illinois, U.S.A.

Objective: To determine the prevalence and significance of indeterminate Western blot (WB) assays in homosexual men with negative Enzyme-Immunoassay (EIA).

Methods: The Chicago component of the WACS followed 394 EIA-negative men from 1984-85 through 10/1988. At 6 mo. intervals an EIA was obtained; WB were performed at 2 or more visits. **Results:** 10/1988, 46 of the 394 had developed a WB confirmed EIA; 24 had seroconverted to WB confirmed EIA by 6 mo. or more products of the GM1, GM2 or HIV gene regions 6 mo. or more before the visit with the diagnostic WB confirmed EIA. In contrast, 15 of 336 who remained EIA negative through 10/88 had similar seroconverted WB at 2 or more visits (P = 0.0001). Of the 35, 7 had 2 bands on at least 1 visit. The mean CD4 cell count of these 15 was 906/mm³ (497-1012) at entry and 866/mm³ (430-1412) at the 9th visit. WB 14 developed a WB confirmed EIA (positive predictive value 61.9%). In contrast, 12 of 337 with seroconverted negative WB remained EIA-negative during the 48 mo. study period (negative predictive value 89.9%). Individuals at risk, with indeterminate WB should be closely monitored for definitive evidence of HIV-1 infection.

W.B.P.166 COMPARISON OF FALSE POSITIVE REACTIONS IN DIRECT BINDING ANTI-HIV ELISA USING CELL LYSATE OR RECOMBINANT ANTIGEN

Erasmus, J., Abbott, R., Collier, M., Marlow, V., Love, E., and Lee, D. National Blood Transfusion Service, Manchester and Lancaster, Public Health Laboratory, Manchester, U.K.

Objective: Comparison of prevalence of false positive reactions in direct binding anti-HIV ELISA in blood donors using antigen from H9 infected cell lysates with those in the same assay using recombinant antigen. **Methods:** In 1987-88 a commercial anti-HIV ELISA using antigen from H9 infected H9 cells was used to screen blood donors in the Manchester and Lancaster blood banks. In April 1988 an ELISA using recombinant antigen from the same country was introduced. Reactions not due to anti-HIV-1 on confirmatory testing and follow-up for 1 year were analysed by Western Blot.

Results: False positive reactions were found at a prevalence of 1/800 (0.125) in 1987-88. Study of 50 of these donors showed 57 reacted by Western Blot; 7 had anti-p24 + SS bands and 50 anti-p18 + SS bands. From April 1988 the recombinant assay had a higher prevalence (0.55) of reactive samples. Post were negative in 13 other immunosays, and by Western Blot - 12 were positive by the Abbott recombinant test only; 9 had anti-p18 + p24 on Western Blot and 7 had anti-gp120/50, one with gp1. Eleven donors positive on screening in 1987-88 reacting by Western Blot, were negative by the recombinant anti-HIV ELISA when referred after April 1988. Further studies continue.

Conclusion: False positive reactions in the recombinant ELISA recognise different epitopes to those recognised by the anti-HIV ELISA using antigen from HIV-1 infected cells.

W.B.P.168 COMPARISON OF INDIRECT IMMUNOFLOURESCENCE AND WESTERN BLOT TESTS FOR DETECTION OF ANTIBODY TO HUMAN IMMUNODEFICIENCY VIRUS.

Hargiss, A. Gustav, Peredo, L.V.M., Castillo, T.M.H., Herrera, L.S., Hospital de Infectologia, Centro Médico La Rosa, I.M.S.S. Ciudad de México, México.

Objective: To compare two laboratory tests in the serological diagnosis of HIV infection with A.I.D.S. virus.

Methods: 277 were 25 u.e.f. from the same number of people that were seronegative in the basis of screening assays immunoenzyme reactive to A.I.D.S. -- virus were tested using indirect immunofluorescence (I.F.A.) and immunoblot assays (W.B.).

Results

GROUP	SAMPLE	I.F.A.	W.B.
		No. T./ No. (n)	No. T./ No. (n)
A.I.D.S. patients	serum	149 / 145	149 / 145
	s.e.f.	25 / 18	25 / 25
Sexual contacts	serum	40 / 39	40 / 39
Haemophiliacs	serum	23 / 22	23 / 22
Blood donors	serum	11 / 9	11 / 9
Renal insufficiency	serum	11 / 8	11 / 8
Arthritis rheumatosa	serum	3 / 3	3 / 3

Conclusion: There was 100% agreement between I.F.A. and W.B. test in the same group of serum of A.I.D.S. patients, their sexual contacts, haemophiliacs and blood donors. However the W.B. was the most acceptable method for the groups of patients with renal insufficiency, arthritis rheumatosa and the samples of s.e.f. of A.I.D.S. patients.

W.B.P.169 RESOLUTION OF INDETERMINATE HIV WESTERN BLOT RESULTS BY ADDITIONAL TESTING

Carlson, James B. and Yost, Johann L.
University of California, Davis, USA.

Objective: Current laboratory practice for the serological diagnosis of HIV infection involves initial screening of the specimen for anti-HIV antibody using an enzyme immunoassay (EIA) and validation of EIA positive results with Western blot (WB). The resolution of indeterminate WB results is a major problem in this algorithm. A practical solution would be to retest specimens using other serological approaches.

Methods: We have investigated the addition of indirect immunofluorescence (IFA), recombinant EIA (ENV-9, E.I. Dupont, Inc., Wilmington, DE), or recombinant immunoblot (EISA HIV-216) Chiron Corp., Emeryville, CA) as tests to resolve EIA positive, WB indeterminate specimens.

Results: 508 of 3104 consecutive specimens were EIA positive. WB test results were: 116 positive, 32 negative, 54 indeterminate. The results of additional testing on the 54 WB indeterminate specimens were ENV-9, 2 positive, 52 negative; EISA HIV-216, 2 positive, 51 negative, 1 indeterminate; and IFA, 1 positive, 41 negative, 11 indeterminate.

Conclusion: These results indicate that the recombinant tests by the most useful in the resolution of WB indeterminate specimens.

W.B.P.170 PROGNOSTIC VALUE OF REPEATED WESTERN BLOT ANALYSIS.

Kamm, Bernd H.; Niese, D.; Bruchmann, H.H.; Kasparek, T.; Eiler, P.; von S., B.
*Universitätsklinik Bonn, FBG, **Institut für experimentelle Hämatologie, Bonn, FBG, ***Massachusetts Institutes of Technology

Objective: To assess the prognostic usefulness of Western blot testing in HIV-infection.
Methods: In 214 asymptomatic patients of the Bonn Hepatitis Cohort Study Western Blot analysis has been performed at intervals of 3 to 6 months since 1986.

Results: Only loss of anti-p24 or loss of anti-p31 was correlated with clinical progression (ABC or AIDS after 2 years).

	Asympt.	ABC	AIDS (after 2 years)
p24 absent (n=33)	155	218	243
p31 present (n=163)	878	63	58
p17 absent (n=70)	678	178	185
p17 present (n=143)	908	62	48

Conclusion: If available, Western blot, together with other serological parameters, might be used in deciding which patients to assign to antiretroviral therapy.

W.B.P.171 SENSITIVITY OF A NEW RECOMBINANT INHIBITION TYPE ELISA SYSTEM FOR THE DETECTION OF HIV-1 ANTIBODIES

Van Der Poel, Coen*, Lalis, M.**; Reesink, H.*; Plaisier, A.*; Wolker, E.*; Vonk-Steen, T.*
* Rad Cross Blood Transfusion Service, Amsterdam, The Netherlands
** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.

Objective: To establish the sensitivity of a new inhibition type ELISA for the detection of HIV-1 antibodies, employing recombinant antigens.

Methods: A serum panel of 1593 confirmed HIV-1 Western Blot positive samples, classified as clear (n=493), turbid (n=1139), haemolytic (n=64), obtained from asymptomatic individuals (n=1217) and from AIDS patients (n=372), was tested with the new Wellcome recombinant HIV-1 ELISA, according to the manufacturers instructions. The assays had been obtained between 1986 and 1988, and had been stored at -20°C.

Results: Out of 1593, 1589 (99.7%) were found initially positive and 4 samples (0.2%) were found initially negative. Of the ELISA negative samples, 3/4 were classified as haemolytic and 1 as turbid; 4/4 were positive when retested at 1:10 serum dilution. The overall sensitivity of the test was 99.7%, among clear and turbid samples the sensitivity was 100% and 99.3% respectively, and among haemolytic samples 93.5% (p < 0.001 Chi sq).

Conclusion: The sensitivity of the Wellcome recombinant inhibition ELISA was very high: 99.7%. The 4 false negative results were observed among haemolytic and turbid sample specimens.

W.B.P.172 PERFORMANCE OF A DOT IMMUNOBLOT KIT FOR HIV ANTIBODY TESTING

C. Sharlicki, L. Cook, H.O. Shaughnessy*, P. Ollivier*,
1. University of British Columbia and Provincial Laboratory, Vancouver;
2. Federal Centre for Aids, Ottawa; 3. Canadian Red Cross National Reference Laboratory, Ottawa, Canada.

Objective: To evaluate the performance of a dot immunoblot kit containing recombinant gp50 protein (MDSearch, MicroGeneSys) as a definitive screening and confirmatory HIV antibody test.

Methods: Sera were received for routine testing and were tested at the B.C. Provincial Lab by EIA (DuPont) and Immunofluorescence (IFA) and/or Western blot (WB). A true positive was defined as EIA and IFA positive (high-rank pattern) or WB positive or both.

Results: 252 sera were tested. Of 218 true positive sera, 196(90.7%) were positive by dot blot (WB), 6 were negative and 14 were indeterminate (faint dots but no color). Of 75 true negative sera, 75 were negative by WB and 1 was indeterminate (specificity 98.7%, pos and neg predictive values 100% and 92.6%), 11 known early seroconverters (p24 only on WB) were also tested, of these, 2 were WB positive, 5 negative and 4 indeterminate.

Conclusion: The figure above shows the WB is a sufficiently sensitive to be used as a screening test, particularly for seroconverters. It has good specificity for confirmatory testing. If indeterminate results are recorded as positive the sensitivity improves (97%) but is still inadequate for screening purposes.

W.B.P.173 USE OF ALLELOTYPE MARKER EXPRESSION, TESTS FOR ANTIBODY TO HIV,

Saai, Peter*, J. Berman**, E. Mitchell***, E. Ruder*
* Virus Research Centre, Kenya Medical Research Institute, Nairobi
** East Bay, National Public Health Laboratories, Nairobi, Kenya
*** AIDS/STI Unit, National Health Institute, North Carolina USA

Objective: To evaluate the significance markers for antibody to HIV as specific tests in field.

Methods: A panel of 1000 sera was tested for HIV-1 antibody using a microinhibition test (MICIT), which, USA were evaluated for use as supplemental tests in comparison with the Western Blot. Some laboratories in Kenya participated in the study. Some from 2,000 blood donors, persons at high risk and suspected HIV patients were initially screened by the MICIT (Opten, USA), all positive specimens and 25% of the negatives were tested by Western Blot. Each test to be evaluated for sensitivity, specificity, and usefulness in these field laboratories.

Results: With through training these tests can readily be performed in laboratories with minimal specialized equipment. Data on sensitivity and specificity will be presented at the conference.

Conclusion: The application tests, such as microinhibition or highly treated WB and are very economical than the conventional techniques used in HIV testing. These tests offer an alternative to the Western Blot techniques as well as their inherent use as screening tests.

W.B.P.174 PERFORMANCE APPRAISAL OF LABORATORIES TESTING DRIED BLOOD SPOT SPECIMENS FOR BLONDED HIV SEROLOGICAL RESULTS IN THE UNITED STATES

*Hanson, Nancy; **Lewis, E.L.; Hester, S.; *George, R.; *Pfeifferman, H.
*Center for Environmental Health and Injury Control, and *Center for Infectious Diseases, Centers for Disease Control, Atlanta, Georgia USA.

Objective: To determine and monitor the quality of analytical performance for HIV antibody analysis of dried blood spots routinely collected for newborn screening programs by laboratories participating in the blinded surveillance survey of childbearing women.

Methods: Dried blood spot (DBS) specimens on filter paper were prepared simulating typical analytical specimens for the performance evaluation of laboratories. A panel of 59 DBS specimens were prepared from individual serum matrices using heat inactivated HIV positive plasma and negative serum. The first monthly test set of 11 blind-coded specimens selected from this panel were distributed to laboratories in July 1988.

Results: Two of 7 laboratories misclassified three different specimens in an initial pilot evaluation of the specimens panel. To date, 31 laboratories and 4 manufacturers have analyzed several sets of 12 blind-coded DBS specimens selected from the panel. The participating laboratories have analyzed a total of 1,234 specimens by EIA and Western blot. For the analyzed 24 sets, 24 sets were analyzed, nine specimens misclassifications and 10 misclassifications of DBS specimens have been recorded. These laboratory evaluations assure the quality of the analytical data for the national surveys.

W.B.P.175 ASSESSMENT OF DRIED BLOOD SPOT QUALITY CONTROL AND PERFORMANCE EVALUATION MATERIALS FOR SEROTYPAL HIV SEROAGGLUTINATION TESTS

SOUSA, J.B.M.; HAMON, M.; LEON, S. Center for Disease Control, Atlanta, Georgia, USA.

Objectives: To characterize dried blood spot (DBS) materials prepared for quality assurance of laboratories screening for HIV seroagglutination. **Methods:** DBS specimens were produced, characterized, and distributed for bench level controls and laboratory evaluation. Quality control (QC) materials were prepared on filter paper using HIV seropositive plasma and/or negative serum combined with red blood cells to an hematocrit of 50%, to yield appropriate target values of high, low, and negative specimens. Bulk production lots of QC contained 4,000 sheets of 15 sheets each for routine use by all laboratories. Stability in both longitudinal and accelerated studies and homogeneity of DBS materials were measured by ELISA and western blot. **Results:** Analysis of 200 materials, stored at 20°C in air-tight bags with desiccant over seven months showed no apparent change in optical density (OD) or hematocrit. Studies of antibody stability with a 1:2 OD specimen under various storage conditions were conducted. For example, exposure of this specimen to 37°C at ambient humidity resulted in a 20% reduction of recoverable antibody (relative OD) in 30 days, while the same specimen maintained at 37°C in a zip-closure bag with desiccant showed a 20% relative loss of antibody in 60 days. From Western blot analysis the detected filter loss appears to be uniform across all antibody bands. **Conclusions:** DBS materials can be prepared that are reliable and stable under normal storage and handling conditions for routine QC, and to monitor and evaluate laboratory performance for this matrix.

W.B.P.177 DEFINE FIELDS FACILITY RESULTS WHEN TESTING FOR ANTIBODIES TO HIV-1. "Meli, Franka, Ph.D., Minsk E. Genguly Ph.D., Mark Lifshitz, M.D., James E. Hays, M.D., St. George's Hospital and Health Center, New York, NY, 10019, and Dept. of Pathology, NY Medical Center, New York, NY, U.S.A."

Sera from a population of 40,438 prospective immigrants to the US presently residing in New York City were tested for the presence of antibodies to HIV-1. Screening was with DuPont EIA and confirmatory testing was with DuPont Western Blot (WB) kits. Of 39 WB tests there were 1,256 (3.13) reactive and 314 (1.28) inconclusive (INC) sera.

A sample of 469 INC sera were further tested by alternative FDA approved EIA assays from Genetic Systems (GS), Ortho, and Abbott. Testing by the GS EIA assay reduced the number of reactive samples by 47%, by the Ortho assay by 74%, and by the Abbott assay by 94%. The Abbott assay is therefore the most appropriate second line EIA assay for reducing the number of false positive EIA assays.

The Ortho-Chiron EIA confirmatory test found 53% of the INC sera to be non-reactive. Confirmatory Cellular immunofluorescence assays using slides prepared by either the Memphis Laboratory, or by Eliconometrics, were applied to a subsample of the INC sera. These assays reduced the frequency of inconclusive results by over 95% each.

W.B.P.179 EVALUATION OF THREE COMMERCIAL KITS FOR SCREENING OF HIV-1 ANTIBODIES IN MEDICAL

SOUSA, J.C.; MORAES, C.; MORAES, C.; VALDESINO, J.L. and BARRON, V.
 *Institute of Biomedical Research, National University of Mexico
 **Ministry of Health of Mexico

Objectives: To evaluate sensitivity, specificity and operative performance of twelve commercial kits for use in screening programs for HIV antibodies in Mexico.

Methods: A 775 sera panel, integrated by 23 AIDS patients sera, 45 HIV-1 seropositive sera, 42 sera from patients with pathologies likely to produce false positive results and 552 randomly selected blood donor sera, was used. The sera were analyzed by seven enzyme immunoassays from Abbott, Behring, Cambridge Biotech, DuPont, Hieser Biotech, Immunit and Organon, DuPont dot immunosorbent, Abbott, Cambridge Biotech and Miles passive agglutination assays, and the Medcor cytoimmunoenzymatic assay. First time reactive sera were retested with the same assays. Commercial Western Blot was used as reference test. **Results:** HIV-1 seropositivity for the total panel was 10.7%. Sensitivities of the assays ranged from 91.6 to 100%; specificities from 96.4 to 100% and operative (evaluated by operative indexes) ranged from 27.2 to 90%. **Conclusions:** Methodological differences between the assays were not relevant for their sensitivity or specificity. Specificity was related to antigen origin. Kits with recombinant antigen gave, in general, higher specificity values.

W.B.P.176 CHRONIC HIV INFECTION WITH DELAYED APPEARANCE OF ANTIBODIES BY USUAL TECHNIQUES AND A CASE OF SEROVERSION

MEHREZ, B.; KARADIMITRA, S.; MOUTOU, C.; SOUSTAS, C.; BRUNTON, J.M.; BEAD, S.M.
 *Greece Ministry of Health, **Mount Sinai Hospital, ***Hospital for Sick Children, Toronto, Ontario, Canada

We describe 2 unusual serology profiles from HIV-infected persons. **Case 1:** A 47 year old male, was intermittently asymptomatic for a year, but not seropositive. The P24 IgG capture assay was persistently reactive. HIV was isolated in 09/88. **Case 2:** A 33 year old female who presented an acute HIV seroconversion and was seropositive. She recovered clinically, became HIV negative, 18 undetectable and later developed multiple infections, 74 cell count fell to 40, HIV isolation was positive. A recombinant-based EIA test showed persistent presence of antibodies in this case.

Results:
 EIA (Dupont) 09/87 11/87 07/88 09/88 09/87 06/89 07/89 08/89 09/89
 Immunoblot - - ind ind + + ind ind ind ind
 Recombigen - - + + + + + + + +
 P24 Ag (Abbott) + + + + + + + + + +
 HIV Culture cat at at at + + + + + + + +
 Conclusions: Case 1 adds to the few cases described as HIV infected without the appearance of detectable antibodies for a prolonged period. **Case 2** shows that seroconversion with apparent clinical recovery may occur but the infection persists. Standard viral lysate EIA tests may not have the sensitivity to detect HIV antibodies in all cases of infection.

W.B.P.178 INTERPRETATION AND FOLLOW-UP OF "INDETERMINATE" WESTERN BLOT (WB) TEST RESULTS

AGUIRRE, H.; GALARRAGA, J.; VILLANOVAS, V.; DEBASKO, D.; CENTRAL AIDS LAB., INSTITUTE FOR INFECTIOUS AND PARASITIC DISEASES, BILBAO, SPAIN

Objective: To describe the follow-up of "indeterminate" in WB test persons.

Methods: 59 "indeterminate" persons (16 belonging to high risk and 37 - to low risk groups) were followed-up for 6-14 months (3-6 sera tested in 4-6 week intervals) using WB HIV-1 IgG (DuPont WB95).

Results: The most characteristic patterns of "indeterminate" WB in low risk persons at the beginning of the study (before seroconversion) were: 1. "indeterminate" on OAD or HIV proteins (54.0%); they became sero-negative or disappear during the follow-up. The sera of high risk persons demonstrate at the beginning of the study mainly multiple bands (61.7%) showing a tendency to persist or to shift to "positive" pattern.

Conclusion: 1. "Indeterminate" WB is not a final result based on our experience and our experience we proposed an own scheme (it will be presented) for diagnostic behavior to "indeterminate" WB results. 2. People belonging to high risk groups have to be retested in 6-6 week intervals, but not at 3-6 months as recommended until now.

Psychiatrie/Neuropsychologie Psychiatry/Neuropsychology

W.B.P.180 NEUROPSYCHOLOGICAL FUNCTION IN PHYSICALLY ASYMPTOMATIC HIV SEROPOSITIVE AND SERONEGATIVE GAY/BISEXUAL MEN

BRADLEY, R.; BARNETT, S.; BRADLEY, R.; JACOBSON, L.
 *Cornell Medical Center, *Long Island Jewish Medical Center, U.S.A.

Objective: To determine if HIV-induced neuropsychological impairment occurs prior to physical manifestations of immunosuppression.

Methods: A 2-year history of neuropsychological tests was administered to 20 HIV seropositive and 20 HIV seronegative gay/bisexual men matched for age, education and distance (NY, N.Y.). **Results:** Neuropsychological status was assessed by thorough medical history and physical exam, and subjects were included with neuropsychological substance dependence (SUD), HIV, neuromuscular (NM), medication during past month, or history of concussion or migraine.

Results: Multiple t-tests and logistical regression failed to find significant differences between the two groups on attention, memory, concentration, or motor language or motor functions. **Conclusions:** The findings further document the need for careful screening and tightly-monitored seronegative comparison subjects before concluding that neurocognitive effects of HIV cause significant dysfunction in asymptomatic seropositive subjects.

THE USE OF THE MINI-MENTAL STATUS EXAM AS A COGNITIVE SCREEN

IN PATIENTS WITH AIDS
 ADINA, JAMES M., BOCCARDI AL, DAVIES A.
 San Francisco General Hospital, University of California San Francisco School of Medicine, Dept. of Psychiatry and UCSF AIDS Health Program, San Francisco, California, U.S.A.

Objective: To examine the utility of the Mini-Mental Status Exam (MMSE) as a screening instrument in detecting cognitive deficits in patients with AIDS.

Methods: Hospitalized subjects (N=50) with first episode *Pneumocystis carinii* pneumonia (PCP) were given a battery of 10 neuropsychological tests (NP), Auditory Stream Separation (ASS), and the MMSE. Improvement on the MMSE was determined by the onset out of onset of CNS.

Results: Sixty-six percent of the subjects had abnormal ASSE and 78% of the subjects were abnormal on at least 6 of the 10 NP measures. However, only 45 of the 50 subjects (90%) scored less than 24 on the MMSE. The 12 scores for this sample were: 19-28. In addition, the MMSE did not correlate with any of the individual NP measures or with the ASSE.

Conclusions: The MMSE appears relatively insensitive in identifying cognitive deficits in patients with HIV infection. Caution should be exercised to use the MMSE to rule out cognitive impairment in this population.

This work has been supported in part by grant # DA04877 from the National Institute on Drug Abuse.

W.B.P.195

NEUROPSYCHOLOGICAL AND IMMUNOLOGICAL ABNORMALITIES IN ADVANCED HIV INFECTION

SEIDENBERG, ERNESTO, LAW, J.K., PROZINSKI, P.P.
 Baylor College of Medicine, Houston, Texas, USA

Objective: To study the relationship between systemic immunodeficiency status and neurobehavioral impairment in advanced HIV infection.

Methods: Eighty subjects (39 ARC/41 AIDS) studied at entry for baseline neuropsychological testing were evaluated for their hematological and immunological status (white blood cell count, absolute T-cell count, and Helper/T-helper suppressor lymphocyte ratio). Correlational analysis was done between neuropsychological test scores and hematological and immunological values. Investigators were blinded to the individual participant's disease status.

Results: No significant differences between ARC or AIDS with respect to age, education, socioeconomic status or substance use were present. Abnormalities in memory reflected by long-term retention (LTR) and consistent long-term retrieval memory reflected significant abnormalities in both groups: 85% of ARC and 75% of AIDS cases fell below one standard deviation below the mean on LTR; 92% of ARC and 100% of AIDS cases fell one standard deviation below the mean on CLTR. Likewise, abnormalities were present in visual scanning, information processing and attention. ARC/AIDS status was not significantly correlated with psychiatric diagnosis. No statistically significant correlations were found between neuropsychological markers, ARC and AIDS subjects' total white blood cell count, total T-cell count, and Helper/suppressor ratios.

Conclusion: Our results suggest a lack of correlation of cognitive dysfunction and immunological status in advanced HIV infection suggesting that HIV-CNS involvement may be independent of indices generally associated with HIV systemic progression.

W.B.P.197

DRUG USE HISTORY IN GAY MEN WITH AIDS AND ITS RELATION TO

NEUROLOGICAL FINDINGS
 D. SANCHEZ, J. BOCARDI, J. JAMES, M. GILLESPIE, A. DAVIS, San Francisco General Hospital, UCSF School of Medicine, San Francisco, California, U.S.A.

Objective: To characterize the drug use histories of gay men with AIDS and to explore possible interactions of drug use and neuropsychological (NP) findings.

Methods: Self reported drug use histories for each prior 6 months and prior 7 years were obtained from 46 gay men during their first hospitalization for AIDS. Demographic and background information was recorded. NP measures given were: Wechsler Memory Scale-Revised version, Shipley, Trail Making Test, and Finger Tapping Test. A man was included for the NP measure to represent an overall index of impairment.

Results: Drug use was reported by 43 of the 46 subjects (93%). Alcohol and marijuana use represented the highest consumption. Average alcohol use for the past 6 months was once a week, and for the 7 year period was 2-6 times a week. Average marijuana use for the past 6 months was once a month and for the 7 year period 2-3 times a month. A significant decrease ($p < .05$) in drug use was found in 6 out of 10 drug categories from the 7 year to 6 month period. No drug use correlation was found in 78% of the sample. Depression or mood of drug use. A multiple regression analysis was not significant between the NP index of impairment and a control drug use score, after controlling for the measures of depression and mood length.

Conclusions: Subjects with AIDS or diagnosis of AIDS reported a significant decrease in drug use over the last several years. This may be due to increasing health concerns and awareness of AIDS. Furthermore, light to moderate alcohol use (as few times weekly) or less does not appear to have exacerbated the period of impairment found in this sample.

W.B.P.194

TRYPTOPHAN LEVELS ARE UNRELATED TO DISTURBANCES OF MOOD IN

HIV-1 INFECTED PATIENTS
 KALLA, JOHN S.; FROM, A.S.; HEYES, M.K.; SADFER, A.E.; PRICE, RW.; SIDDIS, J.J.; * Memorial Sloan-Kettering Cancer Center, NY, NY; * National Institute of Mental Health, Bethesda, MD, USA.

Objective: Disturbances of mood frequently accompany early symptoms of the AIDS Demerita Complex (ADC). Metabolism of tryptophan (TRP), a serotonin precursor, is also disrupted by HIV-1 infection. In order to investigate a possible biochemical mechanism of mood disturbance in ADC, mood and psychiatric symptom ratings were related to TRP levels in both plasma and cerebrospinal fluid (CSF) in HIV-1 infected patients.

Methods: Blood and CSF samples from 45 HIV-1 infected patients, at various stages of disease, were assayed for TRP using high performance liquid chromatography. Samples were drawn following administration of the Neuro-AIDS Study Group neurological history, exam, and neuropsychological battery, which included self-ratings for mood disturbance (Profile of Mood States; POMS) and general psychiatric symptomatology (Brief Symptom Inventory; BSI).

Results: Correlations between mood/psychiatric ratings and both plasma and CSF tryptophan were non-significant (e.g. POMS total vs plasma TRP $r = -.03$, $p = .82$; POMS total vs CSF TRP $r = -.17$, $p = .32$; BSI general severity index vs plasma TRP $r = .17$, $p = .27$; BSI general severity index vs CSF TRP $r = .26$, $p = .22$). In addition, the prevalence of mood/psychiatric disturbance did not differ across above normative cutoffs for mood/psychiatric disturbance but did differ in tryptophan levels from those below these cutoffs.

Conclusions: Levels of tryptophan, a precursor of serotonin, are unrelated to both presence and severity of self-reported mood disturbances in HIV-1 patients.

W.B.P.196 A BRIEF SCREENING TEST BATTERY FOR COGNITIVE

DEFICITS IN HIV INFECTION

WOO, SEUNG-HO; HUNG, J.-T.; SHIM, A.; WITZMAN, G.S.; FERNANDES, R.; BARY, A.*
 *Mount Sinai Hospital, University of Toronto, Toronto, Ontario, Canada

Objective: (1) To design a brief screening measure with the capacity for early detection of neurocognitive impairment in HIV infected individuals. (2) To establish if scores on this measure may be used to infer the degree of CNS or immune impairment.

Methods: This is a 2 year longitudinal study of a case group with HIV infection (AB⁺ = 20, ARC = 5, AIDS = 7), and a control group, similar in age, education and SES. Neuropsychological tests, and measures of depression and anxiety are administered at 3 month intervals. The battery includes: Trail A and B, Controlled Oral Word Association, Graded Difficulty Arithmetic, WAIS-R, Digit Symbol, and Digit Span, Stoop Test, Rey Auditory Verbal Learning Test and Boston Visual Retention.

Results: Initial testing and 3 month follow-up show no global differences between cases and controls. However, 30% of the cases scored in the range of suspected impairment on at least 1 test, and 57% of subjects with AIDS have scored in this range on two or more. Trails A and B show poor performances across the spectrum of HIV infection with many scores falling between 1 and 2 standard deviations below the mean.

Conclusion: These preliminary results suggest some cognitive changes associated with HIV infection which appear to be greater in patients with AIDS. NHRPD Grant#6666-3654-AIDS.

W.B.P.198

RELATIONSHIP BETWEEN NEUROPSYCHOLOGICAL AND IMMUNE

VARIABLES IN HIV POSITIVE ASYMPTOMATIC PATIENTS
 ADINA, JAMES M., BOCCARDI AL, DAVIS A, MOSE, A, BUCHHEI P, and YOUNG, M.
 San Francisco General Hospital, University of California San Francisco School of Medicine, Dept. of Psychiatry and UCSF AIDS Health Program, San Francisco, California, U.S.A.

Objective: To describe the association between neuropsychological (NP) function, immune status and neurocognitive measures in immunologically HIV positive gay men.

Methods: Fifty-six asymptomatic gay men (DEIV = 33, HIV = 23) were given a two battery of NP tests and peripheral blood studies. Measures of immune function were also obtained. Group differences between HIV+ and HIV- groups were determined by use of multiple T-tests. A post-hoc corrected correlation was applied. Correlations were calculated between the immune and NP measures.

Results: 1. No significant differences were found between the positive and negative group on age, education and occupational level. 2. No statistically significant differences were found between the HIV+ and HIV- groups on any of the NP measures. 3. In the HIV+ group, no statistically significant differences were found between those with CD4 < 400 and those with CD4 > 400 on the NP measures. Additionally, no difference was found on the NP measures between the CD4 < 400 and HIV- negative group.

Conclusions: These results help to outline a lack of documented neuropsychological impairment in otherwise asymptomatic HIV+ men. This finding holds up even when comparing those HIV+ men with CD4 counts of 500 with the asymptomatic group.

This work has been supported in part by grant # DA04877 from the National Institute on Drug Abuse.

Session d'affichage Poster Session

W.B.P.199 COGNITIVE DYSFUNCTION AND PSYCHOLOGICAL FACTORS IN SYMPTOMATIC SEROPOSITIVE HIV
 T. Leake, L. Smith, J. Zvanich, F. Insel, D.M. University of California School of Medicine, San Francisco, CA, U.S.A.

Objective: Questions remain about the prevalence and severity of cognitive impairment along the spectrum of HIV disease. Our aim was to determine the presence and degree of cognitive impairment in asymptomatic seropositive men, and whether severity was associated with certain psychosocial factors. **Methods:** 100 seropositive homosexual men with at least one HIV-related symptom were recruited from the UCSF AIDS Clinic and administered neuropsychological tests. Data were adjusted for age and education, and standardized ratings of impairment were determined. Standard measures of distress, coping, and mood were also administered. **Results:** 69% of men showed at least mild impairment, 69% at least moderate impairment, and 45% at least severe impairment. 19% showed impairment on one or more neuropsychological tests. There was no clear differential cognitive impairment: 45-49% had impaired immediate and delayed memory, but only 17% had impaired verbal fluency, while only 19% had impaired total digit span. 29% had impaired Digit Span, and 30% had impaired verbal fluency. Level of impairment on most tests ($r = .18$ to $.31$, $p < .05$ to $.001$). Greater impairment on Digit Span, Verbal Fluency, and Trailmaking was correlated with coping and mood. **Conclusions:** Neuropsychological impairment was associated with $r = .23$ to $.31$, $p < .05$ to $.001$ for emotional control, $r = .19$ to $.29$, $p < .05$ to $.001$ for social support. Few neuropsychological or neuropsychological reports on patients with HIV disorders have included psychosocial measures. The positive correlations in this sample of seropositive men suggest that cognitive impairment may reflect (a) the exacerbation of cognitive impairment by distress and certain coping styles, and/or (b) patients' reactions to awareness of their cognitive impairments.

IMPACT OF HIV DIAGNOSIS ON RICOLO, MASSIMO'S, BASKINS D.J.
 Wilson B****, Thompson C****,
 St. Stephen's Hospital, London; *Richard Cross Medical School, London;
 ****Southampton General Hospital, Southampton;
 ****Royal South Devon Hospital, Southampton, UNITED KINGDOM

Objective: To assess the impact of HIV positivity on mood state. **Method:** As part of the St. Stephen's prospective cohort study, mood is assessed prior to notification of HIV Ab status and reassessed 6 months later. Assessment consists in the following self-report questionnaires: SAD, Zung, GHQ and a Physical Complaints Schedule. **Results:** The baseline SAD anxiety score fell within the borderline pathological range in both groups (HIV+ve: 9.0, range 6.6; HIV-ve: 8.9, range 6.4), whereas at 6 months they fell within the normal range (HIV+ve: 7.00 ± 0.61; HIV-ve: 7.96, range 7.7). Inter- and intra-individual group comparisons, however, were not significant. Other mood scores for HIV+ve and HIV-ve were well within the normal range at baseline and follow-up. **Conclusion:** Reports of clinical impressions indicate that anxiety and/or depression levels rise sharply at the time of diagnosis of HIV+ve status. Our results suggest no evidence of any persistent pathological mood states at 6 month follow-up.

W.B.P.203

REQUEST OF MENTAL HEALTH-CARE INTERVENTION BY PHYSICIANS ATTENDING HIV OR AIDS PATIENTS: THE IMPORTANCE OF A LOCAL REFERENCE CENTRE FOR AIDS TREATMENT.
 H. Cardoso, M. Torres, A. Quirós, A. Navarro, M. Zorrilla
 Hospital Universitario C.I.F. - Federal University of Rio de Janeiro - National Reference Centre for AIDS Treatment.
Objective: To identify and evaluate the reasons that make physicians, dealing with HIV or AIDS patients, request mental health-care intervention. **Method:** Retrospective review of 126 patients assisted by mental health-care workers from a total of 439 hospitalized patients attended in a National Reference Centre for AIDS treatment in 1987. **Results:** There were 158 requests to evaluate patients, 27 patients had 2 requests for evaluation, 2 patients had 3 requests and 1 patient had 4 requests. Requests were classified in 6 groups. The results were: 1) Differential diagnosis: (19/158); 2) Problems related to clinical staff-patients relationship: (46/158); 3) Reactions to diagnosis and/or evolution of the disease: (59/158); 4) Psychomotor agitation: (10/158); 5) Family approach: (10/158); 6) Other: (14/158) 19%. In each group we could identify several causes of request. The most important were: Anxiety (group 3): (26/158); 19%; Difficulties in the disputation of the diagnosis to the patient (group 2): (16/158); 10%; differential diagnosis (group 1) between cognitive deficits (delirium, dementia, depression): (12/158); 7% **Conclusions:** The high proportion of request (28%) to mental health-care professionals shows the importance of an integrated and multidisciplinary approach in the assistance of these patients. Although, an adequate presentation is needed for these professionals due to the complexity of the situations that arise: clinical complications, social problems, staff-patient difficulties and multiple mental syndromes.

W.B.P.200 EARLY DIAGNOSIS OF HIV INFECTION IN INFANTS
 d'Arinios Montoro, Antiochia J.; Novati R.; Marchisio, P.*;
 Zanetta M.***; Lassarini A.*; Torregiani, R.***; Masaroni, G.***
 *Infectious Dis. Clinic, **Pediatric Dept. V, ***Oncology Dept. IV, Milan, Italy

Objective: To evaluate the role of serial IgM anti-HIV and p24Ag testing in the neonatal diagnosis of HIV infection. **Method:** 24 neonates from anti-HIV pos. mothers were followed-up biweekly for 10-6 mo. At each time clinical, immunological (lymphocyte subsets, immunoglobulin levels) and serological (IgM anti-HIV, ELISA and Western Blot (WB)), IgM anti-HIV, WB, p24Ag, ELISA) tests were performed. CDC classification for pediatric HIV infection was used. **Results:** IgM anti-HIV were found at birth (5 cases) or at 2nd-4th mo. (6 cases) p24Ag was detected in 7 cases from 4th mo. to 1st year of life. 12 neonates became asymptomatic (P=2) within 4th mo. (follow-up 118 mo.). All were IgM anti-HIV and/or p24Ag pos. 3 neonates received adequate immunodeficiency (ID) (follow-up 13rd mo.). All were p24Ag pos. (P=1-8). 2 also IgM anti-HIV pos. Among asymptomatic immunocompetent patients 7 were followed at least for 10 mo. (163 mo.) 2 were still seropositive (P=1-4) (previously IgM anti-HIV pos.) 3 were pos. only for p24Ag (1 IgM anti-HIV pos.). 5 patients were followed for 5-63 mo. (4 IgM anti-HIV pos., 1 also p24Ag pos.); finally 4 neonates are too young to be followed. **Conclusions:** IgM anti-HIV and p24Ag seem good predictors of HIV infection and/or disease progression in infants.

W.B.P.202

A VA HOSPITAL SPECIALIZED PSYCHIATRY PROGRAM FOR PATIENTS WITH HIV DISEASE: A REVIEW OF THE FIRST 30 REFERRALS
 Thompson, Douglas
 San Francisco Veterans Administration Hospital and University of California, San Francisco, U.S.A.

Objective: To identify characteristics of a population of patients with HIV Disease referred for outpatient psychiatric consultation in the San Francisco VA Hospital and to use these data for program planning purposes. **Methods:** Since the first cases of HIV disease appeared at the San Francisco VA Hospital in 1982, the number of referrals to psychiatry steadily increased. Initially patients were managed on an individual basis, but it eventually became clear that this population had grown to be a significant proportion of overall referrals. A multidisciplinary committee was formed to evaluate the needs of this population and make specific programmatic recommendations. Meetings were held with various hospital units involved in providing care to HIV patients to assist in planning and coordinating psychiatric services. A trial program was initiated beginning July 1, 1988. Between July 1 and December 31, 1988, 30 patients with HIV Disease were referred for psychiatric consultation. Demographic and other specific HIV-ve pos. were monitored, including reason for referral, DSM-III-R diagnoses, treatment plan, disposition, medication, and outcome. **Results:** Data from this recent 6-month period are in the process of being coded and analyzed at the time of abstract preparation and will be presented at the conference. **Conclusions:** Conclusions regarding using the data for planning for HIV psychiatric services will be presented.

W.B.P.204

PERVALENCE, SEVERITY AND COGNITIVE CHANGE IN AIDS AS NOTED BY PATIENTS AND THEIR CARE AS RELATED TO NEUROPSYCHOLOGICAL TESTING.
 Smith, A.G.; Davis, A.; Newland, J. S. and Jew, J.
 Brompton Hosp., St. Mary's Hospital, London, W 8, U.K.

Objective: To determine if: (1) referral rates of AIDS patients reduce change in their persons after any predictive objective neuropsychological testing; (2) patients' own perceptions are correlated with objective neuropsychological impairment. **Method:** The informal carers of AIDS patients (N=75) rated the patients for changes on the St. Mary's Personality, Behavior and Cognitive Change (PBCC) Questionnaire. These ratings were compared with PBCC self-ratings of the patients and the carers. Scores were compared also with the neuropsychological test results of the patients. In addition carers and patients filled out standardized mood questionnaires. **Results:** 1. Carers' ratings of the patients are independent of the carers' own anxiety and depression levels. 2. Carers' ratings of deterioration in patients' cognitive functioning is significantly correlated with an overall impairment score obtained from neuropsychological testing. However, patients' own ratings of impairment in their cognitive functioning is related only to their own anxiety and depression.

Conclusions: Informal carers can be useful instruments as possible Central Nervous System involvement in patients. However, patients' subjective perception of deterioration in themselves is likely to be variable.

W.B.P.205 COMPETENCY CONSULTATION TO HIV PATIENTS:

A LIAISON HOSPITAL-OUTPATIENT PERSPECTIVE
William Henry Parton, L. Agelli, P.
Queens Hospital Center, Hillingdon, Long Island Jewish Medical Center,
Queens, New York, U.S.A.

Objectifs: 1) To identify the reasons for competency consultation to patients infected with HIV. 2) To classify such consultations by psychiatric diagnosis and 3) To determine the competency consultation provides a significant access route to mental health care for HIV patients.

Méthode: All psychiatric competency consultations to HIV patients at Queens Hospital Center from 1987-1988 were analyzed for demographic characteristics, reasons for consultation, competency, psychiatric diagnosis and psychiatric treatment.

Résultats: In 1987-88 the psychiatric consultation-liaison service saw 50 HIV patients in competency evaluations, representing the largest single medical diagnosis, and composed 21% of all competency evaluations. Forty two percent were referred because they refused treatment, 31% presented with altered mental status, 25% wished to leave the hospital. Forty percent were judged competent. Of the remaining 60%, all but two were diagnosed with organic mental syndrome. Of the 40% judged competent 24% were diagnosed with adjustment disorders, and 16% each personality disorder and substance abuse. Five patients (8%) had no psychiatric diagnosis.

Conclusion: Competency evaluations form a significant portion of psychiatric consultations to HIV patients, reflecting the neuropsychiatric and psychosocial manifestations of the disease. They provide an important route of entry into mental health care.

W.B.P.207 ETUDE DE LA DEMANDE PSYCHOTROPHAPÉUTIQUE CHEZ 100 PATIENTS ATTEINTS DE SIDA

Yves HELL, O. OUVRY, médecine psychiatrique
F. TOUETZ GERRARD, M. NARON-CHODON, J. BOUQUETIE, psychologie
des Maladies Parasitaires et Infectieuses, et Sand Publiche, Unité
IDSRM 313 (Pr M. Gentilini), Groupe Hospitalier Pitié-Salpêtrière, Paris,
France.

L'étude d'un groupe de cent patients séropositifs asymptomatiques non SIDA ou SIDA sévère a été menée par l'équipe médico-psychologique mixte en place dans le Service du Pr M. Gentilini en 1983 pour l'accompagnement psychologique et psychiatrique des malades atteints par le VIH.

A partir d'entrevues individuelles semi-directives et d'un questionnaire d'évaluation (11 items), les auteurs ont mesuré les résultats d'une approche épidémiologique du retournement psychopathologique de l'infection à VIH dans ses corrélations avec la demande de soutien psychologique, les antécédents psychiatriques personnels, les facteurs familiaux et de l'environnement.

Dans le cadre de cette première étude dans un service hospitalier-universitaire, il ressort que :

- 52 % des patients ont demandé un soutien psychologique durant le test d'hépatitase 1; 23 % ont refusé toute intervention psychologique spécialisée; 24 % ont demandé une psychothérapie de soutien (brève ou longue) après l'hospitalisation.
- 18 % des hommes/50 % des femmes, non groupés sous-traités, avaient des affections psychiatriques préexistant l'infection par le VIH.
- Les facteurs influençant le non-dit de la séropositivité, de la toxicomanie, de la sexualité sont corrélés à la relation d'aide de l'entourage (familial).

W.B.P.209 HIV SEROPOSITIVE STUDY OF INVOLUNTARILY HOSPITALIZED MENTALLY ILL HOMELESS FROM THE STREETS OF HONOLULUI, HAWAII

Meyer I., Schoenham P., et al. Creedmore Psychiatric Center, Queens, NY
Psychiatric Inst., NYC - Montefiore Med. Ctr., Bronx, NY USA

Objectifs: To determine the rate of HIV seropositivity and risk taking behavior among a group of high risk psychiatric patients, i.e., the homeless mentally ill who seek health care services and are involuntarily hospitalized by mental health teams.

Méthode: The study is conducted on The Creedmore Psychiatric Center Intensive Placement Unit, which is part of New York City's largest state hospital. Homeless patients removed from the streets are accepted for intermediate care and placement. This population tends to avoid public shelters and is demographically diverse. 232 are female and 72 are male. Ethnically, 46% are white, 39% are black, 13% are hispanic and 2% are Asian.

All ages between 18 and 55 plus are well represented. There is a high rate of medical illness including active TB, positive VDRL and hepatitis B antibodies. Approximately 30% of patients show substance abuse. Anonymous bloods will be tested for HIV antibodies on approximately 100 patients and correlated with histories of risk taking behaviors including alcohol abuse, prostitution and sexual behavior. These findings will also be correlated with geographic mobility, patterns of homelessness and psychiatric and medical illnesses.

Résultats: To be presented at the conference.

W.B.P.206 POSITIVITA' L'VIV IN PROYOGNOSTIC: OSSERVAZIONI SUI 100 NEI.

Severino Pasticciatore di Diagnostica Clinica "Virgilio 1" - Istituto V. V.
Severino Pasticciatore di Diagnostica Clinica "Virgilio 1" - Centro di Medicina Ospedaliera, Ospedale G. Grassi Negrar, Milano, Italia.

Obiettivo: Noto che la presenza dei troubles psichiatrici indica una tale diffusione del concetto di Jageret d'entrare più frequentemente che nella popolazione globale nei tipi di HIV ed è data da cinque per l'infezione di HIV. Per questo motivo non sono stati studiati nella parte la presenza dei soggetti diagnosticati positivamente all'HIV nei tre ospedali di Negrar. **Méthode:** Oltre la VHS e l'ELISA qui non effettuato routinariamente a partire da 1-10-87 non sono state messe in atto per l'HIV nei tre ospedali ospedalieri della rete serologica. Non sono stati utilizzati come gruppi di controllo le diagenosi di sangue di Centro di Trasmissione di HIV Ichnique di Milano. Infine non sono stati i significativi statistiche sono le test di chi sono.

Résultats: Les données à ce sujet se réfèrent aux deux premiers semestres d'observation, du 1-10-87 au 30-06-88. On a effectué le test par l'HIV au 79% (20/25) des hospitalisés en psychiatrie (selon 44,76% female 56,36% male) après 42,6 a.). Les patients positifs à l'HIV dans le premier semestre ont été 14,84 (12/81) et à la fin du deuxième semestre, 16% parcentage ont été vus la 0,15 (16/95) (selon 78% female 23% male) après 29,9 a.). On voit que si l'on considère q'au même temps la prévalence des sujets positifs à l'HIV dans les données de sang de Centre de Transmission et de la C.C. (C.C. Centre de la Inférieur avec une différence statistiquement très significative.

Conclusion: Notre hypothèse paraît être confirmée et donc nous croyons qu'il faudra structurer des applications programées d'éducation sanitaire pour ces patients.

W.B.P.208 CARATTERISTICI DEI TROVATI PSICHIATRICI NEI 100 HIV IN UN CENTRO DI SIDA

Severino Pasticciatore di Diagnostica Clinica "Virgilio 1" - Istituto V. V.
Severino Pasticciatore di Diagnostica Clinica "Virgilio 1" - Centro di Medicina Ospedaliera (Ospedale Prof. G. Grassi), Istituto Inferiore Adulto (Ospedale Prof. G. Grassi), Ospedale G. Grassi Negrar, Milano, Italia.

Obiettivo: In considerazione de la fréquence élevée des troubles psychiatriques constatés pratiquement en cours d'infection de HIV on a pu établir une classe ou comme complication de cette pathologie. **Méthode:** Pour cet étude nous avons pris en considération les patients hospitalisés depuis deux semaines dans les hôpitaux de Negrar à cause de l'HIV et dans lesquels ont été observés les symptômes psychiatriques, des troubles psychiatriques, nous avons mesuré comment ces cas ont été hospitalisés en psychiatrie et dans lesquels on a trouvé une positivité à l'HIV asymptotique du point de vue serologique. Les diagnostics ont été posés selon les principes du DSM III-R.

Résultats: Nous avons constaté 79 patients avec l'infection d'HIV à différents stades et avec une des troubles (14 psychiatriques). Les études étaient la 74,7 (58/79) et les femmes la 26,3 (16/79) l'âge moyen était 29,5 a.). Les facteurs de risque ont résultés être: la toxicomanie (66, 83/79); l'immunoséque 22,6 (30/79); les rapports intrasexuels (9, 5/79); les transfusions 0,5 (0,79). Les diagnostics psychiatriques ont été: Lésion des organes 29,3 (36/79); le 1 de l'humeur 20,8 (26/79); le 1 de l'attention 17,7 (22/79); le 1 de la personnalité 11,4 (14/79); schizophrénie 7,6 (10/79); le 1 de l'identité 6,3 (8/79); psychotiques sans clause altérée 5,1 (6/79).

Conclusion: On confirme la prévalence élevée des troubles psychiatriques mais il nous semble aussi intéressant la considérable présence des troubles psychiatriques en état sans cause la schizophrénie.

W.B.P.210 PSYCHIATRIC DIAGNOSES AMONG VOLUNTEERS FOR HIV TESTING

Jacobson, Lawrence; Perry, S; Fishman, B; Frowner, A; Ryan, J; Fogel, K. Cornell Medical Center, New York, NY

Objectifs: The objective of this DSM-III-R diagnosis among individuals volunteering for HIV testing.

Méthode: We administered the Structured Clinical Interview for DSM-III-R (for Axis I) and the Personality Disorders Questionnaire (for Axis II) to 211 physically asymptomatic adults at perceived risk for AIDS who had enrolled in a prospective psychobehavioral study.

Résultats: Overall rates for the presence of any Axis I disorder were 25.5% current and 64.1% lifetime; for Axis II disorders the overall rate was 28.6%. Compared to reported community samples, these subjects had higher rates of mood disorders, both current (13.9%) and lifetime (24.9%). Lifetime rates of non-alcohol substance dependence were also high (30.3%), even after eliminating from analysis the 21 subjects with lifetime drug use as a risk factor. An Axis II personality disorder or mood prior to HIV serologic testing was a heterogeneous population of 211 physically asymptomatic adults at perceived risk for AIDS who had enrolled in a prospective psychobehavioral study.

Conclusion: A large subgroup of the volunteers for testing had histories of depression and non-alcohol substance dependence. A substantial subpopulation with Axis I psychopathology may have additional treatment needs posed by Axis II disorders.

W.B.P.211

PSYCHIC CHANGES AND TREATMENT OUTCOME IN AN AIDS SPECIALTY CENTER
James Jelliffe, Frederick E. Videman, M.D., Joseph J. New York Hospital-Cornell Medical Center, New York, New York, USA

Objective. We examined baseline patterns of psychiatric referrals, psychiatric diagnosis and treatment outcomes in a cohort of 74 patients in an AIDS specialty center. **Results.** Twenty-eight patients were referred for psychiatric evaluation and treatment in a six month period. This number represents 50% of inpatient admissions and 25% of outpatients followed by the center. Risk factors for HIV infection in the referred population were: 57% IVDA, 36% homosexual contact and 7% heterosexual contact. **Results.** The most prevalent psychiatric diagnosis in the admission register was major depression (44%) and organic brain syndromes (28%). In both groups there was good response to psychotropic medications, with 80% of depressed patients improving on tricyclic antidepressants and 75% of ODS patients improving on neuroleptics and other agents. The most prevalent psychiatric diagnoses in the inpatient setting were organic brain syndromes (50%), ongoing drug treatment (22%) and major depression (17%). Both ODS and major depression were responsive to psychotherapeutic treatment in greater than 75% of cases. In both inpatients and outpatients, psychiatric treatment was not successful in halting ongoing drug abuse. Nevertheless, psychiatric consultation was helpful in establishing realistic treatment goals in both settings. **Conclusions.** In this pilot study, high baseline rates of psychiatric illness were found in an AIDS specialty center. Psychiatric evaluation and psychotherapeutic treatment resulted in symptomatic improvement in these patients suffering with major depression and organic brain syndromes. We conclude that psychiatric treatment and evaluation is an essential feature of the comprehensive care of HIV in the AIDS specialty center.

W.B.P.213

ANALYSIS OF INITIAL PSYCHIATRIC REFERRALS FROM A HOSPITAL HIV SERVICE
*Richardson-Claudio***, Guyer, P.T.*
 *National Naval Medical Center, Bethesda, Maryland, USA, **The Johns Hopkins Hospital, Baltimore, Maryland, USA.

Objective. To determine patterns of initial utilization of psychiatric services by a hospital HIV program. **Methods.** We reviewed 396 admissions to a military hospital's HIV service made by 354 patients over a 12-month period to determine the nature of initial requests for psychiatric consultation. **Results.** Nearly 1/4 of the admissions required psychiatric consultation; that percentage applied equally to newly identified HIV seropositive persons undergoing initial medical evaluation and to persons who had been previously diagnosed, educated about their infection, and counseled and were now admitted for periodic medical reevaluation or treatment. Psychiatric services were especially in demand when patients learned they were antibody positive, began to note early evidence of disease progression, or were in late stages of illness. In order of decreasing frequency, psychiatric diagnoses were adjustment disorders, major affective disorders, substance abuse, and delirium or other organic brain disorders (excluding dementia). **Conclusions.** In a setting of free, readily available medical and psycho-social care, nearly 1/4 of patient admissions required referral to a psychiatrist rather than to other mental health therapists. Similar studies from other medical centers could yield data that might help mental health planners prepare their resources for the still unfolding HIV epidemic.

W.B.P.215

PSYCHIATRIC HISTORY AMONG HOMOSEXUALS AND DRUG-ADDICTS INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS

*Calza, Costanzo**, Martini, S.*; Pergami, A.*; Ronzini, M.*; Russo, R.*; Lazzarini, A. **

*Institute of Psychiatry, **Institute of Infectious Diseases, University of Milan, Italy.

Objective. To evaluate psychiatric history among HIV-infected subjects (homosexuals, drug-addicts and heterosexuals). **Methods.** 218 subjects HIV-infected (111 III, C.D.C.), 60 subjects at risk of HIV infection seropositive for antibody to HIV, 50 healthy heterosexual controls were recruited from the Dept. of Infectious Diseases. We examined each subject with a psychiatric interview in order to collect: 1) previous personal and familial psychopathological history (considered in terms of lifetime prevalence); 2) Early Life Events (E.L.E.); 3) attempted suicides (A.S.). **Results:** a lifetime prevalence of personal and familial psychiatric disorder was higher in Seropositive (S-) (15,25%) and Seronegative (SN-) (27,24%) subjects than in the Control Group (C.G.), 4% of S-, 41% of SN-, 3% of C.G. reported E.L.E.. The prevalence of A.S. was 21% (S-), 17% (SN-) and 9% (C.G.). **Conclusion:** 1) psychiatric morbidity among S- was higher before the onset of HIV-infection, 2) awareness of psychiatric history is important for the monitoring and management of S- at risk of HIV-infection.

W.B.P.212

NEUROLOGICAL SEQUELAE OF 192 PATIENTS WITH HIV INFECTION AND AIDS
Mark Michael, B.
 Institute of Psychiatry, De Crespigny Park, London SE5, U.K.

Objective. Before planning psychological services for patients infected with HIV, we need epidemiological data on immediate and long-term neurological consequences of the diagnosis. **Methods.** HIV positive outpatients were interviewed in a standardized manner at the HIV clinic of 2 London hospitals. **Results:** 192 patients took part; 65 were HIV positive but well, 64 had accompanying symptoms or signs (41 WLL, 23 ARC) and 63 had AIDS. Almost all had revealed their diagnosis to others, 25% involving relatives. 31% had a psychiatric disorder, half of whom reported emotional problems prior to HIV infection. Patients with ARC or those diagnosed less than 1 year ago tended to have more psychological problems. 27% complained of impaired memory or concentration, of whom more than half had comorbid impairment on brief assessment. Extreme health worries predicted wider psychological morbidity. **Conclusion.** This degree of psychological distress is similar to reports for patients with other medical conditions. Subjects with past psychological difficulties disclosed occasionally about their health were more likely to be psychiatrically disturbed. Overall, patients had adapted well, despite the stigma and poor prognosis of their disorder.

W.B.P.214

A COMPARISON OF SUICIDAL BEHAVIORS IN PATIENTS IN AN AIDS RELATED PSYCHIATRIC CLINIC AND IN A GENERAL PSYCHIATRY CLINIC
O'Donnell, Mary Alice, McEagney, P.F., Montefiore Hospital and Montefiore Med.Center, Albert Einstein College of Medicine, Bronx, New York USA

Objective. To assess the extent of suicidal behaviors in a population of AIDS, ARC and HIV positive patients. **Methods:** 69 patients attending a psychiatric outpatient clinic for HIV related problems were surveyed as to past or present suicidal behaviors, and compared to a demographically matched sample of patients attending a general psychiatry outpatient clinic. Both populations were predominantly Hispanic (90% with almost equal numbers of men and women. Major risk factors for the HIV clinic group were IVDA (52%), heterosexual sex partner of person at risk (22%), homosexuality (22%) and were also (52). HIV related diagnoses were: AIDS n=23; ARC n=9; seropositive HIV only; HIV n=8; unknown serology, n=15. **Results:** There were no significant differences in the incidence of suicidal behaviors between patients attending the two clinics. Within the HIV clinic population there were no significant differences in the incidence of suicidal behavior by diagnosis of AIDS, ARC, HIV, HIV-, or unknown serology. There were no significant differences in psychiatric diagnoses among the AIDS diagnosis group. For each of the AIDS diagnosis groups, the mean age of the first suicidal attempt antedated clinic enrollment (AIDS Type I: ARC 17 yrs; HIV- 18 yrs; HIV-13 yrs) thus preceding the diagnosis of AIDS or HIV for most patients. **Conclusions:** HIV related disease status was not associated with increased suicidal ideation or attempts in the surveyed population. There were no differences in the incidence of suicidal behaviors between the HIV related psychiatric clinic population and an age and ethnicity matched general psychiatric outpatient population.

W.B.P.216

A COMPARISON OF PSYCHIATRIC CONSULTATIONS IN AIDS AND NON AIDS PATIENTS
O'Donnell, Mary Alice, McEagney, P.F., Montefiore Hospital Center, Albert Einstein College of Medicine, Bronx, New York USA.

Objective. To identify differences between AIDS patients and age matched medical patients without AIDS seen in psychiatric consultation on the medical service of a large voluntary general hospital. **Methods:** All psychiatric consultations over the year on the acute medical service of a large voluntary hospital were reviewed, comparing AIDS patients (n=67) with other medical patients without AIDS (n=112) under age 55. **Results:** There were significant differences between the two groups of consultation patients in ethnicity (AIDS patients more often Hispanic and less often Caucasian (p<0.1)). The AIDS group was predominantly male (92%) while the non-AIDS group was predominantly female (88%), a difference significant at p<0.01. There were no significant differences between the AIDS and non-AIDS groups in the incidence of diagnosis of depression, suicidal risk, substance abuse, or adjustment disorder. An Axis II diagnosis was made significantly less often in the AIDS group (p<0.05). The incidence of organic mental disorder was significantly higher in the AIDS group (p<0.05). Staff spent an average of 4.0 hours on AIDS consultations compared to 3.4 hours on non-AIDS consultations. There were 26 repeat consultations (42%) requested for the AIDS patients, compared to 17 repeat consultations (12%) in the non-AIDS patients (p<0.1). Comparison with the etiology of DSM and Axis II diagnoses, there were no significant differences in psychiatric diagnoses between AIDS patients and non-AIDS patients seen in psychiatric consultation. AIDS patients required more staff consultation time and repeat consultations, thus creating a heavier time burden on psychiatric services.

W.B.P.235 NEUROPSYCHOLOGICAL FUNCTIONING IN HIV-INFECTION Schickel, U., *Frolich, C., *Naber, D., *Gostel, P., D.*** *Psychiatrische Klinik der Universitäts München **Medizinische Poliklinik der Universitäts München F.R.G.

Objective: To study the natural history of neuropsychological deficits in patients with HIV-infection.
Methods: 132 HIV-positive patients, 100 in early stages, underwent psychiatric exploration and neuropsychological testing. Psychopathologic status was rated by means of the APOC-System, self-rated by SDS, PDMS, STAI and DCL. Neuropsychological examination included: Memory, Vocabulary, Similarities, Digit-Symbol, Color-Word-Interference, Benton, Trail-Making and Auditory-Verbal-Learning.
Results: 27% of patients showed symptoms of depression, 3% of anxiety. Tests revealed normal functioning in 70% of patients in early stages and 51% in late stages. Clinically relevant was the deficit in SA and in IQA respectively. The comparison with HIV-negative controls (n=100) showed for most tests a significant reduction already in early stages. These deficits correlated highly with depression. Cognitive deficits already occur in early stages, but often without clinical relevance. This study does not differentiate non-specific vs. psychogenic etiology. Repeated measurements and correlations with neurological variables are in process.

W.B.P.237 EVALUATION OF TRAINING FOR PHYSICIANS AT THE NATIONAL REFERENCE CENTERS IN BRAZIL Rodrigues, José*, Rodrigues, Lar** *União Paulista, Brasília, MinasGerais de Saúde - Brasília, Brazil

Under the sponsorship of the National Division of STD/AIDS, an evaluation of the clinical training on AIDS delivered by the National Reference Centers (NRC), Universidade Federal do Rio de Janeiro (URJ) and Gaffrée & Guinle (GAG), was conducted. The evaluation took place according to an up by the National Commission on AIDS and derived from Gaffrée's evaluative model (1977). The model comprises four components—Content, Input, Process and Product—which corresponded to the aspect to be assessed in the evaluation. Instruments of time to time were used: (a) interviews with those in charge of the Reference Centers, (b) direct observation by the evaluator, and (c) three pages self-paced instruments, i.e., the Knowledge Test on AIDS, the Impersonal Skills Inventory, and the Content Evaluation.
Results: The scores derived from the teachers' responses—URJ, URJ and GAG—on the Knowledge Test and the Content Evaluation showed no statistically significant differences according to the Kruskal-Wallis method (1975). However, a closer look into particular aspects of the three Centers showed positive characteristics as well as aspects deserving improvement. Such data allowed of some extrapolations pertaining to the evaluator, the DRN STD/AIDS, the Reference Centers and the content responses for the training.

W.B.P.239 INVERSE CORRELATION OF COMPLEMENT-MEDIATED, ANTIBODY-DEPENDENT ENHANCING TITERS WITH STAGE OF DISEASE IN INDIVIDUALS INFECTED WITH HIV-1.

Mitchell, William A., Robinson, W.E., Jr., Modirrousta, A., and Litwin, L.B., Jr. Dept. Pathology and *Preventive Medicine, Vanderbilt University, Nashville.

Objective: Complement-mediated, antibody-dependent enhancement (C-ADe) of HIV-1 infection has been attributed to accelerated infectious progression in HIV-1 neutralizing antibody titers in vitro (Lancet: 790, 1988), and to cause a > 100 fold increase in infectious HIV-1 yields (AIDS - in press). **Objective:** In this report is to ascertain whether titers of antibodies involved in C-ADe and the relationship between neutralizing antibodies and C-ADe correlate with stage of disease.
Methods: Sera from twenty-eight subjects in the Nashville area were examined at a 3-6 month time point for C-ADe titers as well as neutralizing antibodies in the presence or absence of human complement. Stage of disease was evaluated by the Water-Read classification scheme. C-ADe as well as the ratio between neutralizing antibodies in the absence and presence of human complement and the ratio between C-ADe and neutralizing antibody titers in the absence of complement were correlated with disease stage by linear regression analysis.
Results: No correlation between neutralizing antibody titers in the presence and absence of complement or C-ADe and neutralizing antibodies was found with the stage of HIV-1 induced disease. An inverse correlation between C-ADe and the ratio between neutralizing antibodies in the presence and absence of complement was found in initial analysis of a limited number of subjects.

Conclusion: The data in human subjects is consistent with our observation in chimpanzees following initial challenge with HIV-1. C-ADe titers rise prior to neutralizing antibody titers. Titers of the latter increase as C-ADe declines. Effort will continue to expand our data base to correlate with stage of disease as well as to examine the speed of disease progression as a function of C-ADe.

W.B.P.236 QUALITATIVE ASPECTS OF DEPRESSED MOOD AND NEUROPSYCHOLOGICAL FUNCTIONING IN HIV-1 +/- GAY AND BISEXUAL MEN: The Multicenter AIDS Cohort Study (MACS). James J. Becker, F.N. Scherr, L. Kingsley, R. Fox, J.M. New, Depts. Psychiatry & Epidemiology & Statistics, University of Pittsburgh Sch. Med., and Johns Hopkins Med. Inst., U.S.A.

OBJECTIVE: This study evaluated the relationship between mood and neuropsychological measures of affect (BDI) in HIV-1 (+/-) gay/bisexual men.
METHODS: HIV-1 seropositive (n=137) and seronegative (n=133) gay/bisexual men from the Pittsburgh and Baltimore MACS sites completed the Beck Depression Inventory (BDI), Spiegelberg's State/Trait Anxiety Inventory (STAI), and a short history of neuropsychological tests.
RESULTS: Overall, the HIV-1 men had more symptoms of depression (i.e., BDI), seropositive men were categorized based on total number of CD4 cells there were significant differences only in terms of the total BDI score, which was elevated in the men with the lowest CD4 counts. This elevation was not due to an increase in the number or severity of symptoms of abnormal affect (e.g., "dissatisfied with life"), but rather an increase in the number and/or severity of physical symptoms (e.g., weight change) reported on the BDI. No differences in performance on the cognitive tests were seen between seropositive groups. Performance was correlated with the BDI but not the STAI. Further analysis revealed that it was the physical symptoms of depression rather than the affective symptoms which were related to cognitive function.
CONCLUSIONS: These data indicate that the assessment of mood in HIV-1-infected individuals must take into account physical illness. Consistent with other findings from the MACS, neuropsychological performance was predicted by the presence of physical symptoms, but not by dysphoric mood.

W.B.P.238 A COMPREHENSIVE APPROACH TO COMMUNITY HOSPITAL CARE OF AIDS PATIENTS Andrew, Laurie, Kinick, J. (Hertford Community Hospital, Hertford, CONNECTICUT, USA)

Objective: To provide clinical care, education, counseling, testing and social services to HIV infected patients (pts) served by an 850 bed tertiary care community teaching hospital in central Connecticut.
Methods: An AIDS Task Force acts as a reflective and advisory capacity, a recommending policy and procedure to the Infection Control Committee. A patient oriented multidisciplinary HIV Task Force coordinates the delivery of services to in-pats with HIV disease and provides support to hospital staff. Community based volunteers provide support and social services for HIV pts and families. An AIDS program office provides an INFO-line, resource referral and speakers for community groups. A newsletter is periodically distributed updating national and regional AIDS related developments. The hospital provides referrals and acts as a resource for various community based organizations which provide education, outreach and support. The hospital is part of a city wide network of HIV related organizations and area church groups. A regional task force has established a data base, and addresses public policy and legislative issues. The existing Nurse Association and addresses public policy and legislative issues.
Conclusions: Since each hospital's HIV population and problems are both generic and specific, internal coordination and problem solving must be coupled with the establishment and strengthening of links to community services in order for both the hospital and its patients to survive.

W.B.P.240 IMPROVEMENTS TO IVDA ENROLLMENT IN AIDS CLINICAL TRIALS Fairchild, Patrick, Jaffe, Ann, C. Chaseman, J.; Bova, C.; Glavan, S.; Finkbeiner, S.; et al. University of Massachusetts Medical School, Worcester, Massachusetts, U.S.A.

Objective: To ascertain reasons that hinder enrollment of HIV-infected intravenous drug abusers (IVDA) into clinical trials.
Methods: The 1000th hundred IVDA in the IVDA study were evaluated at 100% for entry into HIV ACT clinical trials assessing AIT in asymptomatic infection (protocol 019) and early AIT (protocol 016) utilizing standard inclusion and exclusion criteria.
Results: Of the 141 patients, only 38 (27.0%) were considered eligible for entry into either protocol. Eleven (7.8%) of the 141 patients have been enrolled, 15 (10.6%) eligible patients are considering entry and 12 (8.5%) have refused participation in study. IVDA's considered ineligible for study (103.4%) often had more than one reason for not entering a protocol. These included psychosocial difficulties (53.1%), active IV drug use (23.4%) and exclusion for medical conditions (40.0%). IVDA that entered and remained in study were more likely to be enrolled in a long-term drug free residential facility or have a stable and supportive home environment than those who did not enter study. In contrast, 78 non-IVDA, IVDA (62.8%) were considered eligible for study and 19 (24.4%) were enrolled.
Conclusions: Multiple factors contribute to the low enrollment rate of IVDA into clinical trials. Increased availability of social services support to drug abusers, improved outreach, and enhanced IVDA participation in clinical trials. Expanded medical study inclusion criteria and less restrictive exclusion criteria may further promote entry into study.

W.B.P.241 THE ROLE OF THE GOVERNMENT OF CANADA IN THE NATURE AND DIRECTION OF RESEARCH IN THE MANAGEMENT OF HIV-DISEASE IN CANADA
Reid, B., Khan, and N. N. Joseph

Infection and Immunology Division, Bureau of Human Reproduction Drugs, Drugs Directorate, Health Protection Branch, Ottawa, Canada. Objective: To discuss the key role played by Health and Welfare Canada in supporting, expediting, facilitating, and implementing clinical research in the management of HIV-disease in Canada.

Methods and Results: The Health Protection Branch (HPB) of Health and Welfare Canada plays a crucial but delicate role in determining patient accessibility to experimental drugs for the management of HIV-disease and its ancillary opportunistic infections and problems. New policy initiatives and administrative changes have been recently announced which are intended to streamline the regulatory process and improve patient accessibility. It is our intention to examine the impact of these changes on the availability of experimental agents in Canada and on the climate for clinical research in this country. In addition, we will discuss the mechanisms for the introduction of experimental agents to Canada, the organizational and regulatory framework of HPB, the philosophy governing the evolution and implementation of regulatory change, and the consultative role of the Drugs Directorate.

Conclusion: The Health Protection Branch will continue to play a key role in improving patient accessibility and promoting clinical investigation in the management of HIV-disease in Canada.

W.B.P.242 THERMOGRAPHIC IMAGING OF HIV PATIENTS

Clark, R. J., Goff, M. A., Yoda, M., and Gazdars, B. P.
*Clinical Research Centre, Harrow, Ont. L6, **Theophane Hospital, London, UK.

Objective: To assess the role of high resolution infra-red imaging in HIV infection and Kaposi's sarcoma with particular reference to monitoring abnormal patterns of heat as well as because of peripheral neurological impairment and/or the presence of KS lesions.
